What is Amazon Relational Database Service (Amazon RDS)?

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

Note
This guide covers Amazon RDS database engines other than Amazon Aurora. For information about using Amazon Aurora, see the Amazon Aurora User Guide.

If you are new to AWS products and services, begin learning more with the following resources:

- For an overview of all AWS products, see What is cloud computing?
- Amazon Web Services provides a number of database services. For guidance on which service is best for your environment, see Running databases on AWS.

Overview of Amazon RDS

Why do you want to run a relational database in the AWS Cloud? Because AWS takes over many of the difficult and tedious management tasks of a relational database.

Topics
- Amazon EC2 and on-premises databases (p. 1)
- Amazon RDS and Amazon EC2 (p. 2)
- Amazon RDS Custom for Oracle and Microsoft SQL Server (p. 3)

Amazon EC2 and on-premises databases

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster.

When you buy an on-premises server, you get CPU, memory, storage, and IOPS, all bundled together. With Amazon EC2, these are split apart so that you can scale them independently. If you need more CPU, less IOPS, or more storage, you can easily allocate them.

For a relational database in an on-premises server, you assume full responsibility for the server, operating system, and software. For a database on an Amazon EC2 instance, AWS manages the layers below the operating system. In this way, Amazon EC2 eliminates some of the burden of managing an on-premises database server.

In the following table, you can find a comparison of the management models for on-premises databases and Amazon EC2.

<table>
<thead>

Amazon EC2 isn't a fully managed service. Thus, when you run a database on Amazon EC2, you're more prone to user errors. For example, when you update the operating system or database software manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue.

Amazon RDS and Amazon EC2

Amazon RDS is a managed database service. It's responsible for most management tasks. By eliminating tedious manual tasks, Amazon RDS frees you to focus on your application and your users. We recommend Amazon RDS over Amazon EC2 as your default choice for most database deployments.

In the following table, you can find a comparison of the management models in Amazon EC2 and Amazon RDS.

<table>

Amazon RDS provides the following specific advantages over database deployments that aren’t fully managed:

- You can use the database products you are already familiar with: MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server.
- Amazon RDS manages backups, software patching, automatic failure detection, and recovery.
- You can turn on automated backups, or manually create your own backup snapshots. You can use these backups to restore a database. The Amazon RDS restore process works reliably and efficiently.
- You can get high availability with a primary instance and a synchronous secondary instance that you can fail over to when problems occur. You can also use read replicas to increase read scaling.
- In addition to the security in your database package, you can help control who can access your RDS databases by using AWS Identity and Access Management (IAM) to define users and permissions. You can also help protect your databases by putting them in a virtual private cloud (VPC).

Amazon RDS Custom for Oracle and Microsoft SQL Server

Amazon RDS Custom is an RDS management type that gives you full access to your database and operating system.

You can use the control capabilities of RDS Custom to access and customize the database environment and operating system for legacy and packaged business applications. Meanwhile, Amazon RDS automates database administration tasks and operations.

In this deployment model, you can install applications and change configuration settings to suit your applications. At the same time, you can offload database administration tasks such as provisioning, scaling, upgrading, and backup to AWS. You can take advantage of the database management benefits of Amazon RDS, with more control and flexibility.

For Oracle Database and Microsoft SQL Server, RDS Custom combines the automation of Amazon RDS with the flexibility of Amazon EC2. For more information on RDS Custom, see Working with Amazon RDS Custom (p. 714).

With the shared responsibility model of RDS Custom, you get more control than in Amazon RDS, but also more responsibility. For more information, see Shared responsibility model (p. 716).

DB instances

A DB instance is an isolated database environment in the AWS Cloud. The basic building block of Amazon RDS is the DB instance.

Your DB instance can contain one or more user-created databases. You can access your DB instance by using the same tools and applications that you use with a standalone database instance. You can create and modify a DB instance by using the AWS Command Line Interface, the Amazon RDS API, or the AWS Management Console.

DB engines

A DB engine is the specific relational database software that runs on your DB instance. Amazon RDS currently supports the following engines:
• MySQL
• MariaDB
• PostgreSQL
• Oracle
• Microsoft SQL Server

Each DB engine has its own supported features, and each version of a DB engine may include specific features. Additionally, each DB engine has a set of parameters in a DB parameter group that control the behavior of the databases that it manages.

DB instance classes

A DB instance class determines the computation and memory capacity of a DB instance. A DB instance class consists of both the DB instance type and the size. Each instance type offers different compute, memory, and storage capabilities. For example, db.m6g is a general-purpose DB instance type powered by AWS Graviton2 processors, while db.m6g.2xlarge is a DB instance class.

You can select the DB instance that best meets your needs. If your needs change over time, you can change DB instances. For information, see DB instance classes (p. 9).

Note
For pricing information on DB instance classes, see the Pricing section of the Amazon RDS product page.

DB instance storage

Amazon EBS provides durable, block-level storage volumes that you can attach to a running instance. DB instance storage comes in the following types:

• General Purpose (SSD)
• Provisioned IOPS (PIOPS)
• Magnetic

The storage types differ in performance characteristics and price. You can tailor your storage performance and cost to the needs of your database.

Each DB instance has minimum and maximum storage requirements depending on the storage type and the database engine it supports. It’s important to have sufficient storage so that your databases have room to grow. Also, sufficient storage makes sure that features for the DB engine have room to write content or log entries. For more information, see Amazon RDS DB instance storage (p. 53).

Amazon Virtual Private Cloud (Amazon VPC)

You can run a DB instance on a virtual private cloud (VPC) using the Amazon Virtual Private Cloud (Amazon VPC) service. When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. The basic functionality of Amazon RDS is the same whether it's running in a VPC or not. Amazon RDS manages backups, software patching, automatic failure detection, and recovery. There's no additional cost to run your DB instance in a VPC. For more information on using Amazon VPC with RDS, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

Amazon RDS uses Network Time Protocol (NTP) to synchronize the time on DB Instances.
AWS Regions and Availability Zones

Amazon cloud computing resources are housed in highly available data center facilities in different areas of the world (for example, North America, Europe, or Asia). Each data center location is called an AWS Region.

Each AWS Region contains multiple distinct locations called Availability Zones, or AZs. Each Availability Zone is engineered to be isolated from failures in other Availability Zones. Each is engineered to provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region. By launching instances in separate Availability Zones, you can protect your applications from the failure of a single location. For more information, see Regions, Availability Zones, and Local Zones (p. 60).

You can run your DB instance in several Availability Zones, an option called a Multi-AZ deployment. When you choose this option, Amazon automatically provisions and maintains one or more secondary standby DB instances in a different Availability Zone. Your primary DB instance is replicated across Availability Zones to each secondary DB instance. This approach helps provide data redundancy and failover support, eliminate I/O freezes, and minimize latency spikes during system backups. In a Multi-AZ DB clusters deployment, the secondary DB instances can also serve read traffic. For more information, see Multi-AZ deployments for high availability (p. 65).

Security

A security group controls the access to a DB instance. It does so by allowing access to IP address ranges or Amazon EC2 instances that you specify.

For more information about security groups, see Security in Amazon RDS (p. 1747).

Monitoring an Amazon RDS DB instance

There are several ways that you can track the performance and health of a DB instance. You can use the Amazon CloudWatch service to monitor the performance and health of a DB instance. CloudWatch performance charts are shown in the Amazon RDS console. You can also subscribe to Amazon RDS events to be notified about changes to a DB instance, DB snapshot, DB parameter group, or DB security group. For more information, see Monitoring metrics in an Amazon RDS instance (p. 491).

How to work with Amazon RDS

There are several ways that you can interact with Amazon RDS.

AWS Management Console

The AWS Management Console is a simple web-based user interface. You can manage your DB instances from the console with no programming required. To access the Amazon RDS console, sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

Command line interface

You can use the AWS Command Line Interface (AWS CLI) to access the Amazon RDS API interactively. To install the AWS CLI, see Installing the AWS Command Line Interface. To begin using the AWS CLI for RDS, see AWS Command Line Interface reference for Amazon RDS.
Programming with Amazon RDS

If you are a developer, you can access the Amazon RDS programmatically. For more information, see Amazon RDS application programming interface (API) reference (p. 1893).

For application development, we recommend that you use one of the AWS Software Development Kits (SDKs). The AWS SDKs handle low-level details such as authentication, retry logic, and error handling, so that you can focus on your application logic. AWS SDKs are available for a wide variety of languages. For more information, see Tools for Amazon web services.

AWS also provides libraries, sample code, tutorials, and other resources to help you get started more easily. For more information, see Sample code & libraries.

How you are charged for Amazon RDS

When you use Amazon RDS, you can choose to use on-demand DB instances or reserved DB instances. For more information, see DB instance billing for Amazon RDS (p. 82).

For Amazon RDS pricing information, see the Amazon RDS product page.

What's next?

The preceding section introduced you to the basic infrastructure components that RDS offers. What should you do next?

Getting started

Create a DB instance using instructions in Getting started with Amazon RDS (p. 99).

Topics specific to database engines

You can review information specific to a particular DB engine in the following sections:

- MariaDB on Amazon RDS (p. 836)
- Microsoft SQL Server on Amazon RDS (p. 921)
- MySQL on Amazon RDS (p. 1131)
- Oracle on Amazon RDS (p. 1291)
- PostgreSQL on Amazon RDS (p. 1589)
Amazon RDS DB instances

A DB instance is an isolated database environment running in the cloud. It is the basic building block of Amazon RDS. A DB instance can contain multiple user-created databases, and can be accessed using the same client tools and applications you might use to access a standalone database instance. DB instances are simple to create and modify with the Amazon AWS command line tools, Amazon RDS API operations, or the AWS Management Console.

**Note**
Amazon RDS supports access to databases using any standard SQL client application. Amazon RDS does not allow direct host access.

You can have up to 40 Amazon RDS DB instances, with the following limitations:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

**Note**
If your application requires more DB instances, you can request additional DB instances by using this form.

Each DB instance has a DB instance identifier. This customer-supplied name uniquely identifies the DB instance when interacting with the Amazon RDS API and AWS CLI commands. The DB instance identifier must be unique for that customer in an AWS Region.

The identifier is used as part of the DNS hostname allocated to your instance by RDS. For example, if you specify db1 as the DB instance identifier, then RDS will automatically allocate a DNS endpoint for your instance, such as db1.123456789012.us-east-1.rds.amazonaws.com, where 123456789012 is the fixed identifier for a specific region for your account.

Each DB instance supports a database engine. Amazon RDS currently supports MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server, and Amazon Aurora database engines.

When creating a DB instance, some database engines require that a database name be specified. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. The database name value depends on the database engine:

- For the MySQL and MariaDB database engines, the database name is the name of a database hosted in your DB instance. Databases hosted by the same DB instance must have a unique name within that instance.
- For the Oracle database engine, database name is used to set the value of ORACLE_SID, which must be supplied when connecting to the Oracle RDS instance.
- For the Microsoft SQL Server database engine, database name is not a supported parameter.
- For the PostgreSQL database engine, the database name is the name of a database hosted in your DB instance. A database name is not required when creating a DB instance. Databases hosted by the same DB instance must have a unique name within that instance.

Amazon RDS creates a master user account for your DB instance as part of the creation process. This master user has permissions to create databases and to perform create, delete, select, update, and insert operations on tables the master user creates. You must set the master user password when you create a DB instance, but you can change it at any time using the AWS CLI, Amazon RDS API operations, or the
AWS Management Console. You can also change the master user password and manage users using standard SQL commands.

**Note**
This guide covers non-Aurora Amazon RDS database engines. For information about using Amazon Aurora, see the *Amazon Aurora User Guide.*
DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon RDS DB instance. A DB instance class consists of both the DB instance type and the size. The DB instance class you need depends on your processing power and memory requirements.

For more information about instance class pricing, see Amazon RDS pricing.

Topics

- DB instance class types (p. 9)
- Supported DB engines for DB instance classes (p. 11)
- Determining DB instance class support in AWS Regions (p. 28)
- Changing your DB instance class (p. 31)
- Configuring the processor for a DB instance class (p. 31)
- Hardware specifications for DB instance classes (p. 44)

DB instance class types

Amazon RDS supports three types of instance classes: standard, memory optimized, and burstable performance. For more information about Amazon EC2 instance types, see Instance types in the Amazon EC2 documentation.

The following are the standard DB instance types available:

- **db.m6g** – General-purpose instance classes powered by AWS Graviton2 processors. These deliver balanced compute, memory, and networking for a broad range of general purpose workloads.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as any other DB instance modification.

- **db.m6gd** – General-purpose instance classes powered by AWS Graviton2 processors. These deliver balanced compute, memory, and networking for a broad range of general purpose workloads. These have local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

  These DB instance classes are only supported for Multi-AZ DB clusters. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 71).

- **db.m6i** – General-purpose instance classes that are well suited for a broad range of general purpose workloads.

- **db.m5d** – Newest generation instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.

- **db.m5** – Latest generation general-purpose instance classes that provide a balance of compute, memory, and network resources, and are a good choice for many applications. The db.m5 instance classes provide more computing capacity than the previous db.m4 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.

- **db.m4** – General-purpose instance classes that provide more computing capacity than the previous db.m3 instance classes.

- **db.m3** – General-purpose instance classes that provide more computing capacity than the previous db.m1 instance classes.

The following are the memory optimized DB instance types available:
DB instance class types

- **db.x2g** – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These offer low cost per GiB of memory.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as any other DB instance modification.

- **db.z1d** – Instance classes optimized for memory-intensive applications. These offer both high compute capacity and a high memory footprint. High frequency z1d instances deliver a sustained all core frequency of up to 4.0 GHz.

- **db.x1e** – Instance classes optimized for memory-intensive applications. These offer one of the lowest price per gibibyte (GiB) of RAM among the DB instance classes and up to 3,904 GiB of DRAM-based instance memory.

- **db.x1** – Instance classes optimized for memory-intensive applications. These offer one of the lowest price per GiB of RAM among the DB instance classes and up to 1,952 GiB of DRAM-based instance memory.

- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as any other DB instance modification.

- **db.r6gd** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL. These have local NVMe-based SSD block-level storage for applications that need high-speed, low latency local storage.

  These DB instance classes are only supported for Multi-AZ DB clusters. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 71).

- **db.r6i** – Instance classes that are ideal for running memory-intensive workloads.

- **db.r5b** – Instance classes that are memory optimized for throughput-intensive applications. Powered by the AWS Nitro System, db.r5b instances deliver up to 60 Gbps bandwidth and 260,000 IOPS of EBS performance, which is the fastest block storage performance on EC2.

- **db.r5d** – Instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.

- **db.r5** – Latest generation instance classes optimized for memory-intensive applications. These offer improved networking and Amazon Elastic Block Store (Amazon EBS) performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.

- **db.r3** – Instance classes that provide memory optimization.

The following are the burstable performance DB instance types available:

- **db.t4g** – Newest-generation general-purpose instance classes powered by Arm-based AWS Graviton2 processors. These deliver better price performance than previous-generation burstable performance DB instance classes for a broad set of burstable general-purpose workloads. Amazon RDS T4g instances are configured for Unlimited mode, which means that they can burst beyond the baseline over a 24-hour window for an additional charge.

  You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as with any other DB instance modification.

- **db.t3** – Next generation instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.

- **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T2 instances can be configured for Unlimited mode. We recommend using these instance classes only for development and test servers, or other nonproduction servers.
Note
The DB instance classes that use the AWS Nitro System (db.m5, db.r5, db.t3) are throttled on combined read plus write workload.

For DB instance class hardware specifications, see Hardware specifications for DB instance classes (p. 44).

Supported DB engines for DB instance classes

The following are DB engine–specific considerations for DB instance classes:

Microsoft SQL Server

DB instance class support varies according to the version and edition of SQL Server. For instance class support by version and edition, see DB instance class support for Microsoft SQL Server (p. 925).

Oracle

DB instance class support varies according to the Oracle Database version and edition. RDS for Oracle supports additional memory-optimized instance classes. These classes have names of the form db.r5.instance_size.tpcthreads_per_core.memratio. For the vCPU count and memory allocation for each optimized class, see Supported Oracle DB instance classes (p. 1302).

In the following table, you can find details about supported Amazon RDS DB instance classes for each Amazon RDS DB engine.

<table>
<thead>
<tr>
<th>Instance class</th>
<th>MariaDB</th>
<th>Microsoft SQL Server</th>
<th>MySQL</th>
<th>Oracle</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.m6g – standard instance classes powered by AWS Graviton2 processors</td>

**db.t2 – burstable performance instance classes**
## Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can use the AWS Management Console, the Amazon RDS Pricing page, or the `describe-orderable-db-instance-options` command for the AWS Command Line Interface (AWS CLI).

**Note**

When you perform operations with the AWS CLI, such as creating or modifying a DB instance, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region.

### Contents

- Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions (p. 28)
- Using the AWS CLI to determine DB instance class support in AWS Regions (p. 29)
  - Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 30)
  - Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 30)

### Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions

You can use the Amazon RDS Pricing page to determine the DB instance classes supported by each DB engine in a specific AWS Region.
To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to Amazon RDS Pricing.
2. Choose a DB engine.
3. On the pricing page for the DB engine, choose On-Demand DB Instances or Reserved DB Instances.
4. To see the DB instance classes available in an AWS Region, choose the AWS Region in Region.

Other choices might be available for some DB engines, such as Single-AZ Deployment or Multi-AZ Deployment.

Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region. The following table shows the valid DB engine values.

<table>
<thead>
<tr>
<th>Engine names</th>
<th>Engine values in CLI commands</th>
<th>More information about versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB</td>
<td>mariadb</td>
<td>MariaDB on Amazon RDS versions (p. 838)</td>
</tr>
<tr>

<td>oracle-se</td>
<td></td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>postgres</td>
<td>Available PostgreSQL database versions (p. 1595)</td>
</tr>
</tbody>
</table>

For information about AWS Region names, see AWS Regions (p. 60).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the describe-orderable-db-instance-options AWS CLI command.

Note
To limit the output, these examples show results only for the General Purpose SSD (gp2) storage type. If necessary, you can change the storage type to Provisioned IOPS (io1) or magnetic (standard) in the commands.

Topics
- Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 30)
- Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 30)
Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version \
  --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? \
  StorageType=='gp2'[][].{DBInstanceClass:DBInstanceClass}" \
  --output text \
  --region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version ^ 
  --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? \
  StorageType=='gp2'[][].{DBInstanceClass:DBInstanceClass}" ^ 
  --output text ^ 
  --region region
```

For example, the following command lists the supported DB instance classes for version 12.4 of the RDS for PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 12.4 \
  --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? \
  StorageType=='gp2'[][].{DBInstanceClass:DBInstanceClass}" \
  --output text \
  --region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 12.4 ^ 
  --query "*[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}[]? \
  StorageType=='gp2'[][].{DBInstanceClass:DBInstanceClass}" ^ 
  --output text ^ 
  --region us-east-1
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class \
  --query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}[]? \
  StorageType=='gp2'[][].{EngineVersion:EngineVersion}" \
  --output text \
  --region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class ^ 
  --query "*[].{EngineVersion:EngineVersion,StorageType:StorageType}[]? \
  StorageType=='gp2'[][].{EngineVersion:EngineVersion}" ^ 
  --output text ^ 
  --region region
```
Changing your DB instance class

You can change the CPU and memory available to a DB instance by changing its DB instance class. To change the DB instance class, modify your DB instance by following the instructions in Modifying an Amazon RDS DB instance (p. 309).

Some instance classes require that your DB instance is in a VPC. If your current DB instance isn't in a VPC, and you want to use an instance class that requires one, first move your DB instance into a VPC. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

Configuring the processor for a DB instance class

Amazon RDS DB instance classes support Intel Hyper-Threading Technology, which enables multiple threads to run concurrently on a single Intel Xeon CPU core. Each thread is represented as a virtual CPU (vCPU) on the DB instance. A DB instance has a default number of CPU cores, which varies according to DB instance class. For example, a db.m4.xlarge DB instance class has two CPU cores and two threads per core by default—four vCPUs in total.

**Note**
Each vCPU is a hyperthread of an Intel Xeon CPU core.

**Topics**

- Overview of configuring the processor (p. 32)
- DB instance classes that support processor configuration (p. 32)
- Setting the CPU cores and threads per CPU core for a DB instance class (p. 37)
Overview of configuring the processor

In most cases, you can find a DB instance class that has a combination of memory and number of vCPUs to suit your workloads. However, you can also specify the following processor features to optimize your DB instance for specific workloads or business needs:

- **Number of CPU cores** – You can customize the number of CPU cores for the DB instance. You might do this to potentially optimize the licensing costs of your software with a DB instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.

- **Threads per core** – You can disable Intel Hyper-Threading Technology by specifying a single thread per CPU core. You might do this for certain workloads, such as high-performance computing (HPC) workloads.

You can control the number of CPU cores and threads for each core separately. You can set one or both in a request. After a setting is associated with a DB instance, the setting persists until you change it.

The processor settings for a DB instance are associated with snapshots of the DB instance. When a snapshot is restored, its restored DB instance uses the processor feature settings used when the snapshot was taken.

If you modify the DB instance class for a DB instance with nondefault processor settings, either specify default processor settings or explicitly specify processor settings at modification. This requirement ensures that you are aware of the third-party licensing costs that might be incurred when you modify the DB instance.

There is no additional or reduced charge for specifying processor features on an Amazon RDS DB instance. You're charged the same as for DB instances that are launched with default CPU configurations.

**DB instance classes that support processor configuration**

You can configure the number of CPU cores and threads per core only when the following conditions are met:

- You're configuring an Oracle DB instance. For information about the DB instance classes supported by different Oracle database editions, see RDS for Oracle instance classes (p. 1302).
- Your instance is using the Bring Your Own License (BYOL) licensing option. For more information about Oracle licensing options, see Oracle licensing options (p. 1299).
- Your instance isn't one of the db.r5 instance classes that have predefined processor configurations. These instance classes have names of the form db.r5.instance_size.tpcthreads_per_core.memratio. For example, db.r5.xlarge.tpc2.mem4x is preconfigured with 2 threads per core (tpc2) and 4x as much memory as the standard db.r5.xlarge instance class. You can't configure the processor features of these optimized instance classes. For more information, see Supported Oracle DB instance classes (p. 1302).

In the following table, you can find the DB instance classes that support setting a number of CPU cores and CPU threads per core. You can also find the default value and the valid values for the number of CPU cores and CPU threads per core for each DB instance class.

</tbody>
</table>
Note
You can use AWS CloudTrail to monitor and audit changes to the process configuration of Amazon RDS for Oracle DB instances. For more information about using CloudTrail, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 686).

Setting the CPU cores and threads per CPU core for a DB instance class

You can configure the number of CPU cores and threads per core for the DB instance class when you perform the following operations:

• Creating an Amazon RDS DB instance (p. 175)
• Modifying an Amazon RDS DB instance (p. 309)
• Restoring from a DB snapshot (p. 432)
• Restoring a DB instance to a specified time (p. 480)
• Restoring a backup into a MySQL DB instance (p. 1178)

Note
When you modify a DB instance to configure the number of CPU cores or threads per core, there is a brief DB instance outage.

You can set the CPU cores and the threads per CPU core for a DB instance class using the AWS Management Console, the AWS CLI, or the RDS API.

Console

When you are creating, modifying, or restoring a DB instance, you set the DB instance class in the AWS Management Console. The Instance specifications section shows options for the processor. The following image shows the processor features options.
Configuring the processor

Instance specifications

DB engine
Oracle Database Enterprise Edition

License model
bring-your-own-license

DB engine version
Oracle 12.1.0.2.v12

DB instance class
db.r4.xlarge — 4 vCPU, 30.5 GiB RAM

Multi-AZ deployment
Create replica in different zone
Creates a replica in a different Availability Zone (AZ) to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups.

Storage type
Provisioned IOPS (SSD)

Allocated storage
100 GiB
(Minimum: 100 GiB, Maximum: 16384 GiB)

Provisioned IOPS
1000

Additional configuration

Processor features

Override default values
You can change the number of CPU cores and threads per core on the DB instance class.

Core count
2

Threads per core
2
Set the following options to the appropriate values for your DB instance class under **Processor features**:

- **Core count** – Set the number of CPU cores using this option. The value must be equal to or less than the maximum number of CPU cores for the DB instance class.
- **Threads per core** – Specify 2 to enable multiple threads per core, or specify 1 to disable multiple threads per core.

When you modify or restore a DB instance, you can also set the CPU cores and the threads per CPU core to the defaults for the instance class.

When you view the details for a DB instance in the console, you can view the processor information for its DB instance class on the **Configuration** tab. The following image shows a DB instance class with one CPU core and multiple threads per core enabled.

For Oracle DB instances, the processor information only appears for Bring Your Own License (BYOL) DB instances.

**AWS CLI**

You can set the processor features for a DB instance when you run one of the following AWS CLI commands:

- `create-db-instance`
Configuring the processor

- `modify-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

To configure the processor of a DB instance class for a DB instance by using the AWS CLI, include the `--processor-features` option in the command. Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

The option has the following syntax.

```bash
--processor-features "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

The following are examples that configure the processor:

**Examples**

- Setting the number of CPU cores for a DB instance (p. 40)
- Setting the number of CPU cores and disabling multiple threads for a DB instance (p. 40)
- Viewing the valid processor values for a DB instance class (p. 41)
- Returning to default processor settings for a DB instance (p. 42)
- Returning to the default number of CPU cores for a DB instance (p. 42)
- Returning to the default number of threads per core for a DB instance (p. 43)

**Setting the number of CPU cores for a DB instance**

**Example**

The following example modifies `mydbinstance` by setting the number of CPU cores to 4. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --processor-features "Name=coreCount,Value=4" \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --processor-features "Name=coreCount,Value=4" ^
  --apply-immediately
```

**Setting the number of CPU cores and disabling multiple threads for a DB instance**

**Example**

The following example modifies `mydbinstance` by setting the number of CPU cores to 4 and disabling multiple threads per core. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.
For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1"
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
   --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1"
   --apply-immediately
```

Viewing the valid processor values for a DB instance class

**Example**

You can view the valid processor values for a particular DB instance class by running the `describe-orderable-db-instance-options` command and specifying the instance class for the `--db-instance-class` option. For example, the output for the following command shows the processor options for the db.r3.large instance class.

```bash
aws rds describe-orderable-db-instance-options --engine oracle-ee --db-instance-class db.r3.large
```

Following is sample output for the command in JSON format.

```json
{
   "SupportsIops": true,
   "MaxIopsPerGib": 50.0,
   "LicenseModel": "bring-your-own-license",
   "DBInstanceClass": "db.r3.large",
   "SupportsIAMDatabaseAuthentication": false,
   "MinStorageSize": 100,
   "AvailabilityZones": [
      {
         "Name": "us-west-2a"
      },
      {
         "Name": "us-west-2b"
      },
      {
         "Name": "us-west-2c"
      }
   ],
   "EngineVersion": "12.1.0.2.v2",
   "MaxStorageSize": 32768,
   "MinIopsPerGib": 1.0,
   "MaxIopsPerDbInstance": 40000,
   "ReadReplicaCapable": false,
   "AvailableProcessorFeatures": [
      {
         "Name": "coreCount",
         "DefaultValue": "1",
         "AllowedValues": "1"
      },
      {
         "Name": "threadsPerCore",
         "DefaultValue": "2",
         "AllowedValues": "1,2"
      }
   ]
}
```
In addition, you can run the following commands for DB instance class processor information:

- `describe-db-instances` – Shows the processor information for the specified DB instance.
- `describe-db-snapshots` – Shows the processor information for the specified DB snapshot.
- `describe-valid-db-instance-modifications` – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding commands, the values for the processor features are not null only if the following conditions are met:

- You are using an Oracle DB instance.
- Your Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using `describe-db-instances`. You can get the processor information for this instance type by running the EC2 operation `describe-instance-types`.

**Returning to default processor settings for a DB instance**

**Example**

The following example modifies `mydbinstance` by returning its DB instance class to the default processor values for it. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --use-default-processor-features \
  --apply-immediately
```

For Windows:

```cmd
aws rds modify-db-instance ^
  --use-default-processor-features ^
  --apply-immediately
```

**Returning to the default number of CPU cores for a DB instance**

**Example**

The following example modifies `mydbinstance` by returning its DB instance class to the default number of CPU cores for it. The threads per core setting isn't changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

```bash
aws rds modify-db-instance \
  --use-default-processor-features \
  --apply-immediately
```
For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --processor-features "Name=coreCount,Value=DEFAULT" \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --processor-features "Name=coreCount,Value=DEFAULT" ^
  --apply-immediately
```

### Returning to the default number of threads per core for a DB instance

#### Example

The following example modifies `mydbinstance` by returning its DB instance class to the default number of threads per core for it. The number of CPU cores setting isn’t changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --processor-features "Name=threadsPerCore,Value=DEFAULT" \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --processor-features "Name=threadsPerCore,Value=DEFAULT" ^
  --apply-immediately
```

### RDS API

You can set the processor features for a DB instance when you call one of the following Amazon RDS API operations:

- `CreateDBInstance`
- `ModifyDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

To configure the processor features of a DB instance class for a DB instance by using the Amazon RDS API, include the `ProcessFeatures` parameter in the call.

The parameter has the following syntax.

```
ProcessFeatures "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

You can view the valid processor values for a particular instance class by running the `DescribeOrderableDBInstanceOptions` operation and specifying the instance class for the `DBInstanceClass` parameter. You can also use the following operations:
• DescribeDBInstances – Shows the processor information for the specified DB instance.
• DescribeDBSnapshots – Shows the processor information for the specified DB snapshot.
• DescribeValidDBInstanceModifications – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding operations, the values for the processor features are not null only if the following conditions are met:

• You are using an Oracle DB instance.
• Your Oracle DB instance supports changing processor values.
• The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren’t met, you can get the instance type using DescribeDBInstances. You can get the processor information for this instance type by running the EC2 operation DescribeInstanceTypes.

Hardware specifications for DB instance classes

The following terminology is used to describe hardware specifications for DB instance classes:

vCPU

The number of virtual central processing units (CPUs). A virtual CPU is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

ECU

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

Memory (GiB)

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

VPC Only

The instance class is supported only for DB instances that are in a VPC based on the Amazon VPC service. In some cases, you might want to use an instance class that requires a VPC but your current DB instance isn’t in a VPC. In these cases, start by moving your DB instance into a VPC. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

EBS-Optimized

The DB instance uses an optimized configuration stack and provides additional, dedicated capacity for I/O. This optimization provides the best performance by minimizing contention between I/O and other traffic from your instance. For more information about Amazon EBS–optimized instances, see Amazon EBS–Optimized instances in the Amazon EC2 User Guide for Linux Instances.

Max. Bandwidth (Mbps)

The maximum bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.
Important
General Purpose SSD (gp2) volumes for Amazon RDS DB instances have a throughput limit of 250 MiB/s in most cases. However, the throughput limit can vary depending on volume size. For more information, see Amazon EBS volume types in the Amazon EC2 User Guide for Linux Instances. For information on estimating bandwidth for gp2 storage, see General Purpose SSD storage (p. 53).

Network Performance
The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes.

For information about Amazon RDS DB engine support for each DB instance class, see Supported DB engines for DB instance classes (p. 11).

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of these instance types, see Amazon EBS-optimized instances in the Amazon EC2 User Guide for Linux Instances.

** The r3.8xlarge instance doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. On this instance, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.
Amazon RDS DB instance storage

DB instances for Amazon RDS for MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server use Amazon Elastic Block Store (Amazon EBS) volumes for database and log storage. Depending on the amount of storage requested, Amazon RDS automatically stripes across multiple Amazon EBS volumes to enhance performance.

Amazon RDS storage types

Amazon RDS provides three storage types: General Purpose SSD (also known as gp2), Provisioned IOPS SSD (also known as io1), and magnetic (also known as standard). They differ in performance characteristics and price, which means that you can tailor your storage performance and cost to the needs of your database workload. You can create MySQL, MariaDB, Oracle, and PostgreSQL RDS DB instances with up to 64 tebibytes (TiB) of storage. You can create SQL Server RDS DB instances with up to 16 TiB of storage. For this amount of storage, use the Provisioned IOPS SSD and General Purpose SSD storage types.

The following list briefly describes the three storage types:

- **General Purpose SSD** – General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies and the ability to burst to 3,000 IOPS for extended periods of time. Baseline performance for these volumes is determined by the volume's size.

  For more information about General Purpose SSD storage, including the storage size ranges, see General Purpose SSD storage (p. 53).

- **Provisioned IOPS** – Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, that require low I/O latency and consistent I/O throughput.

  For more information about provisioned IOPS storage, including the storage size ranges, see Provisioned IOPS SSD storage (p. 55).

- **Magnetic** – Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS for any new storage needs. The maximum amount of storage allowed for DB instances on magnetic storage is less than that of the other storage types. For more information, see Magnetic storage (p. 56).

Several factors can affect the performance of Amazon EBS volumes, such as instance configuration, I/O characteristics, and workload demand. For more information about getting the most out of your Provisioned IOPS volumes, see Amazon EBS volume performance.

General Purpose SSD storage

General Purpose SSD storage offers cost-effective storage that is acceptable for most database workloads. The following are the storage size ranges for General Purpose SSD DB instances:

- MariaDB, MySQL, Oracle, and PostgreSQL database instances: 20 GiB–64 TiB
- SQL Server Enterprise, Standard, Web, and Express Editions: 20 GiB–16 TiB

Baseline I/O performance for General Purpose SSD storage is 3 IOPS for each GiB, with a minimum of 100 IOPS. This relationship means that larger volumes have better performance. For example, baseline performance for a 100-GiB volume is 300 IOPS. Baseline performance for a 1-TiB volume is 3,000 IOPS. Maximum baseline performance for a gp2 volume (5.34 TiB and greater) is 16,000 IOPS.
Volumes below 1 TiB in size also have ability to burst to 3,000 IOPS for extended periods of time. Instance I/O credit balance determines burst performance. For more information about instance I/O credits, see I/O credits and burst performance (p. 54).

Many workloads never deplete the burst balance, making General Purpose SSD an ideal storage choice for many workloads. However, some workloads can exhaust the 3,000 IOPS burst storage credit balance, so you should plan your storage capacity to meet the needs of your workloads.

For gp2 volumes larger than 1 TiB, the baseline performance is greater than the burst performance. For such volumes, burst is irrelevant because the baseline performance is better than the 3,000 IOPS burst performance.

Note
DB instances that use General Purpose SSD storage can experience much longer latency after read replica creation, Multi-AZ conversion, and DB snapshot restoration than instances that use Provisioned IOPS storage. If you need a DB instance with minimum latency after these operations, we recommend using Provisioned IOPS storage.

I/O credits and burst performance

General Purpose SSD storage performance is governed by volume size, which dictates the base performance level of the volume and how quickly it accumulates I/O credits. Larger volumes have higher base performance levels and accumulate I/O credits faster. I/O credits represent the available bandwidth that your General Purpose SSD storage can use to burst large amounts of I/O when more than the base level of performance is needed. The more I/O credits your storage has for I/O, the more time it can burst beyond its base performance level and the better it performs when your workload requires more performance.

When using General Purpose SSD storage, your DB instance receives an initial I/O credit balance of 5.4 million I/O credits. This initial credit balance is enough to sustain a burst performance of 3,000 IOPS for 30 minutes. This balance is designed to provide a fast initial boot cycle for boot volumes and to provide a good bootstrapping experience for other applications. Volumes earn I/O credits at the baseline performance rate of 3 IOPS for each GiB of volume size. For example, a 100-GiB SSD volume has a baseline performance of 300 IOPS.

When your storage requires more than the base performance I/O level, it uses I/O credits in the I/O credit balance to burst to the required performance level. Such a burst goes to a maximum of 3,000 IOPS. Storage larger than 1,000 GiB has a base performance that is equal or greater than the maximum burst performance. When your storage uses fewer I/O credits than it earns in a second, unused I/O credits are added to the I/O credit balance. The maximum I/O credit balance for a DB instance using General Purpose SSD storage is equal to the initial I/O credit balance (5.4 million I/O credits).

Suppose that your storage uses all of its I/O credit balance. If so, its maximum performance remains at the base performance level until I/O demand drops below the base level and unused I/O credits are added to the I/O credit balance. (The base performance level is the rate at which your storage earns I/O credits.) The more storage, the greater the base performance is and the faster it replenishes the I/O credit balance.

Note
Storage conversions between magnetic storage and General Purpose SSD storage can potentially deplete your I/O credit balance, resulting in longer conversion times. For more information about scaling storage, see Working with storage for Amazon RDS DB instances (p. 393).

The burst duration of your storage depends on the size of the storage, the burst IOPS required, and the I/O credit balance when the burst begins. This relationship is shown in the equation following.

\[
(Credit\ balance)
\]
You might notice that your storage performance is frequently limited to the base level due to an empty I/O credit balance. If so, consider allocating more General Purpose SSD storage with a higher base performance level. Alternatively, you can switch to Provisioned IOPS storage for workloads that require sustained IOPS performance.

For workloads with steady state I/O requirements, provisioning less than 100 GiB of General Purpose SSD storage might result in higher latencies if you exhaust your I/O credit balance.

**Note**
In general, most workloads never exceed the I/O credit balance.

For a more detailed description of how baseline performance and I/O credit balance affect performance see [Understanding burst vs. baseline performance with Amazon RDS and GP2](#).

## Provisioned IOPS SSD storage

For a production application that requires fast and consistent I/O performance, we recommend Provisioned IOPS (input/output operations per second) storage. Provisioned IOPS storage is a storage type that delivers predictable performance, and consistently low latency. Provisioned IOPS storage is optimized for online transaction processing (OLTP) workloads that have consistent performance requirements. Provisioned IOPS helps performance tuning of these workloads.

**Note**
Your database workload might not be able to achieve 100 percent of the IOPS that you have provisioned. For more information, see [Factors that affect storage performance (p. 57)](#).

When you create a DB instance, you specify the IOPS rate and the size of the volume. The ratio of IOPS to allocated storage (in GiB) must be at least 0.5 (1.0 on RDS for SQL Server) and not more than 50. Amazon RDS provides that IOPS rate for the DB instance until you change it.

The following table shows the range of Provisioned IOPS and storage size range for each database engine.

<table>
<thead>

<td>MySQL</td>
<td>1,000–80,000 IOPS</td>
<td>100 GiB–64 TiB</td>
</tr>
<tr>
<td>Oracle</td>
<td>1,000–256,000 IOPS</td>
<td>100 GiB–64 TiB</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>1,000–80,000 IOPS</td>
<td>100 GiB–64 TiB</td>
</tr>
</tbody>
</table>

The ratio of IOPS to allocated storage (in GiB) must be from 1–50 on RDS for SQL Server, and 0.5–50 on other RDS DB engines.

**Note**
For SQL Server, the maximum 64,000 IOPS is guaranteed only on [Nitro-based instances](#) that are on the m5, m5d, r5, r5b, r5d, and z1d instance types. Other instance families guarantee performance up to 32,000 IOPS.

For Oracle, you can provision the maximum 256,000 IOPS only on the r5b instance type.
For PostgreSQL, the maximum IOPS on the db.m5.8xlarge, db.m5.16xlarge, db.r5.8xlarge, and db.r5.16xlarge instance classes is 40,000.

**Important**
Depending on the instance class you're using, you might see lower IOPS performance than the maximum that RDS allows you to provision. For specific information on IOPS performance for DB instance classes, see Amazon EBS-optimized instances. We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

**Combining Provisioned IOPS storage with Multi-AZ deployments or read replicas**

For production OLTP use cases, we recommend that you use Multi-AZ deployments for enhanced fault tolerance with Provisioned IOPS storage for fast and predictable performance.

You can also use Provisioned IOPS SSD storage with read replicas for MySQL, MariaDB or PostgreSQL. The type of storage for a read replica is independent of that on the primary DB instance. For example, you might use General Purpose SSD for read replicas with a primary DB instance that uses Provisioned IOPS SSD storage to reduce costs. However, your read replica's performance in this case might differ from that of a configuration where both the primary DB instance and the read replicas use Provisioned IOPS SSD storage.

**Provisioned IOPS storage costs**

With Provisioned IOPS storage, you are charged for the provisioned resources whether or not you use them in a given month.

For more information about pricing, see Amazon RDS pricing.

**Getting the best performance from Amazon RDS Provisioned IOPS SSD storage**

If your workload is I/O constrained, using Provisioned IOPS SSD storage can increase the number of I/O requests that the system can process concurrently. Increased concurrency allows for decreased latency because I/O requests spend less time in a queue. Decreased latency allows for faster database commits, which improves response time and allows for higher database throughput.

Provisioned IOPS SSD storage provides a way to reserve I/O capacity by specifying IOPS. However, as with any other system capacity attribute, its maximum throughput under load is constrained by the resource that is consumed first. That resource might be network bandwidth, CPU, memory, or database internal resources.

**Magnetic storage**

Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The following are some limitations for magnetic storage:

- Doesn't allow you to scale storage when using the SQL Server database engine.
- Doesn't support storage autoscaling.
- Doesn't support elastic volumes.
- Limited to a maximum size of 3 TiB.
- Limited to a maximum of 1,000 IOPS.
Monitoring storage performance

Amazon RDS provides several metrics that you can use to determine how your DB instance is performing. You can view the metrics on the summary page for your instance in Amazon RDS Management Console. You can also use Amazon CloudWatch to monitor these metrics. For more information, see Viewing metrics in the Amazon RDS console (p. 505). Enhanced Monitoring provides more detailed I/O metrics; for more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582).

The following metrics are useful for monitoring storage for your DB instance:

- **IOPS** – The number of I/O operations completed each second. This metric is reported as the average IOPS for a given time interval. Amazon RDS reports read and write IOPS separately on 1-minute intervals. Total IOPS is the sum of the read and write IOPS. Typical values for IOPS range from zero to tens of thousands per second.

- **Latency** – The elapsed time between the submission of an I/O request and its completion. This metric is reported as the average latency for a given time interval. Amazon RDS reports read and write latency separately at 1-minute intervals. Typical values for latency are in milliseconds (ms).

- **Throughput** – The number of bytes each second that are transferred to or from disk. This metric is reported as the average throughput for a given time interval. Amazon RDS reports read and write throughput separately on 1-minute intervals using units of megabytes per second (MB/s). Typical values for throughput range from zero to the I/O channel's maximum bandwidth.

- **Queue Depth** – The number of I/O requests in the queue waiting to be serviced. These are I/O requests that have been submitted by the application but have not been sent to the device because the device is busy servicing other I/O requests. Time spent waiting in the queue is a component of latency and service time (not available as a metric). This metric is reported as the average queue depth for a given time interval. Amazon RDS reports queue depth in 1-minute intervals. Typical values for queue depth range from zero to several hundred.

Measured IOPS values are independent of the size of the individual I/O operation. This means that when you measure I/O performance, you should look at the throughput of the instance, not simply the number of I/O operations.

Factors that affect storage performance

System activities, database workload, and DB instance class can affect storage performance.

System activities

The following system-related activities consume I/O capacity and might reduce DB instance performance while in progress:

- Multi-AZ standby creation
- Read replica creation
- Changing storage types

Database workload

In some cases, your database or application design results in concurrency issues, locking, or other forms of database contention. In these cases, you might not be able to use all the provisioned bandwidth directly. In addition, you might encounter the following workload-related situations:

- The throughput limit of the underlying instance type is reached.
- Queue depth is consistently less than 1 because your application is not driving enough I/O operations.
Factors that affect storage performance

- You experience query contention in the database even though some I/O capacity is unused.

In some cases, there isn’t a system resource that is at or near a limit, and adding threads doesn’t increase the database transaction rate. In such cases, the bottleneck is most likely contention in the database. The most common forms are row lock and index page lock contention, but there are many other possibilities. If this is your situation, seek the advice of a database performance tuning expert.

**DB instance class**

To get the most performance out of your Amazon RDS DB instance, choose a current generation instance type with enough bandwidth to support your storage type. For example, you can choose Amazon EBS–optimized instances and instances with 10-gigabit network connectivity.

**Important**
Depending on the instance class you’re using, you might see lower IOPS performance than the maximum that you can provision with RDS. For specific information on IOPS performance for DB instance classes, see Amazon EBS–optimized instances. We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

We encourage you to use the latest generation of instances to get the best performance. Previous generation DB instances can also have lower maximum storage.

Some older 32-bit file systems might have lower storage capacities. To determine the storage capacity of your DB instance, you can use the `describe-valid-db-instance-modifications` AWS CLI command.

The following list shows the maximum storage that most DB instance classes can scale to for each database engine:

- MariaDB: 64 TiB
- Microsoft SQL Server: 16 TiB
- MySQL: 64 TiB
- Oracle: 64 TiB
- PostgreSQL: 64 TiB

The following table shows some exceptions. All RDS for Microsoft SQL Server DB instances have a maximum storage of 16 TiB, so there are no entries for SQL Server.

<table>

For more details about all instance classes supported, see [Previous generation DB instances](#).
Regions, Availability Zones, and Local Zones

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions, Availability Zones, and Local Zones. Each AWS Region is a separate geographic area. Each AWS Region has multiple, isolated locations known as Availability Zones.

**Note**
For information about finding the Availability Zones for an AWS Region, see Describe Your Availability Zones in the Amazon EC2 documentation.

By using Local Zones, you can place resources, such as compute and storage, in multiple locations closer to your users. Amazon RDS enables you to place resources, such as DB instances, and data in multiple locations. Resources aren't replicated across AWS Regions unless you do so specifically.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in a single location that is affected by such a failure, none of your DB instances will be available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, by setting the `AWS_DEFAULT_REGION` environment variable, or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see Configuring the AWS Command Line Interface, specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US) that are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see What is AWS GovCloud (US)?

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

**AWS Regions**

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.
When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

### Region availability

The following table shows the AWS Regions where Amazon RDS is currently available and the endpoint for each Region.

<table>
<thead>
<tr>
<th>Region Name</th>

</tbody>
</table>
If you do not explicitly specify an endpoint, the US West (Oregon) endpoint is the default.

When you work with a DB instance using the AWS CLI or API operations, make sure that you specify its regional endpoint.

### Availability Zones

When you create a DB instance, you can choose an Availability Zone or have Amazon RDS choose one for you randomly. An Availability Zone is represented by an AWS Region code followed by a letter identifier (for example, `us-east-1a`).

You can't choose the Availability Zones for the primary and secondary DB instances in a Multi-AZ DB deployment. Amazon RDS chooses them for you randomly. For more information about Multi-AZ deployments, see [Multi-AZ deployments for high availability](#) (p. 65).

**Note**

Random selection of Availability Zones by RDS doesn't guarantee an even distribution of DB instances among Availability Zones within a single account or DB subnet group. You can request a specific AZ when you create or modify a Single-AZ instance, and you can use more-specific DB subnet groups for Multi-AZ instances. For more information, see [Creating an Amazon RDS DB instance](#) (p. 175) and [Modifying an Amazon RDS DB instance](#) (p. 309).

### Local Zones

A **Local Zone** is an extension of an AWS Region that is geographically close to your users. You can extend any VPC from the parent AWS Region into Local Zones by creating a new subnet and assigning it to the AWS Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as other subnets in your VPC.

When you create a DB instance, you can choose a subnet in a Local Zone. Local Zones have their own connections to the internet and support AWS Direct Connect. Thus, resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

A Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example `us-west-2-lax-1a`.

**Note**

A Local Zone can't be included in a Multi-AZ deployment.

### To use a Local Zone

1. Enable the Local Zone in the Amazon EC2 console.
For more information, see Enabling Local Zones in the Amazon EC2 User Guide for Linux Instances.  

2. Create a subnet in the Local Zone.  
   For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.  

3. Create a DB subnet group in the Local Zone.  
   When you create a DB subnet group, choose the Availability Zone group for the Local Zone.  
   For more information, see Creating a DB instance in a VPC (p. 1852).  

4. Create a DB instance that uses the DB subnet group in the Local Zone.  
   For more information, see Creating an Amazon RDS DB instance (p. 175).  

**Important**  
Currently, the only AWS Local Zone where Amazon RDS is available is Los Angeles in the US West (Oregon) Region.
Multi-AZ deployments for high availability

Multi-AZ deployments can have one standby or two standby DB instances. When the deployment has one standby DB instance, it's called a Multi-AZ DB instance deployment. A Multi-AZ DB instance deployment has one standby DB instance that provides failover support, but doesn't serve read traffic. When the deployment has two standby DB instances, it's called a Multi-AZ DB cluster deployment. A Multi-AZ DB cluster deployment has standby DB instances that provide failover support and can also serve read traffic.

You can use the AWS Management Console to determine whether a Multi-AZ deployment is a Multi-AZ DB instance deployment or a Multi-AZ DB cluster deployment. In the navigation pane, choose Databases, and then choose a DB identifier.

- A Multi-AZ DB instance deployment has the following characteristics:
  - There is only one row for the DB instance.
  - The value of Role is Instance or Primary.
  - The value of Multi-AZ is Yes.
- A Multi-AZ DB cluster deployment has the following characteristics:
  - There is a cluster-level row with three DB instance rows under it.
  - For the cluster-level row, the value of Role is Multi-AZ DB cluster.
  - For each instance-level row, the value of Role is Writer instance or Reader instance.
  - For each instance-level row, the value of Multi-AZ is 3 Zones.

Topics
- Multi-AZ DB instance deployments (p. 66)
- Multi-AZ DB cluster deployments (p. 71)
Multi-AZ DB instance deployments

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments with a single standby DB instance. This type of deployment is called a **Multi-AZ DB instance deployment**. Amazon RDS uses several different technologies to provide this failover support. Multi-AZ deployments for MariaDB, MySQL, Oracle, and PostgreSQL DB instances use the Amazon failover technology. Microsoft SQL Server DB instances use SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For information on SQL Server version support for Multi-AZ, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).

In a Multi-AZ DB instance deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone. The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy and minimize latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance. It can also help protect your databases against DB instance failure and Availability Zone disruption. For more information on Availability Zones, see Regions, Availability Zones, and Local Zones (p. 60).

**Note**
The high availability option isn’t a scaling solution for read-only scenarios. You can’t use a standby replica to serve read traffic. To serve read-only traffic, use a Multi-AZ DB cluster or a read replica instead. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 71). For more information about read replicas, see Working with read replicas (p. 354).

Using the RDS console, you can create a Multi-AZ DB instance deployment by simply specifying Multi-AZ when creating a DB instance. You can use the console to convert existing DB instances to Multi-AZ DB instance deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API. Use the `create-
Multi-AZ DB instance deployments

The RDS console shows the Availability Zone of the standby replica (called the secondary AZ). You can also use the describe-db-instances CLI command or the DescribeDBInstances API operation to find the secondary AZ.

DB instances using Multi-AZ DB instance deployments can have increased write and commit latency compared to a Single-AZ deployment. This can happen because of the synchronous data replication that occurs. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones. For production workloads, we recommend that you use Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see DB instance classes (p. 9).

Modifying a DB instance to be a Multi-AZ DB instance deployment

If you have a DB instance in a Single-AZ deployment and modify it to a Multi-AZ DB instance deployment (for engines other than Amazon Aurora), Amazon RDS takes several steps. First, Amazon RDS takes a snapshot of the primary DB instance from your deployment and then restores the snapshot into another Availability Zone. Amazon RDS then sets up synchronous replication between your primary DB instance and the new DB instance.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

![Important](image)

This action avoids downtime when you convert from Single-AZ to Multi-AZ, but you can experience a performance impact during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency.

To turn on Multi-AZ for a DB instance, RDS takes a snapshot of the primary DB instance's Amazon EBS volume and restores it on the newly created standby replica. RDS then synchronizes both volumes. New volumes created from existing EBS snapshots load lazily in the background. This capability lets large volumes be restored from a snapshot quickly, but it can add latency during the modification and after it's complete. For more information, see Restoring an Amazon EBS volume from a snapshot in the Amazon EC2 documentation.

After the modification is complete, Amazon RDS triggers an event (RDS-EVENT-0025) that indicates the process is complete. You can monitor Amazon RDS events. For more information about events, see Using Amazon RDS event notification (p. 623).

Failover process for Amazon RDS

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time the primary DB instance became unavailable. Failover times are typically 60–120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

![Note](image)

You can force a failover manually when you reboot a DB instance. For more information, see Rebooting a DB instance (p. 350).

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the event log.
## Failover reason

<table>
<thead>
<tr>
<th>Failover reason</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The operating system underlying the RDS database instance is being patched in an offline operation.</td>
<td>A failover was triggered during the maintenance window for an OS patch or a security update. For more information, see Maintaining a DB instance (p. 333).</td>
</tr>
<tr>
<td>The primary host of the RDS Multi-AZ instance is unhealthy.</td>
<td>The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.</td>
</tr>
<tr>
<td>The primary host of the RDS Multi-AZ instance is unreachable due to loss of network connectivity.</td>
<td>RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.</td>
</tr>
<tr>
<td>The RDS instance was modified by customer.</td>
<td>An RDS DB instance modification triggered a failover. For more information, see Modifying an Amazon RDS DB instance (p. 309).</td>
</tr>
<tr>
<td>The RDS Multi-AZ primary instance is busy and unresponsive.</td>
<td>The primary DB instance is unresponsive. We recommend that you do the following:</td>
</tr>
<tr>
<td></td>
<td>• Examine the event and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Using Amazon RDS event notification (p. 623) and Creating a rule that triggers on an Amazon RDS event (p. 642).</td>
</tr>
<tr>
<td></td>
<td>• Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes (p. 9).</td>
</tr>
<tr>
<td></td>
<td>• Use Enhanced Monitoring for real-time operating system metrics. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582).</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>For more information on these recommendations, see Overview of monitoring metrics in Amazon RDS (p. 492) and Best practices for Amazon RDS (p. 161).</td>
</tr>
<tr>
<td>The storage volume underlying the primary host of the RDS Multi-AZ instance experienced a failure.</td>
<td>The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.</td>
</tr>
<tr>
<td>The user requested a failover of the DB instance.</td>
<td>You rebooted the DB instance and chose Reboot with failover.</td>
</tr>
</tbody>
</table>
To determine if your Multi-AZ DB instance has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Using Amazon RDS event notification (p. 623).
- View your DB events by using the RDS console or API operations.
- View the current state of your Multi-AZ DB instance deployment by using the RDS console or API operations.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see Best practices for Amazon RDS (p. 161).

**Setting the JVM TTL for DNS name lookups**

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the time-to-live (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

**Note**

The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see The security manager in the Oracle documentation.

To modify the JVM's TTL, set the networkaddress.cache.ttl property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set networkaddress.cache.ttl=60

- To set the property locally for your application only, set networkaddress.cache.ttl in your application's initialization code before any network connections are established.
java.security.Security.setProperty("networkaddress.cache.ttl", "60");
Multi-AZ DB cluster deployments

A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones in the same AWS Region. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower write latency when compared to Multi-AZ DB instance deployments.

Topics

- Overview of Multi-AZ DB clusters (p. 71)
- Creating and managing a Multi-AZ DB cluster (p. 72)
- Managing connections for Multi-AZ DB clusters (p. 73)
- Managing a Multi-AZ DB cluster with the AWS Management Console (p. 75)

- Replica lag and Multi-AZ DB clusters (p. 77)
- Failover process for Multi-AZ DB clusters (p. 78)
- Limitations for Multi-AZ DB clusters (p. 80)

Important

Multi-AZ DB clusters aren't the same as Aurora DB clusters. For information about Aurora DB clusters, see the Amazon Aurora User Guide.

Overview of Multi-AZ DB clusters

With a Multi-AZ DB cluster, Amazon RDS replicates data from the writer DB instance to both of the reader DB instances using the DB engine's native replication capabilities. When a change is made on the writer DB instance, it's sent to each reader DB instance. Acknowledgment from at least one reader DB instance is required for a change to be committed.

Reader DB instances act as automatic failover targets and also serve read traffic to increase application read throughput. If an outage occurs on your writer DB instance, RDS manages failover to one of the reader DB instances. RDS does this based on which reader DB instance has the most recent change record.

The following diagram shows a Multi-AZ DB cluster.
Multi-AZ DB clusters typically have lower write latency when compared to Multi-AZ DB instance deployments. They also allow read-only workloads to run on reader DB instances. The RDS console shows the Availability Zone of the writer DB instance and the Availability Zones of the reader DB instances. You can also use the describe-db-clusters CLI command or the DescribeDBClusters API operation to find this information.

Creating and managing a Multi-AZ DB cluster

You can create a Multi-AZ DB cluster directly or by restoring from a snapshot. For instructions, see these topics:

- Creating a Multi-AZ DB cluster (p. 195)
- Restoring from a snapshot to a Multi-AZ DB cluster (p. 436)

You can modify, reboot, or delete a Multi-AZ DB by following the instructions in these topics:

- Modifying a Multi-AZ DB cluster (p. 324)
- Rebooting Multi-AZ DB clusters and reader DB instances (p. 352)
• Deleting a Multi-AZ DB cluster (p. 404)

You can create a snapshot of a Multi-AZ DB cluster by following the instructions in Creating a Multi-AZ DB cluster snapshot (p. 430).

You can restore a Multi-AZ DB cluster to a point in time by following the instructions in Restoring a Multi-AZ DB cluster to a specified time (p. 483).

Managing connections for Multi-AZ DB clusters

A Multi-AZ DB cluster has three DB instances instead of a single DB instance. Each connection is handled by a specific DB instance. When you connect to a Multi-AZ DB cluster, the host name and port that you specify point to a fully qualified domain name called an endpoint. The Multi-AZ DB cluster uses the endpoint mechanism to abstract these connections. Thus, you don't have to hardcode all the host names or write your own logic for rerouting connections when some DB instances aren't available.

The writer endpoint connects to the writer DB instance of the DB cluster, which supports both read and write operations. The reader endpoint connects to either of the two reader DB instances, which support only read operations.

Using endpoints, you can map each connection to the appropriate DB instance or group of DB instances based on your use case. For example, to perform DDL and DML statements, you can connect to whichever DB instance is the writer DB instance. To perform queries, you can connect to the reader endpoint, with the Multi-AZ DB cluster automatically managing connections among the reader DB instances. For diagnosis or tuning, you can connect to a specific DB instance endpoint to examine details about a specific DB instance.

For information about connecting to a DB instance, see Connecting to an Amazon RDS DB instance (p. 207).

Topics
• Types of Multi-AZ DB cluster endpoints (p. 73)
• Viewing the endpoints for a Multi-AZ DB cluster (p. 74)
• Using the cluster endpoint (p. 74)
• Using the reader endpoint (p. 75)
• Using the instance endpoints (p. 75)
• How Multi-AZ DB endpoints work with high availability (p. 75)

Types of Multi-AZ DB cluster endpoints

An endpoint is represented by a unique identifier that contains a host address. The following types of endpoints are available from a Multi-AZ DB cluster:

Cluster endpoint

A cluster endpoint (or writer endpoint) for a Multi-AZ DB cluster connects to the current writer DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL and DML statements. This endpoint can also perform read operations.

Each Multi-AZ DB cluster has one cluster endpoint and one writer DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

If the current writer DB instance of a DB cluster fails, the Multi-AZ DB cluster automatically fails over to a new writer DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new writer DB instance, with minimal interruption of service.
The following example illustrates a cluster endpoint for a Multi-AZ DB cluster.

mydcluster.cluster-123456789012.us-east-1.rds.amazonaws.com

Reader endpoint

A reader endpoint for a Multi-AZ DB cluster provides support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as queries. By processing those statements on the reader DB instances, this endpoint reduces the overhead on the writer DB instance. It also helps the cluster to scale the capacity to handle simultaneous SELECT queries. Each Multi-AZ DB cluster has one reader endpoint.

The reader endpoint sends each connection request to one of the reader DB instances. When you use the reader endpoint for a session, you can only perform read-only statements such as SELECT in that session.

The following example illustrates a reader endpoint for a Multi-AZ DB cluster.

mydcluster.cluster-ro-123456789012.us-east-1.rds.amazonaws.com

Instance endpoint

An instance endpoint connects to a specific DB instance within a Multi-AZ DB cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint for the current writer DB instance of the DB cluster, and there is one instance endpoint for each of the reader DB instances in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster. This control can help you address scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different reader DB instances in a DB cluster to distribute read workloads.

The following example illustrates an instance endpoint for a DB instance in a Multi-AZ DB cluster.

mydbinstance.123456789012.us-east-1.rds.amazonaws.com

Viewing the endpoints for a Multi-AZ DB cluster

In the AWS Management Console, you see the cluster endpoint and the reader endpoint on the details page for each Multi-AZ DB cluster. You see the instance endpoint in the details page for each DB instance.

With the AWS CLI, you see the writer and reader endpoints in the output of the describe-db-clusters command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.

```
aws rds describe-db-cluster-endpoints
```

With the Amazon RDS API, you retrieve the endpoints by calling the DescribeDBClusterEndpoints function. The output also shows Amazon Aurora DB cluster endpoints, if any exist.

Using the cluster endpoint

Each Multi-AZ DB cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

You use the cluster endpoint when you administer your DB cluster, perform extract, transform, load (ETL) operations, or develop and test applications. The cluster endpoint connects to the writer DB instance of the cluster. The writer DB instance is the only DB instance where you can create tables and indexes, run INSERT statements, and perform other DDL and DML operations.
The physical IP address pointed to by the cluster endpoint changes when the failover mechanism promotes a new DB instance to be the writer DB instance for the cluster. If you use any form of connection pooling or other multiplexing, be prepared to flush or reduce the time-to-live for any cached DNS information. Doing so ensures that you don't try to establish a read/write connection to a DB instance that became unavailable or is now read-only after a failover.

**Using the reader endpoint**

You use the reader endpoint for read-only connections to your Multi-AZ DB cluster. This endpoint helps your DB cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster. The reader endpoint sends connections to available reader DB instances in a Multi-AZ DB cluster.

Each Multi-AZ cluster has a single built-in reader endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint.

**Using the instance endpoints**

Each DB instance in a Multi-AZ DB cluster has its own built-in instance endpoint, whose name and other attributes are managed by Amazon RDS. You can't create, delete, or modify this kind of endpoint. With a Multi-AZ DB cluster, you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific DB instance in a Multi-AZ DB cluster. While connected to a specific DB instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that DB instance that's different from what's happening for other DB instances in the cluster.

**How Multi-AZ DB endpoints work with high availability**

For Multi-AZ DB clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the writer DB instance of a DB cluster fails, Amazon RDS automatically fails over to a new writer DB instance. It does so by promoting a reader DB instance to a new writer DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted writer DB instance. Or you can use the reader endpoint to reconnect to one of the reader DB instances in the DB cluster. During a failover, the reader endpoint might direct connections to the new writer DB instance of a DB cluster for a short time after a reader DB instance is promoted to the new writer DB instance. If you design your own application logic to manage instance endpoint connections, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster.

**Managing a Multi-AZ DB cluster with the AWS Management Console**

You can manage a Multi-AZ DB cluster with the console.

**To manage a Multi-AZ DB cluster with the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to manage.
The following image shows a Multi-AZ DB cluster in the console.

The available actions in the Actions menu depend on whether the Multi-AZ DB cluster is selected or a DB instance in the cluster is selected.

Choose the Multi-AZ DB cluster to view the cluster details and perform actions at the cluster level.

Choose a DB instance in a Multi-AZ DB cluster to view the DB instance details and perform actions at the DB instance level.

Working with parameter groups for Multi-AZ DB clusters

In a Multi-AZ DB cluster, a DB cluster parameter group acts as a container for engine configuration values that are applied to every DB instance in the Multi-AZ DB cluster.
In a Multi-AZ DB cluster, a **DB parameter group** is set to the default DB parameter group for the DB engine and DB engine version. The settings in the DB cluster parameter group are used for all of the DB instances in the cluster.

For information about parameter groups, see Working with parameter groups (p. 278).

**Replica lag and Multi-AZ DB clusters**

*Replica lag* is the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. The Amazon CloudWatch metric **ReplicaLag** represents this time difference. For more information about CloudWatch metrics, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 508).

Although Multi-AZ DB clusters allow for high write performance, replica lag can still occur due to the nature of engine-based replication. Because any failover must first resolve the replica lag before it promotes a new writer DB instance, monitoring and managing this replica lag is a consideration.

For RDS for MySQL Multi-AZ DB clusters, failover time depends on replica lag of both remaining reader DB instances. Both the reader DB instances must apply unapplied transactions before one of them is promoted to the new writer DB instance.

For RDS for PostgreSQL Multi-AZ DB clusters, failover time depends on the lowest replica lag of the two remaining reader DB instances. The reader DB instance with the lowest replica lag must apply unapplied transactions before it is promoted to the new writer DB instance.

For a tutorial that shows you how to create a CloudWatch alarm when replica lag exceeds a set amount of time, see Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag (p. 514).

**Common causes of replica lag**

In general, replica lag occurs when the write workload is too high for the reader DB instances to apply the transactions efficiently. Various workloads can incur temporary or continuous replica lag. Some examples of common causes are the following:

- High write concurrency or heavy batch updating on the writer DB instance, causing the apply process on the reader DB instances to fall behind.
- Heavy read workload that is using resources on one or more reader DB instances. Running slow or large queries can affect the apply process and can cause replica lag.
- Transactions that modify large amounts of data or DDL statements can sometimes cause a temporary increase in replica lag because the database must preserve commit order.

**Mitigating replica lag**

For Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL, you can mitigate replica lag by reducing the load on your writer DB instance. You can also use flow control to reduce replica lag. **Flow control** works by throttling writes on the writer DB instance, which ensures that replica lag doesn't continue to grow unbounded. Write throttling is accomplished by adding a delay into the end of a transaction, which decreases the write throughput on the writer DB instance. Although flow control doesn't guarantee lag elimination, it can help reduce overall lag in many workloads. The following sections provide information about using flow control with RDS for MySQL and RDS for PostgreSQL.

**Mitigating replica lag with flow control for RDS for MySQL**

When you are using RDS for MySQL Multi-AZ DB clusters, flow control is turned on by default using the dynamic parameter **rpl_semi_sync_master_target_apply_lag**. This parameter specifies the upper limit that you want for replica lag. As replica lag approaches this configured limit, flow control throttles
the write transactions on the writer DB Instance to try to contain the replica lag below the specified value. In some cases, replica lag can exceed the specified limit. By default, this parameter is set to 120 seconds. To turn off flow control, set this parameter to its maximum value of 86400 seconds (one day).

To view the current delay injected by flow control, show the parameter `Rpl_semi_sync_master_flow_control_current_delay` by running the following query.

```
SHOW GLOBAL STATUS like '%flow_control%';
```

Your output looks similar to the following.

```
+-------------------------------------------------+-------+
| Variable_name                                   | Value |
+-------------------------------------------------+-------+
| Rpl_semi_sync_master_flow_control_current_delay | 2010  |
+-------------------------------------------------+-------+
1 row in set (0.00 sec)
```

**Note**
The delay is shown in microseconds.

When you have Performance Insights turned on for an RDS for MySQL Multi-AZ DB cluster, you can monitor the wait event corresponding to a SQL statement indicating that the queries were delayed by a flow control. When a delay was introduced by a flow control, you can view the wait event `/wait/synch/cond/semisync/semi_sync_flow_control_delay_cond` corresponding to the SQL statement on the Performance Insights dashboard. To view these metrics, make sure that the Performance Schema is turned on. For information about Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS (p. 521).

### Mitigating replica lag with flow control for RDS for PostgreSQL

When you are using RDS for PostgreSQL Multi-AZ DB clusters, flow control is deployed as an extension. It turns on a background worker for all DB instances in the DB cluster. By default, the background workers on the reader DB instances communicate the current replica lag with the background worker on the writer DB instance. If the lag exceeds two minutes on any reader DB instance, the background worker on the writer DB instance adds a delay at the end of a transaction. To control the lag threshold, use the parameter `flow_control.target_standby_apply_lag`.

When a flow control throttles a PostgreSQL process, the `Extension` wait event in `pg_stat_activity` and Performance Insights indicates that. The function `get_flow_control_stats` displays details about how much delay is currently being added.

Flow control can benefit most online transaction processing (OLTP) workloads that have short but highly concurrent transactions. If the lag is caused by long-running transactions, such as batch operations, flow control doesn't provide as strong a benefit.

You can turn off flow control by removing the extension from the `preload_shared_libraries` and rebooting your DB instance.

### Failover process for Multi-AZ DB clusters

If there is a planned or unplanned outage of your writer DB instance in a Multi-AZ DB cluster, Amazon RDS automatically fails over to a reader DB instance in different Availability Zone. The time it takes for the failover to complete depends on the database activity and other conditions when the writer DB instance became unavailable. Failover times are typically under 35 seconds. Failover completes when both reader DB instances have applied outstanding transactions from the failed writer. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.
Topics

- Automatic failovers (p. 79)
- Manually failing over a Multi-AZ DB cluster (p. 79)
- Determining whether a Multi-AZ DB cluster has failed over (p. 79)
- Setting the JVM TTL for DNS name lookups (p. 80)

Automatic failovers

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. To fail over, the writer DB instance switches automatically to a reader DB instance.

Manually failing over a Multi-AZ DB cluster

You can fail over a Multi-AZ DB cluster manually using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To fail over a Multi-AZ DB cluster manually

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Multi-AZ DB cluster that you want to fail over.
4. For Actions, choose Failover.
   
   The Failover DB Cluster page appears.
5. Choose Failover to confirm the manual failover.

AWS CLI

To fail over a Multi-AZ DB cluster manually, use the AWS CLI command failover-db-cluster.

Example

```bash
aws rds failover-db-cluster --db-cluster-identifier mymultiazdbcluster
```

RDS API

To fail over a Multi-AZ DB cluster manually, call the Amazon RDS API FailoverDBCluster and specify the DBClusterIdentifier.

Determining whether a Multi-AZ DB cluster has failed over

To determine if your Multi-AZ DB cluster has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Using Amazon RDS event notification (p. 623).
- View your DB events by using the Amazon RDS console or API operations.
- View the current state of your Multi-AZ DB cluster by using the Amazon RDS console, the AWS CLI, and the RDS API.
For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see Best practices for Amazon RDS (p. 161).

**Setting the JVM TTL for DNS name lookups**

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the reader DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a host name to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

**Note**

The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see The security manager in the Oracle documentation.

To modify the JVM's TTL, set the `networkaddress.cache.ttl` property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set `networkaddress.cache.ttl` in the `$JAVA_HOME/jre/lib/security/java.security` file.

```java
networkaddress.cache.ttl=60
```

- To set the property locally for your application only, set `networkaddress.cache.ttl` in your application's initialization code before any network connections are established.

```java
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

**Limitations for Multi-AZ DB clusters**

The following limitations apply to Multi-AZ DB clusters:

- You can create a Multi-AZ DB cluster only with MySQL version 8.0.28 and higher 8.0 versions, and PostgreSQL version 13.4.
- You can create Multi-AZ DB clusters only in the following AWS Regions:
  - US East (Ohio)
  - US East (N. Virginia)
  - US West (Oregon)
Multi-AZ DB clusters only support Provisioned IOPS storage.

You can't change a single-AZ DB instance deployment or Multi-AZ DB instance deployment into a Multi-AZ DB cluster. As an alternative, you can restore a snapshot of a single-AZ DB instance deployment or Multi-AZ DB instance deployment to a Multi-AZ DB cluster.

You can't restore a Multi-AZ DB cluster snapshot to a Multi-AZ DB instance deployment or single-AZ deployment.

Multi-AZ DB clusters don't support modifications at the DB instance level because all modifications are done at the DB cluster level.

Multi-AZ DB clusters don't support the following features:

- Amazon RDS Proxy
- AWS Backup
- AWS CloudFormation
- Exporting Multi-AZ DB cluster snapshot data to an Amazon S3 bucket
- IAM DB authentication
- Kerberos authentication
- Integration with AWS Secrets Manager
- Modifying the port

As an alternative, you can restore a Multi-AZ DB cluster to a point in time and specify a different port.

- Option groups
- Read replicas
- Reserved DB instances
- Restoring a Multi-AZ DB cluster snapshot from an Amazon S3 bucket
- Storage autoscaling by setting the maximum allocated storage

As an alternative, you can scale storage manually.

- Stopping and starting the DB cluster

RDS for MySQL Multi-AZ DB clusters don't support replication to an external target database.

RDS for MySQL Multi-AZ DB clusters support only the following system stored procedures:

- `mysql.rds_rotate_general_log`
- `mysql.rds_rotate_slow_log`
- `mysql.rds_show_configuration`

RDS for MySQL Multi-AZ DB clusters don't support other system stored procedures. For information about these procedures, see MySQL on Amazon RDS SQL reference (p. 1264).

RDS for PostgreSQL Multi-AZ DB clusters don't support the following PostgreSQL extensions: `aws_s3`, `pg_transport`, and `pglogical`.

RDS for PostgreSQL Multi-AZ DB clusters don't support using a custom DNS server for outbound network access.

RDS for PostgreSQL Multi-AZ DB clusters don't support logical replication.
DB instance billing for Amazon RDS

Amazon RDS instances are billed based on the following components:

- **DB instance hours (per hour)** – Based on the DB instance class of the DB instance (for example, `db.t2.small` or `db.m4.large`). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in one second increments, with a minimum of 10 minutes. For more information, see [DB instance classes](#).  
- **Storage (per GiB per month)** – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see [Amazon RDS DB instance storage](#).  
- **I/O requests (per 1 million requests per month)** – Total number of storage I/O requests that you have made in a billing cycle, for Amazon RDS magnetic storage only.  
- **Provisioned IOPS (per IOPS per month)** – Provisioned IOPS rate, regardless of IOPS consumed, for Amazon RDS Provisioned IOPS (SSD) storage only. Provisioned storage for EBS volumes are billed in one second increments, with a minimum of 10 minutes.  
- **Backup storage (per GiB per month)** – Backup storage is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn’t apply to backup storage (metered in GB-month). For more information, see [Backing up and restoring an Amazon RDS DB instance](#).  
- **Data transfer (per GB)** – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand Instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in one second increments, with a minimum of 10 minutes.  
- **Reserved Instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

For Amazon RDS pricing information, see the [Amazon RDS product page](#).

**Topics**

- [On-Demand DB instances for Amazon RDS](#)
- [Reserved DB instances for Amazon RDS](#)
On-Demand DB instances for Amazon RDS

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t2.small or db.m4.large). For Amazon RDS pricing information, see the Amazon RDS product page.

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see Viewing Amazon RDS DB instance status (p. 497).

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.
Reserved DB instances for Amazon RDS

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance. The new DB instance that you create must match the specifications of the reserved DB instance. If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see Size-flexible reserved DB instances (p. 85).

For more information about reserved DB instances, including pricing, see Amazon RDS reserved instances.

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see Amazon RDS reserved DB instances in the AWS Billing and Cost Management User Guide.
Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.m4.large. For more information about instance classes, see DB instance classes (p. 9).

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.m4.large can apply to a db.m4.xlarge, but not to a db.m5.large, because db.m4 and db.m5 are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units) to a Multi-AZ deployment running on two small DB instances (2*2 = 4 normalized units).

Size-flexible reserved DB instances are available for the following Amazon RDS database engines:

- MariaDB
- MySQL
- Oracle, Bring Your Own License
- PostgreSQL

For details about using size-flexible reserved instances with Aurora, see Reserved DB instances for Aurora.

You can compare usage for different reserved DB instance sizes by using normalized units. For example, one unit of usage on two db.m3.large DB instances is equivalent to eight normalized units of usage on one db.m3.small. The following table shows the number of normalized units for each DB instance size.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Single-AZ normalized units</th>
<th>Multi-AZ normalized units</th>
</tr>
</thead>
<tbody>
<tr>
<td>micro</td>
<td>0.5</td>
<td>1</td>
</tr>
<tr>
<td>small</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>medium</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>large</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>xlarge</td>
<td>8</td>
<td>16</td>
</tr>
<tr>
<td>2xlarge</td>
<td>16</td>
<td>32</td>
</tr>
<tr>
<td>4xlarge</td>
<td>32</td>
<td>64</td>
</tr>
<tr>
<td>6xlarge</td>
<td>48</td>
<td>96</td>
</tr>
<tr>
<td>8xlarge</td>
<td>64</td>
<td>128</td>
</tr>
<tr>
<td>10xlarge</td>
<td>80</td>
<td>160</td>
</tr>
<tr>
<td>12xlarge</td>
<td>96</td>
<td>192</td>
</tr>
<tr>
<td>16xlarge</td>
<td>128</td>
<td>256</td>
</tr>
<tr>
<td>24xlarge</td>
<td>192</td>
<td>384</td>
</tr>
<tr>
<td>Instance size</td>
<td>Single-AZ normalized units</td>
<td>Multi-AZ normalized units</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>32xlarge</td>
<td>256</td>
<td>512</td>
</tr>
</tbody>
</table>

For example, suppose that you purchase a `db.t2.medium` reserved DB instance, and you have two running `db.t2.small` DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.

Alternatively, if you have one `db.t2.large` instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.

### Reserved DB instance billing example

The price for a reserved DB instance doesn’t include regular costs associated with storage, backups, and I/O. The following example illustrates the total cost per month for a reserved DB instance:

- An RDS for MySQL reserved Single-AZ `db.r4.large` DB instance class in US East (N. Virginia) with the No Upfront option at a cost of $0.12 for the instance, or $90 per month
- 400 GiB of General Purpose SSD (gp2) storage at a cost of 0.115 per GiB per month, or $45.60 per month
- 600 GiB of backup storage at $0.095, or $19 per month (400 GiB free)
Add all of these options ($90 + $45.60 + $19) with the reserved DB instance, and the total cost per month is $154.60.

If you chose to use an on-demand DB instance instead of a reserved DB instance, an RDS for MySQL Single-AZ db.r4.large DB instance class in US East (N. Virginia) costs $0.1386 per hour, or $101.18 per month. So, for an on-demand DB instance, add all of these options ($101.18 + $45.60 + $19), and the total cost per month is $165.78. You save a little over $11 per month by using the reserved DB instance.

Note
The prices in this example are sample prices and might not match actual prices.
For Amazon RDS pricing information, see the Amazon RDS product page.

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Working with reserved DB instances

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Reserved instances.
3. Choose Purchase Reserved DB Instance.
4. For Product description, choose the DB engine and licensing type.
5. For DB instance class, choose the DB instance class.
6. For Multi-AZ deployment, choose whether you want a Multi-AZ deployment.
7. For Term, choose the length of time you want the DB instance reserved.
8. For Offering type, choose the offering type.

After you select the offering type, you can see the pricing information.

Important
Choose Cancel to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.
To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Reserved instances.
3. Choose Purchase Reserved DB Instance.
4. For Product description, choose the DB engine and licensing type.
5. For DB instance class, choose the DB instance class.
6. For Multi-AZ deployment, choose whether you want a Multi-AZ deployment.
7. For Term, choose the length of time you want the DB instance reserved.
8. For Offering type, choose the offering type.

After you choose the offering type, you can see the pricing information.

9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For Reserved Id, type an identifier for your reserved DB instance.
10. Choose **Continue**.

The **Purchase Reserved DB Instances** dialog box appears, with a summary of the reserved DB instance attributes that you've selected and the payment due.

![Purchase Reserved DB Instances dialog box](image)

11. On the confirmation page, review your reserved DB instance. If the information is correct, choose **Order** to purchase the reserved DB instance.

Alternatively, choose **Back** to edit your reserved DB instance.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

**To get information about reserved DB instances for your AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

2. In the Navigation pane, choose **Reserved instances**.

The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.
AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command `describe-reserved-db-instances-offerings`.

```bash
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

<table>
<thead>
<tr>
<th>OFFERING</th>
<th>OfferingId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Duration</th>
<th>Fixed Price</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>438012d3-4052-4cc7-b2e3-8d3372e0e706</td>
<td>db.m1.large</td>
<td>y</td>
<td>1y</td>
<td>1820.00</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Partial</td>
<td></td>
<td></td>
<td>0.368 USD</td>
</tr>
<tr>
<td></td>
<td>649fd0c8-cf6d-47a0-bfa6-060f8e75e95f</td>
<td>db.m1.small</td>
<td>n</td>
<td>1y</td>
<td>227.50</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Partial</td>
<td></td>
<td></td>
<td>0.046 USD</td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-47a0-bfa6-12345667232f</td>
<td>db.m1.small</td>
<td>n</td>
<td>1y</td>
<td>162.00</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All</td>
<td></td>
<td></td>
<td>0.00 USD</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-37a0-bfa6-12345667232d</td>
<td>db.m1.large</td>
<td>y</td>
<td>1y</td>
<td>700.00</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All</td>
<td></td>
<td></td>
<td>0.00 USD</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-17d0-bfa6-12345667234e</td>
<td>db.m1.xlarge</td>
<td>n</td>
<td>1y</td>
<td>4242.00</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No</td>
<td></td>
<td></td>
<td>2.42 USD</td>
</tr>
</tbody>
</table>

Recurring Charges:
- Amount  | Currency  | Frequency
- 0.123   | USD       | Hourly
- 1.25    | USD       | Hourly
- 4242.00 | USD       | Hourly

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command `purchase-reserved-db-instances-offering` with the following parameters:

- `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID `649fd0c8-cf6d-47a0-bfa6-060f8e75e95f`, and assigns the identifier of `MyReservation`.

For Linux, macOS, or Unix:

```bash
aws rds purchase-reserved-db-instances-offering
   --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f
   --reserved-db-instance-id MyReservation
```

For Windows:

```bash
aws rds purchase-reserved-db-instances-offering
   --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f
   --reserved-db-instance-id MyReservation
```

AWS CLI
The command returns output similar to the following:

<table>
<thead>
<tr>
<th>Reservation</th>
<th>ReservationId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Start Time</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed Price</td>
<td>Usage Price</td>
<td>Count</td>
<td>State</td>
<td>Description</td>
<td>Offering Type</td>
</tr>
<tr>
<td>RESERVATION</td>
<td>MyReservation</td>
<td>db.m1.small</td>
<td>y</td>
<td>2011-12-19T00:30:23.247Z</td>
<td>1y</td>
</tr>
<tr>
<td>455.00 USD</td>
<td>0.092 USD</td>
<td>1</td>
<td>payment-pending</td>
<td>mysql</td>
<td>Partial Upfront</td>
</tr>
</tbody>
</table>

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command `describe-reserved-db-instances`, as shown in the following example.

**Example of getting your reserved DB instances**

```bash
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

<table>
<thead>
<tr>
<th>Reservation</th>
<th>ReservationId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Start Time</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed Price</td>
<td>Usage Price</td>
<td>Count</td>
<td>State</td>
<td>Description</td>
<td>Offering Type</td>
</tr>
<tr>
<td>RESERVATION</td>
<td>MyReservation</td>
<td>db.m1.small</td>
<td>y</td>
<td>2011-12-09T23:37:44.720Z</td>
<td>1y</td>
</tr>
<tr>
<td>455.00 USD</td>
<td>0.092 USD</td>
<td>1</td>
<td>retired</td>
<td>mysql</td>
<td>Partial Upfront</td>
</tr>
</tbody>
</table>

**RDS API**

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation `DescribeReservedDBInstancesOfferings`.
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the `PurchaseReservedDBInstancesOffering` RDS API operation with the following parameters:
  - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
  - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the `DescribeReservedDBInstances` RDS API operation.

**Viewing the billing for your reserved DB instances**

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

**To view reserved DB instance billing**

1. Sign in to the AWS Management Console.
2. From the account menu at the upper right, choose Billing Dashboard.
3. Choose Bill Details at the upper right of the dashboard.
4. Under AWS Service Charges, expand Relational Database Service.
5. Expand the AWS Region where your reserved DB instances are, for example US West (Oregon).

Your reserved DB instances and their hourly charges for the current month are shown under Amazon Relational Database Service for Database Engine Reserved Instances.
The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.

6. Choose the **Cost Explorer** (bar graph) icon next to the **Reserved Instances** heading.

   The Cost Explorer displays the **Monthly EC2 running hours costs and usage** graph.

7. Clear the **Usage Type Group** filter to the right of the graph.

8. Choose the time period and time unit for which you want to examine usage costs.

   The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.

   The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

   The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.
Setting up for Amazon RDS

Before you use Amazon Relational Database Service for the first time, complete the following tasks:

1. Sign up for AWS (p. 93)
2. Create an IAM user (p. 93)
3. Determine requirements (p. 95)
4. Provide access to your DB instance in your VPC by creating a security group (p. 96)

If you already have an AWS account, know your Amazon RDS requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to Getting started with Amazon RDS (p. 99).

Sign up for AWS

When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon RDS. You are charged only for the services that you use.

With Amazon RDS, you pay only for the resources you use. The Amazon RDS DB instances that you create are live (not running in a sandbox). You incur the standard Amazon RDS usage fees for each DB instance until you terminate it. For more information about Amazon RDS usage rates, see the Amazon RDS product page. If you are a new AWS customer, you can get started with Amazon RDS for free; for more information, see AWS free tier.

If you have an AWS account already, skip to the next section, Create an IAM user (p. 93).

If you don't have an AWS account, you can use the following procedure to create one.

To create a new AWS account

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   Note your AWS account number, because you'll need it for the next task.

Create an IAM user

After you create an AWS account and successfully connect to the AWS Management Console, you can create an AWS Identity and Access Management (IAM) user. Instead of signing in with your AWS root account, we recommend that you use an IAM administrative user with Amazon RDS.

One way to do this is to create a new IAM user and grant it administrator permissions. Alternatively, you can add an existing IAM user to an IAM group with Amazon RDS administrative permissions. You can then access AWS from a special URL using the credentials for the IAM user.

If you signed up for AWS but haven't created an IAM user for yourself, you can create one using the IAM console.
To create an administrator user for yourself and add the user to an administrators group (console)

1. Sign in to the IAM console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.

   **Note**
   We strongly recommend that you adhere to the best practice of using the Administrator IAM user that follows and securely lock away the root user credentials. Sign in as the root user only to perform a few account and service management tasks.

2. In the navigation pane, choose Users and then choose Add user.

3. For User name, enter Administrator.

4. Select the check box next to AWS Management Console access. Then select Custom password, and then enter your new password in the text box.

5. (Optional) By default, AWS requires the new user to create a new password when first signing in. You can clear the check box next to User must create a new password at next sign-in to allow the new user to reset their password after they sign in.

6. Choose Next: Permissions.

7. Under Set permissions, choose Add user to group.

8. Choose Create group.

9. In the Create group dialog box, for Group name enter Administrators.

10. Choose Filter policies, and then select AWS managed - job function to filter the table contents.

11. In the policy list, select the check box for AdministratorAccess. Then choose Create group.

   **Note**
   You must activate IAM user and role access to Billing before you can use the AdministratorAccess permissions to access the AWS Billing and Cost Management console. To do this, follow the instructions in step 1 of the tutorial about delegating access to the billing console.

12. Back in the list of groups, select the check box for your new group. Choose Refresh if necessary to see the group in the list.

13. Choose Next: Tags.

14. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM entities in the IAM User Guide.

15. Choose Next: Review to see the list of group memberships to be added to the new user. When you are ready to proceed, choose Create user.

You can use this same process to create more groups and users and to give your users access to your AWS account resources. To learn about using policies that restrict user permissions to specific AWS resources, see Access management and Example policies.

To sign in as the new IAM user, first sign out of the AWS Management Console. Then use the following URL, where your/aws_account_id is your AWS account number without the hyphens. For example, if your AWS account number is 1234-5678-9012, your AWS account ID is 123456789012.

https://your/aws_account_id.signin.aws.amazon.com/console/

Type the IAM user name and password that you just created. When you’re signed in, the navigation bar displays "your_user_name @ your/aws_account_id".

If you don’t want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, choose Customize and type an alias, such as your company name. To sign in after you create an account alias, use the following URL.
Determine requirements

The basic building block of Amazon RDS is the DB instance. In a DB instance, you create your databases. A DB instance provides a network address called an **endpoint**. Your applications use this endpoint to connect to your DB instance. When you create a DB instance, you specify details like storage, memory, database engine and version, network configuration, security, and maintenance periods. You control network access to a DB instance through a security group.

Before you create a DB instance and a security group, you must know your DB instance and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You use these settings to help you determine what DB instance class to use. For specifications about DB instance classes, see [DB instance classes](#).

- **VPC, subnet, and security group** – Your DB instance will most likely be in a virtual private cloud (VPC). To connect to your DB instance, you need to set up security group rules. These rules are set up differently depending on what kind of VPC you use and how you use it: in a default VPC or in a user-defined VPC.

The following list describes the rules for each VPC option:

- **Default VPC** – If your AWS account has a default VPC in the current AWS Region, that VPC is configured to support DB instances. If you specify the default VPC when you create the DB instance, do the following:
  - Make sure to create a VPC **security group** that authorizes connections from the application or service to the Amazon RDS DB instance. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 4: Create a VPC security group (p. 1856).
  - Specify the default DB subnet group. If this is the first DB instance you have created in this AWS Region, Amazon RDS creates the default DB subnet group when it creates the DB instance.

- **User-defined VPC** – If you want to specify a user-defined VPC when you create a DB instance, be aware of the following:
  - Make sure to create a VPC **security group** that authorizes connections from the application or service to the Amazon RDS DB instance. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 4: Create a VPC security group (p. 1856).
  - The VPC must meet certain requirements in order to host DB instances, such as having at least two subnets, each in a separate Availability Zone. For information, see [Amazon Virtual Private Cloud VPCs and Amazon RDS](#) (p. 1849).
  - Make sure to specify a DB subnet group that defines which subnets in that VPC can be used by the DB instance. For information, see the DB subnet group section in [Working with a DB instance in a VPC](#) (p. 1850).
Note
Some legacy accounts don't use a VPC. If you are accessing a new AWS Region or you are a new RDS user (after 2013), you are most likely creating a DB instance inside a VPC. For more information, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).

• **High availability**: Do you need failover support? On Amazon RDS, a Multi-AZ deployment creates a primary DB instance and a secondary standby DB instance in another Availability Zone for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a deployment that isn't Multi-AZ. For more information, see Multi-AZ deployments for high availability (p. 65).

• **IAM policies**: Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management in Amazon RDS (p. 1766).

• **Open ports**: What TCP/IP port does your database listen on? The firewall at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB instance. When you create a DB instance that listens on a port you specify, you can change the port by modifying the DB instance.

• **AWS Region**: What AWS Region do you want your database in? Having your database in close proximity to your application or web service can reduce network latency. For more information, see Regions, Availability Zones, and Local Zones (p. 60).

• **DB disk subsystem**: What are your storage requirements? Amazon RDS provides three storage types:
  - Magnetic (Standard Storage)
  - General Purpose (SSD)
  - Provisioned IOPS (PIOPS)

Magnetic storage offers cost-effective storage that is ideal for applications with light or burst I/O requirements. General purpose, SSD-backed storage, also called gp2, can provide faster access than disk-based storage. Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, which are sensitive to storage performance and consistency in random access I/O throughput. For more information on Amazon RDS storage, see Amazon RDS DB instance storage (p. 53).

When you have the information you need to create the security group and the DB instance, continue to the next step.

**Provide access to your DB instance in your VPC by creating a security group**

VPC security groups provide access to DB instances in a VPC. They act as a firewall for the associated DB instance, controlling both inbound and outbound traffic at the DB instance level. DB instances are created by default with a firewall and a default security group that protect the DB instance.

Before you can connect to your DB instance, you must add rules to a security group that enable you to connect. Use your network and configuration information to create rules to allow access to your DB instance.

For example, suppose that you have an application that accesses a database on your DB instance in a VPC. In this case, you must add a custom TCP rule that specifies the port range and IP addresses that your application uses to access the database. If you have an application on an Amazon EC2 instance, you can use the security group that you set up for the Amazon EC2 instance.
For information about common scenarios for accessing a DB instance, see Scenarios for accessing a DB instance in a VPC (p. 1857).

To create a VPC security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.

   Note
   Make sure you are in the VPC console, not the RDS console.

2. In the top right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB instance. In the list of Amazon VPC resources for that AWS Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.

3. In the navigation pane, choose Security Groups.

4. Choose Create security group.

   The Create security group page appears.

5. In Basic details, enter the Security group name and Description. For VPC, choose the VPC that you want to create your DB instance in.

6. In Inbound rules, choose Add rule.

   a. For Type, choose Custom TCP.
   b. For Port range, enter the port value to use for your DB instance.
   c. For Source, choose a security group name or type the IP address range (CIDR value) from where you access the DB instance. If you choose My IP, this allows access to the DB instance from the IP address detected in your browser.

7. If you need to add more IP addresses or different port ranges, choose Add rule and enter the information for the rule.

8. (Optional) In Outbound rules, add rules for outbound traffic. By default, all outbound traffic is allowed.

9. Choose Create security group.

You can use the VPC security group that you just created as the security group for your DB instance when you create it.

   Note
   If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB instance, you can select the default VPC and use default for DB Subnet Group.

Once you have completed the setup requirements, you can create a DB instance using your requirements and security group by following the instructions in Creating an Amazon RDS DB instance (p. 175). For information about getting started by creating a DB instance that uses a specific DB engine, see the relevant documentation in the following table.

<table>

**Note**
If you can't connect to a DB instance after you create it, see the troubleshooting information in Can't connect to Amazon RDS DB instance (p. 1880).
Getting started with Amazon RDS

In the following examples, you can find how to create and connect to a DB instance using Amazon Relational Database Service (Amazon RDS). You can create a DB instance that uses MariaDB, MySQL, Microsoft SQL Server, Oracle, or PostgreSQL.

**Important**
Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 93).

Creating a DB instance and connecting to a database on an Amazon RDS DB instance is slightly different for each of the DB engines. Choose one of the following DB engines that you want to use for detailed information on creating and connecting to the DB instance. After you have created and connected to your DB instance, there are instructions to help you delete the DB instance.

**Topics**
- Creating a MariaDB DB instance and connecting to a database on a MariaDB DB instance (p. 99)
- Creating a Microsoft SQL Server DB instance and connecting to it (p. 107)
- Creating a MySQL DB instance and connecting to a database on a MySQL DB instance (p. 116)
- Creating an Oracle DB instance and connecting to a database on an Oracle DB instance (p. 124)
- Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance (p. 130)
- Tutorial: Create a web server and an Amazon RDS DB instance (p. 141)

Creating a MariaDB DB instance

The easiest way to create a MariaDB DB instance is to use the AWS Management Console. After you create the DB instance, you can use command line tools such as mysql or graphical tools such as HeidiSQL to connect to a database on the DB instance.

**Important**
Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 93).

**Topics**
- Creating a MariaDB DB instance (p. 99)
- Connecting to a database on a DB instance running the MariaDB database engine (p. 103)
- Deleting a DB instance (p. 106)

Creating a MariaDB DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MariaDB databases.
You can use **Easy create** to create a DB instance running MariaDB with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use **Easy create** to create a DB instance running the MariaDB database engine with a db.t2.micro DB instance class.

**Note**
For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance](p. 175).

**To create a MariaDB DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.

5. In **Configuration**, choose **MariaDB**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.
You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after database creation.

- To change settings with No in that column, use Standard create.
- To change settings with Yes in that column, either use Standard create, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use Standard create to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).
Connecting to a database on a DB instance running MariaDB

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

  If the DB instance should be private, leave **Public access** set to **No**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**
You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see **Modifying an Amazon RDS DB instance** (p. 309).

12. For **Databases**, choose the name of the new Maria DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

### Connecting to a database on a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to a database on the DB instance. In this example, you connect to a database on a Maria DB instance using the mysql command-line tool. For more information on using MariaDB, see the MariaDB documentation.

**To connect to a database on a DB instance using the mysql command-line tool**

1. Install a SQL client that you can use to connect to the DB instance.
You can connect to an Amazon RDS for MariaDB DB instance by using tools like the mysql command-line client. For more information on using the mysql command-line client, see [mysql command-line client](https://mariadb.com/kb/en/mysql-command-line-client/) in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the [Download HeidiSQL page](https://heidisql.com/). For information about installing MySQL (including the mysql command-line client), see [Installing and upgrading MySQL](https://dev.mysql.com/doc/quickstart/en/).

2. Make sure that your DB instance is associated with a security group that provides access to it. For more information, see [Provide access to your DB instance in your VPC by creating a security group](#).

   If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see [Modifying an Amazon RDS DB instance](#).

3. Find the endpoint (DNS name) and port number for your DB instance.
   a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
   b. Choose the Maria DB instance name to display its details.
   c. On the **Connectivity & security** tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.
4. Enter the following command at a command prompt on a client computer to connect to a database on a Maria DB instance. Substitute the DNS name (endpoint) for your DB instance for `<endpoint>`. In addition, substitute the master user name that you used for `<mymasteruser>` and provide the master password that you used when prompted for a password.

```
PROMPT> mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 31
```
Deleting a DB instance

After you have connected to the sample DB instance that you created, you should delete the DB instance so you are no longer charged for it.

**To delete a DB instance with no final DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance you want to delete.
4. For Actions, choose Delete.
5. For Create final snapshot?, choose No, and select the acknowledgment.
6. Choose Delete.
Creating a Microsoft SQL Server DB instance and connecting to it

The basic building block of Amazon RDS is the DB instance. Your Amazon RDS DB instance is similar to your on-premises Microsoft SQL Server. After you create your SQL Server DB instance, you can add one or more custom databases to it.

**Important**
Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 93).

In this topic, you create a sample SQL Server DB instance. You then connect to the DB instance and run a simple query. Finally, you delete the sample DB instance.

Creating a sample SQL Server DB instance

You can use **Easy create** to create a DB instance running Microsoft SQL Server with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use **Easy create** to create a DB instance running the Microsoft SQL Server database engine with a db.t2.micro DB instance class.

**Note**
For information about creating DB instances with **Standard create**, see Creating an Amazon RDS DB instance (p. 175).

**To create a Microsoft SQL Server DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.
   
   ![Create database](image)
   
5. From **Engine type**, choose **Microsoft SQL Server**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter **sample-instance**, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

9. To use an automatically generated master password for the DB instance, select the **Auto generate a password** box.

   To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

   The **Create database** page should look similar to the following image.
10. (Optional) Expand View default settings for Easy create.
Amazon Relational Database Service User Guide
Creating a sample SQL Server DB instance

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use **Standard create** to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see **Provide access to your DB instance in your VPC by creating a security group** (p. 96).
• If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**
You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see **Modifying an Amazon RDS DB instance (p. 309)**.

12. For **Databases**, choose the name of the new Microsoft SQL Server DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

---

**Connecting to your sample SQL Server DB instance**

In the following procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

Before you begin, your database should have a status of **Available**. If it has a status of **Creating** or **Backing-up**, wait until it shows **Available**. The status updates without requiring you to refresh the page. This process can take up to 20 minutes.

Also, make sure that you have SSMS installed. You can also connect to RDS for SQL Server by using a different tool, such as an add-in for your development environment or some other database tool. However, this tutorial only covers using SSMS. To download a standalone version of this SSMS, see **Download SQL Server Management Studio (SSMS)** in the Microsoft documentation.
To connect to a DB instance using SSMS

1. Make sure that your DB instance is associated with a security group that provides access to it. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

2. Find the DNS name and port number for your DB instance.
   a. Open the RDS console, and then choose Databases to display a list of your DB instances.
   b. Hover your mouse cursor over the name sample-instance, which is blue. When you do this, the mouse cursor changes into a selection icon (for example, a pointing hand). Also, the DB instance name becomes underlined.

      Click on the DB instance name to choose it. The screen changes to display the information for the DB instance you choose.
   c. On the Connectivity tab, which opens by default, copy the endpoint. The Endpoint looks something like this: sample-instance.123456789012.us-east-2.rds.amazonaws.com. Also, note the port number. The default port for SQL Server is 1433. If yours is different, write it down.

The **Connect to Server** dialog box appears.

4. Provide the following information for your sample DB instance:

   a. For **Server type**, choose **Database Engine**.

   b. For **Server name**, enter the DNS name, followed by a comma and the port number (the default port is 1433). For example, your server name should look like the following.

   ```
sample-instance.abc2defghije.us-west-2.rds.amazonaws.com,1433
   ```

   c. For **Authentication**, choose **SQL Server Authentication**.
Exploring your sample DB instance

d. For **Login**, enter the user name that you chose to use for your sample DB instance. This is also known as the master user name.

e. For **Password**, enter the password that you chose earlier for your sample DB instance. This is also known as the master user password.

5. **Choose Connect.**

After a few moments, SSMS connects to your DB instance.

For more information about connecting to a Microsoft SQL Server DB instance, see [Connecting to a DB instance running the Microsoft SQL Server database engine](p. 947). For information on connection issues, see [Can't connect to Amazon RDS DB instance](p. 1880).

Exploring your sample SQL Server DB instance

In this procedure, you continue the previous procedure and explore your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

**To explore a DB instance using SSMS**

1. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (master, model, msdb, and tempdb). To explore the system databases, do the following:
   
   a. In SSMS, on the **View** menu, choose **Object Explorer**.
   
   b. Expand your DB instance, expand **Databases**, and then expand **System Databases** as shown.

   ![Object Explorer](image)

   Your SQL Server DB instance also comes with a database named *rdsadmin*. Amazon RDS uses this database to store the objects that it uses to manage your database. The *rdsadmin* database also includes stored procedures that you can run to perform advanced tasks.

2. Start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your sample DB instance, do the following:
   
   a. In SSMS, on the **File** menu point to **New** and then choose **Query with Current Connection**.
Deleting your sample DB instance

After you are done exploring the sample DB instance that you created, you should delete the DB instance so that you are no longer charged for it.

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the button next to sample-instance, or whatever you named your sample DB instance.
4. From Actions, choose Delete.
5. If you see a message that says This database has deletion protection option enabled, follow these steps:
   a. Choose Modify.
   b. On the Deletion protection card (near the bottom of the page), clear the box next to Enable deletion protection. Then choose Continue.
   c. On the Scheduling of modifications card, choose Apply immediately. Then choose Modify DB instance.
   d. Try again to delete the instance by choosing Delete from the Actions menu.
6. Clear the box for Create final snapshot. Because this isn’t a production database, you don’t need to save a copy of it.
7. Verify that you selected the correct database to delete. The name "sample-instance" displays in the title of the screen: Delete sample-instance instance?

   If you don't recognize the name of your sample instance in the title, choose Cancel and start over.
8. To confirm that you want to permanently delete the database that is displayed in the title of this screen, do the following:
Creating a MySQL DB instance and connecting to a database on a MySQL DB instance

The easiest way to create a DB instance is to use the AWS Management Console. After you have created the DB instance, you can use standard MySQL utilities such as MySQL Workbench to connect to a database on the DB instance.

**Important**
Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 93).

**Topics**
- Creating a MySQL DB instance (p. 116)
- Connecting to a database on a DB instance running the MySQL database engine (p. 120)
- Deleting a DB instance (p. 123)

**Creating a MySQL DB instance**

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MySQL databases.

You can use **Easy create** to create a DB instance running MySQL with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use **Easy create** to create a DB instance running the MySQL database engine with a db.t2.micro DB instance class.

**Note**
For information about creating DB instances with **Standard create**, see Creating an Amazon RDS DB instance (p. 175).

**To create a MySQL DB instance with Easy create**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy create** is chosen.
5. In Configuration, choose MySQL.
6. For DB instance size, choose Free tier.
7. For DB instance identifier, enter a name for the DB instance, or leave the default name.
8. For Master username, enter a name for the master user, or leave the default name.

The Create database page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, make sure that the Auto generate a password box is selected.
To enter your master password, clear the Auto generate a password box, and then enter the same password in Master password and Confirm password.

10. (Optional) Open View default settings for Easy create.

You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after database creation.

- To change settings with No in that column, use Standard create.
- To change settings with Yes in that column, either use Standard create, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so,
use **Standard create** to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

- If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

  If the DB instance should be private, leave **Public access** set to **No**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

You can use the user name and password that appears to connect to the DB instance as the master user.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

12. In the **Databases** list, choose the name of the new MySQL DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

### Connecting to a database on a DB instance running the MySQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to a database on the DB instance. In this example, you connect to a database on a MySQL DB instance using MySQL monitor commands.

**To connect to a database on a DB instance using MySQL monitor**

1. Install a SQL client that you can use to connect to the DB instance.
You can connect to a MySQL DB instance by using tools like the mysql command line utility. For more information on using the MySQL client, see `mysqld` - the MySQL command-line client in the MySQL documentation. One GUI-based application that you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page.

For more information on using MySQL, see the MySQL documentation. For information about installing MySQL (including the MySQL client), see Installing and upgrading MySQL.

If your DB instance is publicly accessible, you can install the SQL client outside of your VPC. If your DB instance is private, you typically install the SQL client on a resource inside your VPC, such as an Amazon EC2 instance.

2. Make sure that your DB instance is associated with a security group that provides access to it. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

3. Find the endpoint (DNS name) and port number for your DB instance.
   a. Open the RDS console and then choose Databases to display a list of your DB instances.
   b. Choose the MySQL DB instance name to display its details.
   c. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
4. Connect to the database on a MySQL DB instance. For example, enter the following command at a command prompt on a client computer to connect to a database on a MySQL DB instance using the MySQL client. Substitute the DNS name for your DB instance for `<endpoint>`. In addition, substitute the master user name that you used for `<mymasteruser>`, and provide the master password that you used when prompted for a password.

```
PROMPT> mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
```
Deleting a DB instance

After you have connected to the sample DB instance that you created, you should delete the DB instance so you are no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to delete.
4. For Actions, choose Delete.
5. For Create final snapshot?, choose No, and select the acknowledgment.
6. Choose Delete.
Creating an Oracle DB instance and connecting to a database on an Oracle DB instance

The basic building block of Amazon RDS is the DB instance. Your Amazon RDS DB instance is similar to your on-premises Oracle database.

Important
Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 93).

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

In this topic, you create a sample Oracle DB instance and connect to it. Finally, you delete the sample DB instance.

Creating a sample Oracle DB instance

The DB instance is where you run your Oracle databases.

Note
RDS for Oracle supports a single-tenant architecture, where a pluggable database (PDB) resides in a multitenant container database (CDB). For more information, see RDS for Oracle architecture (p. 1305).

You can use Easy create to create a DB instance running Oracle with the AWS Management Console. With Easy create, you specify only the DB engine type, DB instance size, and DB instance identifier. Easy create uses the default settings for the other configuration options. When you use Standard create instead of Easy create, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use Easy create to create a DB instance running the Oracle database engine with a db.m4.large DB instance class.

For information about creating DB instances with Standard create, see Creating an Amazon RDS DB instance (p. 175). If you want to use free tier, use Standard create.

To create an Oracle DB instance with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database and ensure that Easy create is chosen.
5. In **Configuration**, choose **Oracle**.

6. For **DB instance size**, choose **Free tier**. If **Free tier** isn't available, choose **Dev/Test**.

7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name of **database-1**.

8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.
You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use **Standard create** to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see **Provide access to your DB instance in your VPC by creating a security group** (p. 96).
Connecting to your sample DB instance

• If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

  If the DB instance should be private, leave **Public access** set to **No**.

• If you want to use free tier, use **Standard create** to set the Oracle version lower than version 12.2, and then choose **Free tier** in **Templates**.

11. Choose **Create database**.

    If you used an automatically generated password, the **View credential details** button appears on the **Databases** page.

    To view the master user name and password for the DB instance, choose **View credential details**.

    To connect to the DB instance as the master user, use the user name and password that appear.

    **Important**
    
    You can't view the master user password again. If you don't record it, you might have to change it.

    If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see **Modifying an Amazon RDS DB instance (p. 309)**.

12. For **Databases**, choose the name of the new Oracle DB instance.

    On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Connecting to your sample Oracle DB instance

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this procedure, you connect to your sample DB instance by using the Oracle sqlplus command line utility. To download a standalone version of this utility, see **SQL*Plus User’s Guide and Reference**.
To connect to a DB instance using SQL*Plus

1. Make sure your DB instance is associated with a security group that provides access to it. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

   If you didn’t specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

2. Find the endpoint (DNS name) and port number for your DB instance.
   a. Open the RDS console and then choose Databases to display a list of your DB instances.
   b. Choose the Oracle DB instance name to display its details.
   c. On the Connectivity & security tab, copy the following pieces of information:
      - Endpoint
      - Port

   You need both the endpoint and the port number to connect to the DB instance.

   ![Database Connectivity & Security Tab](image)

   d. On the Configuration tab, copy the following pieces of information:
      - DB name (not the DB instance ID)
      - Master user name

   You need both the DB name and the master user name to connect to the DB instance.

3. Enter the following command on one line at a command prompt to connect to your DB instance by using the sqlplus utility. Use the following values:
   - For dbuser, enter the name of the master user that you copied in the preceding steps.
Deleting your sample DB instance

After you are done exploring the sample DB instance that you created, you should delete the DB instance so that you are no longer charged for it.

**To delete a DB instance with no final DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to delete.
4. For Actions, choose Delete.
5. For Create final snapshot?, choose No, and choose the acknowledgment.
6. Choose Delete.

Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance

The easiest way to create a DB instance is to use the AWS Management Console. After you have created the DB instance, you can use standard SQL client utilities to connect to the DB instance, such as the pgAdmin utility. In this example, you create a DB instance running the PostgreSQL database engine called database-1, with a db.r6g.large DB instance class and 100 gibibytes (GiB) of storage.

**Important**

Before you can create or connect to a DB instance, make sure to complete the tasks in Setting up for Amazon RDS (p. 93).

There’s no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.
Creating a PostgreSQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your PostgreSQL databases.

You can use Easy create to create a DB instance running PostgreSQL with the AWS Management Console. With Easy create, you specify only the DB engine type, DB instance size, and DB instance identifier. Easy create uses the default settings for the other configuration options. When you use Standard create instead of Easy create, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use Easy create to create a DB instance running the PostgreSQL database engine with a db.r6g.large DB instance class.

**Note**
For information about creating DB instances with Standard create, see Creating an Amazon RDS DB instance (p. 175). If you want to use free tier, use Standard create.

To create a PostgreSQL DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database and make sure that Easy create is chosen.

5. In Configuration, choose PostgreSQL.
6. For DB instance size, choose Dev/Test.
7. For DB instance identifier, enter a name for the DB instance, or leave the default name.
8. For Master username, enter a name for the master user, or leave the default name.

The Create database page should look similar to the following image.
9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** box is selected.

   To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.
You can examine the default settings used with Easy create. The Editable after database is created column shows which options you can change after database creation.

- To change settings with No in that column, use Standard create.
- To change settings with Yes in that column, either use Standard create, or modify the DB instance after it is created to change the settings.

The following are important considerations for changing the default settings:

- In some cases, you might want your DB instance to use a specific virtual private cloud (VPC) based on the Amazon VPC service. Or you might require a specific subnet group or security group. If so, use Standard create to specify these resources. You might have created these resources when you set up for Amazon RDS. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).
• If you want to be able to access the DB instance from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB instance should be private, leave **Public access** set to **No**.

• If you want to use free tier, use **Standard create** to set the PostgreSQL version lower than version 13, and then choose **Free tier** in **Templates**.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see **Modifying an Amazon RDS DB instance** (p. 309).

12. For **Databases**, choose the name of the new PostgreSQL DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **Creating** until the DB instance is ready to use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

---

**Connecting to a PostgreSQL DB instance**

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Following, you can find two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. You can download and use pgAdmin without having a local instance of PostgreSQL on your client computer. The second example uses psql, a command line utility that is part of a PostgreSQL installation. To use psql, make sure that you have PostgreSQL or the psql client installed on your client computer.
Before you attempt to connect to the DB instance, make sure that the DB instance is associated with a security group that provides access to it. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

In some cases, you might have difficulty connecting to the DB instance. If so, the problem is most often with the access rules that you set up in the security group that you assigned to the DB instance. If you didn't specify the appropriate security group when you created the DB instance, you can modify the DB instance to change its security group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

For more information about connecting to a PostgreSQL DB instance, see Connecting to a DB instance running the PostgreSQL database engine (p. 1599). If you can't connect to your DB instance, see Troubleshooting connections to your RDS for PostgreSQL instance (p. 1603).

**Topics**
- Using pgAdmin to connect to a PostgreSQL DB instance (p. 135)
- Using psql to connect to a PostgreSQL DB instance (p. 140)

### Using pgAdmin to connect to a PostgreSQL DB instance

**To connect to a PostgreSQL DB instance using pgAdmin**

1. Find the endpoint (DNS name) and port number for your DB instance.
   a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
   b. Choose the PostgreSQL DB instance name to display its details.
   c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
d. On the **Configuration** tab, note the DB name. You don't need this to connect using pgAdmin, but you do need it to connect using psql.
2. Install pgAdmin from https://www.pgadmin.org/. You can download and use pgAdmin without having a local instance of PostgreSQL on your client computer.

3. Launch the pgAdmin application on your client computer.

4. Choose Add Server from the File menu.

5. In the New Server Registration dialog box, enter the DB instance endpoint (for example, database-1.123456789012.us-west-1.rds.amazonaws.com) in the Host box. Don't include the colon or port number as shown on the Amazon RDS console (database-1.c6c8dntfzzhgv0.us-west-1.rds.amazonaws.com:5432).

   Enter the port you assigned to the DB instance for Port. Enter the user name and user password that you entered when you created the DB instance for Username and Password.
6. Choose **OK**.

7. In the Object browser, expand **Server Groups**. Choose the server (the DB instance) you created, and then choose the database name.
8. Choose the plugin icon and choose **PSQL Console**. The psql command window opens for the default database you created.

9. Use the command window to enter SQL or psql commands. Enter `\q` to close the window.
Using `psql` to connect to a PostgreSQL DB instance

If your client computer has PostgreSQL installed, you can use a local instance of `psql` to connect to a PostgreSQL DB instance. To connect to your PostgreSQL DB instance using `psql`, you provide host information, port number, access credentials, and the database name. You can obtain these details by following the first step in the procedure for Using `pgAdmin` to connect to a PostgreSQL DB instance (p. 135)

The following format is used to connect to a PostgreSQL DB instance on Amazon RDS.

```
psql --host=DB_instance_endpoint --port=port --username=master_user_name --password --dbname=database_name
```

For example, the following command connects to a database called `mypgdb` on a PostgreSQL DB instance called `mypostgresql` using fictitious credentials.

```
psql --host=database-1.123456789012.us-west-1.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=postgres
```

Deleting a DB instance

After you have connected to the sample DB instance that you created, you should delete the DB instance so you are no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to delete.
4. For Actions, choose Delete.
5. For Create final snapshot?, choose No, and select the acknowledgment.
6. Choose Delete.
Tutorial: Create a web server and an Amazon RDS DB instance

This tutorial helps you install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is an MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in a virtual private cloud (VPC) based on the Amazon VPC service.

Important
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Note
This tutorial works with Amazon Linux and might not work for other versions of Linux such as Ubuntu.

In the tutorial that follows, you specify the VPC, subnets, and security groups when you create the DB instance. You also specify them when you create the EC2 instance to host your web server. The VPC, subnets, and security groups are required for the DB instance and the web server to communicate. After the VPC is set up, this tutorial shows you how to create the DB instance and install the web server. You connect your web server to your DB instance in the VPC using the DB instance endpoint.

1. Complete the tasks in Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863).

   Before you begin this tutorial, make sure that you have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, complete the following tasks in the tutorial:

   a. Create a VPC with private and public subnets (p. 1863)
   b. Create additional subnets (p. 1864)
   c. Create a VPC security group for a public web server (p. 1865)
   d. Create a VPC security group for a private DB instance (p. 1866)
   e. Create a DB subnet group (p. 1866)

2. Create a DB instance (p. 142)
3. Create an EC2 instance and install a web server (p. 147)

The following diagram shows the configuration when the tutorial is complete.
Create a DB instance

In this step, you create an Amazon RDS for MySQL DB instance that maintains the data used by a web application.

Important
Before you begin this step, make sure that you have a VPC with both public and private subnets, and corresponding security groups. If you don’t have these, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863). Complete the steps in Create a VPC with private and public subnets (p. 1863), Create additional subnets (p. 1864), Create a VPC security group for a public web server (p. 1865), and Create a VPC security group for a private DB instance (p. 1866).

To create a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the DB instance. This example uses the US West (Oregon) Region.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. On the Create database page, shown following, make sure that the Standard create option is chosen, and then choose MySQL.
6. In the Templates section, choose Free tier.
7. In the Settings section, set these values:
   - DB instance identifier – tutorial-db-instance
   - Master username – tutorial_user
   - Auto generate a password – Clear the check box.
   - Master password – Choose a password.
   - Confirm password – Retype the password.
8. In the **DB instance class** section, enable **Include previous generation classes**, and set these values:

- **Burstable classes (includes t classes)**
- **db.t2.micro**
9. In the **Storage** and **Availability & durability** sections, use the default values.

10. In the **Connectivity** section, set these values:

    - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as the `tutorial-vpc (vpc-identifier)` created in Create a VPC with private and public subnets (p. 1863)

        **Note**
        The VPC must have subnets in different Availability Zones.

    - **Subnet group** – The DB subnet group for the VPC, such as the `tutorial-db-subnet-group` created in Create a DB subnet group (p. 1866)

    - **Public access** – **No**

    - **VPC security group** – **Choose existing**

    - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as the `tutorial-db-securitygroup` created in Create a VPC security group for a private DB instance (p. 1866).

        Remove other security groups, such as the default security group, by choosing the **X** associated with each.

    - **Availability Zone** – **No preference**

    - **Open Additional configuration**, and make sure **Database port** uses the default value **3306**.
11. In the **Database authentication** section, make sure **Password authentication** is selected.

12. Open the **Additional configuration** section, and enter **sample** for **Initial database name**. Keep the default settings for the other options.

13. To create your MySQL DB instance, choose **Create database**.

   Your new DB instance appears in the **Databases** list with the status **Creating**.

14. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.

15. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.
Create a web server

Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

16. Complete Create an EC2 instance and install a web server (p. 147).

Create an EC2 instance and install a web server

In this step, you create a web server to connect to the Amazon RDS DB instance that you created in Create a DB instance (p. 142).

Launch an EC2 instance

First, you create an Amazon EC2 instance in the public subnet of your VPC.
To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown following.

3. Choose the **Amazon Linux 2 AMI**.
Create a web server

4. Choose the t2.micro instance type, as shown following, and then choose Next: Configure Instance Details.

5. On the Configure Instance Details page, shown following, set these values and keep the other values as their defaults:
   - **Network**: Choose the VPC with both public and private subnets that you chose for the DB instance, such as the vpc-identifier | tutorial-vpc created in Create a VPC with private and public subnets (p. 1863).
   - **Subnet**: Choose an existing public subnet, such as subnet-identifier | Tutorial public | us-west-2a created in Create a VPC security group for a public web server (p. 1865).
   - **Auto-assign Public IP**: Choose Enable.
6. Choose **Next: Add Storage**.
7. On the **Add Storage** page, keep the default values and choose **Next: Add Tags**.
8. On the **Add Tags** page, shown following, choose **Add Tag**, then enter **Name** for **Key** and enter **tutorial-web-server** for **Value**.

9. Choose **Next: Configure Security Group**.
10. On the **Configure Security Group** page, shown following, choose **Select an existing security group**. Then choose an existing security group, such as the **tutorial-securitygroup** created in **Create a VPC security group for a public web server (p. 1865)**. Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.
11. Choose **Review and Launch**.

12. On the **Review Instance Launch** page, shown following, verify your settings and then choose **Launch**.

13. On the **Select an existing key pair or create a new key pair** page, shown following, choose **Create a new key pair** and set **Key pair name** to **tutorial-key-pair**. Choose **Download Key Pair**, and then save the key pair file on your local machine. You use this key pair file to connect to your EC2 instance.
14. To launch your EC2 instance, choose **Launch Instances**. On the **Launch Status** page, shown following, note the identifier for your new EC2 instance, for example: `i-0288d65fd4470b6a9`. 

---

**Select an existing key pair or create a new key pair**

A key pair consists of a **public key** that AWS stores, and a **private key file** that you store. Together, they allow you to connect to your instance securely. For Windows AMIs, the private key file is required to obtain the password used to log into your instance. For Linux AMIs, the private key file allows you to securely SSH into your instance.

Note: The selected key pair will be added to the set of keys authorized for this instance. Learn more about **removing existing key pairs from a public AMI**.

- **Create a new key pair**
- **Key pair name**
- `tutorial-key-pair`

**Download Key Pair**

You have to download the **private key file** (*.pem file) before you can continue. **Store it in a secure and accessible location.** You will not be able to download the file again after it's created.
15. Choose View Instances to find your instance.

16. Wait until Instance Status for your instance reads as Running before continuing.

**Install an Apache web server with PHP**

Next, you connect to your EC2 instance and install the web server.

**To connect to your EC2 instance and install the Apache web server with PHP**

1. Connect to the EC2 instance that you created earlier by following the steps in Connect to your Linux instance.

2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   **Note**
   
   The –y option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```bash
   sudo yum update -y
   ```

3. After the updates complete, install the PHP software using the `amazon-linux-extras install` command. This command installs multiple software packages and related dependencies at the same time.
Create a web server

4. Install the Apache web server.

```
sudo yum install -y httpd
```

5. Start the web server with the command shown following.

```
sudo systemctl start httpd
```

You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com. If your web server is running, then you see the Apache test page.

If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863). Make sure that your inbound rules include a rule allowing HTTP (port 80) access for the IP address you use to connect to the web server.

**Note**
The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance instead of the Apache test page.

6. Configure the web server to start with each system boot using the `systemctl` command.

```
sudo systemctl enable httpd
```

To allow `ec2-user` to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the `/var/www` directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the apache group, to give the apache group ownership of the `/var/www` directory and assign write permissions to the group.

**To set file permissions for the Apache web server**

1. Add the `ec2-user` user to the apache group.

```
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new apache group.

```
exit
```

3. Log back in again and verify that the apache group exists with the `groups` command.
groups

Your output looks similar to the following:

ec2-user adm wheel apache systemd-journal

4. Change the group ownership of the /var/www directory and its contents to the apache group.

```bash
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```bash
sudo chmod 2775 /var/www
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.

```bash
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

**Note**
A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption. For more information, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI in the Amazon EC2 User Guide.

## Connect your Apache web server to your DB instance

Next, you add content to your Apache web server that connects to your Amazon RDS DB instance.

**To add content to the Apache web server that connects to your DB instance**

1. While still connected to your EC2 instance, change the directory to /var/www and create a new subdirectory named inc.

```bash
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the inc directory named dbinfo.inc, and then edit the file by calling nano (or the editor of your choice).

```bash
>dbinfo.inc
nano dbinfo.inc
```

3. Add the following contents to the dbinfo.inc file. Here, `db_instance_endpoint` is your DB instance endpoint, without the port, and `master_password` is the master password for your DB instance.
Note
We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```php
<?php
define('DB_SERVER', 'db_instance_endpoint');
define('DB_USERNAME', 'tutorial_user');
define('DB_PASSWORD', 'master password');
define('DB_DATABASE', 'sample');
?>
```

4. Save and close the `dbinfo.inc` file.

5. Change the directory to `/var/www/html`.

```bash
cd /var/www/html
```

6. Create a new file in the `html` directory named `SamplePage.php`, and then edit the file by calling `nano` (or the editor of your choice).

```bash
>SamplePage.php
nano SamplePage.php
```

7. Add the following contents to the `SamplePage.php` file:

Note
We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```php
<?php include '../inc/dbinfo.inc'; ?>
<html>
<body>
<h1>Sample page</h1>
<?php
    /* Connect to MySQL and select the database. */
    $connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);
    if (mysqli_connect_errno()) echo "Failed to connect to MySQL: ",
                        mysqli_connect_error();
    $database = mysqli_select_db($connection, DB_DATABASE);
    /* Ensure that the EMPLOYEES table exists. */
    VerifyEmployeesTable($connection, DB_DATABASE);
    /* If input fields are populated, add a row to the EMPLOYEES table. */
    $employee_name = htmlentities($_POST['NAME']);
    $employee_address = htmlentities($_POST['ADDRESS']);
    if (strlen($employee_name) || strlen($employee_address)) {
        AddEmployee($connection, $employee_name, $employee_address);
    }
?>
```
<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
<table border="0">
  <tr>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>
  <tr>
    <td>
      <input type="text" name="NAME" maxlength="45" size="30" />
    </td>
    <td>
      <input type="text" name="ADDRESS" maxlength="90" size="60" />
    </td>
    <td>
      <input type="submit" value="Add Data" />
    </td>
  </tr>
</table>
</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>
<?php
$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");
while($query_data = mysqli_fetch_row($result)) {
  echo "<tr>",
  echo "<td>",$query_data[0], "</td>",
  echo "<td>",$query_data[1], "</td>",
  echo "<td>",$query_data[2], "</td>";
  echo "</tr>";
}
?></table>

<!-- Clean up. -->
<?php
mysqli_free_result($result);
mysqli_close($connection);
?>
</body>
</html>

<?php
/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
  $n = mysqli_real_escape_string($connection, $name);
  $a = mysqli_real_escape_string($connection, $address);
  $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";
  if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>");
}
8. Save and close the SamplePage.php file.

You can use SamplePage.php to add data to your DB instance. The data that you add is then displayed on the page. To verify that the data was inserted into the table, you can install MySQL on the Amazon EC2 instance, connect to the DB instance, and query the table.

For information about installing the MySQL client and connecting to a DB instance, see Connecting to a DB instance running the MySQL database engine (p. 1146).

To make sure that your DB instance is as secure as possible, verify that sources outside of the VPC can't connect to your DB instance.

After you have finished testing your web server and your database, you should delete your DB instance and your Amazon EC2 instance.

- To delete a DB instance, follow the instructions in Deleting a DB instance (p. 401). You don't need to create a final snapshot.
- To terminate an Amazon EC2 instance, follow the instruction in Terminate your instance in the Amazon EC2 User Guide.
Amazon RDS tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon RDS use cases. Many of these tutorials show you how to use Amazon RDS with other AWS services. In addition, you can access sample code in GitHub.

**Note**
You can find more tutorials at the AWS Database Blog. For information about training, see AWS Training and Certification.

**Topics**
- Tutorials in this guide (p. 159)
- Tutorials in other AWS guides (p. 159)
- Tutorials and sample code in GitHub (p. 160)

**Tutorials in this guide**

The following tutorials in this guide show you how to perform common tasks with Amazon RDS:

- **Tutorial: Create an Amazon VPC for use with a DB instance** (p. 1863)
  Learn how to include a DB instance in an Amazon virtual private cloud (VPC) that shares data with a web server that is running on an Amazon EC2 instance in the same VPC.

- **Tutorial: Create a web server and an Amazon RDS DB instance** (p. 141)
  Learn how to install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is a MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in an Amazon VPC.

- **Tutorial: Restore an Amazon RDS DB instance from a DB snapshot** (p. 488)
  Learn how to restore a DB instance from a DB snapshot.

- **Tutorial: Use tags to specify which DB instances to stop** (p. 380)
  Learn how to use tags to specify which DB instances to stop.

- **Tutorial: log the state of an Amazon RDS instance using EventBridge** (p. 643)
  Learn how to log a DB instance state change using Amazon EventBridge and AWS Lambda.

- **Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag** (p. 514)
  Learn how to create a CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the `ReplicaLag` metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

**Tutorials in other AWS guides**

The following tutorials in other AWS guides show you how to perform common tasks with Amazon RDS:
• Tutorial: Rotating a Secret for an AWS Database in the AWS Secrets Manager User Guide

Learn how to create a secret for an AWS database and configure the secret to rotate on a schedule. You trigger one rotation manually, and then confirm that the new version of the secret continues to provide access.

• Tutorial: Configuring a Lambda function to access Amazon RDS in an Amazon VPC in the AWS Lambda Developer Guide

Learn how to create a Lambda function to access a database, create a table, add a few records, and retrieve the records from the table. You also learn how to invoke the Lambda function and verify the query results.

• Tutorials and samples in the AWS Elastic Beanstalk Developer Guide

Learn how to deploy applications that use Amazon RDS databases with AWS Elastic Beanstalk.

• Using Data from an Amazon RDS Database to Create an Amazon ML Datasource in the Amazon Machine Learning Developer Guide

Learn how to create an Amazon Machine Learning (Amazon ML) datasource object from data stored in a MySQL DB instance.

• Manually Enabling Access to an Amazon RDS Instance in a VPC in the Amazon QuickSight User Guide

Learn how to enable Amazon QuickSight access to an Amazon RDS DB instance in a VPC.

Tutorials and sample code in GitHub

The following tutorials and sample code in GitHub show you how to perform common tasks with Amazon RDS:

• Creating the Amazon Relational Database Service item tracker

Learn how to create an application that tracks and reports on work items using Amazon RDS, Amazon Simple Email Service, Elastic Beanstalk, and SDK for Java 2.x.

• SDK for Go code samples for Amazon RDS

View a collection of SDK for Go code samples for Amazon RDS and Aurora.

• SDK for Java 2.x code samples for Amazon RDS

View a collection of SDK for Java 2.x code samples for Amazon RDS and Aurora.

• SDK for PHP code samples for Amazon RDS

View a collection of SDK for PHP code samples for Amazon RDS and Aurora.

• SDK for Ruby code samples for Amazon RDS

View a collection of SDK for Ruby code samples for Amazon RDS and Aurora.
Best practices for Amazon RDS

Learn best practices for working with Amazon RDS. As new best practices are identified, we will keep this section up to date.

Topics
- Amazon RDS basic operational guidelines (p. 161)
- DB instance RAM recommendations (p. 162)
- Using Enhanced Monitoring to identify operating system issues (p. 162)
- Using metrics to identify performance issues (p. 162)
- Tuning queries (p. 166)
- Best practices for working with MySQL (p. 167)
- Best practices for working with MariaDB (p. 168)
- Best practices for working with Oracle (p. 169)
- Best practices for working with PostgreSQL (p. 169)
- Working with DB parameter groups (p. 172)
- Amazon RDS new features and best practices presentation video (p. 173)

Note
For common recommendations for Amazon RDS, see Viewing Amazon RDS recommendations (p. 500).

Amazon RDS basic operational guidelines

The following are basic operational guidelines that everyone should follow when working with Amazon RDS. Note that the Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Use metrics to monitor your memory, CPU, replica lag, and storage usage. Amazon CloudWatch can be set up to notify you when usage patterns change or when you approach the capacity of your deployment, so that you can maintain system performance and availability.

- Scale up your DB instance when you are approaching storage capacity limits. You should have some buffer in storage and memory to accommodate unforeseen increases in demand from your applications.

- Enable automatic backups and set the backup window to occur during the daily low in write IOPS. That's when a backup is least disruptive to your database usage.

- If your database workload requires more I/O than you have provisioned, recovery after a failover or database failure will be slow. To increase the I/O capacity of a DB instance, do any or all of the following:
  - Migrate to a different DB instance class with high I/O capacity.
  - Convert from magnetic storage to either General Purpose or Provisioned IOPS storage, depending on how much of an increase you need. For information on available storage types, see Amazon RDS storage types (p. 53).
If you convert to Provisioned IOPS storage, make sure you also use a DB instance class that is optimized for Provisioned IOPS. For information on Provisioned IOPS, see Provisioned IOPS SSD storage (p. 55).

- If you are already using Provisioned IOPS storage, provision additional throughput capacity.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. Because the underlying IP address of a DB instance can change after a failover, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service.
- Test failover for your DB instance to understand how long the process takes for your particular use case and to ensure that the application that accesses your DB instance can automatically connect to the new DB instance after failover occurs.

DB instance RAM recommendations

An Amazon RDS performance best practice is to allocate enough RAM so that your working set resides almost completely in memory. The working set is the data and indexes that are frequently in use on your instance. The more you use the DB instance, the more the working set will grow.

To tell if your working set is almost all in memory, check the ReadIOPS metric (using Amazon CloudWatch) while the DB instance is under load. The value of ReadIOPS should be small and stable. If scaling up the DB instance class—to a class with more RAM—results in a dramatic drop in ReadIOPS, your working set was not almost completely in memory. Continue to scale up until ReadIOPS no longer drops dramatically after a scaling operation, or ReadIOPS is reduced to a very small amount. For information on monitoring a DB instance's metrics, see Viewing metrics in the Amazon RDS console (p. 505).

Using Enhanced Monitoring to identify operating system issues

When Enhanced Monitoring is enabled, Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information about Enhanced Monitoring, see Monitoring OS metrics with Enhanced Monitoring (p. 582).

Using metrics to identify performance issues

To identify performance issues caused by insufficient resources and other common bottlenecks, you can monitor the metrics available for your Amazon RDS DB instance.

Viewing performance metrics

You should monitor performance metrics on a regular basis to see the average, maximum, and minimum values for a variety of time ranges. If you do so, you can identify when performance is degraded. You can also set Amazon CloudWatch alarms for particular metric thresholds so you are alerted if they are reached.
To troubleshoot performance issues, it's important to understand the baseline performance of the system. When you set up a new DB instance and get it running with a typical workload, you should capture the average, maximum, and minimum values of all of the performance metrics at a number of different intervals (for example, one hour, 24 hours, one week, two weeks) to get an idea of what is normal. It helps to get comparisons for both peak and off-peak hours of operation. You can then use this information to identify when performance is dropping below standard levels.

If you are using Multi-AZ DB clusters, you can monitor the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance. This difference is called replica lag. For more information, see Replica lag and Multi-AZ DB clusters (p. 77).

**To view performance metrics**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a DB instance.
3. Choose Monitoring. The first eight performance metrics display. The metrics default to showing information for the current day.
4. Use the numbered buttons at top right to page through the additional metrics, or choose adjust the settings to see more metrics.
5. Choose a performance metric to adjust the time range in order to see data for other than the current day. You can change the Statistic, Time Range, and Period values to adjust the information displayed. For example, to see the peak values for a metric for each day of the last two weeks, set Statistic to Maximum, Time Range to Last 2 Weeks, and Period to Day.

   **Note**
   Changing the Statistic, Time Range, and Period values changes them for all metrics. The updated values persist for the remainder of your session or until you change them again.

You can also view performance metrics using the CLI or API. For more information, see Viewing metrics in the Amazon RDS console (p. 505).

**To set a CloudWatch alarm**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a DB instance.
3. Choose Logs & events.
4. In the CloudWatch alarms section, choose Create alarm.
5. For **Send notifications**, choose **Yes**, and for **Send notifications to**, choose **New email or SMS topic**.

6. For **Topic name**, enter a name for the notification, and for **With these recipients**, enter a comma-separated list of email addresses and phone numbers.

7. For **Metric**, choose the alarm statistic and metric to set.

8. For **Threshold**, specify whether the metric must be greater than, less than, or equal to the threshold, and specify the threshold value.

9. For **Evaluation period**, choose the evaluation period for the alarm, and for **consecutive period(s) of**, choose the period during which the threshold must have been reached in order to trigger the alarm.

10. For **Name of alarm**, enter a name for the alarm.

11. Choose **Create Alarm**.
Evaluating performance metrics

A DB instance has a number of different categories of metrics, and how to determine acceptable values depends on the metric.

**CPU**
- CPU Utilization – Percentage of computer processing capacity used.

**Memory**
- Freeable Memory – How much RAM is available on the DB instance, in megabytes. The red line in the Monitoring tab metrics is marked at 75% for CPU, Memory and Storage Metrics. If instance memory consumption frequently crosses that line, then this indicates that you should check your workload or upgrade your instance.
- Swap Usage – How much swap space is used by the DB instance, in megabytes.

**Disk space**
- Free Storage Space – How much disk space is not currently being used by the DB instance, in megabytes.

**Input/output operations**
- Read IOPS, Write IOPS – The average number of disk read or write operations per second.
- Read Latency, Write Latency – The average time for a read or write operation in milliseconds.
- Read Throughput, Write Throughput – The average number of megabytes read from or written to disk per second.
- Queue Depth – The number of I/O operations that are waiting to be written to or read from disk.

**Network traffic**
- Network Receive Throughput, Network Transmit Throughput – The rate of network traffic to and from the DB instance in bytes per second.

**Database connections**
- DB Connections – The number of client sessions that are connected to the DB instance.

For more detailed individual descriptions of the performance metrics available, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 508).

Generally speaking, acceptable values for performance metrics depend on what your baseline looks like and what your application is doing. Investigate consistent or trending variances from your baseline. Advice about specific types of metrics follows:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, provided that they are in keeping with your goals for your application (like throughput or concurrency) and are expected.
• **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.

• **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and Internet connection. Investigate network traffic if throughput is consistently lower than expected.

• **Database connections** – Consider constraining database connections if you see high numbers of user connections in conjunction with decreases in instance performance and response time. The best number of user connections for your DB instance will vary based on your instance class and the complexity of the operations being performed. You can determine the number of database connections by associating your DB instance with a parameter group where the **User Connections** parameter is set to other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see Working with parameter groups (p. 278).

• **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure your typical working set will fit into memory to minimize read and write operations.

For issues with any performance metrics, one of the first things you can do to improve performance is tune the most used and most expensive queries to see if that lowers the pressure on system resources. For more information, see Tuning queries (p. 166).

If your queries are tuned and an issue persists, consider upgrading your Amazon RDS DB instance classes (p. 9) to one with more of the resource (CPU, RAM, disk space, network bandwidth, I/O capacity) that is related to the issue you are experiencing.

### Tuning queries

One of the best ways to improve DB instance performance is to tune your most commonly used and most resource-intensive queries to make them less expensive to run. For information on improving queries, use the following resources:

- **MySQL** – See Optimizing SELECT statements in the MySQL documentation. For additional query tuning resources, see MySQL performance tuning and optimization resources.

- **Oracle** – See Database SQL Tuning Guide in the Oracle documentation.

- **SQL Server** – See Analyzing a query in the Microsoft documentation. You can also use the execution-, index-, and I/O-related data management views (DMVs) described in System Dynamic Management Views in the Microsoft documentation to troubleshoot SQL Server query issues.

A common aspect of query tuning is creating effective indexes. For potential index improvements for your DB instance, see Database Engine Tuning Advisor in the Microsoft documentation. For information on using Tuning Advisor on RDS for SQL Server, see Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor (p. 1116).

- **PostgreSQL** – See Using EXPLAIN in the PostgreSQL documentation to learn how to analyze a query plan. You can use this information to modify a query or underlying tables in order to improve query performance.

For information about how to specify joins in your query for the best performance, see Controlling the planner with explicit JOIN clauses.

- **MariaDB** – See Query optimizations in the MariaDB documentation.
Best practices for working with MySQL

Both table sizes and number of tables in a MySQL database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MySQL databases. So, the limits usually aren’t determined by internal MySQL constraints.

On a MySQL DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MySQL table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time. For more information, see MySQL file size limits in Amazon RDS (p. 1262).

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as ALTER TABLE, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MySQL for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of actively used tables. To find the ten largest tables and indexes in a database, use the following query:

```sql
SELECT CONCAT(table_schema, '.', table_name),
       CONCAT(ROUND(table_rows / 1000000, 2), 'M') rows,
       CONCAT(ROUND(data_length / ( 1024 * 1024 * 1024 ), 2), 'G') DATA,
       CONCAT(ROUND(index_length / ( 1024 * 1024 * 1024 ), 2), 'G') idx,
       CONCAT(ROUND(( data_length + index_length ) / ( 1024 * 1024 * 1024 ), 2), 'G') total_size,
       ROUND(index_length / data_length, 2) idxfrac
FROM information_schema.TABLES
WHERE table_rows > 0
ORDER BY data_length + index_length DESC
LIMIT 10;
```

Number of tables

While the underlying file system might have a limit on the number of files that represent tables, MySQL has no limit on the number of tables. However, the total number of tables in the MySQL InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MySQL DB instance. Doing so might limit the number of files in a directory but won’t solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MySQL working with storage files, including opening and closing them. To address this issue, you can increase the size of the table_open_cache and table_definition_cache parameters. However, increasing the values of those parameters might significantly increase the amount of memory MySQL uses, and might even use all of the available memory. For more information, see How MySQL Opens and Closes Tables in the MySQL documentation.

In addition, too many tables can significantly affect MySQL startup time. Both a clean shutdown and restart and a crash recovery can be affected, especially in versions prior to MySQL 8.0.

We recommend having fewer than ten thousand tables total across all of the databases in a DB instance. For a use case with a large number of tables in a MySQL database, see One Million Tables in MySQL 8.0.
Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MySQL require a crash-recoverable storage engine and are supported for the InnoDB storage engine only. Although MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, the MyISAM storage engine does not support reliable crash recovery and might prevent a Point-In-Time Restore or snapshot restore from working as intended. This might result in lost or corrupt data when MySQL is restarted after a crash.

InnoDB is the recommended and supported storage engine for MySQL DB instances on Amazon RDS. InnoDB instances can also be migrated to Aurora, while MyISAM instances can't be migrated. However, MyISAM performs better than InnoDB if you require intense, full-text search capability. If you still choose to use MyISAM with Amazon RDS, following the steps outlined in Automated backups with unsupported MySQL storage engines (p. 415) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the MySQL documentation. MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

In addition, Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

Best practices for working with MariaDB

Both table sizes and number of tables in a MariaDB database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MariaDB databases. So, the limits usually aren't determined by internal MariaDB constraints.

On a MariaDB DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MariaDB table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time.

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as ALTER TABLE, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MariaDB for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of actively used tables. To find the ten largest tables and indexes in a database, use the following query:

```
SELECT CONCAT(table_schema, '.', table_name),
       CONCAT(ROUND(table_rows / 1000000, 2), 'M') rows,
       CONCAT(ROUND(data_length / (1024 * 1024 * 1024), 2), 'G') DATA,
       CONCAT(ROUND(index_length / (1024 * 1024 * 1024), 2), 'G') idx,
       CONCAT(ROUND((data_length + index_length) / (1024 * 1024 * 1024), 2), 'G') total_size,
       ROUND(index_length / data_length, 2) idxfrac
FROM   information_schema.TABLES
```
Number of tables

While the underlying file system might have a limit on the number of files that represent tables, MariaDB has no limit on the number of tables. However, the total number of tables in the MariaDB InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MariaDB DB instance. Doing so might limit the number of files in a directory but won't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MariaDB working with storage files, including opening and closing them. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MariaDB uses, and might even use all of the available memory. For more information, see Optimizing `table_open_cache` in the MariaDB documentation.

In addition, too many tables can significantly affect MariaDB startup time. Both a clean shutdown and restart and a crash recovery can be affected. We recommend having fewer than ten thousand tables total across all of the databases in a DB instance.

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MariaDB require a crash-recoverable storage engine. Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, although Aria is a crash-safe replacement for MyISAM, it might still prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MariaDB is restarted after a crash. InnoDB is the recommended and supported storage engine for MariaDB DB instances on Amazon RDS. If you still choose to use Aria with Amazon RDS, following the steps outlined in Automated backups with unsupported MariaDB storage engines (p. 416) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the MariaDB documentation. MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

Best practices for working with Oracle

For information about best practices for working with Amazon RDS for Oracle, see Best practices for running Oracle database on Amazon Web Services.

A 2020 AWS virtual workshop included a presentation on running production Oracle databases on Amazon RDS. A video of the presentation is available here.

Best practices for working with PostgreSQL

Two important areas where you can improve performance with PostgreSQL on Amazon RDS are when loading data into a DB instance and when using the PostgreSQL autovacuum feature. The following sections cover some of the practices we recommend for these areas.
Loading data into a PostgreSQL DB instance

When loading data into an Amazon RDS PostgreSQL DB instance, you should modify your DB instance settings and your DB parameter group values to allow for the most efficient importing of data into your DB instance.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0)
- Disable Multi-AZ

Modify your DB parameter group to include the following settings. You should test the parameter settings to find the most efficient settings for your DB instance:

- Increase the value of the `maintenance_work_mem` parameter. For more information about PostgreSQL resource consumption parameters, see the PostgreSQL documentation.
- Increase the value of the `max_wal_size` and `checkpoint_timeout` parameters to reduce the number of writes to the wal log.
- Disable the `synchronous_commit` parameter.
- Disable the PostgreSQL autovacuum parameter.
- Make sure none of the tables you are importing are unlogged. Data stored in unlogged tables can be lost during a failover. For more information, see CREATE TABLE UNLOGGED.

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

After the load operation completes, return your DB instance and DB parameters to their normal settings.

Working with the PostgreSQL autovacuum feature

The autovacuum feature for PostgreSQL databases is a feature that we strongly recommend you use to maintain the health of your PostgreSQL DB instance. Autovacuum automates the execution of the VACUUM and ANALYZE command; using autovacuum is required by PostgreSQL, not imposed by Amazon RDS, and its use is critical to good performance. The feature is enabled by default for all new Amazon RDS PostgreSQL DB instances, and the related configuration parameters are appropriately set by default.

Your database administrator needs to know and understand this maintenance operation. For the PostgreSQL documentation on autovacuum, see The Autovacuum Daemon.

Autovacuum is not a "resource free" operation, but it works in the background and yields to user operations as much as possible. When enabled, autovacuum checks for tables that have had a large number of updated or deleted tuples. It also protects against loss of very old data due to transaction ID wraparound. For more information, see Preventing transaction ID wraparound failures.

Autovacuum should not be thought of as a high-overhead operation that can be reduced to gain better performance. On the contrary, tables that have a high velocity of updates and deletes will quickly deteriorate over time if autovacuum is not run.

Important
Not running autovacuum can result in an eventual required outage to perform a much more intrusive vacuum operation. When an Amazon RDS PostgreSQL DB instance becomes unavailable because of an over conservative use of autovacuum, the PostgreSQL database will
shut down to protect itself. At that point, Amazon RDS must perform a single-user-mode full vacuum directly on the DB instance, which can result in a multi-hour outage. Thus, we strongly recommend that you do not turn off autovacuum, which is enabled by default.

The autovacuum parameters determine when and how hard autovacuum works. The `autovacuum_vacuum_threshold` and `autovacuum_vacuum_scale_factor` parameters determine when autovacuum is run. The `autovacuum_max_workers`, `autovacuum_nap_time`, `autovacuum_cost_limit`, and `autovacuum_cost_delay` parameters determine how hard autovacuum works. For more information about autovacuum, when it runs, and what parameters are required, see Routine Vacuuming in the PostgreSQL documentation.

The following query shows the number of "dead" tuples in a table named table1:

```
PROMPT> select relname, n_dead_tup, last_vacuum, last_autovacuum from pg_catalog.pg_stat_all_tables where n_dead_tup > 0 and relname = 'table1';
```

The results of the query will resemble the following:

```
<table>
<thead>
<tr>
<th>relname</th>
<th>n_dead_tup</th>
<th>last_vacuum</th>
<th>last_autovacuum</th>
</tr>
</thead>
<tbody>
<tr>
<td>tasks</td>
<td>81430522</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(1 row)
```

Amazon RDS for PostgreSQL best practices video

The 2020 AWS re:Invent conference included a presentation on new features and best practices for working with PostgreSQL on Amazon RDS. A video of the presentation is available here.

Best practices for working with SQL Server

Best practices for a Multi-AZ deployment with a SQL Server DB instance include the following:

- Use Amazon RDS DB events to monitor failovers. For example, you can be notified by text message or email when a DB instance fails over. For more information about Amazon RDS events, see Using Amazon RDS event notification (p. 623).
- If your application caches DNS values, set time to live (TTL) to less than 30 seconds. Setting TTL as so is a good practice in case there is a failover, where the IP address might change and the cached value might no longer be in service.
- We recommend that you do not enable the following modes because they turn off transaction logging, which is required for Multi-AZ:
  - Simple recover mode
  - Offline mode
  - Read-only mode
- Test to determine how long it takes for your DB instance to failover. Failover time can vary due to the type of database, the instance class, and the storage type you use. You should also test your application's ability to continue working if a failover occurs.
- To shorten failover time, you should do the following:
  - Ensure that you have sufficient Provisioned IOPS allocated for your workload. Inadequate I/O can lengthen failover times. Database recovery requires I/O.
  - Use smaller transactions. Database recovery relies on transactions, so if you can break up large transactions into multiple smaller transactions, your failover time should be shorter.
• Take into consideration that during a failover, there will be elevated latencies. As part of the failover process, Amazon RDS automatically replicates your data to a new standby instance. This replication means that new data is being committed to two different DB instances, so there might be some latency until the standby DB instance has caught up to the new primary DB instance.

• Deploy your applications in all Availability Zones. If an Availability Zone does go down, your applications in the other Availability Zones will still be available.

When working with a Multi-AZ deployment of SQL Server, remember that Amazon RDS creates replicas for all SQL Server databases on your instance. If you don't want specific databases to have secondary replicas, set up a separate DB instance that doesn't use Multi-AZ for those databases.

**Amazon RDS for SQL Server best practices video**

The 2019 AWS re:Invent conference included a presentation on new features and best practices for working with SQL Server on Amazon RDS. A video of the presentation is available [here](#).

**Working with DB parameter groups**

We recommend that you try out DB parameter group changes on a test DB instance before applying parameter group changes to your production DB instances. Improperly setting DB engine parameters in a DB parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying DB engine parameters and back up your DB instance before modifying a DB parameter group.

For information about backing up your DB instance, see [Backing up and restoring an Amazon RDS DB instance](#) (p. 406).

**Best practices for automating DB instance creation**

It's an Amazon RDS best practice to create a DB instance with the preferred minor version of the database engine. You can use the AWS CLI, Amazon RDS API, or AWS CloudFormation to automate DB instance creation. When you use these methods, you can specify only the major version and Amazon RDS automatically creates the instance with the preferred minor version. For example, if PostgreSQL 12.5 is the preferred minor version, and if you specify version 12 with `create-db-instance`, the DB instance will be version 12.5.

To determine the preferred minor version, you can run the `describe-db-engine-versions` command with the `--default-only` option as shown in the following example.

```bash
aws rds describe-db-engine-versions --default-only --engine postgres
{
  "DBEngineVersions": [
    {
      "Engine": "postgres",
      "EngineVersion": "12.5",
      "DBParameterGroupFamily": "postgres12",
      "DBEngineDescription": "PostgreSQL",
      "DBEngineVersionDescription": "PostgreSQL 12.5-R1",
      ...some output truncated...
    }
  ]
}
```
Amazon RDS new features and best practices presentation video

The 2019 AWS re:Invent conference included a presentation on new Amazon RDS features and best practices for monitoring, analyzing, and tuning database performance using RDS. A video of the presentation is available [here](#).
Configuring an Amazon RDS DB instance

This section shows how to set up your Amazon RDS DB instance. Before creating a DB instance, decide on the DB instance class that will run the DB instance. Also, decide where the DB instance will run by choosing an AWS Region. Next, create the DB instance.

You can configure a DB instance with an option group and a DB parameter group.

- An option group specifies features, called options, that are available for a particular Amazon RDS DB instance.
- A DB parameter group acts as a container for engine configuration values that are applied to one or more DB instances.

The options and parameters that are available depend on the DB engine and DB engine version. You can specify an option group and a DB parameter group when you create a DB instance, or you can modify a DB instance to specify them.

Topics
- Creating an Amazon RDS DB instance (p. 175)
- Creating a Multi-AZ DB cluster (p. 195)
- Creating Amazon RDS resources with AWS CloudFormation (p. 206)
- Connecting to an Amazon RDS DB instance (p. 207)
- Using Amazon RDS Proxy (p. 213)
- Working with option groups (p. 262)
- Working with parameter groups (p. 278)
Creating an Amazon RDS DB instance

The basic building block of Amazon RDS is the DB instance, where you create your databases. You choose the engine-specific characteristics of the DB instance when you create it. You also choose the storage capacity, CPU, memory, and so on, of the AWS instance on which the database server runs.

**Important**
Before you can create or connect to a DB instance, you must complete the tasks in Setting up for Amazon RDS (p. 93).

**Console**

You can create a DB instance by using the AWS Management Console with Easy create enabled or not enabled. With Easy create enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. Easy create uses the default setting for other configuration options. With Easy create not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

**Note**
In the following procedure, Standard create is enabled, and Easy create isn't enabled. This procedure uses Microsoft SQL Server as an example.
For examples that use Easy create to walk you through creating and connecting to sample DB instances for each engine, see Getting started with Amazon RDS (p. 99). For an example that uses the original console to create a DB instance, see Original console example (p. 190).

**To create a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. In Choose a database creation method, select Standard Create.
6. In Engine options, choose the engine type: MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL. **Microsoft SQL Server** is shown here.
7. For **Edition**, if you’re using Oracle or SQL Server choose the DB engine edition that you want to use. MySQL has only one option for the edition, and MariaDB and PostgreSQL have none.

8. For **Version**, choose the engine version.

9. In **Templates**, choose the template that matches your use case. If you choose **Production**, the following are preselected in a later step:

   - **Multi-AZ** failover option
   - **Provisioned IOPS** storage option
   - **Enable deletion protection** option

   We recommend these features for any production environment.

   **Note**
   Template choices vary by edition.

10. To enter your master password, do the following:

    a. In the **Settings** section, open **Credential Settings**.
b. If you want to specify a password, clear the **Auto generate a password** check box if it is selected.

c. (Optional) Change the **Master username** value.

d. Enter the same password in **Master password** and **Confirm password**.

11. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances](p. 178).

12. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](p. 309).

13. For **Databases**, choose the name of the new DB instance.

On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new instance to be available.

**AWS CLI**

To create a DB instance by using the AWS CLI, call the `create-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--vpc-security-group-ids`
- `--db-subnet-group`
- `--engine`

177
Available settings

- `--master-username`
- `--master-user-password`
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see Settings for DB instances (p. 178).

This example uses Microsoft SQL Server.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --engine sqlserver-se \
  --db-instance-identifier mymsftsqlserver \
  --allocated-storage 250 \
  --db-instance-class db.t3.large \
  --vpc-security-group-ids mysecuritygroup \
  --db-subnet-group mydbsubnetgroup \
  --master-username masterawsuser \
  --master-user-password masteruserpassword \
  --backup-retention-period 3
```

For Windows:

```bash
aws rds create-db-instance ^
  --engine sqlserver-se ^
  --db-instance-identifier mydbinstance ^
  --allocated-storage 250 ^
  --db-instance-class db.t3.large ^
  --vpc-security-group-ids mysecuritygroup ^
  --db-subnet-group mydbsubnetgroup ^
  --master-username masterawsuser ^
  --master-user-password masteruserpassword ^
  --backup-retention-period 3
```

This command produces output similar to the following.

```
DBINSTANCE  mydbinstance  db.t3.large  sqlserver-se  250  sa  creating  3  ****  n
10.50.2789
SECGROUP  default  active
PARAMGRP  default.sqlserver-se-14  in-sync
```

RDS API

To create a DB instance by using the Amazon RDS API, call the `CreateDBInstance` operation.

For information about each setting, see Settings for DB instances (p. 178).

Settings for DB instances

In the following table, you can find details about settings that you choose when you create a DB instance. The table also shows the DB engines for which each setting is supported.
You can create a DB instance using the console, the `create-db-instance` CLI command, or the `CreateDBInstance` RDS API operation.

<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
<th>Supported DB engines</th>
</tr>
</thead>
</table>
| Allocated storage     | The amount of storage to allocate for your DB instance (in gibibytes). In some cases, allocating a higher amount of storage for your DB instance than the size of your database can improve I/O performance. For more information, see Amazon RDS DB instance storage (p. 53). | CLI option:  
  --allocated-storage  
  API parameter:  
  AllocatedStorage | All

| Architecture settings | The architecture of the database: CDB (single-tenant) or non-CDB. Oracle Database 21c uses CDB architecture only. Oracle Database 19c can use either CDB or non-CDB architecture. Releases lower than Oracle Database 19c use non-CDB only.  
  If you choose Use multitenant architecture, RDS for Oracle creates a container database (CDB). This CDB contains one pluggable database (PDB). If you don't choose this option, RDS for Oracle creates a non-CDB. A non-CDB uses the traditional Oracle architecture.  
  For more information, see RDS for Oracle architecture (p. 1305). | CLI option:  
  --engine oracle-ee-cdb (multitenant)  
  --engine oracle-se2-cdb (multitenant)  
  --engine oracle-ee (traditional)  
  --engine oracle-se2 (traditional)  
  API parameter:  
  Engine | Oracle

| Auto minor version upgrade | Enable auto minor version upgrade to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.  
  For more information, see Automatically upgrading the minor engine version (p. 346). | CLI option:  
  --auto-minor-version-upgrade  
  --no-auto-minor-version-upgrade  
  API parameter:  
  AutoMinorVersionUpgrade | All

| Availability zone     | The Availability Zone for your DB instance. Use the default value of No Preference unless you want to specify an Availability Zone. | CLI option:  
  --availability-zone  
  API parameter:  
  AvailabilityZone | All |
<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
<th>Supported DB engines</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS KMS key</strong></td>
<td>Only available if <strong>Encryption</strong> is set to <strong>Enable encryption</strong>. Choose the AWS KMS key to use for encrypting this DB instance. For more information, see Encrypting Amazon RDS resources (p. 1750).</td>
<td><strong>CLI option:</strong> &lt;br&gt;--kms-key-id <strong>&lt;br&gt;API parameter:</strong> KmsKeyId</td>
<td>All</td>
</tr>
<tr>
<td><strong>Backup replication</strong></td>
<td>Choose <strong>Enable replication in another AWS Region</strong> to create backups in an additional Region for disaster recovery. Then choose the <strong>Destination Region</strong> for the additional backups.</td>
<td>Not available when creating a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see Enabling cross-Region automated backups (p. 419).</td>
<td>Oracle, PostgreSQL, SQL Server</td>
</tr>
<tr>
<td><strong>Backup retention period</strong></td>
<td>The number of days that you want automatic backups of your DB instance to be retained. For any nontrivial DB instance, set this value to 1 or greater. For more information, see Working with backups (p. 407).</td>
<td><strong>CLI option:</strong> &lt;br&gt;--backup-retention-period <strong>&lt;br&gt;API parameter:</strong> BackupRetentionPeriod</td>
<td>All</td>
</tr>
<tr>
<td><strong>Backup target</strong></td>
<td>Choose <strong>AWS Cloud</strong> to store automated backups and manual snapshots in the parent AWS Region. Choose <strong>Outposts (on-premises)</strong> to store them locally on your Outpost. This option setting applies only to RDS on Outposts. For more information, see Creating DB instances for Amazon RDS on AWS Outposts (p. 829).</td>
<td><strong>CLI option:</strong> &lt;br&gt;--backup-target <strong>&lt;br&gt;API parameter:</strong> BackupTarget</td>
<td>MySQL, PostgreSQL, SQL Server</td>
</tr>
<tr>
<td><strong>Backup window</strong></td>
<td>The time period during which Amazon RDS automatically takes a backup of your DB instance. Unless you have a specific time that you want to have your database backed up, use the default of <strong>No Preference</strong>. For more information, see Working with backups (p. 407).</td>
<td><strong>CLI option:</strong> &lt;br&gt;--preferred-backup-window <strong>&lt;br&gt;API parameter:</strong> PreferredBackupWindow</td>
<td>All</td>
</tr>
<tr>
<td>Console setting</td>
<td>Setting description</td>
<td>CLI option and RDS API parameter</td>
<td>Supported DB engines</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
</tbody>
</table>
| **Character set**   | The character set for your DB instance. The default value of AL32UTF8 for the DB character set is for the Unicode 5.0 UTF-8 Universal character set. You can't change the DB character set after you create the DB instance. In a single-tenant configuration, a non-default DB character set affects only the PDB, not the CDB. For more information, see RDS for Oracle architecture (p. 1305). The DB character set is different from the national character set, which is called the NCHAR character set. Unlike the DB character set, the NCHAR character set specifies the encoding for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata. For more information, see RDS for Oracle character sets (p. 1306). | **CLI option:**  
  --character-set-name  
  **API parameter:**  
  CharacterSetName | Oracle |
| **Collation**       | A server-level collation for your DB instance. For more information, see Server-level collation for Microsoft SQL Server (p. 1118). | **CLI option:**  
  --character-set-name  
  **API parameter:**  
  CharacterSetName | SQL Server |
| **Copy tags to snapshots** | This option copies any DB instance tags to a DB snapshot when you create a snapshot. For more information, see Tagging Amazon RDS resources (p. 375). | **CLI option:**  
  --copy-tags-to-snapshot  
  --no-copy-tags-to-snapshot  
  **RDS API parameter:**  
  CopyTagsToSnapshot | All |
## Database authentication

<table>
<thead>
<tr>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
<th>Supported DB engines</th>
</tr>
</thead>
</table>
| The database authentication option that you want to use. Choose **Password authentication** to authenticate database users with database passwords only. Choose **Password and IAM DB authentication** to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786). This option is only supported for MySQL and PostgreSQL. Choose **Password and Kerberos authentication** to authenticate database users with database passwords and Kerberos authentication through an AWS Managed Microsoft AD created with AWS Directory Service. Next, choose the directory or choose Create a new Directory. For more information, see one of the following:  
  - Using Kerberos authentication for MySQL (p. 1250)  
  - Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1325)  
  - Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 1611) | IAM:  
  - CL option:  
    --enable-iam-database-authentication  
    --no-enable-iam-database-authentication  
  - RDS API parameter:  
    EnableIAMDatabaseAuthentication | MySQL  
  - Oracle  
  - PostgreSQL |

## Database management type

<table>
<thead>
<tr>
<th>Setting description</th>
<th>Supported DB engines</th>
</tr>
</thead>
</table>
| Choose **Amazon RDS** if you don't need to customize your environment. Choose **Amazon RDS Custom** if you want to customize the database, OS, and infrastructure. For more information, see Working with Amazon RDS Custom (p. 714). | Oracle  
  - SQL Server |
<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
<th>Supported DB engines</th>
</tr>
</thead>
</table>
| Database port   | The port that you want to access the DB instance through. The default port is shown. If you use a DB security group with your DB instance, this port value must be the same one that you provided when creating the DB security group. **Note** The firewalls at some companies block connections to the default MariaDB, MySQL, and PostgreSQL ports. If your company firewall blocks the default port, enter another port for your DB instance. | CLI option: --port  
RDS API parameter: Port | All |
| DB engine version | The version of database engine that you want to use.                                | CLI option: --engine-version  
RDS API parameter: EngineVersion | All |
| DB instance class | The configuration for your DB instance. For example, a `db.t3.small` DB instance class has 2 GiB memory, 2 vCPUs, 1 virtual core, a variable ECU, and a moderate I/O capacity. If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory, the system can avoid writing to disk, which improves performance. For more information, see DB instance classes (p. 9).  
In RDS for Oracle, you can select **Include additional memory configurations**. These configurations are optimized for a high ratio of memory to vCPU. For example, `db.r5.6xlarge.tpc2.mem4x` is a db.r5.8x DB instance that has 2 threads per core (tpc2) and 4x the memory of a standard db.r5.6xlarge DB instance. For more information, see RDS for Oracle instance classes (p. 1302). | CLI option: --db-instance-class  
RDS API parameter: DBInstanceClass | All |
<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
<th>Supported DB engines</th>
</tr>
</thead>
</table>
| DB instance identifier | The name for your DB instance. Name your DB instances in the same way that you name your on-premises servers. Your DB instance identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | **CLI option:**<br>--db-instance-identifier
**RDS API parameter:**<br>DBInstanceIdentifier                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | All                 |
| DB parameter group   | A parameter group for your DB instance. You can choose the default parameter group, or you can create a custom parameter group. For more information, see [Working with parameter groups (p. 278)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Working-with-parameter-groups.html).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | **CLI option:**<br>--db-parameter-group-name
**RDS API parameter:**<br>DBParameterGroupName                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | All                 |
| Deletion protection  | **Enable deletion protection** to prevent your DB instance from being deleted. If you create a production DB instance from the AWS Management Console, deletion protection is enabled by default. For more information, see [Deleting a DB instance (p. 401)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Deleting-a-DB-instance.html).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | **CLI option:**<br>--deletion-protection
--no-deletion-protection
**RDS API parameter:**<br>DeletionProtection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | All                 |
| Encryption           | **Enable Encryption** to enable encryption at rest for this DB instance. For more information, see [Encrypting Amazon RDS resources (p. 1750)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Encrypting-RDS-resources.html).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | **CLI option:**<br>--storage-encrypted
--no-storage-encrypted
**RDS API parameter:**<br>StorageEncrypted                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | All                 |
| Enhanced Monitoring  | **Enable enhanced monitoring** to enable gathering metrics in real time for the operating system that your DB instance runs on. For more information, see [Monitoring OS metrics with Enhanced Monitoring (p. 582)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Enhanced-Monitoring.html).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | **CLI options:**<br>--monitoring-interval
--monitoring-role-arn
**RDS API parameters:**<br>MonitoringInterval
MonitoringRoleArn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | All                 |
| Engine type          | Choose the database engine to be used for this DB instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | **CLI option:**<br>--engine
**RDS API parameter:**<br>Engine                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | All                 |

| **Initial database name** | The name for the database on your DB instance. If you don't provide a name, Amazon RDS doesn't create a database on the DB instance (except for Oracle and PostgreSQL). The name can't be a word reserved by the database engine, and has other constraints depending on the DB engine. MariaDB and MySQL:  
• It must contain 1–64 alphanumeric characters.  
Oracle:  
• It must contain 1–8 alphanumeric characters.  
• It can't be `NULL`. The default value is `ORCL`.  
• It must begin with a letter.  
PostgreSQL:  
• It must contain 1–63 alphanumeric characters.  
• It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9).  
• The initial database name is `postgres`. | **CLI option:**  
`--db-name`  
**RDS API parameter:**  
`DBName` | All except SQL Server |
| **License** | The license model:  
• Choose `license-included` for Microsoft SQL Server.  
• Choose `license-included` or `bring-your-own-license` for Oracle. | **CLI option:**  
`--license-model`  
**RDS API parameter:**  
`LicenseModel` | Oracle SQL Server |
| **Log exports** | The types of database log files to publish to Amazon CloudWatch Logs. For more information, see Publishing database logs to Amazon CloudWatch Logs (p. 648). | **CLI option:**  
`--enable-cloudwatch-logs-exports`  
**RDS API parameter:**  
`EnableCloudwatchLogsExports` | All |

| Maintenance window              | The 30-minute window in which pending modifications to your DB instance are applied. If the time period doesn't matter, choose No Preference. For more information, see The Amazon RDS maintenance window (p. 337). | CLI option: --preferred-maintenance-window  
RDS API parameter: PreferredMaintenanceWindow | All                  |
| Master password                  | The password for your master user account. The password has the following number of printable ASCII characters (excluding /, *, a space, and @) depending on the DB engine:  
• Oracle: 8–30  
• MariaDB and MySQL: 8–41  
• SQL Server and PostgreSQL: 8–128 | CLI option: --master-user-password  
RDS API parameter: MasterUserPassword | All                  |
| Master username                  | The name that you use as the master user name to log on to your DB instance with all database privileges.  
• It can contain 1–16 alphanumeric characters and underscores.  
• Its first character must be a letter.  
• It can't be a word reserved by the database engine.  
For more information on privileges granted to the master user, see Master user account privileges (p. 1835). | CLI option: --master-username  
RDS API parameter: MasterUsername | All                  |
| Microsoft SQL Server Windows Authentication | Enable Microsoft SQL Server Windows authentication, then Browse Directory to choose the directory where you want to allow authorized domain users to authenticate with this SQL Server instance using Windows Authentication. | CLI options:  
--domain  
--domain-iam-role-name  
RDS API parameters:  
Domain  
DomainIAMRoleName | SQL Server               |

| Multi-AZ deployment     | Create a standby instance to create a passive secondary replica of your DB instance in another Availability Zone for failover support. We recommend Multi-AZ for production workloads to maintain high availability. For development and testing, you can choose Do not create a standby instance. For more information, see Multi-AZ deployments for high availability (p. 65). | CLI option: --multi-az --no-multi-az  
RDS API parameter: MultiAZ                                                                 | All                                              |
| National character set  | The national character set for your DB instance, commonly called the NCHAR character set. You can set the national character set to either AL16UTF16 (default) or UTF-8. You can't change the national character set after you create the DB instance. The national character set is different from the DB character set. Unlike the DB character set, the national character set specifies the encoding only for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata. For more information, see RDS for Oracle character sets (p. 1306). | CLI option: --nchar-character-set-name  
API parameter: NcharCharacterSetName | Oracle                                           |
| Option group            | An option group for your DB instance. You can choose the default option group or you can create a custom option group. For more information, see Working with option groups (p. 262). | CLI option: --option-group-name  
RDS API parameter: OptionGroupName | All                                              |

**Original console example**

You can create a DB instance with the original AWS Management Console. This example uses Microsoft SQL Server.

**To launch a SQL Server DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.

   If the navigation pane is closed, choose the menu icon at the top left to open it.
4. Choose **Create database** to open the **Select engine** page.
5. Choose the **Microsoft SQL Server** icon.
6. Choose the SQL Server DB engine edition that you want to use. The SQL Server editions that are available vary by AWS Region.

7. For some editions, the Use Case step asks if you are planning to use the DB instance you are creating for production. If you are, choose Production. If you choose Production, the following are all preselected in a later step:
   - Multi-AZ failover option
• **Provisioned IOPS** storage option
• **Enable deletion protection** option

We recommend these features for any production environment.

8. Choose **Next** to continue. The **Specify DB Details** page appears.

On the **Specify DB Details** page, specify your DB instance information. For information about each setting, see *Settings for DB instances* (p. 178).

9. Choose **Next** to continue. The **Configure Advanced Settings** page appears.

On the **Configure Advanced Settings** page, provide additional information that Amazon RDS needs to launch the DB instance. For information about each setting, see *Settings for DB instances* (p. 178).
10. Choose **Launch DB Instance**.

11. On the final page of the wizard, choose **Close**.

On the RDS console, the new DB instance appears in the list of DB instances. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.
Amazon Relational Database Service User Guide

Creating a Multi-AZ DB cluster

Creating a Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 71).

Note
Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

In the following topic, you can find out how to create a Multi-AZ DB cluster. To get started, first see DB cluster prerequisites (p. 195).

For instructions on connecting to your Multi-AZ DB cluster, see Connecting to an Amazon RDS DB instance (p. 207).

DB cluster prerequisites

Before you create a Multi-AZ DB cluster, make sure to complete the tasks in Setting up for Amazon RDS (p. 93). The following are additional prerequisites to creating a Multi-AZ DB cluster.

VPC prerequisites

You can only create a Multi-AZ DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service, in an AWS Region that has at least three Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least three Availability Zones. This configuration ensures that your DB cluster always has at least two DB instance available for failover, in the unlikely event of an Availability Zone failure.

If you are using the AWS Management Console to create your Multi-AZ DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Multi-AZ DB cluster. Your VPC must have at least one subnet in each of at least three Availability Zones for you to use it with a Multi-AZ DB cluster. For information on VPCs, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

If you don't have a default VPC or you haven't created a VPC, and you don't plan to use the console, do the following:

- Create a VPC with at least one subnet in each of at least three of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see Working with a DB instance in a VPC (p. 1850).
- Specify a VPC security group that authorizes connections to your DB cluster. For more information, see Working with a DB instance in a VPC (p. 1850).
- Specify an RDS DB subnet group that defines at least three subnets in the VPC that can be used by the Multi-AZ DB cluster. For more information, see Working with DB subnet groups (p. 1851).

Additional prerequisites

If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management in Amazon RDS (p. 1766).

If you are using IAM to access the Amazon RDS console, first sign on to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.
If you want to tailor the configuration parameters for your DB cluster, specify a DB cluster parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group, see Working with parameter groups for Multi-AZ DB clusters (p. 76).

Determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, choose another port for your DB cluster. All DB instances in a DB cluster use the same port.

Creating a DB cluster

You can create a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

You can create a Multi-AZ DB cluster by choosing Multi-AZ DB cluster in the Availability and durability section.

To create a Multi-AZ DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.
   
   Only the US East (N. Virginia), US West (Oregon), and Europe (Ireland) AWS Regions support Multi-AZ DB clusters.
3. In the navigation pane, choose Databases.
4. Choose Create database.
5. In Engine type, choose MySQL or PostgreSQL.
6. For Version, choose the DB engine version.
   
   You can create a Multi-AZ DB cluster only with MySQL version 8.0.28 and higher 8.0 versions, and PostgreSQL version 13.4 and higher 13 versions.
7. In Templates, choose the appropriate template for your deployment.
8. In Availability and durability, choose Multi-AZ DB cluster.

<table>
<thead>
<tr>
<th>Availability and durability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deployment options Info</td>
</tr>
<tr>
<td>The deployment options below are limited to those supported by the engine you selected above.</td>
</tr>
</tbody>
</table>

- Multi-AZ DB cluster:
  Creates a DB cluster with a primary DB instance and two readable standby DB instances, with each DB instance in a different Availability Zone (AZ). Provides high availability, data redundancy and increases capacity to serve read workloads.

- Multi-AZ DB instance:
  Creates a primary DB instance and a standby DB instance in a different AZ. Provides high availability and data redundancy, but the standby DB instance doesn't support connections for read workloads.

- Single DB instance:
  Creates a single DB instance with no standby DB instances.

9. In DB cluster identifier, enter the identifier for your DB cluster.
10. In Master username, enter your master user name, or keep the default setting.
11. Enter your master password:
a. In the **Settings** section, open **Credential Settings**.

b. If you want to specify a password, clear the **Auto generate a password** box if it is selected.

c. (Optional) Change the **Master username** value.

d. Enter the same password in **Master password** and **Confirm password**.

12. In **DB instance class**, choose a DB instance class.

13. For the remaining sections, specify your DB cluster settings. For information about each setting, see **Settings for creating Multi-AZ DB clusters (p. 199)**.

14. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB cluster, choose **View credential details**.

To connect to the DB cluster as the master user, use the user name and password that appear.

**Important**

You can’t view the master user password again.

15. For **Databases**, choose the name of the new DB cluster.

On the RDS console, the details for the new DB cluster appear. The DB cluster has a status of **Creating** until the DB cluster is created and ready for use. When the state changes to **Available**, you can connect to the DB cluster. Depending on the DB cluster class and storage allocated, it can take several minutes for the new DB cluster to be available.

**AWS CLI**

Before you create a Multi-AZ DB cluster using the AWS CLI, make sure to fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see **DB cluster prerequisites (p. 195)**.

To create a Multi-AZ DB cluster by using the AWS CLI, call the `create-db-cluster` command. Specify the `--db-cluster-identifier`. For the `--engine` option, specify either `mysql` or `postgres`.

For information about each option, see **Settings for creating Multi-AZ DB clusters (p. 199)**.

The `create-db-cluster` command creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

For example, the following command creates a MySQL 8.0 Multi-AZ DB cluster named `mysql-multi-az-db-cluster`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster
--db-cluster-identifier mysql-multi-az-db-cluster
--engine mysql
--engine-version 8.0.26
--master-user-password password
--master-username admin
```
Creating a DB cluster

For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier mysql-multi-az-db-cluster ^
  --engine mysql ^
  --engine-version 8.0.26 ^
  --master-user-password password ^
  --master-username admin ^
  --port 3306 ^
  --backup-retention-period 1 ^
  --db-subnet-group-name default ^
  --allocated-storage 4000 ^
  --storage-type io1 ^
  --iops 10000 ^
  --db-cluster-instance-class db.r6gd.xlarge
```

The following command creates a PostgreSQL 13.4 Multi-AZ DB cluster named postgresql-multi-az-db-cluster.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster 
  --db-cluster-identifier postgresql-multi-az-db-cluster 
  --engine postgres 
  --engine-version 13.4 
  --master-user-password password 
  --master-username postgres 
  --port 5432 
  --backup-retention-period 1 
  --db-subnet-group-name default 
  --allocated-storage 4000 
  --storage-type io1 
  --iops 10000 
  --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier postgresql-multi-az-db-cluster ^
  --engine postgres ^
  --engine-version 13.4 ^
  --master-user-password password ^
  --master-username postgres ^
  --port 5432 ^
  --backup-retention-period 1 ^
  --db-subnet-group-name default ^
  --allocated-storage 4000 ^
  --storage-type io1 ^
  --iops 10000 ^
  --db-cluster-instance-class db.r6gd.xlarge
```
RDS API

Before you can create a Multi-AZ DB cluster using the RDS API, make sure to fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites (p. 195).

To create a Multi-AZ DB cluster by using the RDS API, call the `CreateDBCluster` operation. Specify the `DBClusterIdentifier`. For the `Engine` parameter, specify either `mysql` or `postgresql`.

For information about each option, see Settings for creating Multi-AZ DB clusters (p. 199).

The `CreateDBCluster` operation creates the writer DB instance for your DB cluster, and two reader DB instances. Each DB instance is in a different Availability Zone.

Settings for creating Multi-AZ DB clusters

For details about settings that you choose when you create a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see `create-db-cluster`. For more information about the RDS API parameters, see `CreateDBCluster`.

<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allocated storage</td>
<td>The amount of storage to allocate for each DB instance in your DB cluster (in gibibyte). For more information, see Amazon RDS DB instance storage (p. 53).</td>
<td>CLI option: <code>--allocated-storage</code>&lt;br&gt;API parameter: <code>AllocatedStorage</code></td>
</tr>
<tr>
<td>Auto minor version upgrade</td>
<td>Enable auto minor version upgrade to have your DB cluster receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.</td>
<td>CLI option: <code>--auto-minor-version-upgrade</code>&lt;br&gt;<code>--no-auto-minor-version-upgrade</code>&lt;br&gt;API parameter: <code>AutoMinorVersionUpgrade</code></td>
</tr>
<tr>
<td>Backup retention period</td>
<td>The number of days that you want automatic backups of your DB cluster to be retained. For a Multi-AZ DB cluster, this value must be set to 1 or greater. For more information, see Working with backups (p. 407).</td>
<td>CLI option: <code>--backup-retention-period</code>&lt;br&gt;API parameter: <code>BackupRetentionPeriod</code></td>
</tr>
<tr>
<td>Backup window</td>
<td>The time period during which Amazon RDS automatically takes a backup of your DB cluster. Unless you have a specific time that you want to have your database backed up, use the default of No preference. For more information, see Working with backups (p. 407).</td>
<td>CLI option: <code>--preferred-backup-window</code>&lt;br&gt;API parameter: <code>PreferredBackupWindow</code></td>
</tr>

</tbody>
</table>
| Copy tags to snapshots | This option copies any DB cluster tags to a DB snapshot when you create a snapshot. For more information, see Tagging Amazon RDS resources (p. 375).                                                                                                                                                | CLI option:  
- copy-tags-to-snapshot  
- no-copy-tags-to-snapshot  
RDS API parameter:  
CopyTagsToSnapshot                                                                                                               |
| Database authentication | For Multi-AZ DB clusters, only **Password authentication** is supported.                                                                                                                                                                                                                                                                               | None because password authentication is the default.                                                                 |
| Database port        | The port that you want to access the DB cluster through. The default port is shown. If you use a DB security group with your DB cluster, this port value must be the same one that you provided when creating the DB security group.  
The port can't be changed after the DB cluster is created.  
The firewalls at some companies block connections to the default ports. If your company firewall blocks the default port, enter another port for your DB cluster. | CLI option:  
--port  
RDS API parameter:  
Port                                                                                                                                                                    |
| DB cluster identifier | The name for your DB cluster. Name your DB clusters in the same way that you name your on-premises servers. Your DB cluster identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose.  | CLI option:  
--db-cluster-identifier  
RDS API parameter:  
DBClusterIdentifier                                                                                                                                                           |
| DB cluster instance class | The compute and memory capacity of each DB instance in the Multi-AZ DB cluster, for example db.r6gd.xlarge.  
If possible, choose a DB instance class large enough that a typical query working set can be held in memory. When working sets are held in memory the system can avoid writing to disk, which improves performance.  
Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes (p. 9). | CLI option:  
--db-cluster-instance-class  
RDS API parameter:  
DBClusterInstanceClass                                                                                                                                                     |

</tbody>
</table>
| **Initial database name** | The name for the database on your DB cluster. If you don't provide a name, Amazon RDS doesn't create a database on the DB cluster for MySQL, but it does create a database on the DB cluster for PostgreSQL. The name can't be a word reserved by the database engine, and has other constraints depending on the DB engine.  
  
  MySQL:                                                                                                                                   | CLI option:                        |
<p>|                        | • It must contain 1–64 alphanumeric characters.                                                                                                                                                                        | <code>--database-name</code>                 |
|                        | PostgreSQL:                                                                                                                                           | <strong>RDS API parameter:</strong>             |
|                        | • It must contain 1–63 alphanumeric characters.                                                                                                                                                                     | <code>DatabaseName</code>                    |
|                        | • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0-9).                                                                                             |                                  |
|                        | • The initial database name is <code>postgres</code>.                                                                                                                                                                           |                                  |
| <strong>Log exports</strong>        | The types of database log files to publish to Amazon CloudWatch Logs. For more information, see Publishing database logs to Amazon CloudWatch Logs (p. 648).                                                                 | CLI option:                      |
|                        |                                                                                                                                                    | <code>--enable-cloudwatch-logs-exports</code> |
|                        | <strong>RDS API parameter:</strong>                                                                                                                                | <strong>RDS API parameter:</strong>             |
|                        |                                                                                                                                                    | <code>EnableCloudwatchLogsExports</code>     |
| <strong>Maintenance window</strong> | The 30-minute window in which pending modifications to your DB cluster are applied. If the time period doesn't matter, choose No preference. For more information, see The Amazon RDS maintenance window (p. 337). | CLI option:                      |
|                        |                                                                                                                                                    | <code>--preferred-maintenance-window</code>  |
|                        | <strong>RDS API parameter:</strong>                                                                                                                                | <strong>RDS API parameter:</strong>             |
|                        |                                                                                                                                                    | <code>PreferredMaintenanceWindow</code>      |
| <strong>Master password</strong>     | The password for your master user account.                                                                                                                                                                        | CLI option:                      |
|                        |                                                                                                                                                      | <code>--master-user-password</code>          |
|                        |                                                                                                                                                      | <strong>RDS API parameter:</strong>             |
|                        |                                                                                                                                                      | <code>MasterUserPassword</code>              |</p>
<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
</tr>
</thead>
</table>
| **Master username** | The name that you use as the master user name to log on to your DB cluster with all database privileges.  
  - It can contain 1–16 alphanumeric characters and underscores.  
  - Its first character must be a letter.  
  - It can't be a word reserved by the database engine.  
  For more information on privileges granted to the master user, see [Master user account privileges](p. 1835). | **CLI option:**  
  `--master-username`  
  **RDS API parameter:**  
  `MasterUsername` |
| **Performance Insights** | Enable Performance Insights to monitor your DB cluster load so that you can analyze and troubleshoot your database performance.  
  Choose a retention period to determine how much rolling data history to keep. The default of seven days is in the free tier. Long-term retention (two years) is priced per vCPU per month.  
  Choose a master key to use to protect the key used to encrypt this database volume. Choose from the master keys in your account, or enter the key from a different account.  
  For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](p. 521). | **CLI options:**  
  `--enable-performance-insights`  
  `--no-enable-performance-insights`  
  `--performance-insights-retention-period`  
  `--performance-insights-kms-key-id`  
  **RDS API parameters:**  
  `EnablePerformanceInsights`  
  `PerformanceInsightsRetentionPeriod`  
  `PerformanceInsightsKMSKeyId` |
| **Provisioned IOPS** | The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB cluster. This setting is available only if Provisioned IOPS (io1) is selected as the storage type.  
  For more information, see [Provisioned IOPS SSD storage](p. 55). | **CLI option:**  
  `--iops`  
  **RDS API parameter:**  
  `Iops` |
### Available settings

<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
</tr>
</thead>
</table>
| **Public access**       | **Publicly accessible** to give the DB cluster a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB cluster also has to be in a public subnet in the VPC. **Not publicly accessible** to make the DB cluster accessible only from inside the VPC. For more information, see Hiding a DB instance in a VPC from the internet (p. 1851). To connect to a DB cluster from outside of its VPC, the DB cluster must be publicly accessible. Also, access must be granted using the inbound rules of the DB cluster's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1880). If your DB cluster isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1765). | CLI option:  
  --publicly-accessible  
  --no-publicly-accessible  
  RDS API parameter:  
  PubliclyAccessible |
| **Storage type**        | The storage type for your DB cluster. Only Provisioned IOPS (io1) storage is supported. For more information, see Amazon RDS storage types (p. 53). | CLI option:  
  --storage-type  
  RDS API parameter:  
  StorageType |
| **Subnet group**        | A DB subnet group to associate with this DB cluster. For more information, see Working with DB subnet groups (p. 1851). | CLI option:  
  --db-subnet-group-name  
  RDS API parameter:  
  DBSubnetGroupName |
| **Virtual Private Cloud (VPC)** | A Amazon VPC to associate with this DB cluster. For more information, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849). | For the CLI and API, you specify the VPC security group IDs. |

Creating Amazon RDS resources with AWS CloudFormation

Amazon RDS is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB instances and DB parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your RDS resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

RDS and AWS CloudFormation templates

To provision and configure resources for RDS and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you’re unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

RDS supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the RDS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide
Connecting to an Amazon RDS DB instance

Before you can connect to a DB instance, you must create the DB instance. For information, see Creating an Amazon RDS DB instance (p. 175). After Amazon RDS provisions your DB instance, you can use any standard client application or utility for your DB engine to connect to the DB instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

Topics

- Finding the connection information for an Amazon RDS DB instance (p. 207)
- Database authentication options (p. 210)
- Encrypted connections (p. 211)
- Scenarios for accessing a DB instance in a VPC (p. 211)
- Connecting to a DB instance that is running a specific DB engine (p. 211)
- Managing connections with RDS Proxy (p. 212)

Finding the connection information for an Amazon RDS DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, for a MySQL DB instance, suppose that the endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
- For port, specify 3306.
- For user, specify admin.

The endpoint is unique for each DB instance, and the values of the port and user can vary. The following list shows the most common port for each DB engine:

- MariaDB – 3306
- Microsoft SQL Server – 1433
- MySQL – 3306
- Oracle – 1521
- PostgreSQL – 5432

To connect to a DB instance, use any client for a DB engine. For example, you might use the mysql utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance, or the psql command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.
Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases to display a list of your DB instances.
3. Choose the name of the DB instance to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

**AWS CLI**

To find the connection information for a DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
Database authentication options

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances
--query "[*].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```bash
aws rds describe-db-instances
--query "[*].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```json
[
  [
    "mydb",
    "mydb.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "myoracledb",
    "myoracledb.123456789012.us-east-1.rds.amazonaws.com",
    1521,
    "dbadmin"
  ],
  [
    "mypostgresql",
    "mypostgresql.123456789012.us-east-1.rds.amazonaws.com",
    5432,
    "postgresadmin"
  ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Database authentication options

Amazon RDS supports the following ways to authenticate database users:

- **Password authentication** – Your DB instance performs all administration of user accounts. You create users and specify passwords with SQL statements. The SQL statements you can use depend on your DB engine.
- **AWS Identity and Access Management (IAM) database authentication** – You don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.
- **Kerberos authentication** – You use external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

IAM database authentication and Kerberos authentication are available only for specific DB engines and versions.
For more information, see Database authentication with Amazon RDS (p. 1748).

Encrypted connections

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance. Each DB engine has its own process for implementing SSL/TLS. For more information, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

Scenarios for accessing a DB instance in a VPC

Using Amazon Virtual Private Cloud (Amazon VPC), you can launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC). When you use Amazon VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists.

A VPC security group controls access to DB instances inside a VPC. Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group.

Before attempting to connect to your DB instance, configure your VPC for your use case. The following are common scenarios for accessing a DB instance in a VPC:

- **A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC**– A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. The EC2 instance might run a web server with an application that interacts with the DB instance.

- **A DB instance in a VPC accessed by an EC2 instance in a different VPC**– When your DB instance is in a different VPC from the EC2 instance that you're using to access it, you can use VPC peering to access the DB instance.

- **A DB instance in a VPC accessed by a client application through the internet**– To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

  To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1880).

- **A DB instance in a VPC accessed by a private network**– If your DB instance isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network.

- **A DB instance in a VPC accessed by an EC2 instance not in a VPC**– You can communicate between a DB instance that is in a VPC and an EC2 instance that is not in a VPC by using ClassicLink.

For more information, see Scenarios for accessing a DB instance in a VPC (p. 1857).

Connecting to a DB instance that is running a specific DB engine

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

- Connecting to a DB instance running the MariaDB database engine (p. 851)
Managing connections with RDS Proxy

You can also use Amazon RDS Proxy to manage connections to MySQL and PostgreSQL DB instances. RDS Proxy allows applications to pool and share database connections to improve scalability.

- Using Amazon RDS Proxy (p. 213)
Using Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

**Note**

RDS Proxy is fully compatible with MySQL and PostgreSQL. You can enable RDS Proxy for most applications with no code changes.

Using RDS Proxy, you can handle unpredictable surges in database traffic that otherwise might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool without the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

**Supported engines and Region availability for RDS Proxy**

RDS Proxy supports the following database engine versions:

- RDS for MySQL – MySQL 5.6, 5.7, and 8.0
- RDS for PostgreSQL – version 10.10 and higher minor versions, version 11.5 and higher minor versions, and version 12.5 and higher minor versions

RDS Proxy is available in the following AWS Regions:
Quotas and limitations apply to RDS Proxy:

- You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to with up to 200 different user accounts at any given time.
- You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see Overview of proxy endpoints (p. 241).

For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.

- You can't use RDS Proxy with Aurora Serverless clusters.
- Using RDS Proxy with Aurora clusters that are part of an Aurora global database isn't currently supported.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping on a local host, you can't connect to your RDS Proxy unless you set up dedicated networking. This is the case because your local host is outside of the proxy's VPC.
Note
For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see Accessing Aurora and RDS databases across VPCs (p. 242).

- You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.
- If you use RDS Proxy with an RDS DB instance or Aurora DB cluster that has IAM authentication enabled, make sure that all users who connect through a proxy authenticate through user names and passwords. See Setting up AWS Identity and Access Management (IAM) policies (p. 223) for details about IAM support in RDS Proxy.
- You can't use RDS Proxy with custom DNS.
- RDS Proxy is available for the MySQL and PostgreSQL engine families.
- Each proxy can be associated with a single target DB instance or cluster. However, you can associate multiple proxies with the same DB instance or cluster.

The following RDS Proxy limitations apply to MySQL:

- RDS Proxy doesn't support the MySQL sha2.56_password and caching_sha2_password authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the read_only parameter in its DB parameter group set to 1.
- Proxies don't support MySQL compressed mode. For example, they don't support the compression used by the --compress or -C options of the mysql command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning (p. 238).

The following RDS Proxy limitations apply to PostgreSQL:

- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a CancelRequest. This is the case for example, when you cancel a long-running query in an interactive psql session by using Ctrl+C.
- The results of the PostgreSQL function lastval aren't always accurate. As a work-around, use the INSERT statement with the RETURNING clause.
- RDS Proxy doesn't multiplex connections when your client application drivers use the PostgreSQL extended query protocol.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB instance or cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance or cluster.
- For DB instances or clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
• You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance or cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance or cluster is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 247).

• AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

• Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.

• Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance or cluster.

• You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances and clusters. If so, you can leave the existing authentication methods in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

• RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). To ensure overall high availability for your database, deploy your Amazon RDS DB instance or Aurora cluster in a Multi-AZ configuration.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances and Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instances and Aurora DB clusters. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

Topics

• Overview of RDS Proxy concepts (p. 217)
• Connection pooling (p. 217)
• RDS Proxy security (p. 218)
• Failover (p. 219)
• Transactions (p. 220)
Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the Proxies page.

Each proxy handles connections to a single RDS DB instance or Aurora DB cluster. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instances and Aurora provisioned clusters. For Aurora multi-master clusters, the proxy connects to one of the writer instances and uses the other writer instances as hot standby targets.

The connections that a proxy keeps open and available for your database application to use make up the connection pool.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called multiplexing. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called borrowing the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called pinning.

A proxy has a default endpoint. You connect to this endpoint when you work with an RDS DB instance or Aurora DB cluster, instead of connecting to the read/write endpoint that connects directly to the instance or cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see Overview of proxy endpoints (p. 241).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within an Aurora cluster. If you are using other AWS services such as AWS Lambda to connect to RDS databases, you change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This target group embodies the RDS DB instance or Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The RDS DB instance associated with a proxy, or the Aurora DB cluster and its instances, are called the targets of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An engine family is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated RDS or Aurora database. Connection pooling is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one, such as Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With multiplexing, RDS Proxy performs all the operations for a transaction using one underlying database connection, then
can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

**RDS Proxy security**

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see Security in Amazon RDS (p. 1747). If you aren't familiar with how RDS and Aurora work with authentication, authorization, and other areas of security, make sure to familiarize yourself with how RDS and Aurora work with those areas first.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports only TLS 1.0 or 1.1. You can connect to the proxy using an IAM role, even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance or Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

**Using TLS/SSL with RDS Proxy**

You can connect to RDS Proxy using the TLS/SSL protocol.

**Note**

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you use RDS Proxy, when you rotate your TLS/SSL certificate you don't need to update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL and Aurora MySQL, specify the requirement on the client side with the **--ssl-mode** parameter when you run the **mysql** command.
- For Amazon RDS PostgreSQL and Aurora PostgreSQL, specify **sslmode=require** as part of the **conninfo** string when you run the **psql** command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the **--ssl-mode** option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

**PREFERRED**

SSL is the first choice, but it isn't required.
DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

Note

You can use the SSL mode VERIFY_IDENTITY when connecting to the default proxy endpoint. You can't use that SSL mode when you connect to proxy endpoints that you create.

When using a client with --ssl-mode VERIFY_CA or VERIFY_IDENTITY, specify the --ssl-ca option pointing to a CA in .pem format. For a .pem file that you can use, download the Amazon root CA 1 trust store from Amazon Trust Services.

RDS Proxy uses wildcard certificates, which apply to a both a domain and its subdomains. If you use the mysql client to connect with SSL mode VERIFY_IDENTITY, currently you must use the MySQL 8.0-compatible mysql command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration, and Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted to take the place of the one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a
transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the
database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection
rates and more open connections. It offloads the expensive overhead of frequent reconnects from the
database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This
approach is particularly important for TLS connections, where setup costs are significant.

**Transactions**

All the statements within a single transaction always use the same underlying database connection.
The connection becomes available for use by a different session when the transaction ends. Using the
transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL or Aurora
  MySQL `autocommit` setting is enabled.
- Conversely, when the `autocommit` setting is disabled, the first statement you issue in a session
  begins a new transaction. Thus, if you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data
  manipulation language (DML) statements, connection reuse doesn't happen until you issue a `COMMIT`,
  `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that
  statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client
application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in
the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session
to a different connection. In these cases, it turns off multiplexing for that connection the remainder
of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for
the session. This operation is called *pinning*. For ways to detect and minimize pinning, see *Avoiding
pinning* (p. 238).

**Getting started with RDS Proxy**

In the following sections, you can find how to set up RDS Proxy. You can also find how to set the related
security options that control who can access each proxy and how each proxy connects to DB instances.

**Topics**

- Setting up network prerequisites (p. 220)
- Setting up database credentials in AWS Secrets Manager (p. 221)
- Setting up AWS Identity and Access Management (IAM) policies (p. 223)
- Creating an RDS Proxy (p. 225)
- Viewing an RDS Proxy (p. 228)
- Connecting to a database through RDS Proxy (p. 229)

**Setting up network prerequisites**

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB
cluster or RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are
in different Availability Zones. Your account can either own these subnets or share them with other
accounts. For information about VPC sharing, see *Work with shared VPCs*. Your client application
resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC or in a separate VPC from the proxy. Note that if you've successfully connected to any RDS DB instances or Aurora DB clusters, you already have the required network resources.

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```bash
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster or RDS DB instance. For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance by examining the nested fields within the DBSubnetGroup and Subnets attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```bash
# # Optional first step, only needed if you're starting from an Aurora cluster. Find the ID of any DB instance in the cluster.
# aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[].[DBClusterMembers][0][0][*].DBInstanceIdentifier' --output text
my_instance_id
instance_id_2
instance_id_3
...
# # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet IDs.
# aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0][0][Subnets][0][*].SubnetIdentifier' --output text
subnet_id_1
subnet_id_2
subnet_id_3
...

As an alternative, you can first find the VPC ID for the DB instance. Then you can examine the VPC to find its subnets. The following Linux example shows how.

```bash
# # From the DB instance, find the VPC.
# aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0][0].VpcId' --output text
my_vpc_id
# aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]' --output text
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

### Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance or Aurora DB cluster.
In Secrets Manager, you create these secrets with values for the `username` and `password` fields. Doing so allows the proxy to connect to the corresponding database users on whichever RDS DB instances or Aurora DB clusters that you associate with the proxy. To do this, you can use the setting **Credentials for other database, Credentials for RDS database, or Other type of secrets**. Fill in the appropriate values for the `User name` and `Password` fields, and placeholder values for any other required fields. The proxy ignores other fields such as `Host` and `Port` if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named `username` and `password`.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies if you use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the **Creating a secret** page in the Secrets Manager documentation. Use one of the following techniques:

- Use **Secrets Manager** in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```bash
aws secretsmanager create-secret
   --name "secret_name"
   --description "secret_description"
   --region region_name
   --secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named `admin` and the other named `app-user`.

```bash
aws secretsmanager create-secret
   --name admin_secret_name --description "db admin user"
   --secret-string '{"username":"admin","password":"choose_your_own_password"}';
aws secretsmanager create-secret
   --name proxy_secret_name --description "application user"
   --secret-string '{"username":"app-user","password":"choose_your_own_password"}';
```

To see the secrets owned by your AWS account, use a command such as the following.

```bash
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.
To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for `your_secret_name`.

```bash
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```json
"SecretString": "{"username":"your_username","password":"your_password"}
```

### Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM with RDS and Aurora, see Identity and access management in Amazon RDS (p. 1766).

**Tip**

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

**To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy**

1. Sign in to the IAM console. Follow the Create role process, as described in Creating IAM roles. Include the Add Role to Database step.

2. For the new role, perform the Add inline policy step. Use the same general procedures as in Editing IAM policies. Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for `us-east-2`. Substitute the Amazon Resource Names (ARNs) for the secrets that you created. For the `kms:Decrypt` action, substitute the ARN of the default AWS KMS key or your own KMS key depending on which one you used to encrypt the Secrets Manager secrets.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "secretsmanager:GetSecretValue",
      "Resource": [
        "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
        "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
      ]
    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": "kms:Decrypt",
      "Condition": {
        "StringEquals": {
          "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
        }
      }
    }
  ]
}
```
3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "",
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

The following commands perform the same operation through the AWS CLI.

```bash
PREFIX=choose_an_identifier
aws iam create-role --role-name choose_role_name
   --assume-role-policy-document '{"Version":"2012-10-17","Statement": ["Effect":"Allow","Principal":{"Service":"rds.amazonaws.com"},"Action":"sts:AssumeRole"]}'

aws iam put-role-policy --role-name same_role_name_as_previous
   --policy-name $PREFIX-secret-reader-policy --policy-document "same_json_as_in_previous_example"

aws kms create-key --description "$PREFIX-test-key" --policy ""
   {"Id":"$PREFIX-kms-policy","Version":"2012-10-17","Statement": [
      {
         "Sid":"Enable IAM User Permissions",
         "Effect":"Allow",
         "Principal":{"AWS":"arn:aws:iam::<account_id>:root"},
         "Action":"kms:*","Resource":"
      },
      {
         "Sid":"Allow access for Key Administrators",
         "Effect":"Allow",
         "Principal": {
            "AWS": ["$USER_ARN","arn:aws:iam::<account_id>:role/Admin"]
         },
         "Action": [
            "kms:Create",
            "kms:Describe",
            "kms:Enable",
            "kms:List",
            "kms:Put",
            "kms:Update",
            "kms:Revoke",
            "kms:Disable",
            "kms:Get",
            "kms:Delete",
            "kms:TagResource",
            "kms:TagResource",
            "kms:UntagResource"
         ]
      }
   ]
```
Creating an RDS Proxy

To manage connections for a specified set of DB instances, you can create a proxy. You can associate a proxy with an RDS for MySQL DB instance, PostgreSQL DB instance, or an Aurora DB cluster.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. Choose Create proxy.
4. Choose all the settings for your proxy.

For Proxy configuration, provide information for the following:

- **Proxy identifier.** Specify a name of your choosing, unique within your AWS account ID and current AWS Region.
- **Engine compatibility.** Choose either MySQL or POSTGRESQL.
- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. When you use an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Idle client connection timeout.** Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For Target group configuration, provide information for the following:

- **Database.** Choose one RDS DB instance or Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in Creating an Amazon RDS DB instance (p. 175). Then try creating the proxy again.
• **Connection pool maximum connections.** Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see `MaxConnectionsPercent` (p. 237).

• **Session pinning filters.** (Optional) This is an advanced setting, for troubleshooting performance issues with particular applications. Currently, the only choice is `EXCLUDE_VARIABLE_SETS`. Choose a filter only if both of following are true: Your application isn't reusing connections due to certain kinds of SQL statements, and you can verify that reusing connections with those SQL statements doesn't affect application correctness. For more information, see Avoiding pinning (p. 238).

• **Connection borrow timeout.** In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.

• **Initialization query.** (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`. Initialization query is not currently supported for PostgreSQL.

For **Connectivity**, provide information for the following:

• **Secrets Manager secrets.** Choose at least one Secrets Manager secret that contains DB user credentials for the RDS DB instance or Aurora DB cluster that you intend to access with this proxy.

• **IAM role.** Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.

• **IAM Authentication.** Choose whether to require or disallow IAM authentication for connections to your proxy. The choice of IAM authentication or native database authentication applies to all DB users that access this proxy.

• **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

• **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that.

  **Note**

  This security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

  (Optional) Provide advanced configuration:
• **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging, and only when you have security measures in place to safeguard any sensitive information that appears in the logs.

To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

**AWS CLI**

To create a proxy, use the AWS CLI command `create-db-proxy`. The `--engine-family` value is case-sensitive.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-proxy \
  --db-proxy-name proxy_name \
  --engine-family { MYSQL | POSTGRESQL } \
  --auth ProxyAuthenticationConfig_JSON_string \
  --role-arn iam_role \
  --vpc-subnet-ids space_separated_list \
  [--vpc-security-group-ids space_separated_list] \
  [--require-tls | --no-require-tls] \
  [--idle-client-timeout value] \
  [--debug-logging | --no-debug-logging] \
  [--tags comma_separated_list]
```

For Windows:

```bash
aws rds create-db-proxy ^
  --db-proxy-name proxy_name ^
  --engine-family { MYSQL | POSTGRESQL } ^
  --auth ProxyAuthenticationConfig_JSON_string ^
  --role-arn iam_role ^
  --vpc-subnet-ids space_separated_list ^
  [--vpc-security-group-ids space_separated_list] ^
  [--require-tls | --no-require-tls] ^
  [--idle-client-timeout value] ^
  [--debug-logging | --no-debug-logging] ^
  [--tags comma_separated_list]
```

**Tip**

If you don’t already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see [Setting up network prerequisites (p. 220)]() for examples of how to find the subnet IDs that you can use.

**Note**

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to
the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.

When using a shared VPC, you can’t use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn’t exist, create one. For more information about this limitation, see Work with shared VPCs.

To create the required information and associations for the proxy, you also use the register-db-proxy-targets command. Specify the target group name default. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
  --db-proxy-name value
  [--target-group-name target_group_name]
  [--db-instance-identifiers space_separated_list]  # rds db instances, or
  [--db-cluster-identifiers cluster_id]        # rds db cluster (all instances), or
  [--db-cluster-endpoint endpoint_name]          # rds db cluster endpoint (all instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation CreateDBProxy. You pass a parameter with the AuthConfig data structure.

RDS Proxy automatically creates a target group named default when you create each proxy. You associate an RDS DB instance or Aurora DB cluster with the target group by calling the function RegisterDBProxyTargets.

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose Proxies.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the Target groups section shows how the proxy is associated with a specific RDS DB instance or Aurora DB cluster. You can follow the link to the default target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy, such as maximum connection percentage, connection borrow timeout, engine compatibility, and session pinning filters.

CLI

To view your proxy using the CLI, use the describe-db-proxies command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the --db-proxy-name parameter.
To view the other information associated with the proxy, use the following commands.

```bash
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run `describe-db-proxies`.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run `describe-db-proxy-target-groups --db-proxy-name` and use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance or Aurora DB cluster associated with the returned target group, run `describe-db-proxy-targets`.

**RDS API**

To view your proxies using the RDS API, use the `DescribeDBProxies` operation. It returns values of the `DBProxy` data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the `DescribeDBProxyTargetGroups` operation. It returns values of the `DBProxyTargetGroup` data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the `DescribeDBProxyTargets` operation. It returns values of the `DBProxyTarget` data type.

**Connecting to a database through RDS Proxy**

You connect to an RDS DB instance or Aurora DB cluster through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the instance or cluster endpoint. For an Aurora DB cluster, by default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy and use that endpoint the same way. For more information, see Overview of proxy endpoints (p. 241).

**Topics**

- Connecting to a proxy using native authentication (p. 229)
- Connecting to a proxy using IAM authentication (p. 230)
- Considerations for connecting to a proxy with PostgreSQL (p. 231)

**Connecting to a proxy using native authentication**

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the `describe-db-proxies` command. The following example shows how.

```bash
# Add --output text to get output as a simple tab-separated list.
```
$ aws rds describe-db-proxies --query '(*[*].{DBProxyName:DBProxyName,Endpoint:Endpoint})'

[  
  
  
  
  
  
  
  
  
  ]

2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.

3. Supply the same database user name and password as you usually do.

**Connecting to a proxy using IAM authentication**

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn’t go through IAM.

To connect to RDS Proxy using IAM authentication, follow the same general procedure as for connecting to an RDS DB instance or Aurora cluster using IAM authentication. For general information about using IAM with RDS and Aurora, see Security in Amazon RDS (p. 1747).

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

  The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see Connecting to your DB instance using IAM authentication (p. 1793).

- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

  In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.
You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
```

### Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message that includes pairs of parameter name and value strings. For details, see the `StartupMessage` in [PostgreSQL message formats](https://www.postgresql.org/docs/13/message-contents.html) in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`
- `replication`

The startup message can also include the following additional runtime parameters:

- `application_name`
- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`

For more information about PostgreSQL messaging, see the [Frontend/Backend protocol](https://www.postgresql.org/docs/13/message-contents.html) in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least 9.0 to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to `any/your-application-name` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.
- Set the JDBC connection parameter `preferQueryMode` to `extendedForPrepared` to avoid pinning. The `extendedForPrepared` ensures that the extended mode is used only for prepared statements.

The default for the `preferQueryMode` parameter is `extended`, which uses the extended mode for all queries. The extended mode uses a series of `Prepare`, `Bind`, `Execute`, and `Sync` requests and corresponding responses. This type of series causes connection pinning in an RDS proxy.

### Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU
and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

**Topics**
- Modifying an RDS Proxy (p. 232)
- Adding a new database user (p. 236)
- Changing the password for a database user (p. 236)
- Configuring connection settings (p. 236)
- Avoiding pinning (p. 238)
- Deleting an RDS Proxy (p. 240)

**Modifying an RDS Proxy**

You can change certain settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

**AWS Management Console**

**To modify the settings for a proxy**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
   - **Proxy identifier** – Rename the proxy by entering a new identifier.
   - **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
   - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
   - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
   - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
   - **IAM Authentication** – Require or disallow IAM authentication for connections to the proxy.
   - **VPC security group** – Add or remove VPC security groups for the proxy to use.
   - **Enable enhanced logging** – Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The target group associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

**To modify the settings for a proxy target group**

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the default target group, choose Modify.

4. Choose new settings for the properties that you can modify:

   • **Database** – Choose a different RDS DB instance or Aurora cluster.
   • **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
   • **Session pinning filters** – (Optional) Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection.
   • **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
   • **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`. Initialization query is not currently supported for PostgreSQL.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose Modify target group.

**AWS CLI**

To modify a proxy using the AWS CLI, use the commands `modify-db-proxy`, `modify-db-proxy-target-group`, `deregister-db-proxy-targets`, and `register-db-proxy-targets`.

With the `modify-db-proxy` command, you can change properties such as the following:

   • The set of Secrets Manager secrets used by the proxy.
   • Whether TLS is required.
   • The idle client timeout.
   • Whether to log additional information from SQL statements for debugging.
   • The IAM role used to retrieve Secrets Manager secrets.
   • The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```bash
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named default. When working with this target group, you specify the name of the proxy and default for the name of the target group.

The following example shows how to first check the MaxIdleConnectionsPercent setting for a proxy and then change it, using the target group.

```bash
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy
{
```
With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option. When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option instead.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.
RDS API

To modify a proxy using the RDS API, you use the operations ModifyDBProxy, ModifyDBProxyTargetGroup, DeregisterDBProxyTargets, and RegisterDBProxyTargets operations.
With ModifyDBProxy, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With ModifyDBProxyTargetGroup, you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named default. When working with this target group, you specify the name of the proxy and default for the name of the target group.

With DeregisterDBProxyTargets and RegisterDBProxyTargets, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

**Adding a new database user**

In some cases, you might add a new database user to an RDS DB instance or Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

- Create a new Secrets Manager secret, using the procedure described in Setting up database credentials in AWS Secrets Manager (p. 221).
- Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
- If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

**Changing the password for a database user**

In some cases, you might change the password for a database user in an RDS DB instance or Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

**Configuring connection settings**

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- IdleClientTimeout (p. 236)
- MaxConnectionsPercent (p. 237)
- MaxIdleConnectionsPercent (p. 237)
- ConnectionBorrowTimeout (p. 237)

**IdleClientTimeout**

You can specify how long a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open...
and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, consider lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, consider raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see [AWS Management Console (p. 232)](https://docs.aws.amazon.com/rds/latest/userguide/). To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command `modify-db-proxy` or the API operation `ModifyDBProxy`.

### MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the database. You specify the limit as a percentage of the maximum connections available for your database. The proxy doesn't create all of these connections in advance. This setting reserves the right for the proxy to establish these connections as the workload needs them.

For example, suppose that you configured RDS Proxy to use 75 percent of the maximum connections for your database that supports a maximum of 1,000 concurrent connections. In that case, RDS Proxy can open up to 750 database connections.

This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API. To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see [AWS Management Console (p. 232)](https://docs.aws.amazon.com/rds/latest/userguide/). To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command `modify-db-proxy-target-group` or the API operation `ModifyDBProxyTargetGroup`.

For information on database connection limits, see [Maximum number of database connections](https://docs.aws.amazon.com/rds/latest/userguide/).

### MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. RDS Proxy considers a database connection in it's pool to be *idle* when there's been no activity on the connection for five minutes.

You specify the limit as a percentage of the maximum connections available for your database. The default value is 50 percent and the upper limit is the value of `MaxConnectionsPercent`. With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent` so that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the AWS CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command `modify-db-proxy-target-group` or the API operation `ModifyDBProxyTargetGroup`.

**Note**

RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

For information on database connection limits, see [Maximum number of database connections](https://docs.aws.amazon.com/rds/latest/userguide/).

### ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when
the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no appropriate database instance is available to handle the request because, for example, a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see **AWS Management Console (p. 232)**. To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command `modify-db-proxy-target-group` or the API operation `ModifyDBProxyTargetGroup`.

Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through `SET` or `SELECT` statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as **pinning**. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, if your application changes a session variable or configuration parameter, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

This rule doesn't apply to all parameters you can set. RDS Proxy tracks changes to the character set, collation, time zone, autocommit, current database, SQL mode, and `session_track_schema` settings. Thus RDS Proxy doesn't pin the session when you modify these. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings.

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning. You can do so by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- Apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see **Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 247)**.
- If you use `SET` statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.
For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding SET statements from your application code, so that they don't interfere with transaction-level multiplexing.

**Important**
For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- Explicit MySQL statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for SET operations not to cause pinning. For information about how to do so by setting the `SessionPinningFilters` property, see Creating an RDS Proxy (p. 225).
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the MySQL functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.

The exact circumstances where these functions cause pinning might differ between Aurora MySQL versions that are compatible with MySQL 5.6 and MySQL 5.7.

Calling MySQL stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

For PostgreSQL, the following interactions also cause pinning:

- Using SET commands
- Using the PostgreSQL extended query protocol such as by using JDBC default settings
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state
- Listening on a notification channel
- Loading a library module such as `auto_explain`
- Manipulating sequences using functions such as `nextval` and `setval`
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`
- Using prepared statements, setting parameters, or resetting a parameter to its default

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the `Session pinning filters` option when creating the
proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

For metrics about how often pinning occurs for a proxy, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 247).

Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. Choose the proxy to delete from the list.

AWS CLI

To delete a DB proxy, use the AWS CLI command delete-db-proxy. To remove related associations, also use the deregister-db-proxy-targets command.

```bash
aws rds delete-db-proxy --name proxy_name
```

```bash
aws rds deregister-db-proxy-targets
  --db-proxy-name proxy_name
  [--target-group-name target_group_name]
  [--target-ids comma_separated_list] # or
  [--db-instance-identifiers instance_id] # or
  [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function DeleteDBProxy. To delete related items and associations, you also call the functions DeleteDBProxyTargetGroup and DeregisterDBProxyTargets.

Working with Amazon RDS Proxy endpoints

Following, you can learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics
Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints and RDS instance endpoints. If you aren't familiar with RDS endpoints, find more information in Connecting to a DB instance running the MySQL database engine and Connecting to a DB instance running the PostgreSQL database engine.

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a consequence, this endpoint sends all requests to the writer instance of the cluster, and all of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries, the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see Limits for proxy endpoints (p. 247).

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see Monitoring RDS Proxy metrics with Amazon CloudWatch (p. 247).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Reader endpoints

With RDS Proxy, you can create and use reader endpoints. However, these endpoints only work for proxies associated with Aurora DB clusters. You might see references to reader endpoints in the AWS Management Console. If you use the RDS CLI or API, you might see the `TargetRole` attribute with a value of `READ_ONLY`. You can take advantage of these features by changing the target of a proxy from an RDS DB instance to an Aurora DB cluster. To learn about reader endpoints, see Managing connections with Amazon RDS Proxy in the Aurora User Guide.
Accessing Aurora and RDS databases across VPCs

By default, the components of your RDS and Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance or an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora cluster or RDS instance in one VPC from resources such as EC2 instances in another VPC. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. If you aren’t familiar with creating proxy endpoints, see Working with Amazon RDS Proxy endpoints (p. 240) for details. The proxy itself resides in the same VPC as the Aurora DB cluster or RDS instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can’t access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora and RDS work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult Getting started with Amazon RDS (p. 99) for the steps to set up another VPC to use RDS successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.

2. Create a DB proxy associated with the Aurora DB cluster or RDS instance that you want to connect to. Follow the procedure in Creating an RDS Proxy (p. 225).

3. On the Details page for your proxy in the RDS console, under the Proxy endpoints section, choose Create endpoint. Follow the procedure in Creating a proxy endpoint (p. 242).

4. Choose whether to make the cross-VPC endpoint read/write or read-only.

5. Instead of accepting the default of the same VPC as the Aurora DB cluster or RDS instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.

6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster or RDS instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.

7. You don’t need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.

8. Wait for the new endpoint to reach the Available state.

9. Make a note of the full endpoint name. This is the value ending in Region_name.rds.amazonaws.com that you supply as part of the connection string for your database application.

10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the mysql or psql commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

   The details page for that proxy appears.
4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

   The **Create proxy endpoint** window appears.
5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

   Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

   Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora’s clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don’t impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don’t slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default if you plan to access the endpoint from the same EC2 instances or other resources where you normally access the proxy or its associated database. If you want to set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora and RDS databases across VPCs](#) (p. 242).
8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. If you want to restrict access to the endpoint so that only a portion of the address range of the VPC can connect to it, remove one or more subnets from the set of choices.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can leave the default choice.

   If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.
10. Choose **Create proxy endpoint**.

**AWS CLI**

To create a proxy endpoint, use the AWS CLI `create-db-proxy-endpoint` command.

Include the following required parameters:

* --db-proxy-name `value`
* --db-proxy-endpoint-name `value`
* --vpc-subnet-ids `list_of_ids`. Separate the subnet IDs with spaces. You don’t specify the ID of the VPC itself.

You can also include the following optional parameters:

* --target-role { READ_WRITE | READ_ONLY }. This parameter defaults to **READ_WRITE**. The **READ_ONLY** value only has an effect on Aurora provisioned clusters that contain one or more reader
Working with RDS Proxy endpoints

DB instances. When the proxy is associated with an RDS instance or with an Aurora cluster that only contains a writer DB instance, you can’t specify `READ_ONLY`.

- `--vpc-security-group-ids value`. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-proxy-endpoint \\
  --db-proxy-name my-proxy \\
  --db-proxy-endpoint-name my-endpoint \\
  --vpc-subnet-ids subnet_id subnet_id subnet_id ... \\
  --target-role READ_ONLY \\
  --vpc-security-group-ids security_group_id
```

For Windows:

```bash
aws rds create-db-proxy-endpoint ^
  --db-proxy-name my-proxy ^
  --db-proxy-endpoint-name my-endpoint ^
  --vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
  --target-role READ_ONLY ^
  --vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API `CreateProxyEndpoint` action.

Viewing proxy endpoints

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Proxies.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the Proxy endpoints section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:

   - Whether the endpoint is read/write or read-only.
   - The endpoint address that you use in a database connection string.
   - The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more DB proxy endpoints, use the AWS CLI `describe-db-proxy-endpoints` command.
You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

**Example**

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
  --db-proxy-endpoint-name my-endpoint
```

**RDS API**

To describe one or more proxy endpoints, use the RDS API `DescribeDBProxyEndpoints` operation.

**Modifying a proxy endpoint**

**Console**

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

**AWS CLI**

To modify a DB proxy endpoint, use the AWS CLI `modify-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.
The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint \
  --new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```bash
aws rds modify-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint ^
  --new-db-proxy-endpoint-name new-endpoint-name
```

**RDS API**

To modify a proxy endpoint, use the RDS API `ModifyDBProxyEndpoint` operation.

**Deleting a proxy endpoint**

You can delete an endpoint for your proxy using the console as described following.

**Note**

You can't delete the default endpoint that RDS Proxy automatically creates for each proxy. When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

**Console**

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose Proxies.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the Proxy endpoints section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the Proxy endpoints section, choose Delete. Or on the proxy endpoint details page, for Actions, choose Delete.

**AWS CLI**

To delete a proxy endpoint, run the `delete-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:
aws rds delete-db-proxy-endpoint
  --db-proxy-endpoint-name my-endpoint

RDS API

To delete a proxy endpoint with the RDS API, run the DeleteDBProxyEndpoint operation. Specify the name of the proxy endpoint for the DBProxyEndpointName parameter.

Limits for proxy endpoints

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

Reader endpoints aren't available for Aurora multi-writer clusters.

You can connect to proxy endpoints that you create using the SSL modes REQUIRED and VERIFY_CA. You can't connect to an endpoint that you create using the SSL mode VERIFY_IDENTITY.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose Metrics, then choose RDS, and choose Per-Proxy Metrics. For more information, see Using Amazon CloudWatch metrics in the Amazon CloudWatch User Guide.

Note
RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances. Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name default for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group proxy.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints (p. 240).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the ProxyName dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: ProxyName
- Dimension set 2: ProxyName, EndpointName
• Dimension set 3: ProxyName, TargetGroup, Target
• Dimension set 4: ProxyName, TargetGroup, TargetRole

<table>
<thead>
<tr>

</tbody>
</table>

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the Log groups page.

**Important**

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change. In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.
Working with RDS Proxy events

An event indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon RDS generates an event when you create or modify an RDS Proxy. Amazon RDS delivers events to CloudWatch Events and Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events (p. 622).
- To learn how to configure Amazon RDS to send events to EventBridge, see Creating a rule that triggers on an Amazon RDS event (p. 642).

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0204</td>
<td>RDS modified the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0207</td>
<td>RDS modified the endpoint of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0213</td>
<td>RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0214</td>
<td>RDS detected the deletion of the DB instance and automatically removed it from the target group of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-XXXX</td>
<td>RDS detected the deletion of the DB cluster and automatically removed it from the target group of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Creation</td>
<td>RDS-EVENT-0203</td>
<td>RDS created the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Creation</td>
<td>RDS-EVENT-0206</td>
<td>RDS created the endpoint for the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Deletion</td>
<td>RDS-EVENT-0205</td>
<td>RDS deleted the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Deletion</td>
<td>RDS-EVENT-0208</td>
<td>RDS deleted the endpoint of DB proxy (RDS Proxy).</td>
</tr>
</tbody>
</table>

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

```json
{
    "version": "0",
    ...
}
```
RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

Examples

- Preserving Connections to a MySQL Database Across a Failover
- Adjusting the max_connections Setting for an Aurora DB Cluster

Example  Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover, for example when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named the-proxy and an Aurora DB cluster with DB instances instance-8898 and instance-9814. When you run the failover-db-cluster command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p Enter password: ...
mysql> select @@aurora_server_id;
+--------------------+
<table>
<thead>
<tr>
<th>@@aurora_server_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-9814</td>
</tr>
</tbody>
</table>
+--------------------+
1 row in set (0.01 sec)
```

When you run the failover-db-cluster command:

```
$ # Initially, instance-9814 is the writer.
$ # After a short time, the console shows that the failover operation is complete.
```
Example Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.6 or 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```bash
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-56-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-56

aws rds create-db-parameter-group --region $REGION \
  --db-parameter-group-family aurora5.6 \
  --db-parameter-group-name $CLUSTER_PARAM_GROUP \
  --description "Aurora MySQL 5.6 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
  --query '[*].{DBParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --query '[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}'
```
Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name default for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints (p. 240).

Topics

- Verifying connectivity for a proxy (p. 255)
- Common issues and solutions (p. 256)

Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the describe-db-proxies command. Also examine the associated target group using the describe-db-proxy-target-groups command. Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the describe-db-proxy-targets command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the describe-db-proxy-targets command includes a TargetHealth field. You can examine the fields State, Reason, and Description inside TargetHealth to check if the proxy can communicate with the underlying DB instance.

- A State value of AVAILABLE indicates that the proxy can connect to the DB instance.
• A State value of UNAVAILABLE indicates a temporary or permanent connection problem. In this case, examine the Reason and Description fields. For example, if Reason has a value of PENDING_PROXY_CAPACITY, try connecting again after the proxy finishes its scaling operation. If Reason has a value of UNREACHABLE, CONNECTION_FAILED, or AUTH_FAILURE, use the explanation from the Description field to help you diagnose the issue.

• The State field might have a value of REGISTERING for a brief time before changing to AVAILABLE or UNAVAILABLE.

If the following Netcat command (nc) is successful, you can access the proxy endpoint from the EC2 instance or other system where you’re logged in. This command reports failure if you’re not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can’t log into the proxy unless you’re in the same VPC.

```
nc -zs MySQL_proxy_endpoint 3306
nc -zs PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the SecretString field displayed by get-secret-value is encoded as a JSON string that includes username and password fields. The following example shows the format of the SecretString field.

```
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": "{"username":"some_username","password":"some_password"}'",
  "VersionStages": [ "some_stage" ],
  "CreatedDate": some_timestamp
}
```

Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Causes or workarounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>403: The security token included in the request is invalid</td>
<td>Select an existing IAM role instead of choosing to create a new one.</td>
</tr>
</tbody>
</table>
You might encounter the following issues while connecting to a MySQL proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Causes or workarounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR 1040 (HY000): Connections rate limit exceeded (limit_value)</td>
<td>The rate of connection requests from the client to the proxy has exceeded the limit.</td>
</tr>
<tr>
<td>ERROR 1040 (HY000): IAM authentication rate limit exceeded</td>
<td>The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.</td>
</tr>
<tr>
<td>ERROR 1040 (HY000): Number simultaneous connections exceeded (limit_value)</td>
<td>The number of simultaneous connection requests from the client to the proxy exceeded the limit.</td>
</tr>
</tbody>
</table>
| ERROR 1045 (28000): Access denied for user 'DB_USER'@'%' (using password: YES) | Some possible reasons include the following:  
  - The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret. |
| ERROR 1105 (HY000): Unknown error | An unknown error occurred. |
| ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of value | The value set for the character_set_client parameter is not valid. For example, the value ucs2 is not valid because it can crash the MySQL server. |
| ERROR 3159 (HY000): This RDS Proxy requires TLS connections. | You enabled the setting Require Transport Layer Security in the proxy but your connection included the parameter ssl-mode=DISABLED in the MySQL client. Do either of the following:  
  - Disable the setting Require Transport Layer Security for the proxy.  
  - Connect to the database using the minimum setting of ssl-mode=REQUIRED in the MySQL client. |
| ERROR 2026 (HY000): SSL connection error: Internal Server Error | The TLS handshake to the proxy failed. Some possible reasons include the following:  
  - SSL is required but the server doesn't support it.  
  - An internal server error occurred.  
  - A bad handshake occurred. |
| ERROR 9501 (HY000): Timed-out waiting to | The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: |
### Error: acquire database connection

<table>
<thead>
<tr>
<th>Causes or workarounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>• The proxy is unable to establish a database connection because the maximum connections have been reached</td>
</tr>
<tr>
<td>• The proxy is unable to establish a database connection because the database is unavailable.</td>
</tr>
</tbody>
</table>

You might encounter the following issues while connecting to a PostgreSQL proxy.

<table>
<thead>
<tr>
<th>Error</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM authentication is allowed only with SSL connections.</td>
<td>The user tried to connect to the database using IAM authentication with the setting sslmode=disable in the PostgreSQL client.</td>
<td>The user needs to connect to the database using the minimum setting of sslmode=require in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.</td>
</tr>
<tr>
<td>This RDS Proxy requires TLS connections.</td>
<td>The user enabled the option Require Transport Layer Security but tried to connect with sslmode=disable in the PostgreSQL client.</td>
<td>To fix this error, do one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Disable the proxy’s Require Transport Layer Security option.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Connect to the database using the minimum setting of sslmode=allow in the PostgreSQL client.</td>
</tr>
<tr>
<td>IAM authentication failed for user <strong>user_name</strong>. Check the IAM token for this user and try again.</td>

<td>The password for this role doesn't match the Secrets Manager secret.</td>
<td>Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.</td>
</tr>
<tr>
<td>The IAM authentication failed for the role <code>role_name</code>. Check the IAM token for this role and try again.</td>
<td>There is a problem with the IAM token used for IAM authentication.</td>
<td>Generate a new authentication token and use it in a new connection.</td>
</tr>
<tr>
<td>IAM is allowed only with SSL connections.</td>
<td>A client tried to connect using IAM authentication, but SSL wasn't enabled.</td>
<td>Enable SSL in the PostgreSQL client.</td>
</tr>
</tbody>
</table>
Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources, including a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: DBProxy and DBProxyTargetGroup.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn: !Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds: !Fn::Split: [",", !Fn::ImportValue: SubnetIds]
  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy
```
TargetGroupName: default
DBInstanceIdentifiers:
- Fn::ImportValue: DBInstanceName
 DependsOn: DBProxy

For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see RDS resource type reference.
Working with option groups

Some DB engines offer additional features that make it easier to manage data and databases, and to provide additional security for your database. Amazon RDS uses option groups to enable and configure these features. An option group can specify features, called options, that are available for a particular Amazon RDS DB instance. Options can have settings that specify how the option works. When you associate a DB instance with an option group, the specified options and option settings are enabled for that DB instance.

Amazon RDS supports options for the following database engines:

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Relevant documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB</td>
<td>Options for MariaDB database engine (p. 906)</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>Options for the Microsoft SQL Server database engine (p. 1044)</td>
</tr>
<tr>
<td>MySQL</td>
<td>Options for MySQL DB instances (p. 1234)</td>
</tr>
<tr>
<td>Oracle</td>
<td>Adding options to Oracle DB instances (p. 1450)</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>PostgreSQL does not use options and option groups. PostgreSQL uses extensions and modules to provide additional features. For more information, see Supported PostgreSQL extension versions (p. 1597).</td>
</tr>
</tbody>
</table>

Option groups overview

Amazon RDS provides an empty default option group for each new DB instance. You can't modify or delete this default option group, but any new option group that you create derives its settings from the default option group. To apply an option to a DB instance, you must do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add one or more options to the option group.
3. Associate the option group with the DB instance.

To associate an option group with a DB instance, modify the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Both DB instances and DB snapshots can be associated with an option group. In some cases, you might restore from a DB snapshot or perform a point-in-time restore for a DB instance. In these cases, the option group associated with the DB snapshot or DB instance is, by default, associated with the restored DB instance. You can associate a different option group with a restored DB instance. However, the new option group must contain any persistent or permanent options that were included in the original option group. Persistent and permanent options are described following.

Options require additional memory to run on a DB instance. Thus, you might need to launch a larger instance to use them, depending on your current use of your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems or out-of-memory errors.

Persistent and permanent options

Two types of options, persistent and permanent, require special consideration when you add them to an option group.
Persistent options can't be removed from an option group while DB instances are associated with the option group. An example of a persistent option is the TDE option for Microsoft SQL Server transparent data encryption (TDE). You must disassociate all DB instances from the option group before a persistent option can be removed from the option group. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a persistent option, you can only associate the restored DB instance with that option group.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, can never be removed from an option group. You can change the option group of a DB instance that is using the permanent option. However, the option group associated with the DB instance must include the same permanent option. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a permanent option, you can only associate the restored DB instance with an option group with that permanent option.

For Oracle DB instances, you can copy shared DB snapshots that have the options Timezone or OLS (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see Oracle time zone (p. 1533) and Oracle Label Security (p. 1494).

VPC and platform considerations

When an option group is assigned to a DB instance, it is linked to the platform that the DB instance is on. That platform can either be a VPC supported by the Amazon VPC service, or EC2-Classic (non-VPC) supported by the Amazon EC2 service. For details on these two platforms, see Amazon EC2 and Amazon Virtual Private Cloud.

If a DB instance is in a VPC, the option group associated with the instance is linked to that VPC. This means that you can't use the option group assigned to a DB instance if you try to restore the instance to a different VPC or a different platform. If you restore a DB instance to a different VPC or a different platform, you can do one of the following:

- Assign the default option group to the DB instance.
- Assign an option group that is linked to that VPC or platform.
- Create a new option group and assign it to the DB instance.

With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

Option settings control the behavior of an option. For example, the Oracle Advanced Security option NATIVE_NETWORK_ENCRYPTION has a setting that you can use to specify the encryption algorithm for network traffic to and from the DB instance. Some options settings are optimized for use with Amazon RDS and cannot be changed.

Mutually exclusive options

Some options are mutually exclusive. You can use one or the other, but not both at the same time. The following options are mutually exclusive:

- Oracle Enterprise Manager Database Express (p. 1480) and Oracle Management Agent for Enterprise Manager Cloud Control (p. 1484).
- Oracle native network encryption (p. 1503) and Oracle Secure Sockets Layer (p. 1514).
Creating an option group

You can create a new option group that derives its settings from the default option group, and then add one or more options to the new option group. Alternatively, if you already have an existing option group, you can copy that option group with all of its options to a new option group. For more information, see Copying an option group (p. 265).

After you create a new option group, it has no options. To learn how to add options to the option group, see Adding an option to an option group (p. 266). After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific engine listed at Working with option groups (p. 262).

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
   a. For Name, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.
   b. For Description, type a brief description of the option group. The description is used for display purposes.
   c. For Engine, choose the DB engine that you want.
   d. For Major engine version, choose the major version of the DB engine that you want.
5. To continue, choose Create. To cancel the operation instead, choose Cancel.

AWS CLI

To create an option group, use the AWS CLI create-option-group command with the following required parameters.

- --option-group-name
- --engine-name
- --major-engine-version
- --option-group-description

Example

The following example creates an option group named testoptiongroup, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```bash
aws rds create-option-group \
```
Copying an option group

For Windows:

```bash/aws rds create-option-group ^
--option-group-name testoptiongroup ^
--engine-name oracle-ee ^
--major-engine-version 12.1 ^
--option-group-description "Test option group"
```

RDS API

To create an option group, call the Amazon RDS API `CreateOptionGroup` operation. Include the following parameters:

- OptionGroupName
- EngineName
- MajorEngineVersion
- OptionGroupDescription

Copying an option group

You can use the AWS CLI or the Amazon RDS API copy an option group. Copying an option group is convenient when you have an existing option group and you want to include most of its custom parameters and values in a new option group. You can also make a copy of an option group that you use in production and then modify the copy to test other option settings.

**Note**
Currently, you can't copy an option group to a different AWS Region.

AWS CLI

To copy an option group, use the AWS CLI `copy-option-group` command. Include the following required options:

- `--source-option-group-identifier`
- `--target-option-group-identifier`
- `--target-option-group-description`

**Example**

The following example creates an option group named `new-option-group`, which is a local copy of the option group `my-option-group`.

For Linux, macOS, or Unix:

```bash
/aws rds copy-option-group ^
--source-option-group-identifier my-option-group ^
```

Adding an option to an option group

```
--target-option-group-identifier new-option-group \\
--target-option-group-description "My new option group"
```

For Windows:

```
aws rds copy-option-group ^
  --source-option-group-identifier my-option-group ^
  --target-option-group-identifier new-option-group ^
  --target-option-group-description "My new option group"
```

RDS API

To copy an option group, call the Amazon RDS API CopyOptionGroup operation. Include the following required parameters:

- `SourceOptionGroupIdentifier`
- `TargetOptionGroupIdentifier`
- `TargetOptionGroupDescription`

Adding an option to an option group

You can add an option to an existing option group. After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific DB engine listed at Working with option groups (p. 262).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the `OEM` option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `-apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

**Note**

If you specify a security group as a value for an option in an option group, you manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

**Console**

You can use the AWS Management Console to add an option to an option group.

**To add an option to an option group by using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you want to modify, and then choose **Add option**.
4. In the **Add option** window, do the following:
   
a. Choose the option that you want to add. You might need to provide additional values, depending on the option that you select. For example, when you choose the OEM option, you must also type a port value and specify a security group.

b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose Yes. If you choose No (the default), the option is enabled for each associated DB instance during its next maintenance window.
5. When the settings are as you want them, choose **Add option**.

**AWS CLI**

To add an option to an option group, run the AWS CLI `add-option-to-option-group` command with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `--apply-immediately` parameter. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

* `--option-group-name`

**Example**

The following example adds the Oracle Enterprise Manager Database Control (OEM) option to an option group named `testoptiongroup` and immediately enables it. Even if you use the default security group, you must specify that security group.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
```
Adding an option to an option group

```
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,DbSecurityGroupMemberships=default \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,DbSecurityGroupMemberships=default ^
--apply-immediately
```

Command output is similar to the following:

```
Test Option Group  testoptiongroup default  
OPTIONS Oracle 12c EM Express   OEM     False   False   5500  
DBSECURITYGROUPMEMBERSHIPS   default authorized  
```

Example

The following example adds the Oracle OEM option to an option group. It also specifies a custom port and a pair of Amazon EC2 VPC security groups to use for that port.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" ^
--apply-immediately
```

Command output is similar to the following:

```
Test Option Group  testoptiongroup vpc-test  
OPTIONS Oracle 12c EM Express   OEM     False   False   5500  
VPCSECURITYGROUPMEMBERSHIPS   active  sg-test1  
VPCSECURITYGROUPMEMBERSHIPS   active  sg-test2  
```

Example

The following example adds the Oracle option NATIVE_NETWORK_ENCRYPTION to an option group and specifies the option settings. If no option settings are specified, default values are used.
Listing the options and option settings for an option group

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
   --option-group-name testoptiongroup
   --options '[["OptionSettings":{{"Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"},
   {{"Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES"}},"OptionName":"NATIVE_NETWORK_ENCRYPTION"}],
   --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group
   --option-group-name testoptiongroup
   --options "OptionSettings"="{{"Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"},
   {{"Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES"}},"OptionName":"NATIVE_NETWORK_ENCRYPTION"

   --apply-immediately
```

Command output is similar to the following:

```
Test Option Group testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption NATIONAL_NETWORK_ENCRYPTION
   False False
OPTIONSETTINGS
   RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
   STATIC STRING
   RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
   Specifies list of encryption algorithms in order of intended use
   True True SQLNET.ENCRYPTION_TYPES_SERVER AES256,AES192,DES
   OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED
   Specifies the desired encryption behavior False True SQLNET.ENCRYPTION_SERVER
   REQUIRED
   OPTIONSETTINGS SHA1,MD5 STATIC STRING SHA1,MD5
   Specifies list of checksumming algorithms in order of intended use True True
   SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
   SHA1,MD5
```

RDS API

To add an option to an option group using the Amazon RDS API, call the `ModifyOptionGroup` operation with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

* OptionGroupName

You can list all the options and option settings for an option group.
Console

You can use the AWS Management Console to list all of the options and option settings for an option group.

**To list the options and option settings for an option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to display its details. The options and option settings in the option group are listed.

AWS CLI

To list the options and option settings for an option group, use the AWS CLI `describe-option-groups` command. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

**Example**

The following example lists the options and option settings for all option groups.

```
aws rds describe-option-groups
```

**Example**

The following example lists the options and option settings for an option group named testoptiongroup.

```
aws rds describe-option-groups --option-group-name testoptiongroup
```

RDS API

To list the options and option settings for an option group, use the Amazon RDS API `DescribeOptionGroups` operation. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Modifying an option setting

After you have added an option that has modifiable option settings, you can modify the settings at any time. If you change options or option settings in an option group, those changes are applied to all DB instances that are associated with that option group. For more information on what settings are available for the various options, see the documentation for your specific engine listed at Working with option groups (p. 262).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the OEM option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when
using the RDS API. Options that don't include port values can be applied immediately, or can be applied
during the next maintenance window for the DB instance.

**Note**
If you specify a security group as a value for an option in an option group, you manage the
security group by modifying the option group. You can't change or remove this security group
by modifying a DB instance. Also, the security group doesn't appear in the DB instance details
in the AWS Management Console or in the output for the AWS CLI command `describe-db-
instances`.

**Console**

You can use the AWS Management Console to modify an option setting.

**To modify an option setting by using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
   console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option that you want to modify, and then choose **Modify option**.
4. In the **Modify option** window, from **Installed Options**, choose the option whose setting you want to
   modify. Make the changes that you want.
5. To enable the option as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No**
   (the default), the option is enabled for each associated DB instance during its next maintenance
   window.
6. When the settings are as you want them, choose **Modify Option**.

**AWS CLI**

To modify an option setting, use the AWS CLI `add-option-to-option-group` command with the
option group and option that you want to modify. By default, the option is enabled for each associated
DB instance during its next maintenance window. To apply the change immediately to all associated
DB instances, include the `--apply-immediately` parameter. To modify an option setting, use the `--
settings` argument.

**Example**

The following example modifies the port that the Oracle Enterprise Manager Database Control (OEM)
uses in an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --option-group-name testoptiongroup \
  --options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
  --option-group-name testoptiongroup ^
  --options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default ^
  --apply-immediately
```
Command output is similar to the following:

```
                      Test option Group testoptiongroup
OPTIONS Oracle 12c EM Express OEM False False 5432
DBSECURITYGROUPMEMBERSHIPS default authorized
```

**Example**

The following example modifies the Oracle option NATIVE_NETWORK_ENCRYPTION and changes the option settings.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --option-group-name testoptiongroup \
  --options '{"OptionSettings": [{"Name":"SQLNET.ENCRYPTION_SERVER","Value":"REQUIRED"}, \n  {"Name":"SQLNET.ENCRYPTION_TYPES_SERVER","Value":"AES256,AES192,DES,RC4_256"}],"OptionName":"NATIVE_NETWORK_ENCRYPTION"} \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
  --option-group-name testoptiongroup ^
  --options "OptionSettings"=
  ["Name"="SQLNET.ENCRYPTION_SERVER","Value"="REQUIRED"],
  ["Name"="SQLNET.ENCRYPTION_TYPES_SERVER","Value"="AES256\,AES192\,DES\,RC4_256"],"OptionName"="NATIVE_NETWORK_ENCRYPTION" ^
  --apply-immediately
```

Command output is similar to the following:

```
                      Test option Group testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption NATIVE_NETWORK_ENCRYPTION False False
OPTIONSETTINGS
  RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 STATIC STRING
  RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40 Specifies list of encryption algorithms in order of intended use
  True True SQLNET.ENCRYPTION_TYPES_SERVER AES256,AES192,DES,RC4_256
OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED Specifies the desired encryption behavior False True SQLNET.ENCRYPTION_SERVER REQUIRED
OPTIONSETTINGS SHA1,MD5 STATIC STRING SHA1,MD5 Specifies list of checksumming algorithms in order of intended use True True SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER SHA1,MD5
OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED Specifies the desired data integrity behavior False True SQLNET.CRYPTO_CHECKSUM_SERVER REQUESTED
```
RDS API

To modify an option setting, use the Amazon RDS API `ModifyOptionGroup` command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`.

Removing an option from an option group

Some options can be removed from an option group, and some cannot. A persistent option cannot be removed from an option group until all DB instances associated with that option group are disassociated. A permanent option can never be removed from an option group. For more information about what options are removable, see the documentation for your specific engine listed at Working with option groups (p. 262).

If you remove all options from an option group, Amazon RDS doesn't delete the option group. DB instances that are associated with the empty option group continue to be associated with it; they just won't have any active options. Alternatively, to remove all options from a DB instance, you can associate the DB instance with the default (empty) option group.

Console

You can use the AWS Management Console to remove an option from an option group.

To remove an option from an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Select the option group whose option you want to remove, and then choose Delete option.
4. In the Delete option window, do the following:
   - Select the check box for the option that you want to delete.
   - For the deletion to take effect as soon as you make it, for Apply immediately, choose Yes. If you choose No (the default), the option is deleted for each associated DB instance during its next maintenance window.
5. When the settings are as you want them, choose Yes, Delete.

AWS CLI

To remove an option from an option group, use the AWS CLI `remove-option-from-option-group` command with the option that you want to delete. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `--apply-immediately` parameter.

Example

The following example removes the Oracle Enterprise Manager Database Control (OEM) option from an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```bash
aws rds remove-option-from-option-group \
  --option-group-name testoptiongroup \
  --options OEM \
  --apply-immediately
```

For Windows:

```bash
aws rds remove-option-from-option-group ^
  --option-group-name testoptiongroup ^
  --options OEM ^
  --apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP    testoptiongroup oracle-ee   12.1    Test option group
```

RDS API

To remove an option from an option group, use the Amazon RDS API `ModifyOptionGroup` action. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `ApplyImmediately` parameter and set it to true.

Include the following parameters:

- `OptionGroupName`
- `OptionsToRemove.OptionName`

Deleting an option group

You can delete an option group that is not associated with any Amazon RDS resource. An option group can be associated with a DB instance, a manual DB snapshot, or an automated DB snapshot.

You can't delete a default option group. In addition, if you try to delete an option group that is associated with an Amazon RDS resource, an error similar to the following is returned.
An error occurred (InvalidOptionGroupStateFault) when calling the DeleteOptionGroup operation: The option group 'optionGroupName' cannot be deleted because it is in use.

To find the Amazon RDS resources associated with an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the name of the option group to show its details.
4. Check the Associated Instances and Snapshots section for the associated Amazon RDS resources.

If a DB instance is associated with the option group, modify the DB instance to use a different option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

If a manual DB snapshot is associated with the option group, modify the DB snapshot to use a different option group using the AWS CLI modify-db-snapshot command.

Note
You can't modify the option group of an automated DB snapshot.

Console

One way of deleting an option group is by using the AWS Management Console.

To delete an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group.
4. Choose Delete group.
5. On the confirmation page, choose Delete to finish deleting the option group, or choose Cancel to cancel the deletion.

AWS CLI

To delete an option group, use the AWS CLI delete-option-group command with the following required parameter.

• --option-group-name

Example

The following example deletes an option group named testoptiongroup.

For Linux, macOS, or Unix:

```
aws rds delete-option-group \ 
   --option-group-name testoptiongroup
```
For Windows:

```bash
aws rds delete-option-group
   --option-group-name testoptiongroup
```

**RDS API**

To delete an option group, call the Amazon RDS API `DeleteOptionGroup` operation. Include the following parameter:

- `OptionGroupName`
Working with parameter groups

*Database parameters* specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Multi-AZ DB clusters with parameter groups. Amazon RDS defines parameter groups with default settings.

**Important**
You can define your own parameter groups with customized settings. Then you can modify your DB instances Multi-AZ DB clusters to use your own parameter groups. For information about modifying a DB instance, see *Modifying an Amazon RDS DB instance* (p. 309). For information about modifying a Multi-AZ DB clusters, see *Modifying a Multi-AZ DB cluster* (p. 324).

**Note**
Some DB engines offer additional features that you can add to your database as options in an option group. For information about option groups, see *Working with option groups* (p. 262).

A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

*DB cluster parameter groups* only apply to Multi-AZ DB clusters. In a Multi-AZ DB cluster, the settings in the DB cluster parameter group are used for all of the DB instances in the cluster. The default DB parameter group for the DB engine and DB engine version is used for each DB instance in the DB cluster.

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create a Multi-AZ DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance. You can't modify the parameter settings of a default parameter group. Instead, you create your own parameter group where you choose your own parameter settings. Not all DB engine parameters can be changed in a parameter group that you create.

To use your own parameter group, you create a new parameter group and modify the parameters that you want to modify. You then modify your DB instance or DB cluster to use the new parameter group. If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within a Multi-AZ DB cluster parameter group, the changes apply to all Aurora clusters that are associated with that DB cluster parameter group.

You can copy an existing DB parameter group with the AWS CLI `copy-db-parameter-group` command. You can copy an existing DB cluster parameter group with the AWS CLI `copy-db-cluster-parameter-group` command. Copying a parameter group can be convenient when you want to include most of an existing DB parameter group's custom parameters and values in a new DB parameter group.

Here are some important points about working with parameters in a parameter group:

- Database parameters are either *static* or *dynamic*. When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the DB instance. You can reboot a DB instance using the RDS console, by calling the `reboot-db-instance` CLI command, or by calling the `RebootDBInstance` API operation. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call, such as calling `ModifyDBInstance` to change DB instance class or scale storage.

  When you change a dynamic parameter and save the DB parameter group, the change is applied to the parameter group immediately regardless of the *Apply Immediately* setting. If you use the
pending-reboot setting in the AWS CLI or RDS API, the change is still applied to the parameter group immediately. However, applying the parameter change to DB instances that use the parameter group requires a reboot.

**Note**

Using pending-reboot with dynamic parameters in the AWS CLI or RDS API on RDS for SQL Server DB instances generates an error. Use apply-immediately on RDS for SQL Server.

If a DB instance isn’t using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of pending-reboot. The pending-reboot parameter groups status doesn’t result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

- When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see Modifying an Amazon RDS DB instance (p. 309).

- After you change the DB cluster parameter group associated with a Multi-AZ DB cluster, reboot the DB cluster to apply the changes to all of the DB instances in the DB cluster.

For information about rebooting a Multi-AZ DB cluster, see Rebooting Multi-AZ DB clusters and reader DB instances (p. 352).

- You can specify integer and Boolean parameters using expressions, formulas, and functions. Functions can include a mathematical log expression. For more information, see Specifying DB parameters (p. 298).

- Set any parameters that relate to the character set or collation of your database in your parameter group before creating the DB instance or Multi-AZ DB cluster and before you create a database in it. This ensures that the default database and new databases use the character set and collation values that you specify. If you change character set or collation parameters, the parameter changes aren’t applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the `ALTER DATABASE` command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

- Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always be cautious when modifying database parameters, and back up your data before modifying a parameter group. Try out parameter group setting changes on a test DB instance or DB cluster before applying those parameter group changes to a production DB instance or DB cluster.

- To determine the supported parameters for your DB engine, you can view the parameters in the DB parameter group and DB cluster parameter group used by the DB instance or DB cluster. For more information, see Viewing parameter values for a DB parameter group (p. 289) and Viewing parameter values for a DB cluster parameter group (p. 297).

**Topics**

- Working with DB parameter groups (p. 280)
- Working with DB cluster parameter groups for Multi-AZ DB clusters (p. 290)
- Comparing DB parameter groups (p. 298)
- Specifying DB parameters (p. 298)
Working with DB parameter groups

DB instances use DB parameter groups. The following sections describe configuring and managing DB instance parameter groups.

Topics

• Creating a DB parameter group (p. 280)
• Associating a DB parameter group with a DB instance (p. 281)
• Modifying parameters in a DB parameter group (p. 282)
• Resetting parameters in a DB parameter group to their default values (p. 284)
• Copying a DB parameter group (p. 287)
• Listing DB parameter groups (p. 288)
• Viewing parameter values for a DB parameter group (p. 289)

Creating a DB parameter group

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
   The Create parameter group window appears.
4. In the Parameter group family list, select a DB parameter group family.
5. In the Type list, select DB Parameter Group.
6. In the Group name box, enter the name of the new DB parameter group.
7. In the Description box, enter a description for the new DB parameter group.
8. Choose Create.

AWS CLI

To create a DB parameter group, use the AWS CLI create-db-parameter-group command. The following example creates a DB parameter group named mydbparametergroup for MySQL version 5.6 with a description of "My new parameter group."

Include the following required parameters:

• --db-parameter-group-name
• --db-parameter-group-family
• --description

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```
Note
The output contains duplicates.

Example
For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --db-parameter-group-family MySQL5.6 \
  --description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
  --db-parameter-group-name mydbparametergroup ^
  --db-parameter-group-family MySQL5.6 ^
  --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  mysql5.6  My new parameter group
```

RDS API
To create a DB parameter group, use the RDS API CreateDBParameterGroup operation.

Include the following required parameters:

- DBParameterGroupName
- DBParameterGroupFamily
- Description

Associating a DB parameter group with a DB instance
You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see Creating a DB parameter group (p. 280). For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 175). For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Note
When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot.

Console
To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. Change the **DB parameter group** setting.
5. Choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause an outage in some cases. For more information, see Using the Apply Immediately setting (p. 310).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.
   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

**AWS CLI**

To associate a DB parameter group with a DB instance, use the AWS CLI `modify-db-instance` command with the following options:

- `--db-instance-identifier`
- `--db-parameter-group-name`

The following example associates the `mydbpg` DB parameter group with the `database-1` DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window. For more information, see Using the Apply Immediately setting (p. 310).

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier database-1 \
   --db-parameter-group-name mydbpg \
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier database-1 ^
   --db-parameter-group-name mydbpg ^
   --apply-immediately
```

**RDS API**

To associate a DB parameter group with a DB instance, use the RDS API `ModifyDBInstance` operation with the following parameters:

- `DBInstanceName`
- `DBParameterGroupName`

**Modifying parameters in a DB parameter group**

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.
Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

### Console

**To modify a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   
   You can't change values in a default parameter group.
6. Choose **Save changes**.
Working with DB parameter groups

AWS CLI

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:

- `--db-parameter-group-name`
- `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named `mydbparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name mydbparametergroup ^
  --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
  "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP  mydbparametergroup
```

RDS API

To modify a DB parameter group, use the RDS API `ModifyDBParameterGroup` operation with the following required parameters:

- `DBParameterGroupName`
- `Parameters`

**Resetting parameters in a DB parameter group to their default values**

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values, but you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values, and you can reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status
of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, if the DB instance isn’t using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

**Note**
In a default DB parameter group, parameters are always set to their default values.

**Console**

**To reset parameters in a DB parameter group to their default values**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.
AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI `reset-db-parameter-group` command with the following required option: `--db-parameter-group-name`.

To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds reset-db-parameter-group
   --db-parameter-group-name mydbparametergroup
   --reset-all-parameters
```

For Windows:

```bash
aws rds reset-db-parameter-group
   --db-parameter-group-name mydbparametergroup
   --reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named `mydbparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds reset-db-parameter-group
   --db-parameter-group-name mydbparametergroup
   --parameters "ParameterName=max_connections,ApplyMethod=immediate"
   "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds reset-db-parameter-group
   --db-parameter-group-name mydbparametergroup
   --parameters "ParameterName=max_connections,ApplyMethod=immediate"
   "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

<table>
<thead>
<tr>
<th>DBParameterGroupName</th>
<th>mydbparametergroup</th>
</tr>
</thead>
</table>

RDS API

To reset parameters in a DB parameter group to their default values, use the RDS API `ResetDBParameterGroup` command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.
**Copying a DB parameter group**

You can copy custom DB parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB parameter group and you want to include most of the custom parameters and values from that group in a new DB parameter group. You can copy a DB parameter group by using the AWS Management Console, the AWS CLI `copy-db-parameter-group` command, or the RDS API `CopyDBParameterGroup` operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the **Parameter Groups** option of the Amazon RDS console or the `describe-db-parameters` command to verify that your DB parameter group is created.

**Note**

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Currently, you can't copy a parameter group to a different AWS Region.

**Console**

**To copy a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

**AWS CLI**

To copy a DB parameter group, use the AWS CLI `copy-db-parameter-group` command with the following required options:

- `--source-db-parameter-group-identifier`
- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds copy-db-parameter-group
   --source-db-parameter-group-identifier mygroup1
   --target-db-parameter-group-identifier mygroup2
```
For Windows:

```bash
aws rds copy-db-parameter-group
  --source-db-parameter-group-identifier mygroup1
  --target-db-parameter-group-identifier mygroup2
  --target-db-parameter-group-description "DB parameter group 2"
```

**RDS API**

To copy a DB parameter group, use the RDS API `CopyDBParameterGroup` operation with the following required parameters:

- `SourceDBParameterGroupIdentifier`
- `TargetDBParameterGroupIdentifier`
- `TargetDBParameterGroupDescription`

**Listing DB parameter groups**

You can list the DB parameter groups you've created for your AWS account.

**Note**

Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

**Console**

**To list all DB parameter groups for an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
   
   The DB parameter groups appear in a list.

**AWS CLI**

To list all DB parameter groups for an AWS account, use the AWS CLI `describe-db-parameter-groups` command.

**Example**

The following example lists all available DB parameter groups for an AWS account.

```bash
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

<table>
<thead>
<tr>
<th>DBPARAMETERGROUP</th>
<th>default.mysql5.6</th>
<th>mysql5.6</th>
<th>Default parameter group for MySQL5.6</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBPARAMETERGROUP</td>
<td>mydbparametergroup</td>
<td>mysql5.6</td>
<td>My new parameter group</td>
</tr>
</tbody>
</table>
The following example describes the *mydbparamgroup1* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameter-groups
  --db-parameter-group-name mydbparamgroup1
```

For Windows:

```
aws rds describe-db-parameter-groups
  --db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

```
DBPARAMETERGROUP  mydbparametergroup1  mysql5.6  My new parameter group
```

**RDS API**

To list all DB parameter groups for an AWS account, use the RDS API *DescribeDBParameterGroups* operation.

**Viewing parameter values for a DB parameter group**

You can get a list of all parameters in a DB parameter group and their values.

**Console**

**To view the parameter values for a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose *Parameter groups*.
3. The DB parameter groups appear in a list.
4. Choose the name of the parameter group to see its list of parameters.

**AWS CLI**

To view the parameter values for a DB parameter group, use the AWS CLI *describe-db-parameters* command with the following required parameter.

- `--db-parameter-group-name`

**Example**

The following example lists the parameters and parameter values for a DB parameter group named *mydbparametergroup*.

```
aws rds describe-db-parameters
  --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

```
DBPARAMETER  Parameter Name  Parameter Value  Source  Data Type  Apply Type  Is Modifiable
```
Working with DB cluster parameter groups for Multi-AZ DB clusters

Multi-AZ DB clusters use DB cluster parameter groups. The following sections describe configuring and managing DB cluster parameter groups.

Topics
- Creating a DB cluster parameter group (p. 290)
- Modifying parameters in a DB cluster parameter group (p. 292)
- Resetting parameters in a DB cluster parameter group (p. 293)
- Copying a DB cluster parameter group (p. 294)
- Listing DB cluster parameter groups (p. 296)
- Viewing parameter values for a DB cluster parameter group (p. 297)

Creating a DB cluster parameter group

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Parameter group family list, select a DB parameter group family
5. In the Type list, select DB Cluster Parameter Group.
6. In the Group name box, enter the name of the new DB cluster parameter group.
7. In the Description box, enter a description for the new DB cluster parameter group.
8. Choose Create.
AWS CLI

To create a DB cluster parameter group, use the AWS CLI `create-db-cluster-parameter-group` command.

The following example creates a DB cluster parameter group named `mydbclusterparametergroup` for RDS for MySQL version 8.0 with a description of "My new cluster parameter group."

Include the following required parameters:

- `--db-cluster-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

**Note**
The output contains duplicates.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbclusterparametergroup \
  --db-parameter-group-family mysql8.0 \
  --description "My new cluster parameter group"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbclusterparametergroup ^
  --db-parameter-group-family mysql8.0 ^
  --description "My new cluster parameter group"
```

This command produces output similar to the following:

```
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "mydbclusterparametergroup",
        "DBParameterGroupFamily": "mysql8.0",
        "Description": "My new cluster parameter group",
        "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-pg:mydbclusterparametergroup2"
    }
}
```

**RDS API**

To create a DB cluster parameter group, use the RDS API `CreateDBClusterParameterGroup` action.

Include the following required parameters:

- `DBClusterParameterGroupName`
• DBParameterGroupFamily
• Description

Modifying parameters in a DB cluster parameter group

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Console

To modify a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group that you want to modify.
4. For Parameter group actions, choose Edit.
5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   
   You can't change values in a default parameter group.
6. Choose Save changes.
7. Reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

AWS CLI

To modify a DB cluster parameter group, use the AWS CLI modify-db-cluster-parameter-group command with the following required parameters:

• --db-cluster-parameter-group-name
• --parameters

The following example modifies the server_audit_logging and server_audit_logs_upload values in the DB cluster parameter group named mydbclusterparametergroup.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group \
   --db-cluster-parameter-group-name mydbclusterparametergroup \
   --parameters "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \
   "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name mydbclusterparametergroup ^
```
```
--parameters
  "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBCLUSTERPARAMETERGROUP  mydbclustercustomergroup
```

**RDS API**

To modify a DB cluster parameter group, use the RDS API `ModifyDBClusterParameterGroup` command with the following required parameters:

- `DBClusterParameterGroupName`
- `Parameters`

**Resetting parameters in a DB cluster parameter group**

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

**Note**

In a default DB cluster parameter group, parameters are always set to their default values.

**Console**

**To reset parameters in a DB cluster parameter group to their default values**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   - You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.
7. Reboot the primary DB instance in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

**AWS CLI**

To reset parameters in a DB cluster parameter group to their default values, use the AWS CLI `reset-db-cluster-parameter-group` command with the following required option: `--db-cluster-parameter-group-name`.

To reset all of the parameters in the DB cluster parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.
Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group
  --db-cluster-parameter-group-name mydbparametergroup
  --reset-all-parameters
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbparametergroup ^
  --reset-all-parameters
```

The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named `mydbclusterparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group
  --db-cluster-parameter-group-name mydbclusterparametergroup
  --parameters "ParameterName=server_audit_logging,ApplyMethod=immediate"
  "ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbclusterparametergroup ^
  --parameters "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBClusterParameterGroupName  mydbclusterparametergroup
```

RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API `ResetDBClusterParameterGroup` command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB cluster parameter group

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group. You can copy a DB cluster parameter group by using the AWS CLI `copy-db-cluster-parameter-group` command or the RDS API `CopyDBClusterParameterGroup` operation.
After you copy a DB cluster parameter group, wait at least 5 minutes before creating your first DB cluster that uses that DB cluster parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used as the default for a new DB cluster. You can use the Parameter Groups option of the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

**Note**
You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

**Console**

To copy a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the custom parameter group that you want to copy.
4. For Parameter group actions, choose Copy.
5. In New DB parameter group identifier, enter a name for the new parameter group.
6. In Description, enter a description for the new parameter group.
7. Choose Copy.

**AWS CLI**

To copy a DB cluster parameter group, use the AWS CLI copy-db-cluster-parameter-group command with the following required parameters:

- --source-db-cluster-parameter-group-identifier
- --target-db-cluster-parameter-group-identifier
- --target-db-cluster-parameter-group-description

The following example creates a new DB cluster parameter group named mygroup2 that is a copy of the DB cluster parameter group mygroup1.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds copy-db-cluster-parameter-group \
    --source-db-cluster-parameter-group-identifier mygroup1 \
    --target-db-cluster-parameter-group-identifier mygroup2 \
    --target-db-cluster-parameter-group-description "DB parameter group 2"
```

For Windows:

```bash
aws rds copy-db-cluster-parameter-group ^
    --source-db-cluster-parameter-group-identifier mygroup1 ^
    --target-db-cluster-parameter-group-identifier mygroup2 ^
    --target-db-cluster-parameter-group-description "DB parameter group 2"
```

**RDS API**

To copy a DB cluster parameter group, use the RDS API CopyDBClusterParameterGroup operation with the following required parameters:
Listing DB cluster parameter groups

You can list the DB cluster parameter groups you've created for your AWS account.

**Note**
Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

**Console**

**To list all DB cluster parameter groups for an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.

   The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.

**AWS CLI**

To list all DB cluster parameter groups for an AWS account, use the AWS CLI `describe-db-cluster-parameter-groups` command.

**Example**

The following example lists all available DB cluster parameter groups for an AWS account.

```
aws rds describe-db-cluster-parameter-groups
```

The following example describes the `mydbclusterparametergroup` parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameter-groups
   --db-cluster-parameter-group-name mydbclusterparametergroup
```

For Windows:

```
aws rds describe-db-cluster-parameter-groups
   --db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```json
{
   "DBClusterParameterGroups": [
      {
         "DBClusterParameterGroupName": "mydbclusterparametergroup2",
         "DBParameterGroupFamily": "mysql8.0",
```

"Description": "My new cluster parameter group",
"DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-
pg:mydbclusterparametergroup"
]}

RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API DescribeDBClusterParameterGroups action.

Viewing parameter values for a DB cluster parameter group

You can get a list of all parameters in a DB cluster parameter group and their values.

Console

To view the parameter values for a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups. The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.
3. Choose the name of the DB cluster parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB cluster parameter group, use the AWS CLI describe-db-cluster-parameters command with the following required parameter.

• --db-cluster-parameter-group-name

Example

The following example lists the parameters and parameter values for a DB cluster parameter group named mydbclusterparametergroup, in JSON format.

The command returns a response like the following:

```bash
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name mydbclusterparametergroup
```

```json
{
"Parameters": [
{
 "ParameterName": "activate_all_roles_on_login",
 "ParameterValue": "0",
 "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
 "Source": "engine-default",
 "ApplyType": "dynamic",
 "DataType": "boolean",
 "AllowedValues": "0,1",
 "IsModifiable": true,
 "ApplyMethod": "pending-reboot",
```
Comparing DB parameter groups

You can use the AWS Management Console to view the differences between two parameter groups for the same DB engine and version.

To compare two parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the two parameter groups that you want to compare.
4. For Parameter group actions, choose Compare.

Note
If the items you selected aren't equivalent, you can't choose Compare. For example, you can't compare a MySQL 5.6 and a MySQL 5.7 parameter group. You can't compare a DB parameter group and an Aurora DB cluster parameter group.

Specifying DB parameters

DB parameter types include the following:

- Integer
- Boolean
- String
- Long
- Double
- Timestamp
• Object of other defined data types
• Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

For the Oracle engine, you can use the `DBInstanceClassHugePagesDefault` formula variable to specify a Boolean DB parameter. See DB parameter formula variables (p. 299).

For the PostgreSQL engine, you can use an expression to specify a Boolean DB parameter. See Boolean DB parameter expressions (p. 301).

Contents

- DB parameter formulas (p. 299)
  - DB parameter formula variables (p. 299)
  - DB parameter formula operators (p. 300)
- DB parameter functions (p. 300)
- Boolean DB parameter expressions (p. 301)
- DB parameter log expressions (p. 302)
- DB parameter value examples (p. 302)

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {}. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}
{FormulaVariable*Integer}
{FormulaVariable*Integer/Integer}
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

*AllocatedStorage*

Returns an integer representing the size, in bytes, of the data volume.

*DBInstanceClassHugePagesDefault*

Returns a Boolean value. Currently, it's only supported for Oracle engines.

For more information, see Enabling HugePages for an Oracle DB instance (p. 1424).

*DBInstanceClassMemory*

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by taking the total amount of memory for the DB instance class and subtracting memory reserved for the operating system and the RDS processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in DB instance classes (p. 9). The exact value depends on a combination of
instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

**DBInstanceVCPU**

Returns an integer representing the number of virtual central processing units (vCPUs) used by Amazon RDS to manage the instance. Currently, it's only supported for the PostgreSQL engine.

**EndPointPort**

Returns an integer representing the port used when connecting to the DB instance.

### DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

**Division operator:** `/`

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

**Syntax**

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

**Multiplication operator:** `*`

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

**Syntax**

```
extpression * expression
```

Both expressions must be integers.

### DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as `argument1, argument3`. Function names are case-insensitive.

**IF**

Returns an argument.

Currently, it's only supported for Oracle engines, and the only supported first argument is `{DBInstanceClassHugePagesDefault}`. For more information, see [Enabling HugePages for an Oracle DB instance](p. 1424).

**Syntax**

```
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.
**GREATEST**

Returns the largest value from a list of integers or parameter formulas.

**Syntax**

\[ \text{GREATEST}(\text{argument1}, \text{argument2}, \ldots, \text{argumentn}) \]

Returns an integer.

**LEAST**

Returns the smallest value from a list of integers or parameter formulas.

**Syntax**

\[ \text{LEAST}(\text{argument1}, \text{argument2}, \ldots, \text{argumentn}) \]

Returns an integer.

**SUM**

Adds the values of the specified integers or parameter formulas.

**Syntax**

\[ \text{SUM}(\text{argument1}, \text{argument2}, \ldots, \text{argumentn}) \]

Returns an integer.

**Boolean DB parameter expressions**

A Boolean DB parameter expression resolves to a Boolean value of 1 or 0. The expression is enclosed in quotation marks.

**Note**

Boolean DB parameter expressions are only supported for the PostgreSQL engine.

**Syntax**

```
"expression operator expression"
```

Both expressions must resolve to integers. An expression can be the following:

- integer constant
- DB parameter formula
- DB parameter function
- DB parameter variable

Boolean DB parameter expressions support the following inequality operators:

**The greater than operator:** >

**Syntax**

```
"expression > expression"
```
The less than operator: <

Syntax

"expression < expression"

The greater than or equal to operators: >=, =>

Syntax

"expression >= expression"
"expression => expression"

The less than or equal to operators: <=, =<

Syntax

"expression <= expression"
"expression =< expression"

Example using a Boolean DB parameter expression

The following Boolean DB parameter expression example compares the result of a parameter formula with an integer to modify the Boolean DB parameter wal_compression for a PostgreSQL DB instance. The parameter expression compares the number of vCPUs with the value 2. If the number of vCPUs is greater than 2, then the wal_compression DB parameter is set to true.

aws rds modify-db-parameter-group --db-parameter-group-name group-name 
--parameters "ParameterName=wal_compression,ParameterValue="\{DBInstanceVCPU} > 2\" "

DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}. For example:

{log(DBInstanceClassMemory/8187281418)*1000}

The log function represents log base 2. This example also uses the DBInstanceClassMemory formula variable. See DB parameter formula variables (p. 299).

Note
Currently, you can't specify the MySQL innodb_log_file_size parameter with any value other than an integer.

DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

Note
DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

Warning
Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying
database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

Example using the DB parameter function **GREATEST**

You can specify the `GREATEST` function in an Oracle `processes` parameter. Use it to set the number of user processes to the larger of either 80 or `DBInstanceClassMemory` divided by 9,868,951.

```plaintext
GREATEST({DBInstanceClassMemory/9868951},80)
```

Example using the DB parameter function **LEAST**

You can specify the `LEAST` function in a MySQL `max_binlog_cache_size` parameter value. Use it to set the maximum cache size a transaction can use in a MySQL instance to the lesser of 1 MB or `DBInstanceClassMemory/256`.

```plaintext
LEAST({DBInstanceClassMemory/256},10485760)
```
Managing an Amazon RDS DB instance

Following, you can find instructions for managing and maintaining your Amazon RDS DB instance.

Topics
- Stopping an Amazon RDS DB instance temporarily (p. 305)
- Starting an Amazon RDS DB instance that was previously stopped (p. 308)
- Modifying an Amazon RDS DB instance (p. 309)
- Modifying a Multi-AZ DB cluster (p. 324)
- Maintaining a DB instance (p. 333)
- Upgrading a DB instance engine version (p. 344)
- Renaming a DB instance (p. 348)
- Rebooting a DB instance (p. 350)
- Rebooting Multi-AZ DB clusters and reader DB instances (p. 352)
- Working with read replicas (p. 354)
- Tagging Amazon RDS resources (p. 375)
- Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385)
- Working with storage for Amazon RDS DB instances (p. 393)
- Deleting a DB instance (p. 401)
- Deleting a Multi-AZ DB cluster (p. 404)
Stopping an Amazon RDS DB instance temporarily

If you use a DB instance intermittently, for temporary testing, or for a daily development activity, you can stop your Amazon RDS DB instance temporarily to save money. While your DB instance is stopped, you are charged for provisioned storage (including Provisioned IOPS) and backup storage (including manual snapshots and automated backups within your specified retention window), but not for DB instance hours. For more information, see Billing FAQs.

**Note**

In some cases, a large amount of time is required to stop a DB instance. If you want to stop your DB instance and restart it immediately, you can reboot the DB instance. For information about rebooting a DB instance, see Rebooting a DB instance (p. 350).

You can stop and start DB instances that are running the following engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Stopping and starting a DB instance is supported for all DB instance classes, and in all AWS Regions.

You can stop and start a DB instance whether it is configured for a single Availability Zone or for Multi-AZ, for database engines that support Multi-AZ deployments. You can’t stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.

**Note**

For a Multi-AZ deployment, a large amount of time might be required to stop a DB instance. If you have at least one backup after a previous failover, then you can speed up the stop DB instance operation by performing a reboot with failover operation before stopping the DB instance.

When you stop a DB instance, the DB instance performs a normal shutdown and stops running. The status of the DB instance changes to stopping and then stopped. Occasionally, an RDS for PostgreSQL DB instance doesn’t shut down cleanly. If this happens, you see that the instance goes through a recovery process when you restart it later. This is expected behavior of the database engine, intended to protect database integrity. Some memory-based statistics and counters don’t retain history and are re-initialized after restart, to capture the operational workload moving forward.

At the end of the normal shutdown process, any storage volumes remain attached to the DB instance, and their data is kept. Any data stored in the RAM of the DB instance is deleted.

Stopping a DB instance removes pending actions, except for pending actions for the DB instance’s option group or DB parameter group.

Automated backups aren’t created while a DB instance is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn’t include time spent in the stopped state when the backup retention window is calculated.

**Important**

You can stop a DB instance for up to seven days. If you don’t manually start your DB instance after seven days, your DB instance is automatically started so that it doesn’t fall behind any required maintenance updates.
Benefits

Stopping and starting a DB instance is faster than creating a DB snapshot, and then restoring the snapshot.

When you stop a DB instance it retains its ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a DB instance, it has the same configuration as when you stopped it. In addition, if you stop a DB instance, Amazon RDS retains the Amazon Simple Storage Service (Amazon S3) transaction logs so you can do a point-in-time restore if necessary.

Limitations

The following are some limitations to stopping and starting a DB instance:

- You can't stop a DB instance that has a read replica, or that is a read replica.
- You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.
- You can't modify a stopped DB instance.
- You can't delete an option group that is associated with a stopped DB instance.
- You can't delete a DB parameter group that is associated with a stopped DB instance.
- In a Multi-AZ configuration, the primary and secondary Availability Zones might be switched after you start the DB instance.

Option and parameter group considerations

You can't remove persistent options (including permanent options) from an option group if there are DB instances associated with that option group. This functionality is also true of any DB instance with a state of stopping, stopped, or starting.

You can change the option group or DB parameter group that is associated with a stopped DB instance, but the change does not occur until the next time you start the DB instance. If you chose to apply changes immediately, the change occurs when you start the DB instance. Otherwise the change occurs during the next maintenance window after you start the DB instance.

Public IP address

When you stop a DB instance, it retains its DNS endpoint. If you stop a DB instance that has a public IP address, Amazon RDS releases its public IP address. When the DB instance is restarted, it has a different public IP address.

Note
You should always connect to a DB instance using the DNS endpoint, not the IP address.

Stopping a DB instance temporarily

You can stop a DB using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To stop a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to stop.
3. For Actions, choose Stop.
4. (Optional) In the Stop DB Instance window, choose Yes for Create Snapshot? and enter the snapshot name for Snapshot name. Choose Yes if you want to create a snapshot of the DB instance before stopping it.
5. Choose Yes, Stop Now to stop the DB instance, or choose Cancel to cancel the operation.

AWS CLI

To stop a DB instance by using the AWS CLI, call the stop-db-instance command with the following option:

- --db-instance-identifier – the name of the DB instance.

Example

```
aws rds stop-db-instance --db-instance-identifier mydbinstance
```

RDS API

To stop a DB instance by using the Amazon RDS API, call the StopDBInstance operation with the following parameter:

- DBInstanceIdentifier – the name of the DB instance.
Starting an Amazon RDS DB instance that was previously stopped

You can stop your Amazon RDS DB instance temporarily to save money. After you stop your DB instance, you can restart it to begin using it again. For more details about stopping and starting DB instances, see Stopping an Amazon RDS DB instance temporarily (p. 305).

When you start a DB instance that you previously stopped, the DB instance retains the ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a stopped instance, you are charged a full instance hour.

**Console**

To start a DB instance
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to start.
3. For Actions, choose Start.

**AWS CLI**

To start a DB instance by using the AWS CLI, call the start-db-instance command with the following option:

- --db-instance-identifier – The name of the DB instance.

**Example**

```
aws rds start-db-instance --db-instance-identifier mydbinstance
```

**RDS API**

To start a DB instance by using the Amazon RDS API, call the StartDBInstance operation with the following parameter:

- DBInstanceIdentifier – The name of the DB instance.
Modifying an Amazon RDS DB instance

You can change the settings of a DB instance to accomplish tasks such as adding additional storage or changing the DB instance class. In this topic, you can find out how to modify an Amazon RDS DB instance and learn about the settings for DB instances.

We recommend that you test any changes on a test instance before modifying a production instance, so that you fully understand the impact of each change. Testing is especially important when upgrading database versions.

Most modifications to a DB instance you can either apply immediately or defer until the next maintenance window. Some modifications, such as parameter group changes, require that you manually reboot your DB instance for the change to take effect.

**Important**

Some modifications result in downtime because Amazon RDS must reboot your DB instance for the change to take effect. Review the impact to your database and applications before modifying your DB instance settings.

**Console**

**To modify a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. Change any of the settings that you want. For information about each setting, see **Settings for DB instances** (p. 310).
5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see **Using the Apply Immediately setting** (p. 310).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

**AWS CLI**

To modify a DB instance by using the AWS CLI, call the `modify-db-instance` command. Specify the DB instance identifier and the values for the options that you want to modify. For information about each option, see **Settings for DB instances** (p. 310).

**Example**

The following code modifies `mydbinstance` by setting the backup retention period to 1 week (7 days). The code enables deletion protection by using `--deletion-protection`. To disable deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see **Using the Apply Immediately setting** (p. 310).
Apply Immediately setting

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 7 \
  --deletion-protection \
  --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 7 ^
  --deletion-protection ^
  --no-apply-immediately
```

RDS API

To modify a DB instance by using the Amazon RDS API, call the `ModifyDBInstance` operation. Specify the DB instance identifier, and the parameters for the settings that you want to modify. For information about each parameter, see Settings for DB instances (p. 310).

Using the Apply Immediately setting

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately, you choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` parameter when calling the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

**Important**

If any of the pending modifications require the DB instance to be temporarily unavailable (`downtime`), choosing the apply immediately option can cause unexpected downtime.

When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.

If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes.

To see how the different database settings interact with the apply immediately setting, see Settings for DB instances (p. 310).

Settings for DB instances

In the following table, you can find details about which settings you can and can't modify, when changes can be applied, and whether the changes cause downtime for your DB instance. Note that by using Amazon RDS features such as Multi-AZ, you can minimize downtime if you later modify the DB instance. For more information, see Multi-AZ deployments for high availability (p. 65).

You can modify a DB instance using the console, the `modify-db-instance` CLI command, or the `ModifyDBInstance` RDS API operation.

If you don't choose to apply the change immediately, it occurs during the next maintenance window. | Downtime occurs during this change. | All DB engines |

The subnet group for the DB instance. You can use this setting to move your DB instance to a different VPC. If your DB instance isn't in a VPC, you can use this setting to move your DB instance into a VPC.

For more information, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).
Modifying a Multi-AZ DB cluster

A Multi-AZ DB cluster has a writer DB instance and two reader DB instances in three separate Availability Zones. Multi-AZ DB clusters provide high availability, increased capacity for read workloads, and lower latency when compared to Multi-AZ deployments. For more information about Multi-AZ DB clusters, see Multi-AZ DB cluster deployments (p. 71).

You can modify a Multi-AZ DB cluster to change its settings. You can also perform operations on a Multi-AZ DB cluster, such as taking a snapshot of it. However, you can’t modify the DB instances in a Multi-AZ DB cluster, and the only supported operation is rebooting a DB instance.

**Note**
Multi-AZ DB clusters are supported only for the MySQL and PostgreSQL DB engines.

You can modify a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To modify a Multi-AZ DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to modify.
4. Change any of the settings that you want. For information about each setting, see Settings for modifying Multi-AZ DB clusters (p. 325).
5. When all the changes are as you want them, choose Continue and check the summary of modifications.
6. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Using the Apply Immediately setting (p. 325).
7. On the confirmation page, review your changes. If they’re correct, choose Modify DB cluster to save your changes.

Or choose Back to edit your changes or Cancel to cancel your changes.

**AWS CLI**

To modify a Multi-AZ DB cluster by using the AWS CLI, call the modify-db-cluster command. Specify the DB cluster identifier and the values for the options that you want to modify. For information about each option, see Settings for modifying Multi-AZ DB clusters (p. 325).

**Example**

The following code modifies my-multi-az-dbcluster by setting the backup retention period to 1 week (7 days). The code turns on deletion protection by using --deletion-protection. To turn off deletion protection, use --no-deletion-protection. The changes are applied during the next maintenance window by using --no-apply-immediately. Use --apply-immediately to apply the changes immediately. For more information, see Using the Apply Immediately setting (p. 325).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
   --db-cluster-identifier my-multi-az-dbcluster \
   --backup-retention-period 7 \
```
Apply Immediately setting

```
--deletion-protection \n--no-apply-immediately
```

For Windows:
```
aws rds modify-db-cluster ^
  --db-cluster-identifier my-multi-az-dbcluster ^
  --backup-retention-period 7 ^
  --deletion-protection ^
  --no-apply-immediately
```

RDS API

To modify a Multi-AZ DB cluster by using the Amazon RDS API, call the ModifyDBCluster operation. Specify the DB cluster identifier, and the parameters for the settings that you want to modify. For information about each parameter, see Settings for modifying Multi-AZ DB clusters (p. 325).

Using the Apply Immediately setting

When you modify a Multi-AZ DB cluster, you can apply the changes immediately. To apply changes immediately, you choose the Apply Immediately option in the AWS Management Console. Or you use the --apply-immediately option when calling the AWS CLI or set the ApplyImmediately parameter to true when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

**Important**

If any of the pending modifications require the DB cluster to be temporarily unavailable (downtime), choosing the apply immediately option can cause unexpected downtime.

When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.

If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the --apply-immediately option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see Settings for modifying Multi-AZ DB clusters (p. 325).

Settings for modifying Multi-AZ DB clusters

For details about settings that you can use to modify a Multi-AZ DB cluster, see the following table. For more information about the AWS CLI options, see modify-db-cluster. For more information about the RDS API parameters, see ModifyDBCluster.

Settings that don't apply when modifying Multi-AZ DB clusters

The following settings in the AWS CLI command `modify-db-cluster` and the RDS API operation `ModifyDBCluster` don't apply to Multi-AZ DB clusters.

You also can't modify these settings for Multi-AZ DB clusters in the console.
Maintaining a DB instance

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the DB instance's underlying hardware, underlying operating system (OS), or database engine version. Updates to the operating system most often occur for security issues and should be done as soon as possible.

Some maintenance items require that Amazon RDS take your DB instance offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently (typically once every few months) and seldom requires more than a fraction of your maintenance window.

Deferred DB instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change the DB instance class or parameter group during the maintenance window. Such modifications that you specify using the pending reboot setting don’t show up in the Pending maintenance list. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Viewing pending maintenance

You can view whether a maintenance update is available for your DB instance by using the RDS console, the AWS CLI, or the Amazon RDS API. If an update is available, it is indicated in the Maintenance column for the DB instance on the Amazon RDS console, as shown following.

If no maintenance update is available for a DB instance, the column value is none for it.

If a maintenance update is available for a DB instance, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:
- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from **Actions**. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

**Note**

Certain OS updates are marked as **required**. If you defer a required update, you get a notice from Amazon RDS indicating when the update will be performed. Other updates are marked as **available**, and these you can defer indefinitely.

To take an action, choose the DB instance to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.

The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see **The Amazon RDS maintenance window** (p. 337).

You can also view whether a maintenance update is available for your DB instance by running the `describe-pending-maintenance-actions` AWS CLI command.
Applying updates for a DB instance

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

**Console**

**To manage an update for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that has a required update.
4. For **Actions**, choose one of the following:
   - **Upgrade now**
   - **Upgrade at next window**

   **Note**
   If you choose **Upgrade at next window** and later want to delay the update, you can choose **Defer upgrade**. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable **Auto minor version upgrade**.

**AWS CLI**

To apply a pending update to a DB instance, use the `apply-pending-maintenance-action` AWS CLI command.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds apply-pending-maintenance-action \
  --apply-action system-update \
  --opt-in-type immediate
```

For Windows:

```bash
aws rds apply-pending-maintenance-action ^
  --apply-action system-update ^
  --opt-in-type immediate
```

**Note**

To defer a maintenance action, specify `undo-opt-in` for `--opt-in-type`. You can't specify `undo-opt-in` for `--opt-in-type` if the maintenance action has already started.

To cancel a maintenance action, run the `modify-db-instance` AWS CLI command and specify `--no-auto-minor-version-upgrade`.

To return a list of resources that have at least one pending update, use the `describe-pending-maintenance-actions` AWS CLI command.
Example

For Linux, macOS, or Unix:

```bash
aws rds describe-pending-maintenance-actions
```

For Windows:

```bash
aws rds describe-pending-maintenance-actions
```

You can also return a list of resources for a DB instance by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=filter-name,Value=resource-id,....`

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-instance1` and `sample-instance2` DB instances.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-pending-maintenance-actions
    --filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

For Windows:

```bash
aws rds describe-pending-maintenance-actions
    --filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

**RDS API**

To apply an update to a DB instance, call the Amazon RDS API `ApplyPendingMaintenanceAction` operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API `DescribePendingMaintenanceActions` operation.

**Maintenance for Multi-AZ deployments**

Running a DB instance as a Multi-AZ deployment can further reduce the impact of a maintenance event, because Amazon RDS applies operating system updates by following these steps:

1. Perform maintenance on the standby.
2. Promote the standby to primary.
3. Perform maintenance on the old primary, which becomes the new standby.
When you modify the database engine for your DB instance in a Multi-AZ deployment, then Amazon RDS upgrades both the primary and secondary DB instances at the same time. In this case, the database engine for the entire Multi-AZ deployment is shut down during the upgrade.

For more information on Multi-AZ deployments, see Multi-AZ deployments for high availability (p. 65).

**The Amazon RDS maintenance window**

Every DB instance has a weekly maintenance window during which any system changes are applied. You can think of the maintenance window as an opportunity to control when modifications and software patching occur, in the event either are requested or required. If a maintenance event is scheduled for a given week, it is initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.

The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don’t specify a preferred maintenance window when you create the DB instance, then Amazon RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS will consume some of the resources on your DB instance while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Time Block</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>03:00–11:00 UTC</td>

</tr>
</tbody>
</table>
Adjusting the preferred DB instance maintenance window

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB instance will only be unavailable during this time if the system changes, such as a change in DB instance class, are being applied and require an outage, and only for the minimum amount of time required to make the necessary changes.

In the following example, you adjust the preferred maintenance window for a DB instance.

For the purpose of this example, we assume that the DB instance named `mydbinstance` exists and has a preferred maintenance window of "Sun:05:00-Sun:06:00" UTC.

**Console**

**To adjust the preferred maintenance window**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB instance that you want to modify.
3. Choose Modify. The Modify DB Instance page appears.
4. In the Maintenance section, update the maintenance window.
   
   **Note**
   
   The maintenance window and the backup window for the DB instance cannot overlap. If you enter a value for the maintenance window that overlaps the backup window, an error message appears.
5. Choose Continue.

   On the confirmation page, review your changes.
6. To apply the changes to the maintenance window immediately, select Apply immediately.
7. Choose **Modify DB Instance** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

### AWS CLI

To adjust the preferred maintenance window, use the AWS CLI `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--preferred-maintenance-window`

**Example**

The following code example sets the maintenance window to Tuesdays from 4:00-4:30AM UTC.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --preferred-maintenance-window Tue:04:00-Tue:04:30
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --preferred-maintenance-window Tue:04:00-Tue:04:30
```

### RDS API

To adjust the preferred maintenance window, use the Amazon RDS API `ModifyDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `PreferredMaintenanceWindow`

### Working with mandatory operating system updates

RDS for MySQL and RDS for PostgreSQL DB instances occasionally require mandatory operating system updates. Amazon RDS upgrades the operating system to a newer version to improve database performance and customers' overall security posture. Typically, the updates take about 10 minutes. The updates don't affect how the DB instances function.

Whether a mandatory operating system update is required for a DB instance depends on its DB engine version and DB instance class. In the following sections, you can find descriptions of the affected DB engine versions and DB instance classes for RDS for MySQL and RDS for PostgreSQL.

For information about viewing whether a maintenance update is available for your DB instance, see [Viewing pending maintenence](p. 333).

### Topics

- [Mandatory operating system updates for RDS for MySQL](p. 340)
- [Mandatory operating system updates for RDS for PostgreSQL](p. 341)
Mandatory operating system updates for RDS for MySQL

We plan to use the following schedule for operating system updates for RDS for MySQL. For each date in the table, the start time is 00:00 Universal Coordinated Time (UTC).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Date range</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you update the operating system for your RDS for MySQL DB instances. To update the operating system, follow the instructions in Applying updates for a DB instance (p. 335).</td>
<td>Now–January 31, 2022</td>
</tr>
<tr>
<td>Amazon RDS starts automatic upgrades of the operating system for your RDS for MySQL DB instances to the latest version in a maintenance window.</td>
<td>January 31, 2022–March 30, 2022</td>
</tr>
<tr>
<td>Amazon RDS starts automatic upgrades of the operating system for your RDS for MySQL DB instances to the latest version regardless of whether they are in a maintenance window.</td>
<td>After March 30, 2022</td>
</tr>
</tbody>
</table>

For this operating system update to be required, a DB instance must be running the versions with "Yes" in the following table for each DB instance class.

**Mandatory operating system updates by version and DB instance class for RDS for MySQL**

<table>
<thead>
<tr>
<th>RDS for MySQL version</th>
<th>db.t2</th>
<th>db.r4</th>
<th>db.m4</th>
<th>db.t3</th>
<th>db.r5</th>
<th>db.m5</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.0.23 and higher 8.0 versions</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>8.0.21 and lower 8.0 versions</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>5.7.33 and higher 5.7 versions</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>5.7.31 and lower 5.7 versions</td>
<td>No</td>

<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>5.6.51 and higher 5.6 versions</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>5.6.49 and lower 5.6 versions</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
Mandatory operating system updates for RDS for PostgreSQL

We plan to use the following schedule for operating system updates for RDS for PostgreSQL. For each date in the table, the start time is 00:00 Universal Coordinated Time (UTC).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Date range</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you update the operating system for your RDS for PostgreSQL DB instances.</td>
<td>Now–June 30, 2022</td>
</tr>
<tr>
<td>To update the operating system, follow the instructions in Applying updates for a DB instance (p. 335).</td>
<td></td>
</tr>
<tr>
<td>Amazon RDS starts automatic upgrades of the operating system for your RDS for PostgreSQL DB instances to the latest version in a maintenance window.</td>
<td>June 30, 2022–October 30, 2022</td>
</tr>
<tr>
<td>Amazon RDS starts automatic upgrades of the operating system for your RDS for PostgreSQL DB instances to the latest version regardless of whether they are in a maintenance window.</td>
<td>After October 30, 2022</td>
</tr>
</tbody>
</table>

For this operating system update to be required, a DB instance must be running the versions with "Yes" in the following table for each DB instance class.

### Mandatory operating system updates by version and DB instance class for RDS for PostgreSQL

<table>
<thead>
<tr>
<th>RDS for PostgreSQL version</th>
<th>db.t2</th>

### Recommended actions for mandatory operating system updates

Whether a mandatory operating system update is required for a DB instance depends on its DB engine version and DB instance class. You can find the affected DB engine versions and DB instance classes in Mandatory operating system updates by DB engine version and DB instance class for RDS for MySQL (p. 340) and Mandatory operating system updates by DB engine version and DB instance class for RDS for PostgreSQL (p. 341).

If an operating system update is required for your DB instance based on its DB engine version and DB instance class, the required update appears in the AWS Management Console. In this case, update the operating system by following the instructions in Applying updates for a DB instance (p. 335).

Although we recommend the actions described in this section, Amazon RDS won't upgrade or modify the DB instance class of your DB instances automatically. Amazon RDS won't upgrade the DB engine version of a DB instance unless the auto minor version upgrade option is turned on. For more information about the auto minor version upgrade option, see Automatically upgrading the minor engine version (p. 346).

If you are unable to identify any mandatory operating system updates in the AWS Management Console, we recommend the following actions:

- Your DB instance doesn't use a DB engine version that requires this operating system update. Your DB instance uses an affected DB instance class.

  Take the following recommended actions:

  1. Upgrade your DB engine version to a version that requires this operating system update. For more information, see Upgrading a DB instance engine version (p. 344).
  2. Update the operating system by following the instructions in Applying updates for a DB instance (p. 335).

- Your DB instance uses a DB engine version that requires this operating system update. Your DB instance uses an older DB instance class in a DB instance class family that is affected by this update.

  We recommend that you modify your DB instance to use a DB instance class that requires this operating system update. For example, if your DB instance uses a db.r3 DB instance class, we recommend that you modify your DB instance to use a db.r4 or db.r5 DB instance class. Similarly, if your DB instance uses a db.m3 DB instance class, we recommend that you modify your DB instance to use a db.m4 or db.m5 DB instance class. In this case, you don't need to update the operating system...
because the DB instance class modification applies the operating system update. You can also modify your DB instance to use a different DB instance class family, such as db.m6g or db.r6g.

If your DB instance already uses a DB instance class that isn't in a DB instance class family that is affected by this operating system update, then you don't need to modify its DB instance class. For example, if your DB instance uses a db.m6g, db.x2g, or db.z1d DB instance class, then you don't need to modify its DB instance class.

For more information about DB instance classes, see DB instance classes (p. 9). For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

• Your DB instance doesn't use a DB engine version that requires this operating system update. Your DB instance uses an older DB instance class in a DB instance class family that is affected by this operating system update.

Take the following recommended actions:
1. Upgrade your DB engine version to a version that requires this operating system update. For more information, see Upgrading a DB instance engine version (p. 344).
2. Modify your DB instance to use a newer DB instance class to use newer DB instance in the same DB instance class family in a different DB instance class family.

For example, if your DB instance uses a db.r3 DB instance class, we recommend that you modify your DB instance to use a db.r4 or db.r5 DB instance class. Similarly, if your DB instance uses a db.m3 DB instance class, we recommend that you modify your DB instance to use a db.m4 or db.m5 DB instance class. In this case, you don't need to update the operating system because the DB instance class modification applies the operating system update. You can also modify your DB instance to use a different DB instance class family, such as db.m6g or db.r6g.

For more information about DB instance classes, see DB instance classes (p. 9). For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).
Upgrading a DB instance engine version

Amazon RDS provides newer versions of each supported database engine so you can keep your DB instance up-to-date. Newer versions can include bug fixes, security enhancements, and other improvements for the database engine. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your database DB instances.

There are two kinds of upgrades: major version upgrades and minor version upgrades. In general, a major engine version upgrade can introduce changes that are not compatible with existing applications. In contrast, a minor version upgrade includes only changes that are backward-compatible with existing applications.

The version numbering sequence is specific to each database engine. For example, RDS for MySQL 5.7 and 8.0 are major engine versions and upgrading from any 5.7 version to any 8.0 version is a major version upgrade. RDS for MySQL version 5.7.22 and 5.7.23 are minor versions and upgrading from 5.7.22 to 5.7.23 is a minor version upgrade.

**Important**

You can't modify a DB instance when it is being upgraded. During an upgrade, the DB instance status is upgrading.

For more information about major and minor version upgrades for a specific DB engine, see the following documentation for your DB engine:

- Upgrading the MariaDB DB engine (p. 861)
- Upgrading the Microsoft SQL Server DB engine (p. 957)
- Upgrading the MySQL DB engine (p. 1159)
- Upgrading the Oracle DB engine (p. 1548)
- Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1626)

For major version upgrades, you must manually modify the DB engine version through the AWS Management Console, AWS CLI, or RDS API. For minor version upgrades, you can manually modify the engine version, or you can choose to enable auto minor version upgrades.

**Topics**

- Manually upgrading the engine version (p. 344)
- Automatically upgrading the minor engine version (p. 346)

Manually upgrading the engine version

To manually upgrade the engine version of a DB instance, you can use the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To upgrade the engine version of a DB instance by using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. For **DB engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Using the Apply Immediately setting (p. 310).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

**AWS CLI**

To upgrade the engine version of a DB instance, use the CLI `modify-db-instance` command. Specify the following parameters:

- `--db-instance-identifier` – the name of the DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

For information about valid engine versions, use the AWS CLI `describe-db-engine-versions` command.

- `--allow-major-version-upgrade` – to upgrade the major version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --engine-version new_version
   --allow-major-version-upgrade
   --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --engine-version new_version ^
   --allow-major-version-upgrade ^
   --no-apply-immediately
```

**RDS API**

To upgrade the engine version of a DB instance, use the **ModifyDBInstance** action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example **mydbinstance**.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the **DescribeDBEngineVersions** operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`. 
Automatically upgrading the minor engine version

A *minor engine version* is an update to a DB engine version within a major engine version. For example, a major engine version might be 9.6 with the minor engine versions 9.6.11 and 9.6.12 within it.

If you want Amazon RDS to upgrade the DB engine version of a database automatically, you can enable auto minor version upgrades for the database.

When Amazon RDS designates a minor engine version as the preferred minor engine version, each database that meets both of the following conditions is upgraded to the minor engine version automatically:

- The database is running a minor version of the DB engine that is lower than the preferred minor engine version.
- The database has auto minor version upgrade enabled.

You can control whether auto minor version upgrade is enabled for a DB instance when you perform the following tasks:

- Creating a DB instance (p. 175)
- Modifying a DB instance (p. 309)
- Creating a read replica (p. 359)
- Restoring a DB instance from a snapshot (p. 432)
- Restoring a DB instance to a specific time (p. 480)
- Importing a DB instance from Amazon S3 (p. 1178) (for a MySQL backup on Amazon S3)

When you perform these tasks, you can control whether auto minor version upgrade is enabled for the DB instance in the following ways:

- Using the console, set the *Auto minor version upgrade* option.
- Using the AWS CLI, set the `--auto-minor-version-upgrade|--no-auto-minor-version-upgrade` option.
- Using the RDS API, set the `AutoMinorVersionUpgrade` parameter.

To determine whether a maintenance update, such as a DB engine version upgrade, is available for your DB instance, you can use the console, AWS CLI, or RDS API. You can also upgrade the DB engine version manually and adjust the maintenance window. For more information, see *Maintaining a DB instance* (p. 333).

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified minor DB engine version in a specific AWS Region. You can find the possible `--engine` values for this command in the description for the `Engine` parameter in *CreateDBInstance*.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine engine \
  --engine-version minor-version \
  --region region \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
  --output text
```

For Windows:
For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions
--engine mysql
--engine-version 8.0.11
--region us-east-2
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" 
--output table
```

Your output is similar to the following.

```
----------------------------------
<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoUpgrade</td>
</tr>
<tr>
<td>--------------</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>

</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>True</td>
</tr>
<tr>
<td>False</td>
</tr>
<tr>
<td>--------------</td>
</tr>
</tbody>
</table>
----------------------------------
```

In this example, the AutoUpgrade value is True for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

**Important**

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster in the near future, we strongly recommend that you disable auto minor version upgrades for the DB instance early in the migration planning phase. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL. For information about Aurora PostgreSQL versions, see Engine versions for Amazon Aurora PostgreSQL.
Renaming a DB instance

You can rename a DB instance by using the AWS Management Console, the AWS CLI `modify-db-instance` command, or the Amazon RDS API `ModifyDBInstance` action. Renaming a DB instance can have far-reaching effects. The following is a list of considerations before you rename a DB instance.

- When you rename a DB instance, the endpoint for the DB instance changes, because the URL includes the name you assigned to the DB instance. You should always redirect traffic from the old URL to the new one.
- When you rename a DB instance, the old DNS name that was used by the DB instance is immediately deleted, although it could remain cached for a few minutes. The new DNS name for the renamed DB instance becomes effective in about 10 minutes. The renamed DB instance is not available until the new name becomes effective.
- You cannot use an existing DB instance name when renaming an instance.
- All read replicas associated with a DB instance remain associated with that instance after it is renamed. For example, suppose you have a DB instance that serves your production database and the instance has several associated read replicas. If you rename the DB instance and then replace it in the production environment with a DB snapshot, the DB instance that you renamed will still have the read replicas associated with it.
- Metrics and events associated with the name of a DB instance are maintained if you reuse a DB instance name. For example, if you promote a read replica and rename it to be the name of the previous primary DB instance, the events and metrics associated with the primary DB instance are associated with the renamed instance.
- DB instance tags remain with the DB instance, regardless of renaming.
- DB snapshots are retained for a renamed DB instance.

Note
A DB instance is an isolated database environment running in the cloud. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing DB instance

The most common reasons for renaming a DB instance are that you are promoting a read replica or you are restoring data from a DB snapshot or point-in-time recovery (PITR). By renaming the database, you can replace the DB instance without having to change any application code that references the DB instance. In these cases, you would do the following:

1. Stop all traffic going to the primary DB instance. This can involve redirecting traffic from accessing the databases on the DB instance or some other way you want to use to prevent traffic from accessing your databases on the DB instance.
2. Rename the primary DB instance to a name that indicates it is no longer the primary DB instance as described later in this topic.
3. Create a new primary DB instance by restoring from a DB snapshot or by promoting a read replica, and then give the new instance the name of the previous primary DB instance.
4. Associate any read replicas with the new primary DB instance.

If you delete the old primary DB instance, you are responsible for deleting any unwanted DB snapshots of the old primary DB instance.

For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance (p. 361).
Important
The DB instance is rebooted when it is renamed.

Console

To rename a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to rename.
4. Choose Modify.
5. In Settings, enter a new name for DB instance identifier.
6. Choose Continue.
7. To apply the changes immediately, choose Apply immediately. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon RDS DB instance (p. 309).
8. On the confirmation page, review your changes. If they are correct, choose Modify DB Instance to save your changes.

Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

AWS CLI

To rename a DB instance, use the AWS CLI command modify-db-instance. Provide the current --db-instance-identifier value and --new-db-instance-identifier parameter with the new name of the DB instance.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \   --db-instance-identifier DBInstanceIdentifier \   --new-db-instance-identifier NewDBInstanceIdentifier
```

For Windows:

```bash
aws rds modify-db-instance ^       --db-instance-identifier DBInstanceIdentifier ^       --new-db-instance-identifier NewDBInstanceIdentifier
```

RDS API

To rename a DB instance, call Amazon RDS API operation ModifyDBInstance with the following parameters:

- DBInstanceIdentifier — existing name for the instance
- NewDBInstanceIdentifier — new name for the instance
Rebooting a DB instance

You might need to reboot your DB instance, usually for maintenance reasons. For example, if you make certain modifications, or if you change the DB parameter group associated with the DB instance, you must reboot the instance for the changes to take effect.

**Note**
If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of pending-reboot. The pending-reboot parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see Working with parameter groups (p. 278).

Rebooting a DB instance restarts the database engine service. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to rebooting.

If the Amazon RDS DB instance is configured for Multi-AZ, you can perform the reboot with a failover. An Amazon RDS event is created when the reboot is completed. If your DB instance is a Multi-AZ deployment, you can force a failover from one Availability Zone (AZ) to another when you reboot. When you force a failover of your DB instance, Amazon RDS automatically switches to a standby replica in another Availability Zone, and updates the DNS record for the DB instance to point to the standby DB instance. As a result, you need to clean up and re-establish any existing connections to your DB instance. Rebooting with failover is beneficial when you want to simulate a failure of a DB instance for testing, or restore operations to the original AZ after a failover occurs. For more information, see Multi-AZ deployments for high availability (p. 65).

**Warning**
When you force a failover of your DB instance, the database is abruptly interrupted. The DB instance and its client sessions might not have time to shut down gracefully. To avoid the possibility of data loss, we recommend stopping transactions on your DB instance before rebooting with a failover.

On RDS for Microsoft SQL Server, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

**Note**
When you force a failover from one Availability Zone to another when you reboot, the Availability Zone change might not be reflected in the AWS Management Console, and in calls to the AWS CLI and RDS API, for several minutes.

You can't reboot your DB instance if it isn't in the available state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

For a DB instance with read replicas, you can reboot the source DB instance and its read replicas independently. After a reboot completes, replication resumes automatically.
**Console**

**To reboot a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to reboot.
3. For Actions, choose Reboot.
   - The Reboot DB Instance page appears.
4. (Optional) Choose Reboot with failover? to force a failover from one AZ to another.
5. Choose Reboot to reboot your DB instance.
   - Alternatively, choose Cancel.

**AWS CLI**

To reboot a DB instance by using the AWS CLI, call the `reboot-db-instance` command.

**Example Simple reboot**

For Linux, macOS, or Unix:

```bash
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

For Windows:

```bash
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

**Example Reboot with failover**

To force a failover from one AZ to the other, use the `--force-failover` parameter.

For Linux, macOS, or Unix:

```bash
aws rds reboot-db-instance --db-instance-identifier mydbinstance --force-failover
```

For Windows:

```bash
aws rds reboot-db-instance --db-instance-identifier mydbinstance ^
--force-failover
```

**RDS API**

To reboot a DB instance by using the Amazon RDS API, call the RebootDBInstance operation.
Rebooting Multi-AZ DB clusters and reader DB instances

You might need to reboot your Multi-AZ DB cluster, usually for maintenance reasons. For example, if you make certain modifications or change the DB cluster parameter group associated with a DB cluster, you reboot the DB cluster. Doing so causes the changes to take effect.

If a DB cluster isn't using the latest changes to its associated DB cluster parameter group, the AWS Management Console shows the DB cluster parameter group with a status of `pending-reboot`. The `pending-reboot` parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB cluster, manually reboot the DB cluster. For more information about parameter groups, see Working with parameter groups for Multi-AZ DB clusters (p. 76).

Rebooting a DB cluster restarts the database engine service. Rebooting a DB cluster results in a momentary outage, during which the DB cluster status is set to `rebooting`.

You can't reboot your DB cluster if it isn't in the Available state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

**Important**
When you reboot the writer instance of a Multi-AZ DB cluster, it doesn't affect the reader DB instances in that DB cluster and no failover occurs. When you reboot a reader DB instance, no failover occurs. To fail over a Multi-AZ DB cluster, choose Failover in the console, call the AWS CLI command `failover-db-cluster`, or call the API operation `FailoverDBCluster`.

The time required to reboot your DB cluster depends on the crash recovery process, the database activity at the time of reboot, and the behavior of your specific DB cluster. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

Multi-AZ DB clusters don't support reboot with a failover.

**Console**

**To reboot a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to reboot.
3. For Actions, choose Reboot.

   The Reboot DB cluster page appears.
4. Choose Reboot to reboot your DB cluster.
   
   Or choose Cancel.

**AWS CLI**

To reboot a Multi-AZ DB cluster by using the AWS CLI, call the `reboot-db-cluster` command.

```bash
aws rds reboot-db-cluster --db-cluster-identifier mymultiazdbcluster
```
RDS API

To reboot a Multi-AZ DB cluster by using the Amazon RDS API, call the `RebootDBCluster` operation.
Working with read replicas

Amazon RDS uses the MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. The source DB instance becomes the primary DB instance. Updates made to the primary DB instance are asynchronously copied to the read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

Note
The information following applies to creating Amazon RDS read replicas either in the same AWS Region as the source DB instance, or in a separate AWS Region. The information following doesn’t apply to setting up replication with an instance that is running on an Amazon EC2 instance or that is on-premises.

When you create a read replica, you first specify an existing DB instance as the source. Then Amazon RDS takes a snapshot of the source instance and creates a read-only instance from the snapshot. Amazon RDS then uses the asynchronous replication method for the DB engine to update the read replica whenever there is a change to the primary DB instance. The read replica operates as a DB instance that allows only
read-only connections. Applications connect to a read replica the same way they do to any DB instance. Amazon RDS replicates all databases in the source DB instance.

**Note**
The Oracle DB engine supports replica databases in mounted mode. A mounted replica doesn't accept user connections and so can't serve a read-only workload. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see Working with Oracle replicas for Amazon RDS (p. 1443).

In some cases, a read replica resides in a different AWS Region from its primary DB instance. In these cases, Amazon RDS sets up a secure communications channel between the primary DB instance and the read replica. Amazon RDS establishes any AWS security configurations needed to enable the secure channel, such as adding security group entries. For more information about cross-Region read replicas, see Creating a read replica in a different AWS Region (p. 366).

You can configure a read replica for a DB instance that also has a standby replica configured for high availability in a Multi-AZ deployment. Replication with the standby replica is synchronous, and the standby replica can't serve read traffic.

For more information about high availability and standby replicas, see Multi-AZ deployments for high availability (p. 65).
Read replicas are supported by the MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL DB engines. In this section, you can find general information about using read replicas with all of these engines. For information about using read replicas with a specific engine, see the following sections:

- Working with MariaDB read replicas (p. 887)
- Working with read replicas for Microsoft SQL Server in Amazon RDS (p. 988)
- Working with MySQL read replicas (p. 1206)
- Working with Oracle replicas for Amazon RDS (p. 1443)
- Working with PostgreSQL read replicas in Amazon RDS (p. 1640)

**Overview of Amazon RDS read replicas**

Deploying one or more read replicas for a given source DB instance might make sense in a variety of scenarios, including the following:

- Scaling beyond the compute or I/O capacity of a single DB instance for read-heavy database workloads. You can direct this excess read traffic to one or more read replicas.
- Serving read traffic while the source DB instance is unavailable. In some cases, your source DB instance might not be able to take I/O requests, for example due to I/O suspension for backups or scheduled maintenance. In these cases, you can direct read traffic to your read replicas. For this use case, keep in mind that the data on the read replica might be "stale" because the source DB instance is unavailable.
- Business reporting or data warehousing scenarios where you might want business reporting queries to run against a read replica, rather than your production DB instance.
- Implementing disaster recovery. You can promote a read replica to a standalone instance as a disaster recovery solution if the primary DB instance fails.

By default, a read replica is created with the same storage type as the source DB instance. However, you can create a read replica that has a different storage type from the source DB instance based on the options listed in the following table.

<table>
<thead>
<tr>
<th>Source DB instance storage type</th>
<th>Source DB instance storage allocation</th>
<th>Read replica storage type options</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIOPS</td>
<td>100 GiB–32 TiB</td>
<td>PIOPS, GP2, Standard</td>
</tr>
<tr>
<td>GP2</td>
<td>100 GiB–32 TiB</td>
<td>PIOPS, GP2, Standard</td>
</tr>
<tr>
<td>GP2</td>
<td>&lt;100 GiB</td>
<td>GP2, Standard</td>
</tr>
<tr>
<td>Standard</td>
<td>100 GiB–6 TiB</td>
<td>PIOPS, GP2, Standard</td>
</tr>
<tr>
<td>Standard</td>
<td>&lt;100 GiB</td>
<td>GP2, Standard</td>
</tr>
</tbody>
</table>

**Note**

When you increase the allocated storage of a read replica, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Amazon RDS doesn't support circular replication. You can't configure a DB instance to serve as a replication source for an existing DB instance. You can only create a new read replica from an existing DB instance. For example, if `MyDBInstance` replicates to `ReadReplica1`, you can't configure `ReadReplica1` to replicate back to `MyDBInstance`. For MariaDB and MySQL you can create a read replica from an existing read replica. For example, from `ReadReplica1`, you can create a new read...
replica, such as ReadReplica2. For Oracle, PostgreSQL, and SQL Server, you can't create a read replica from an existing read replica.

If you no longer need read replicas, you can explicitly delete them using the same mechanisms for deleting a DB instance. If you delete a source DB instance without deleting its read replicas in the same AWS Region, each read replica is promoted to a standalone DB instance. For information about deleting a DB instance, see Deleting a DB instance (p. 401). For information about read replica promotion, see Promoting a read replica to be a standalone DB instance (p. 361).

If you have cross-Region read replicas, see Cross-Region replication considerations (p. 371) for information related to deleting the source DB instance for a cross-Region read replica.

### Differences between read replicas for different DB engines

Because Amazon RDS DB engines implement replication differently, there are several significant differences you should know about, as shown in the following table.

<table>
<thead>
<tr>
<th>Feature or behavior</th>
<th>MySQL and MariaDB</th>
<th>Oracle</th>
<th>PostgreSQL</th>
<th>SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>How are transaction logs purged?</td>
<td>RDS for MySQL and RDS for MariaDB keep any binary logs that haven't been applied.</td>
<td>If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of transaction logs on the source DB instance. Logs are purged from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. Logs are purged from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database. In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction</td>
<td>PostgreSQL has the parameter wal_keep_segments that dictates how many write ahead log (WAL) files are kept to provide data to the read replicas. The parameter value specifies the number of logs to keep.</td>
<td>The Virtual Log File (VLF) of the transaction log file on the primary replica can be truncated after it is no longer required for the secondary replicas. The VLF can only be marked as inactive when the log records have been hardened in the replicas. Regardless of how fast the disk subsystems are in the primary replica, the transaction log will keep the VLFs until</td>
</tr>
<tr>
<td>Feature or behavior</td>
<td>MySQL and MariaDB</td>
<td>Oracle</td>
<td>PostgreSQL</td>
<td>SQL Server</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------</td>
<td>--------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas.</td>
<td></td>
<td></td>
<td></td>
<td>the slowest replica has hardened it.</td>
</tr>
<tr>
<td>For information about setting archive log retention hours, see Retaining archived redo logs (p. 1386).</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Can a replica be made writable?</td>
<td>Yes. You can enable the MySQL or MariaDB read replica to be writable.</td>
<td>No. An Oracle read replica is a physical copy, and Oracle doesn't allow for writes in a read replica. You can promote the read replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.</td>
<td>No. A PostgreSQL read replica is a physical copy, and PostgreSQL doesn't allow for a read replica to be made writable.</td>
<td>No. A SQL Server read replica is a physical copy and also doesn't allow for writes. You can promote the read replica to make it writable. The promoted read replica has the replicated data up to the point when the request was made to promote it.</td>
</tr>
<tr>
<td>Can backups be performed on the replica?</td>
<td>Yes. You can enable automatic backups on a MySQL or MariaDB read replica.</td>
<td>No. You can't create manual snapshots of Amazon RDS for Oracle read replicas or enable automatic backups for them.</td>
<td>Yes, you can create a manual snapshot of a PostgreSQL read replica, but you can't enable automatic backups.</td>
<td>No. You can't create manual snapshots of Amazon RDS for SQL Server read replicas or enable automatic backups for them.</td>
</tr>
</tbody>
</table>
Creating a read replica

You can create a read replica from an existing DB instance using the AWS Management Console, AWS CLI, or RDS API. You create a read replica by specifying `SourceDBInstanceIdentifier`, which is the DB instance identifier of the source DB instance that you want to replicate from.

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. As a result, you experience a brief I/O suspension on your source DB instance while the DB snapshot occurs.

**Note**

The I/O suspension typically lasts about one minute. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica. If you create multiple read replicas in parallel from the same source DB instance, Amazon RDS takes only one snapshot at the start of the first create action.

When creating a read replica, there are a few things to consider. First, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. To enable automatic backups on an RDS for MySQL version 5.6 and later read replica, first create the read replica, then modify the read replica to enable automatic backups.

**Note**

Within an AWS Region, we strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC as the source DB instance. If you create a read replica in a different VPC from the source DB instance, classless inter-domain routing (CIDR) ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica

<table>
<thead>
<tr>
<th>Feature or behavior</th>
<th>MySQL and MariaDB</th>
<th>Oracle</th>
<th>PostgreSQL</th>
<th>SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can you use parallel replication?</td>
<td>Yes. MySQL version 5.6 and later and all supported MariaDB versions allow for parallel replication threads.</td>
<td>Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.</td>
<td>No. PostgreSQL has a single process handling replication.</td>
<td>Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.</td>
</tr>
<tr>
<td>Can you maintain a replica in a mounted rather than a read-only state?</td>
<td>No.</td>
<td>Yes. The primary use for mounted replicas is cross-Region disaster recovery. An Active Data Guard license isn’t required for mounted replicas. For more information, see Working with Oracle replicas for Amazon RDS (p. 1443).</td>
<td>No.</td>
<td>No.</td>
</tr>
</tbody>
</table>
unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see Working with a DB instance in a VPC (p. 1849). You can't create a read replica in a different AWS account from the source DB instance.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For Actions, choose Create read replica.
5. For DB instance identifier, enter a name for the read replica.
6. Choose your instance specifications. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
7. For Multi-AZ deployment, choose Yes to create a standby of your replica in another Availability Zone for failover support for the replica.

   Note
   Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

8. To create an encrypted read replica:
   a. Choose Enable encryption.
   b. For AWS KMS key, choose the AWS KMS key identifier of the KMS key.

   Note
   The source DB instance must be encrypted. To learn more about encrypting the source DB instance, see Encrypting Amazon RDS resources (p. 1750).

9. Choose other options, such as storage autoscaling.
10. Choose Create read replica.

After the read replica is created, you can see it on the Databases page in the RDS console. It shows Replica in the Role column.

AWS CLI

To create a read replica from a source DB instance, use the AWS CLI command create-db-instance-read-replica. This example also enables storage autoscaling.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --max-allocated-storage 1000
```

For Windows:
Promoting a read replica

To create a read replica from a source MySQL, MariaDB, Oracle, PostgreSQL, or SQL Server DB instance, call the Amazon RDS API CreateDBInstanceReadReplica operation with the following required parameters:

- DBInstanceIdentifier
- SourceDBInstanceIdentifier

### Promoting a read replica to be a standalone DB instance

You can promote a read replica into a standalone DB instance. When you promote a read replica, the DB instance is rebooted before it becomes available.
There are several reasons you might want to promote a read replica to a standalone DB instance:

- **Performing DDL operations (MySQL and MariaDB only)** – DDL operations, such as creating or rebuilding indexes, can take time and impose a significant performance penalty on your DB instance. You can perform these operations on a MySQL or MariaDB read replica once the read replica is in sync with its primary DB instance. Then you can promote the read replica and direct your applications to use the promoted instance.

- **Sharding** – Sharding embodies the “share-nothing” architecture and essentially involves breaking a large database into several smaller databases. One common way to split a database is splitting tables that are not joined in the same query onto different hosts. Another method is duplicating a table across multiple hosts and then using a hashing algorithm to determine which host receives a given update. You can create read replicas corresponding to each of your shards (smaller databases) and
promote them when you decide to convert them into standalone shards. You can then carve out the key space (if you are splitting rows) or distribution of tables for each of the shards depending on your requirements.

- **Implementing failure recovery** – You can use read replica promotion as a data recovery scheme if the primary DB instance fails. This approach complements synchronous replication, automatic failure detection, and failover.

If you are aware of the ramifications and limitations of asynchronous replication and you still want to use read replica promotion for data recovery, you can. To do this, first create a read replica and then monitor the primary DB instance for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB instance.
3. Create a replacement read replica with the promoted DB instance as its source.

When you promote a read replica, the new DB instance that is created retains the option group and the parameter group of the former read replica. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB instance, it's just like any other DB instance. For example, you can create read replicas from the new DB instance and perform point-in-time restore operations. Because the promoted DB instance is no longer a read replica, you can't use it as a replication target. If a source DB instance has several read replicas, promoting one of the read replicas to a DB instance has no effect on the other replicas.

Backup duration is a function of the number of changes to the database since the previous backup. If you plan to promote a read replica to a standalone instance, we recommend that you enable backups and complete at least one backup prior to promotion. In addition, you can't promote a read replica to a standalone instance when it has the backing-up status. If you have enabled backups on your read replica, configure the automated backup window so that daily backups don't interfere with read replica promotion.

The following steps show the general process for promoting a read replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the primary DB instance, and this replication lag can vary significantly. Use the **Replica Lag** metric to determine when all updates have been made to the read replica.
2. For MySQL and MariaDB only: If you need to make changes to the MySQL or MariaDB read replica, you must set the `read_only` parameter to 0 in the DB parameter group for the read replica. You can then perform all needed DDL operations, such as creating indexes, on the read replica. Actions taken on the read replica don't affect the performance of the primary DB instance.
3. Promote the read replica by using the **Promote** option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the **PromoteReadReplica** Amazon RDS API operation. **Note**
   The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the read replica is rebooted. When the reboot is complete, the read replica is available as a new DB instance.
4. (Optional) Modify the new DB instance to be a Multi-AZ deployment. For more information, see **Modifying an Amazon RDS DB instance** (p. 309) and **Multi-AZ deployments for high availability** (p. 65).

**Console**

**To promote a read replica to a standalone DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.

3. Choose the read replica that you want to promote.

4. For **Actions**, choose **Promote**.

5. On the **Promote Read Replica** page, enter the backup retention period and the backup window for the newly promoted DB instance.

6. When the settings are as you want them, choose **Continue**.

7. On the acknowledgment page, choose **Promote Read Replica**.

**AWS CLI**

To promote a read replica to a standalone DB instance, use the AWS CLI `promote-read-replica` command.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica
   --db-instance-identifier myreadreplica
```

For Windows:

```bash
aws rds promote-read-replica
   --db-instance-identifier myreadreplica
```

**RDS API**

To promote a read replica to a standalone DB instance, call the Amazon RDS API `PromoteReadReplica` operation with the required parameter `DBInstanceIdentifier`.

**Monitoring read replication**

You can monitor the status of a read replica in several ways. The Amazon RDS console shows the status of a read replica in the **Replication** section of the **Connectivity & security** tab in the read replica details. To view the details for a read replica, choose the name of the read replica in the list of DB instances in the Amazon RDS console.
You can also see the status of a read replica using the AWS CLI `describe-db-instances` command or the Amazon RDS API `DescribeDBInstances` operation.

The status of a read replica can be one of the following:

- **replicating** – The read replica is replicating successfully.
- **replication degraded (SQL Server only)** – Replicas are receiving data from the primary instance, but one or more databases might be not getting updates. This can occur, for example, when a replica is in the process of setting up newly created databases.

  The status doesn't transition from replication degraded to error, unless an error occurs during the degraded state.
- **error** – An error has occurred with the replication. Check the Replication Error field in the Amazon RDS console or the event log to determine the exact error. For more information about troubleshooting a replication error, see Troubleshooting a MySQL read replica problem (p. 1216).
- **terminated (MariaDB, MySQL, or PostgreSQL only)** – Replication is terminated. This occurs if replication is stopped for more than 30 consecutive days, either manually or due to a replication error. In this case, Amazon RDS terminates replication between the primary DB instance and all read replicas. Amazon RDS does this to prevent increased storage requirements on the source DB instance and long failover times.

  Broken replication can affect storage because the logs can grow in size and number due to the high volume of errors messages being written to the log. Broken replication can also affect failure recovery due to the time Amazon RDS requires to maintain and process the large number of logs during recovery.
- **stopped (MariaDB or MySQL only)** – Replication has stopped because of a customer-initiated request.
- **replication stop point set (MySQL only)** – A customer-initiated stop point was set using the `mysql.rds_start_replication_until` (p. 1277) stored procedure and the replication is in progress.
- **replication stop point reached (MySQL only)** – A customer-initiated stop point was set using the `mysql.rds_start_replication_until` (p. 1277) stored procedure and replication is stopped because the stop point was reached.

You can see where a DB instance is being replicated and if so, check its replication status. On the Databases page in the RDS console, it shows Primary in the Role column. Choose its DB instance name. On its detail page, on the Connectivity & security tab, its replication status is under Replication.

### Monitoring replication lag

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric.

For MariaDB and MySQL, the ReplicaLag metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command. Common causes for replication lag for MySQL and MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL and the XtraDB storage engine on MariaDB.

**Note**

Previous versions of MariaDB and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`. 
When the ReplicaLag metric reaches 0, the replica has caught up to the primary DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

For Oracle, the ReplicaLag metric is the sum of the Apply_Lag value and the difference between the current time and the apply lag's DATUM_TIME value. The DATUM_TIME value is the last time the read replica received data from its source DB instance. For more information, see V$DATAGUARD_STATS in the Oracle documentation.

For SQL Server, the ReplicaLag metric is the maximum lag of databases that have fallen behind, in seconds. For example, if you have two databases that lag 5 seconds and 10 seconds, respectively, then ReplicaLag is 10 seconds. The ReplicaLag metric returns the value of the following query.

```sql
SELECT ag.name name, MAX(hdrs.secondary_lag_seconds) max_lag FROM sys.dm_hadr_database_replica_state
```

For more information, see secondary_lag_seconds in the Microsoft documentation.

ReplicaLag returns -1 if RDS can't determine the lag, such as during replica setup, or when the read replica is in the error state.

**Note**

New databases aren't included in the lag calculation until they are accessible on the read replica.

For PostgreSQL, the ReplicaLag metric returns the value of the following query.

```sql
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS reader_lag
```

PostgreSQL versions 9.5.2 and later use physical replication slots to manage write ahead log (WAL) retention on the source instance. For each cross-Region read replica instance, Amazon RDS creates a physical replication slot and associates it with the instance. Two Amazon CloudWatch metrics, Oldest Replication Slot Lag and Transaction Logs Disk Usage, show how far behind the most lagging replica is in terms of WAL data received and how much storage is being used for WAL data. The Transaction Logs Disk Usage value can substantially increase when a cross-Region read replica is lagging significantly.

For more information about monitoring a DB instance with CloudWatch, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 508).

### Creating a read replica in a different AWS Region

With Amazon RDS, you can create a MariaDB, MySQL, Oracle, or PostgreSQL read replica in a different AWS Region from the source DB instance. Creating a cross-Region read replica isn't supported for SQL Server on Amazon RDS.
Creating a read replica in a different AWS Region

You create a read replica in a different AWS Region to do the following:

- Improve your disaster recovery capabilities.
- Scale read operations into an AWS Region closer to your users.
- Make it easier to migrate from a data center in one AWS Region to a data center in another AWS Region.

Creating a read replica in a different AWS Region from the source instance is similar to creating a replica in the same AWS Region. You can use the AWS Management Console, run the `create-db-instance-read-replica` command, or call the `CreateDBInstanceReadReplica` API operation.

**Note**
To create an encrypted read replica in a different AWS Region from the source DB instance, the source DB instance must be encrypted.

Creating a cross-Region read replica

The following procedures show how to create a read replica from a source MariaDB, MySQL, Oracle, or PostgreSQL DB instance in a different AWS Region.

**Console**

You can create a read replica across AWS Regions using the AWS Management Console.

**To create a read replica across AWS Regions with the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the MariaDB, MySQL, Oracle, or PostgreSQL DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Choose the **Destination Region**.
7. Choose the instance specifications you want to use. We recommend that you use the same DB instance class and storage type for the read replica.
8. To create an encrypted read replica in another AWS Region:
   a. Choose **Enable encryption**.
   b. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key in the destination AWS Region.

   **Note**
   To create an encrypted read replica, the source DB instance must be encrypted. To learn more about encrypting the source DB instance, see **Encrypting Amazon RDS resources** (p. 1750).
9. Choose other options, such as storage autoscaling.
10. Choose **Create read replica**.

**AWS CLI**

To create a read replica from a source MySQL, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can use the `create-db-instance-read-replica` command. In this case, you use `create-db-instance-read-replica` from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to this example:

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see **Working with Amazon Resource Names (ARNs) in Amazon RDS** (p. 385).

To create a read replica in a different AWS Region from the source DB instance, you can use the AWS CLI `create-db-instance-read-replica` command from the destination AWS Region. The following parameters are required for creating a read replica in another AWS Region:

- `--region` – The destination AWS Region where the read replica is created.
- `--source-db-instance-identifier` – The DB instance identifier for the source DB instance. This identifier must be in the ARN format for the source AWS Region.
- `--db-instance-identifier` – The identifier for the read replica in the destination AWS Region.

**Example of a cross-Region read replica**

The following code creates a read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica
   --db-instance-identifier myreadreplica
   --region us-west-2
```
Creating a read replica in a different AWS Region

For Windows:

```bash
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --region us-west-2 \
  --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance \
  --source-region us-east-1 \
  --kms-key-id my-us-west-2-key
```

The following parameters are also required for creating an encrypted read replica in another AWS Region:

- `--source-region` - The AWS Region of the source DB instance.

  If `--source-region` isn't specified, you must specify a `--pre-signed-url` value. A presigned URL is a URL that contains a Signature Version 4 signed request for the `CreateDBInstanceReadReplica` operation that is called in the source AWS Region. For more information about presigned URLs, see `CreateDBInstanceReadReplica`.

- `--kms-key-id` - The AWS KMS key identifier of the KMS key to use to encrypt the read replica in the destination AWS Region.

**Example of an encrypted cross-Region read replica**

The following code creates an encrypted read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance-read-replica \
  --db-instance-identifier myreadreplica \
  --region us-west-2 \
  --source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance \
  --source-region us-east-1 \
  --kms-key-id my-us-west-2-key
```

For Windows:

```bash
aws rds create-db-instance-read-replica ^
  --db-instance-identifier myreadreplica ^
  --region us-west-2 ^
  --source-region us-east-1 ^
  --kms-key-id my-us-west-2-key
```

**RDS API**

To create a read replica from a source MySQL, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can call the Amazon RDS API function `CreateDBInstanceReadReplica`. In this case, you call `CreateDBInstanceReadReplica` from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

To create an encrypted read replica in a different AWS Region from the source DB instance, you can use the Amazon RDS API `CreateDBInstanceReadReplica` operation from the destination AWS Region. To create an encrypted read replica in another AWS Region, you must specify a value for `PreSignedURL`. `PreSignedURL` should contain a request for the `CreateDBInstanceReadReplica` operation to call
Creating a read replica in a different AWS Region

in the source AWS Region where the read replica is created in. To learn more about PreSignedUrl, see CreateDBInstanceReadReplica.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to the following.

```
ar:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).

```

How Amazon RDS does cross-Region replication

Amazon RDS uses the following process to create a cross-Region read replica. Depending on the AWS Regions involved and the amount of data in the databases, this process can take hours to complete. You can use this information to determine how far the process has proceeded when you create a cross-Region read replica:

1. Amazon RDS begins configuring the source DB instance as a replication source and sets the status to modifying.
2. Amazon RDS begins setting up the specified read replica in the destination AWS Region and sets the status to creating.
3. Amazon RDS creates an automated DB snapshot of the source DB instance in the source AWS Region. The format of the DB snapshot name is rds:<InstanceID>-<timestamp>, where <InstanceID> is the identifier of the source instance, and <timestamp> is the date and time the copy started. For example, rds:mysourceinstance-2013-11-14-09-24 was created from the instance
Creating a read replica in a different AWS Region

mysourceinstance at 2013-11-14-09-24. During the creation of an automated DB snapshot, the source DB instance status remains modifying, the read replica status remains creating, and the DB snapshot status is creating. The progress column of the DB snapshot page in the console reports how far the DB snapshot creation has progressed. When the DB snapshot is complete, the status of both the DB snapshot and source DB instance are set to available.

4. Amazon RDS begins a cross-Region snapshot copy for the initial data transfer. The snapshot copy is listed as an automated snapshot in the destination AWS Region with a status of creating. It has the same name as the source DB snapshot. The progress column of the DB snapshot display indicates how far the copy has progressed. When the copy is complete, the status of the DB snapshot copy is set to available.

5. Amazon RDS then uses the copied DB snapshot for the initial data load on the read replica. During this phase, the read replica is in the list of DB instances in the destination, with a status of creating. When the load is complete, the read replica status is set to available, and the DB snapshot copy is deleted.

6. When the read replica reaches the available status, Amazon RDS starts by replicating the changes made to the source instance since the start of the create read replica operation. During this phase, the replication lag time for the read replica is greater than 0.

For information about replication lag time, see Monitoring read replication (p. 364).

Cross-Region replication considerations

All of the considerations for performing replication within an AWS Region apply to cross-Region replication. The following extra considerations apply when replicating between AWS Regions:

- You can only replicate between AWS Regions when using the following Amazon RDS DB instances:
  - MariaDB (all versions)
  - MySQL version 5.6 and higher
  - Oracle Enterprise Edition (EE) of Oracle Database 12c Release 1 (12.1) using 12.1.0.2.v10 and higher, Oracle Database 12c Release 2 (12.2), and Oracle Database 19c using the non-CDB architecture
    
    **Note**
    
    Oracle DB instances that you create using the CDB architecture aren't supported.

  - PostgreSQL (all versions)

- A source DB instance can have cross-Region read replicas in multiple AWS Regions.
- You can only create a cross-Region Amazon RDS read replica from a source Amazon RDS DB instance that is not a read replica of another Amazon RDS DB instance.
- You can replicate between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, but not into or out of AWS GovCloud (US).
- You can expect to see a higher level of lag time for any read replica that is in a different AWS Region than the source instance. This lag time comes from the longer network channels between regional data centers.
- For cross-Region read replicas, any of the create read replica commands that specify the --db-subnet-group-name parameter must specify a DB subnet group from the same VPC.
- Due to the limit on the number of access control list (ACL) entries for a VPC, we can't guarantee more than five cross-Region read replica instances.
- The read replica uses the default DB parameter group and DB option group for the specified DB engine.
- The read replica uses the default security group.
- For MariaDB, MySQL, and Oracle DB instances, when the source DB instance for a cross-Region read replica is deleted, the read replica is promoted.
• For PostgreSQL DB instances, when the source DB instance for a cross-Region read replica is deleted, the replication status of the read replica is set to terminated. The read replica isn’t promoted.

You have to promote the read replica manually or delete it.

**Requesting a cross-Region read replica**

To communicate with the source Region to request the creation of a cross-Region read replica, the requester (IAM role or IAM user) must have access to the source DB instance and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that the source DB instance is in US East (Ohio) and the read replica is created in US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

• The requester's policy has a condition for `aws:RequestedRegion`.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": "us-east-1"
  }
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": [
      "us-east-1",
      "us-east-2"
    ]
  }
}
```

• The requester's policy doesn't allow access to the source DB instance.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
...
```

For a successful request, specify both the source instance and the replica.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": [
]
• The requester's policy denies `aws:ViaAWSService`.

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
  "Bool": {
    "aws:ViaAWSService": "false"
  }
}
```

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

• The requester's policy has a condition for `aws:SourceVpc` or `aws:SourceVpce`.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with `aws:CalledVia` in your policy to make the request succeed. For example, you can use `aws:CalledVia` with `aws:SourceVpce` as shown here:

```json
...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
  "Condition": {
    "ForAnyValue:StringEquals": {
      "aws:SourceVpce": "vpce-1a2b3c4d"
    }
  },
  "Effect": "Allow",
  "Action": [
    "rds:CreateDBInstanceReadReplica"
  ],
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "aws:CalledVia": [
        "rds.amazonaws.com"
      ],
      "ForAnyValue:StringEquals": {
        "aws:CalledVia": ["rds.amazonaws.com"]
      }
    }
  }
}
```

For more information, see Policies and permissions in IAM in the IAM User Guide.

**Authorizing the read replica**

After a cross-Region DB read replica creation request returns success, RDS starts the replica creation in the background. An authorization for RDS to access the source DB instance is created. This authorization links the source DB instance to the read replica, and allows RDS to copy only to the specified read replica.

The authorization is verified by RDS using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the replica is authorized, RDS communicates with the source Region and completes the replica creation.
RDS doesn't have access to DB instances that weren't authorized previously by a CreateDBInstanceReadReplica request. The authorization is revoked when read replica creation completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the replication creation process, the creation fails.

For more information, see Using service-linked roles in the IAM User Guide.

**Using AWS Security Token Service credentials**

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the assumeRole API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to Valid in all AWS Regions in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

**Cross-Region replication costs**

The data transferred for cross-Region replication incurs Amazon RDS data transfer charges. These cross-Region replication actions generate charges for the data transferred out of the source AWS Region:

- When you create a read replica, Amazon RDS takes a snapshot of the source instance and transfers the snapshot to the read replica AWS Region.
- For each data modification made in the source databases, Amazon RDS transfers data from the source AWS Region to the read replica AWS Region.

For more information about data transfer pricing, see Amazon RDS pricing.

For MySQL and MariaDB instances, you can reduce your data transfer costs by reducing the number of cross-Region read replicas that you create. For example, suppose that you have a source DB instance in one AWS Region and want to have three read replicas in another AWS Region. In this case, you create only one of the read replicas from the source DB instance. You create the other two replicas from the first read replica instead of the source DB instance.

For example, if you have source-instance-1 in one AWS Region, you can do the following:

- Create read-replica-1 in the new AWS Region, specifying source-instance-1 as the source.
- Create read-replica-2 from read-replica-1.
- Create read-replica-3 from read-replica-1.

In this example, you are only charged for the data transferred from source-instance-1 to read-replica-1. You aren't charged for the data transferred from read-replica-1 to the other two replicas because they are all in the same AWS Region. If you create all three replicas directly from source-instance-1, you are charged for the data transfers to all three replicas.
Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB security groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints

**Note**
Currently, you can't tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

**Topics**
- Overview of Amazon RDS resource tags (p. 375)
- Using tags for access control with IAM (p. 376)
- Using tags to produce detailed billing reports (p. 376)
- Adding, listing, and removing tags (p. 377)
- Using the AWS Tag Editor (p. 379)
- Copying tags to DB instance snapshots (p. 379)
- Tutorial: Use tags to specify which DB instances to stop (p. 380)
- Using tags to enable backups in AWS Backup (p. 382)

**Overview of Amazon RDS resource tags**

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign arbitrary information to an Amazon RDS resource. You can use a tag key, for example, to define a category, and the tag value might be an item in that category. For example, you might define a tag key
Using tags for access control with IAM

You can use tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see Identity and access management in Amazon RDS (p. 1766).

Using tags to produce detailed billing reports

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your
billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using Cost Allocation Tags in the AWS Billing User Guide.

**Note**
You can add a tag to a snapshot, however, your bill will not reflect this grouping.

### Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances.

**Console**

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

**To add a tag to a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
   
   **Note**
   To filter the list of DB instances in the **Databases** pane, enter a text string for **Filter databases**. Only DB instances that contain the string appear.
3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose **Add**. The **Add tags** window appears.

   ![Add tags window](image)

6. Enter a value for **Tag key** and **Value**.
7. To add another tag, you can choose **Add another Tag** and enter a value for its **Tag key** and **Value**.

   Repeat this step as many times as necessary.
8. Choose **Add**.
To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
   
   **Note**
   
   To filter the list of DB instances in the Databases pane, enter a text string in the Filter databases box. Only DB instances that contain the string appear.
3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the Tags section.
5. Choose the tag you want to delete.
6. Choose Delete, and then choose Delete in the Delete tags window.

**AWS CLI**

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command `add-tags-to-resource`.
- To list the tags on an Amazon RDS resource, use the AWS CLI command `list-tags-for-resource`.
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command `remove-tags-from-resource`.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS (p. 385).

**RDS API**

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the `AddTagsToResource` operation.
- To list tags that are assigned to an Amazon RDS resource, use the `ListTagsForResource`.
- To remove tags from an Amazon RDS resource, use the `RemoveTagsFromResource` operation.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS (p. 385).

When working with XML using the Amazon RDS API, tags use the following schema:

```xml
<Tagging>
  <TagSet>
    <Tag>
      <TagKey>
        workload-type
      </TagKey>
      <Value>
        other
      </Value>
    </Tag>
  </TagSet>
</Tagging>
```
Using the AWS Tag Editor

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see Tag Editor in the AWS Resource Groups User Guide.

Copying tags to DB instance snapshots

When you create or restore a DB instance, you can specify that the tags from the DB instance are copied to snapshots of the DB instance. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB instance, and that any access policies for the DB snapshots also match those of the source DB instance.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB instance.
- Restoring a DB instance.

The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

<table>
<thead>
<tr>
<th>Tagging element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TagSet</td>
<td>A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.</td>
</tr>
<tr>
<td>Tag</td>
<td>A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.</td>
</tr>
<tr>
<td>Key</td>
<td>A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with <code>aws:</code> or <code>rds:</code>. The string can only contain only the set of Unicode letters, digits, white-space, <code>_</code> , <code>;</code> , <code>/', </code>=<code>, </code>+<code>, </code>-' (Java regex: <code>&quot;^[\p{L}\p{Z}\p{N}_.:/=+\-]*$&quot;</code>). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.</td>
</tr>
<tr>
<td>Value</td>
<td>A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with <code>aws:</code> or <code>rds:</code>. The string can only contain only the set of Unicode letters, digits, white-space, <code>_</code> , <code>;</code> , <code>/' , </code>=<code>, </code>+<code>, </code>-' (Java regex: <code>&quot;^[\p{L}\p{Z}\p{N}_.:/=+\-]*$&quot;</code>). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.</td>
</tr>
</tbody>
</table>
• Creating a read replica.
• Copying a DB snapshot.

In most cases, tags aren't copied by default. However, when you restore a DB instance from a DB
snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored
DB instance. If there are no new tags, RDS looks for the tags from the source DB instance for the DB
snapshot, and then adds those tags to the restored DB instance.

To prevent tags from source DB instances from being added to restored DB instances, we recommend
that you specify new tags when restoring a DB instance.

Note
If you include a value for the --tag-key parameter of the create-db-snapshot AWS CLI
command (or supply at least one tag to the CreateDBSnapshot API operation) then RDS doesn't
copy tags from the source DB instance to the new DB snapshot. This functionality applies even
if the source DB instance has the --copy-tags-to-snapshot (CopyTagsToSnapshot) option enabled. If you take this approach, you can create a copy of a DB instance from a DB
snapshot and avoid adding tags that don't apply to the new DB instance. After you create your
DB snapshot using the AWS CLI create-db-snapshot command (or the CreateDBSnapshot
Amazon RDS API operation), you can then add tags as described later in this topic.

Tutorial: Use tags to specify which DB instances to stop

Suppose that you're creating a number of DB instances in a development or test environment. You
need to keep all of these DB instances for several days. Some of the DB instances run tests overnight.
Other DB instances can be stopped overnight and started again the next day. The following example
shows how to assign a tag to those DB instances that are suitable to stop overnight. Then the example
shows how a script can detect which DB instances have that tag and then stop those DB instances. In this
example, the value portion of the key-value pair doesn't matter. The presence of the stoppable tag
signifies that the DB instance has this user-defined property.

To specify which DB instances to stop

1. Determine the ARN of a DB instance that you want to designate as stoppable.

The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across
AWS Regions, AWS accounts, and different types of resources that might have identical short
names. You can specify the ARN instead of the DB instance ID in CLI commands that operate on
DB instances. Substitute the name of your own DB instances for dev-test-db-instance. In
subsequent commands that use ARN parameters, substitute the ARN of your own DB instance. The
ARN includes your own AWS account ID and the name of the AWS Region where your DB instance is
located.

```bash
$ aws rds describe-db-instances --db-instance-identifier dev-test-db-instance
--query "[*].{DBInstance:DBInstanceArn}" --output text
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
```

2. Add the tag stoppable to this DB instance.

The name for this tag is chosen by you. Using a tag like this is an alternative to devising a naming
convention that encodes all the relevant information in the name of the DB instance (or other types
of resources). Because this example treats the tag as an attribute that is either present or absent, it
omits the Value= part of the --tags parameter.

```bash
$ aws rds add-tags-to-resource \
```

380
3. Confirm that the tag is present in the DB instance.

These commands retrieve the tag information for the DB instance in JSON format and in plain tab-separated text.

```bash
# aws rds list-tags-for-resource
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
{
  "TagList": [
    {
      "Key": "stoppable",
      "Value": "",
    }
  ]
}
aws rds list-tags-for-resource
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance --output text
TAGLIST stoppable
```

4. To stop all the DB instances that are designated as stoppable, prepare a list of all your DB instances. Loop through the list and check if each DB instance is tagged with the relevant attribute.

This Linux example uses shell scripting to save the list of DB instance ARNs to a temporary file and then perform CLI commands for each DB instance.

```bash
# aws rds describe-db-instances --query "*[].[DBInstanceArn]" --output text >tmp/db_instance_arns.lst
# for arn in $(cat /tmp/db_instance_arns.lst)
do
  match="$(aws rds list-tags-for-resource --resource-name $arn --output text | grep stoppable)"
  if [[ ! -z "$match" ]];
    then
echo "DB instance $arn is tagged as stoppable. Stopping it now."
  fi
# Note that you need to get the DB instance identifier from the ARN.
dbid=$(echo $arn | sed -e 's/.*://')
aws rds stop-db-instance --db-instance-identifier $dbid
done
```

You can run a script like this at the end of each day to make sure that nonessential DB instances are stopped. You might also schedule a job using a utility such as `cron` to perform such a check each night, in case some DB instances were left running by mistake. In that case, you might fine-tune the command that prepares the list of DB instances to check. The following command produces a list of your DB instances, but only the ones in `available` state. The script can ignore DB instances that are already stopped, because they will have different status values such as `stopped` or `stopping`.

```bash
# aws rds describe-db-instances \
```
Tip
Once you’re familiar with the general procedure of assigning tags and finding DB instances that have those tags, you can use the same technique to reduce costs in other ways. For example, in this scenario with DB instances used for development and testing, you might designate some DB instances to be deleted at the end of each day, or to have their DB instances changed to a small DB instance classes during times of expected low usage.

Using tags to enable backups in AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan.

This example assumes that you have already created a backup plan in AWS Backup. You use exactly the same tag for your DB instance that is in your backup plan, as shown in the following figure.

For more information about AWS Backup, see the [AWS Backup Developer Guide](#).

You can assign a tag to a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. The following examples are for the console and CLI.

**Console**

**To assign a tag to a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`
2. In the navigation pane, choose **Databases**.
3. Choose the link for the DB instance to which you want to assign a tag.
4. On the database details page, choose the **Tags** tab.
5. Under **Tags**, choose **Add tags**.
6. Under **Add tags**:
   a. For **Tag key**, enter `BackupPlan`.
   b. For **Value**, enter `Test`.
   c. Choose **Add**.

The result is shown under **Tags**.
To assign a tag to a DB instance

- Use the following CLI command:

  For Linux, macOS, or Unix:
  
  ```
  aws rds add-tags-to-resource \
  --resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db \
  --tags Key=BackupPlan,Value=Test
  ```

  For Windows:
  
  ```
  aws rds add-tags-to-resource ^
  --tags Key=BackupPlan,Value=Test
  ```

  The `add-tags-to-resource` CLI command returns no output.

To confirm that the DB instance is tagged

- Use the following CLI command:

  For Linux, macOS, or Unix:
  
  ```
  aws rds list-tags-for-resource \
  ```

  For Windows:
  
  ```
  aws rds list-tags-for-resource ^
  ```

  The `list-tags-for-resource` CLI command returns the following output:

```json
{
   "TagList": [
      {
         "Key": "BackupPlan",
         "Value": "Test"
      }
   ]
}
```
Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

```
arn:aws:rds:<region>:<account number>:<resourcetype>:<name>
```

<table>

</table>

**Getting an existing ARN**

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

**Console**

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource. For example, you can get the ARN for a DB instance from the **Configuration** tab of the DB instance details, as shown following.
AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

<table>
<thead>
<tr>
<th>AWS CLI command</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td>describe-event-subscriptions</td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td>describe-certificates</td>
<td>CertificateArn</td>
</tr>
</tbody>
</table>
For example, the following AWS CLI command gets the ARN for a DB instance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances 
--db-instance-identifier DBInstanceIdentifier 
--region us-west-2 
--query "[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

For Windows:

```bash
aws rds describe-db-instances ^
--db-instance-identifier DBInstanceIdentifier ^
--region us-west-2 ^
--query "[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```json
[
  {
    "DBInstanceIdentifier": "instance_id"
  }
]
```

**RDS API**

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.
<table>
<thead>
<tr>
<th>RDS API operation</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribeEventSubscriptions</td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td>DescribeCertificates</td>
<td>CertificateArn</td>
</tr>
<tr>
<td>DescribeDBParameterGroups</td>
<td>DBParameterGroupArn</td>
</tr>
<tr>
<td>DescribeDBClusterParameterGroups</td>
<td>DBClusterParameterGroupArn</td>
</tr>
<tr>
<td>DescribeDBInstances</td>
<td>DBInstanceArn</td>
</tr>
<tr>
<td>DescribeDBSecurityGroups</td>
<td>DBSecurityGroupArn</td>
</tr>
<tr>
<td>DescribeDBSnapshots</td>
<td>DBSnapshotArn</td>
</tr>
<tr>
<td>DescribeEvents</td>
<td>SourceArn</td>
</tr>
<tr>
<td>DescribeReservedDBInstances</td>
<td>ReservedDBInstanceArn</td>
</tr>
<tr>
<td>DescribeDBSubnetGroups</td>
<td>DBSubnetGroupArn</td>
</tr>
<tr>
<td>DescribeOptionGroups</td>
<td>OptionGroupArn</td>
</tr>
<tr>
<td>DescribeDBClusters</td>
<td>DBClusterArn</td>
</tr>
<tr>
<td>DescribeDBClusterSnapshots</td>
<td>DBClusterSnapshotArn</td>
</tr>
</tbody>
</table>
Working with storage for Amazon RDS DB instances

To specify how you want your data stored in Amazon RDS, choose a storage type and provide a storage size when you create or modify a DB instance. Later, you can increase the amount or change the type of storage by modifying the DB instance. For more information about which storage type to use for your workload, see Amazon RDS storage types (p. 53).

Topics
- Increasing DB instance storage capacity (p. 393)
- Managing capacity automatically with Amazon RDS storage autoscaling (p. 394)
- Modifying SSD storage settings for Provisioned IOPS (p. 399)

Increasing DB instance storage capacity

If you need space for additional data, you can scale up the storage of an existing DB instance. To do so, you can use the Amazon RDS Management Console, the Amazon RDS API, or the AWS Command Line Interface (AWS CLI). For information about storage limits, see Amazon RDS DB instance storage (p. 53).

Note
Scaling storage for Amazon RDS for Microsoft SQL Server DB instances is supported only for General Purpose SSD or Provisioned IOPS SSD storage types.

To monitor the amount of free storage for your DB instance so you can respond when necessary, we recommend that you create an Amazon CloudWatch alarm. For more information on setting CloudWatch alarms, see Using CloudWatch alarms.

Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is storage-optimization.

Note
Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

However, a special case is if you have a SQL Server DB instance and haven't modified the storage configuration since November 2017. In this case, you might experience a short outage of a few minutes when you modify your DB instance to increase the allocated storage. After the outage, the DB instance is online but in the storage-optimization state. Performance might be degraded during storage optimization.

Note
You can't reduce the amount of storage for a DB instance after storage has been allocated. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Console

To increase storage for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Enter a new value for **Allocated storage**. It must be greater than the current value.

   <table>
   <tr>
   <td>Storage type</td>
   <td>General Purpose (SSD)</td>
   </tr>
   <tr>
   <td>Allocated storage</td>
   <td>16384 GiB</td>
   </tr>
   </table>

   This instance supports multiple storage ranges between 20 and 16384 GiB. See all

   ![Scaling your instance storage can:](image)

   • Deplete the initial General Purpose (SSD) I/O credits, leading to longer conversion times. Learn more
   • Impact instance performance until operation completes. Learn more

6. Choose **Continue** to move to the next screen.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the storage changes to the DB instance immediately.

   Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. When the settings are as you want them, choose **Modify DB instance**.

### AWS CLI

To increase the storage for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

   Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage](p. 53).

### Amazon RDS API

To increase storage for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `ApplyImmediately` – Set this option to `True` to apply the storage changes immediately. Set this option to `False` (the default) to apply the changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage](p. 53).

### Managing capacity automatically with Amazon RDS storage autoscaling

If your workload is unpredictable, you can enable storage autoscaling for an Amazon RDS DB instance. To do so, you can use the Amazon RDS console, the Amazon RDS API, or the AWS CLI.

---

394
For example, you might use this feature for a new mobile gaming application that users are adopting rapidly. In this case, a rapidly increasing workload might exceed the available database storage. To avoid having to manually scale up database storage, you can use Amazon RDS storage autoscaling.

With storage autoscaling enabled, when Amazon RDS detects that you are running out of free database space it automatically scales up your storage. Amazon RDS starts a storage modification for an autoscaling-enabled DB instance when these factors apply:

- Free available space is less than 10 percent of the allocated storage.
- The low-storage condition lasts at least five minutes.
- At least six hours have passed since the last storage modification, or storage optimization has completed on the instance, whichever is longer.

The additional storage is in increments of whichever of the following is greater:

- 5 GiB
- 10 percent of currently allocated storage
- Storage growth prediction for 7 hours based on the FreeStorageSpace metrics change in the past hour. For more information on metrics, see Monitoring with Amazon CloudWatch.

The maximum storage threshold is the limit that you set for autoscaling the DB instance. It has the following constraints:

- You must set the maximum storage threshold to at least 10% more than the current allocated storage.

  For example, if you have DB instance with 1000 GiB of allocated storage, then set the maximum storage threshold to at least 1100 GiB. If you don't, you get an error such as Invalid max storage size for engine_name.

- You can't set the maximum storage threshold for autoscaling-enabled instances to a value greater than the maximum allocated storage.

  For example, SQL Server Standard Edition on db.m5.xlarge has a default allocated storage for the instance of 20 GiB (the minimum) and a maximum allocated storage of 16,384 GiB. The default maximum storage threshold for autoscaling is 1,000 GiB. If you use this default, the instance doesn't autoscale above 1,000 GiB. This is true even though the maximum allocated storage for the instance is 16,384 GiB.

  **Note**
  
  We recommend that you carefully choose the maximum storage threshold based on usage patterns and customer needs. If there are any aberrations in the usage patterns, the maximum storage threshold can prevent scaling storage to an unexpectedly high value when autoscaling predicts a very high threshold. After a DB instance has been autoscaled, its allocated storage can't be reduced.

**Limitations**

The following limitations apply to storage autoscaling:

- Autoscaling doesn't occur if the maximum storage threshold would be equaled or exceeded by the storage increment.
- Autoscaling can't completely prevent storage-full situations for large data loads. This is because further storage modifications can't be made for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.
If you perform a large data load, and autoscaling doesn't provide enough space, the database might remain in the storage-full state for several hours. This can harm the database.

- If you start a storage scaling operation at the same time that Amazon RDS starts an autoscaling operation, your storage modification takes precedence. The autoscaling operation is canceled.
- Autoscaling can't be used with magnetic storage.
- Autoscaling can't be used with the following previous-generation instance classes that have less than 6 TiB of orderable storage: db.m3.large, db.m3.xlarge, and db.m3.2xlarge.
- Autoscaling operations aren't logged by AWS CloudTrail. For more information on CloudTrail, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 686).

Although automatic scaling helps you to increase storage on your Amazon RDS DB instance dynamically, you should still configure the initial storage for your DB instance to an appropriate size for your typical workload.

**Enabling storage autoscaling for a new DB instance**

When you create a new Amazon RDS DB instance, you can choose whether to enable storage autoscaling. You can also set an upper limit on the storage that Amazon RDS can allocate for the DB instance.

**Note**

When you clone an Amazon RDS DB instance that has storage autoscaling enabled, that setting isn't automatically inherited by the cloned instance. The new DB instance has the same amount of allocated storage as the original instance. You can turn storage autoscaling on again for the new instance if the cloned instance continues to increase its storage requirements.

**Console**

**To enable storage autoscaling for a new DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database. On the Select engine page, choose your database engine and specify your DB instance information as described in Getting started with Amazon RDS (p. 99).
5. In the Storage autoscaling section, set the Maximum storage threshold value for the DB instance.
6. Specify the rest of your DB instance information as described in Getting started with Amazon RDS (p. 99).

**AWS CLI**

To enable storage autoscaling for a new DB instance, use the AWS CLI command `create-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Turns on storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:
• SupportsStorageAutoscaling – Indicates whether the DB instance or instance class supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

Amazon RDS API

To enable storage autoscaling for a new DB instance, use the Amazon RDS API operation CreateDBInstance. Set the following parameter:

• MaxAllocatedStorage – Turns on Amazon RDS storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API DescribeValidDbInstanceModifications operation for an existing instance, or the DescribeOrderableDBInstanceOptions operation before creating an instance. Check the following field in the return value:

• SupportsStorageAutoscaling – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

Changing the storage autoscaling settings for a DB instance

You can turn storage autoscaling on for an existing Amazon RDS DB instance. You can also change the upper limit on the storage that Amazon RDS can allocate for the DB instance.

Console

To change the storage autoscaling settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify, and choose Modify. The Modify DB instance page appears.
4. Change the storage limit in the Autoscaling section. For more information, see Modifying an Amazon RDS DB instance (p. 309).
5. When all the changes are as you want them, choose Continue and check your modifications.
6. On the confirmation page, review your changes. If they're correct, choose Modify DB Instance to save your changes. If they aren't correct, choose Back to edit your changes or Cancel to cancel your changes.

   Changing the storage autoscaling limit occurs immediately. This setting ignores the Apply immediately setting.

AWS CLI

To change the storage autoscaling settings for a DB instance, use the AWS CLI command modify-db-instance. Set the following parameter:

• --max-allocated-storage – Sets the upper limit on storage size, in gibibytes. If the value is greater than the --allocated-storage parameter, storage autoscaling is turned on. If the value is the same as the --allocated-storage parameter, storage autoscaling is turned off.
To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

**Amazon RDS API**

To change the storage autoscaling settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the `DescribeOrderableDBInstanceOptions` operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

**Turning off storage autoscaling for a DB instance**

If you no longer need Amazon RDS to automatically increase the storage for an Amazon RDS DB instance, you can turn off storage autoscaling. After you do, you can still manually increase the amount of storage for your DB instance.

**Console**

**To turn off storage autoscaling for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify and choose Modify. The Modify DB instance page appears.
4. Clear the Enable storage autoscaling check box in the Storage autoscaling section. For more information, see Modifying an Amazon RDS DB instance (p. 309).
5. When all the changes are as you want them, choose Continue and check the modifications.
6. On the confirmation page, review your changes. If they're correct, choose Modify DB Instance to save your changes. If they aren’t correct, choose Back to edit your changes or Cancel to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the Apply immediately setting.

**AWS CLI**

To turn off storage autoscaling for a DB instance, use the AWS CLI command `modify-db-instance` and the following parameter:
• `--max-allocated-storage` – Specify a value equal to the `--allocated-storage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

Amazon RDS API

To turn off storage autoscaling for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

• `MaxAllocatedStorage` – Specify a value equal to the `AllocatedStorage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

Modifying SSD storage settings for Provisioned IOPS

You can modify the settings for a DB instance that uses Provisioned IOPS SSD storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, and the amount of Provisioned IOPS that you require. You can choose from a range between 1,000 IOPS and 100 GiB of storage up to 80,000 IOPS and 64 TiB (64,000 GiB) of storage. The range depends on your database engine and instance type.

Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the amount of General Purpose SSD or magnetic storage allocated.

In most cases, scaling storage doesn't require any outage and doesn't degrade performance of the server. After you modify the storage IOPS for a DB instance, the status of the DB instance is `storage-optimization`.

**Note**
Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer.

Console

To change the Provisioned IOPS settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
   
   **Note**
   To filter the list of DB instances, for Filter databases enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.
3. Choose the DB instance with Provisioned IOPS that you want to modify.
4. Choose Modify.
5. On the Modify DB Instance page, choose Provisioned IOPS for Storage type and then provide a Provisioned IOPS value.
If the value you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message is displayed. This message gives the range of values required for the other parameter.

6. Choose **Continue**.
7. To apply the changes to the DB instance immediately, choose **Apply immediately** in the **Scheduling of modifications** section. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.

An immediate outage occurs when the storage type changes. For more information about storage, see [Amazon RDS DB instance storage (p. 53)](#).

8. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

The new value for allocated storage or for Provisioned IOPS appears in the **Status** column.

**AWS CLI**

To change the Provisioned IOPS setting for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--storage-type` – Set to `io1` for Provisioned IOPS.
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--iops` – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.
- `--apply-immediately` – Use `--apply-immediately` to apply changes immediately. Use `--no-apply-immediately` (the default) to apply changes during the next maintenance window.

**Amazon RDS API**

To change the Provisioned IOPS settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `StorageType` – Set to `io1` for Provisioned IOPS.
- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `Iops` – The new IOPS rate for the DB instance, expressed in I/O operations per second.
- `ApplyImmediately` – Set this option to `True` to apply changes immediately. Set this option to `False` (the default) to apply changes during the next maintenance window.
Deleting a DB instance

To delete a DB instance, you must do the following:

- Provide the name of the instance
- Enable or disable the option to take a final DB snapshot of the instance
- Enable or disable the option to retain automated backups

If you delete a DB instance that has read replicas in the same AWS Region, each read replica is promoted to a standalone DB instance. For more information, see Promoting a read replica to be a standalone DB instance (p. 361). If your DB instance has read replicas in different AWS Regions, see Cross-Region replication considerations (p. 371) for information related to deleting the source DB instance for a cross-Region read replica.

**Note**
When the status for a DB instance is deleting, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

Deletion protection

You can only delete instances that don't have deletion protection enabled. When you create or modify a DB instance, you have the option to enable deletion protection so that users can't delete the DB instance. Deletion protection is disabled by default for you when you use AWS CLI and API commands. Deletion protection is enabled for you when you use the AWS Management Console to create a production DB instance. However, Amazon RDS enforces deletion protection when you use the console, the CLI, or the API to delete a DB instance. To delete a DB instance that has deletion protection enabled, first modify the instance and disable deletion protection. Enabling or disabling deletion protection doesn't cause an outage.

Creating a final snapshot and retaining automated backups

When you delete a DB instance, you can choose to do one or both of the following:

- Create a final DB snapshot.
  - To be able to restore your deleted DB instance later, create a final DB snapshot. The final snapshot is retained, along with any manual snapshots that were taken.
  - To delete a DB instance quickly, you can skip creating a final DB snapshot.

  **Note**
  You can't create a final DB snapshot of your DB instance if it has the status creating, failed, incompatible-restore, or incompatible-network. For more information, see Viewing Amazon RDS DB instance status (p. 497).

- Retain automated backups.
  - Your automated backups are retained for the retention period that is set on the DB instance at the time when you delete it. This set retention period occurs whether or not you choose to create a final DB snapshot.
  - If you don't choose to retain automated backups, your automated backups in the same AWS Region as the DB instance are deleted. They can't be recovered after you delete the DB instance.
Note
Automated backups that are replicated to another AWS Region are retained even if you choose not to retain automated backups. For more information, see Replicating automated backups to another AWS Region (p. 417).

- You typically don’t need to retain automated backups if you create a final DB snapshot.
- To delete a retained automated backup, follow the instructions in Deleting retained automated backups (p. 412).

Important
If you skip the final DB snapshot, to restore your DB instance do one of the following:

- Use an earlier manual snapshot of the DB instance to restore the DB instance to that DB snapshot's point in time.
- Retain automated backups. You can use them to restore your DB instance during your retention period, but not after your retention period has ended.

Note
Regardless of your choice, manual DB snapshots aren't deleted. For more information on snapshots, see Creating a DB snapshot (p. 428).

Deleting a DB instance
You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a DB instance can vary depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

Note
You can't delete a DB instance when deletion protection is enabled for it. For more information, see Deletion protection (p. 401).
You can disable deletion protection by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Console
To delete a DB instance
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to delete.
3. For Actions, choose Delete.
4. To create a final DB snapshot for the DB instance, choose Create final snapshot?.
5. If you chose to create a final snapshot, enter the Final snapshot name.
6. To retain automated backups, choose Retain automated backups.
7. Enter delete me in the box.
8. Choose Delete.

AWS CLI
To delete a DB instance by using the AWS CLI, call the delete-db-instance command with the following options:

- --db-instance-identifier
Deleting a DB instance

Example With a final snapshot and no retained automated backups

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance \
  --db-instance-identifier mydbinstance \
  --final-db-snapshot-identifier mydbinstancefinalsnapshot \
  --delete-automated-backups
```

For Windows:

```bash
aws rds delete-db-instance ^
  --db-instance-identifier mydbinstance ^
  --final-db-snapshot-identifier mydbinstancefinalsnapshot ^
  --delete-automated-backups
```

Example With retained automated backups and no final snapshot

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance \
  --db-instance-identifier mydbinstance \
  --skip-final-snapshot \
  --no-delete-automated-backups
```

For Windows:

```bash
aws rds delete-db-instance ^
  --db-instance-identifier mydbinstance ^
  --skip-final-snapshot ^
  --no-delete-automated-backups
```

RDS API

To delete a DB instance by using the Amazon RDS API, call the `DeleteDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`
Deleting a Multi-AZ DB cluster

You can delete a DB Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a Multi-AZ DB cluster can vary depending on certain factors. These are the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

You can’t delete a Multi-AZ DB cluster when deletion protection is turned on for it. For more information, see Deletion protection (p. 401). You can turn off deletion protection by modifying the Multi-AZ DB cluster. For more information, see Modifying a Multi-AZ DB cluster (p. 324).

Console

To delete a Multi-AZ DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Multi-AZ DB cluster that you want to delete.
3. For Actions, choose Delete.
4. Choose Create final snapshot? to create a final DB snapshot for the Multi-AZ DB cluster.
   If you create a final snapshot, enter a name for Final snapshot name.
5. Choose Retain automated backups to retain automated backups.
6. Enter delete me in the box.
7. Choose Delete.

AWS CLI

To delete a Multi-AZ DB cluster by using the AWS CLI, call the delete-db-cluster command with the following options:

- --db-cluster-identifier
- --final-db-snapshot-identifier or --skip-final-snapshot

Example With a final snapshot

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster
    --db-cluster-identifier mymultiazdbcluster
    --final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

For Windows:

```bash
aws rds delete-db-instance
    --db-cluster-identifier mymultiazdbcluster
    --final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```

Example With no final snapshot

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster
    --db-cluster-identifier mymultiazdbcluster
    --final-db-snapshot-identifier mymultiazdbclusterfinalsnapshot
```
Deleting a Multi-AZ DB cluster

aws rds delete-db-instance
   --db-cluster-identifier mymultiazdbcluster
   --skip-final-snapshot

For Windows:

aws rds delete-db-instance ^
   --db-cluster-identifier mymultiazdbcluster ^
   --skip-final-snapshot

RDS API

To delete a Multi-AZ DB cluster by using the Amazon RDS API, call the DeleteDBCluster operation with the following parameters:

- DBClusterIdentifier
- FinalDBSnapshotIdentifier or SkipFinalSnapshot
Backing up and restoring an Amazon RDS DB instance

This section shows how to back up and restore a DB instance.

• Restoring a Multi-AZ DB cluster to a specified time (p. 483)
• Deleting a snapshot (p. 486)
• Tutorial: Restore an Amazon RDS DB instance from a DB snapshot (p. 488)
Working with backups

Amazon RDS creates and saves automated backups of your DB instance during the backup window of your DB instance. RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period.

Automated backups follow these rules:

- Your DB instance must be in the AVAILABLE state for automated backups to occur. Automated backups don't occur while your DB instance is in a state other than AVAILABLE, for example STORAGE_FULL.
- Automated backups don't occur while a DB snapshot copy is running in the same AWS Region for the same DB instance.

You can also back up your DB instance manually, by manually creating a DB snapshot. For more information about creating a DB snapshot, see Creating a DB snapshot (p. 428).

The first snapshot of a DB instance contains the data for the full DB instance. Subsequent snapshots of the same DB instance are incremental, which means that only the data that has changed after your most recent snapshot is saved.

You can copy both automatic and manual DB snapshots, and share manual DB snapshots. For more information about copying a DB snapshot, see Copying a snapshot (p. 438). For more information about sharing a DB snapshot, see Sharing a DB snapshot (p. 452).

Topics

- Backup storage (p. 407)
- Backup window (p. 408)
- Backup retention period (p. 409)
- Enabling automated backups (p. 409)
- Retaining automated backups (p. 411)
- Deleting retained automated backups (p. 412)
- Disabling automated backups (p. 413)

Backup storage

Your Amazon RDS backup storage for each AWS Region is composed of the automated backups and manual DB snapshots for that Region. Total backup storage space equals the sum of the storage for all backups in that Region. Moving a DB snapshot to another Region increases the backup storage in the destination Region. Backups are stored in Amazon S3.

For more information about backup storage costs, see Amazon RDS pricing.

If you chose to retain automated backups when you delete a DB instance, the automated backups are saved for the full retention period. If you don't choose Retain automated backups when you delete a DB
instance, all automated backups are deleted with the DB instance. After they are deleted, the automated backups can't be recovered. If you choose to have Amazon RDS create a final DB snapshot before it deletes your DB instance, you can use that to recover your DB instance. Or you can use a previously created manual snapshot. Manual snapshots are not deleted. You can have up to 100 manual snapshots per Region.

**Backup window**

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends, until it finishes. The backup window can't overlap with the weekly maintenance window for the DB instance.

During the automatic backup window, storage I/O might be suspended briefly while the backup process initializes (typically under a few seconds). You might experience elevated latencies for a few minutes during backups for Multi-AZ deployments. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

Automated backups might occasionally be skipped if the DB instance has a heavy workload at the time a backup is supposed to start. If a backup is skipped, you can still do a point-in-time-recovery (PITR), and a backup is still attempted during the next backup window. For more information on PITR, see [Restoring a DB instance to a specified time](p. 480).

If you don't specify a preferred backup window when you create the DB instance, Amazon RDS assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Time Block</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>03:00–11:00 UTC</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>03:00–11:00 UTC</td>
</tr>

</tbody>
</table>
Backup retention period

You can set the backup retention period when you create a DB instance. If you don’t set the backup retention period, the default backup retention period is one day if you create the DB instance using the Amazon RDS API or the AWS CLI. The default backup retention period is seven days if you create the DB instance using the console.

After you create a DB instance, you can modify the backup retention period. You can set the backup retention period to between 0 and 35 days. Setting the backup retention period to 0 disables automated backups. Manual snapshot limits (100 per Region) do not apply to automated backups.

Automated backups aren’t created while a DB instance is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn’t include time spent in the stopped state when the backup retention window is calculated.

**Important**
An outage occurs if you change the backup retention period from 0 to a nonzero value or from a nonzero value to 0. This applies to both Single-AZ and Multi-AZ DB instances.

### Enabling automated backups

If your DB instance doesn’t have automated backups enabled, you can enable them at any time. You enable automated backups by setting the backup retention period to a positive nonzero value. When automated backups are enabled, your RDS instance and database is taken offline and a backup is immediately created.

**Note**
If you manage your backups in AWS Backup, you can’t enable automated backups. For more information, see Using AWS Backup to manage automated backups (p. 415).
Console

To enable automated backups immediately
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
4. For Backup retention period, choose a positive nonzero value, for example 3 days.
5. Choose Continue.
6. Choose Apply immediately.
7. On the confirmation page, choose Modify DB instance to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI modify-db-instance command.

Include the following parameters:

- --db-instance-identifier
- --backup-retention-period
- --apply-immediately or --no-apply-immediately

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --backup-retention-period 3 \
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --backup-retention-period 3 ^
   --apply-immediately
```

RDS API

To enable automated backups, use the RDS API ModifyDBInstance operation with the following required parameters:

- DBInstanceIdentifier
- BackupRetentionPeriod
Viewing automated backups

To view your automated backups, choose Automated backups in the navigation pane. To view individual snapshots associated with an automated backup, choose Snapshots in the navigation pane. Alternatively, you can describe individual snapshots associated with an automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe the automated backups for your existing DB instances using the AWS CLI, use one of the following commands:

```bash
aws rds describe-db-instance-automated-backups --db-instance-identifier DBInstanceIdentifier
```

or

```bash
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe the retained automated backups for your existing DB instances using the RDS API, call the DescribeDBInstanceAutomatedBackups action with one of the following parameters:

- DBInstanceIdentifier
- DbiResourceId

Retaining automated backups

When you delete a DB instance, you can retain automated backups.

Retained automated backups contain system snapshots and transaction logs from a DB instance. They also include your DB instance properties like allocated storage and DB instance class, which are required to restore it to an active instance.

You can retain automated backups for RDS instances running the MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server engines.

You can restore or remove retained automated backups using the AWS Management Console, RDS API, and AWS CLI.

Topics
- Retention period (p. 411)
- Viewing retained backups (p. 412)
- Restoration (p. 412)
- Retention costs (p. 412)
- Limitations and recommendations (p. 412)

Retention period

The system snapshots and transaction logs in a retained automated backup expire the same way that they expire for the source DB instance. Because there are no new snapshots or logs created for this instance, the retained automated backups eventually expire completely. Effectively, they live as long their last system snapshot would have done, based on the settings for retention period the source instance had when you deleted it. Retained automated backups are removed by the system after their last system snapshot expires.
You can remove a retained automated backup in the same way that you can delete a DB instance. You can remove retained automated backups using the console or the RDS API operation `DeleteDBInstanceAutomatedBackup`.

Final snapshots are independent of retained automated backups. We strongly suggest that you take a final snapshot even if you retain automated backups, because the retained automated backups eventually expire. The final snapshot doesn't expire.

**Viewing retained backups**

To view your retained automated backups, choose `Automated backups` in the navigation pane, then choose `Retained`. To view individual snapshots associated with a retained automated backup, choose `Snapshots` in the navigation pane. Alternatively, you can describe individual snapshots associated with a retained automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe your retained automated backups using the AWS CLI, use the following command:

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe your retained automated backups using the RDS API, call the `DescribeDBInstanceAutomatedBackups` action with the `DbiResourceId` parameter.

**Restoration**

For information on restoring DB instances from automated backups, see [Restoring a DB instance to a specified time (p. 480)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_MigrateAutomatedBackups.html).

**Retention costs**

The cost of a retained automated backup is the cost of total storage of the system snapshots that are associated with it. There is no additional charge for transaction logs or instance metadata. All other pricing rules for backups apply to restorable instances.

For example, suppose that your total allocated storage of running instances is 100 GB. Suppose also that you have 50 GB of manual snapshots plus 75 GB of system snapshots associated with a retained automated backup. In this case, you are charged only for the additional 25 GB of backup storage, like this: (50 GB + 75 GB) – 100 GB = 25 GB.

**Limitations and recommendations**

The following limitations apply to retained automated backups:

- The maximum number of retained automated backups in one AWS Region is 40. It's not included in the DB instances limit. You can have 40 running DB instances and an additional 40 retained automated backups at the same time.
- Retained automated backups don't contain information about parameters or option groups.
- You can restore a deleted instance to a point in time that is within the retention period at the time of delete.
- You can't modify a retained automated backup. That's because it consists of system backups, transaction logs, and the DB instance properties that existed at the time that you deleted the source instance.

**Deleting retained automated backups**

You can delete retained automated backups when they are no longer needed.
Disabling automated backups

**Console**

**To delete a retained automated backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. On the **Retained** tab, choose the retained automated backup that you want to delete.
4. For **Actions**, choose **Delete**.
5. On the confirmation page, enter `delete me` and choose **Delete**.

**AWS CLI**

You can delete a retained automated backup by using the AWS CLI command `delete-db-instance-automated-backup` with the following option:

- `--dbi-resource-id` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by running the AWS CLI command `describe-db-instance-automated-backups`.

**Example**

The following example deletes the retained automated backup with source DB instance resource identifier `db-123ABCEXAMPLE`.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance-automated-backup \
   --dbi-resource-id db-123ABCEXAMPLE
```

For Windows:

```bash
aws rds delete-db-instance-automated-backup ^
   --dbi-resource-id db-123ABCEXAMPLE
```

**RDS API**

You can delete a retained automated backup by using the Amazon RDS API operation `DeleteDBInstanceAutomatedBackup` with the following parameter:

- `DbiResourceId` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup using the Amazon RDS API operation `DescribeDBInstanceAutomatedBackups`.

**Disabling automated backups**

You might want to temporarily disable automated backups in certain situations, for example while loading large amounts of data.

**Important**

We highly discourage disabling automated backups because it disables point-in-time recovery. Disabling automatic backups for a DB instance deletes all existing automated backups for the
instance. If you disable and then re-enable automated backups, you can restore starting only from the time you re-enabled automated backups.

**Console**

**To disable automated backups immediately**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **Backup retention period**, choose **0 days**.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. On the confirmation page, choose **Modify DB instance** to save your changes and disable automated backups.

**AWS CLI**

To disable automated backups immediately, use the **modify-db-instance** command and set the backup retention period to 0 with **--apply-immediately**.

**Example**

The following example immediately disabled automatic backups.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 0 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 0 ^
  --apply-immediately
```

To know when the modification is in effect, call **describe-db-instances** for the DB instance until the value for backup retention period is 0 and mydbinstance status is available.

```bash
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

**RDS API**

To disable automated backups immediately, call the **ModifyDBInstance** operation with the following parameters:

- **DBInstanceIdentifier** = mydbinstance
- **BackupRetentionPeriod** = 0
Using AWS Backup to manage automated backups

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan. For more information, see Using tags to enable backups in AWS Backup (p. 382).

**Note**

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the DB snapshot quota for RDS. Backups that were created with AWS Backup have names ending in `awsbackup:backup-job-number`.

For more information about AWS Backup, see the [AWS Backup Developer Guide](https://docs.aws.amazon.com/backup/latest/userguide/).

**To view backups managed by AWS Backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Backup service** tab.

Your AWS Backup backups are listed under **Backup service snapshots**.

Automated backups with unsupported MySQL storage engines

For the MySQL DB engine, automated backups are only supported for the InnoDB storage engine. Use of these features with other MySQL storage engines, including MyISAM, can lead to unreliable behavior while restoring from backups. Specifically, since storage engines like MyISAM don't support reliable crash recovery, your tables can be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command, for example: `ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;`
- If you choose to use MyISAM, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR` command. For more information, see `REPAIR TABLE statement` in the MySQL documentation. However, as noted in the MySQL documentation, there is a good chance that you might not be able to recover all your data.
- If you want to take a snapshot of your MyISAM tables before restoring, follow these steps:
  1. Stop all activity to your MyISAM tables (that is, close all sessions).
You can close all sessions by calling the `mysql.rds_kill` command for each process that is returned from the `SHOW FULL PROCESSLIST` command.

2. Lock and flush each of your MyISAM tables. For example, the following commands lock and flush two tables named `myisam_table1` and `myisam_table2`:

```sql
mysql> FLUSH TABLES myisam_table1, myisam_table2 WITH READ LOCK;
```

3. Create a snapshot of your DB instance. When the snapshot has completed, release the locks and resume activity on the MyISAM tables. You can release the locks on your tables using the following command:

```sql
mysql> UNLOCK TABLES;
```

These steps force MyISAM to flush data stored in memory to disk, which ensures a clean start when you restore from a DB snapshot. For more information on creating a DB snapshot, see Creating a DB snapshot (p. 428).

### Automated backups with unsupported MariaDB storage engines

For the MariaDB DB engine, automated backups are only supported with the InnoDB storage engine. Use of these features with other MariaDB storage engines, including Aria, might lead to unreliable behavior while restoring from backups. Even though Aria is a crash-resistant alternative to MyISAM, your tables can still be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing Aria tables to InnoDB tables, you can use the `ALTER TABLE` command. For example:
  ```sql
  ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;
  ```

- If you choose to use Aria, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR TABLE` command. For more information, see [http://mariadb.com/kb/en/mariadb/repair-table/](http://mariadb.com/kb/en/mariadb/repair-table/).

- If you want to take a snapshot of your Aria tables before restoring, follow these steps:
  1. Stop all activity to your Aria tables (that is, close all sessions).
  2. Lock and flush each of your Aria tables.
  3. Create a snapshot of your DB instance. When the snapshot has completed, release the locks and resume activity on the Aria tables. These steps force Aria to flush data stored in memory to disk, thereby ensuring a clean start when you restore from a DB snapshot.
Replicating automated backups to another AWS Region

For added disaster recovery capability, you can configure your Amazon RDS database instance to replicate snapshots and transaction logs to a destination AWS Region of your choice. When backup replication is configured for a DB instance, RDS initiates a cross-Region copy of all snapshots and transaction logs as soon as they are ready on the DB instance.

DB snapshot copy charges apply to the data transfer. After the DB snapshot is copied, standard charges apply to storage in the destination Region. For more details, see RDS Pricing.

Backup replication is available for RDS DB instances running the following database engines:

- Oracle Database version 12.1.0.2.v10 and higher
- PostgreSQL version 9.6 and higher
- Microsoft SQL Server version 2012 and higher

Backup replication isn't supported for encrypted SQL Server DB instances. Make sure to clear the Enable encryption check box when you create a SQL Server DB instance for which you want to use backup replication.

For an example of using backup replication, see the AWS online tech talk Managed Disaster Recovery with Amazon RDS for Oracle Cross-Region Automated Backups.

Topics

- AWS Region support (p. 417)
- Enabling cross-Region automated backups (p. 419)
- Finding information about replicated backups (p. 421)
- Restoring to a specified time from a replicated backup (p. 424)
- Stopping automated backup replication (p. 425)
- Deleting replicated backups (p. 426)

AWS Region support

Backup replication is supported between the following AWS Regions.

<table>
<thead>
<tr>
<th>Source Region</th>
<th>Destination Regions available</th>

</tbody>
</table>
Enabling cross-Region automated backups

You can enable backup replication on new or existing DB instances using the Amazon RDS console. You can also use the `start-db-instance-automated-backups-replication` AWS CLI command or the `StartDBInstanceAutomatedBackupsReplication` RDS API operation.

**Note**
To be able to replicate automated backups, make sure to enable them. For more information, see Enabling automated backups (p. 409).

### Console

You can enable backup replication for a new or existing DB instance:

- For a new DB instance, enable it when you launch the instance. For more information, see Settings for DB instances (p. 178).
- For an existing DB instance, use the following procedure.

**To enable backup replication for an existing DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. On the **Current Region** tab, choose the DB instance for which you want to enable backup replication.

4. For **Actions**, choose **Manage cross-Region replication**.

5. Under **Backup replication**, choose **Enable replication to another AWS Region**.

6. Choose the **Destination Region**.

7. Choose the **Replicated backup retention period**.

8. If you've enabled encryption on the source DB instance, choose the **AWS KMS key** for encrypting the backups.

9. Choose **Save**.

In the source Region, replicated backups are listed on the **Current Region** tab of the **Automated backups** page. In the destination Region, replicated backups are listed on the **Replicated backups** tab of the **Automated backups** page.

**AWS CLI**

Enable backup replication by using the `start-db-instance-automated-backups-replication` AWS CLI command.

The following CLI example replicates automated backups from a DB instance in the US West (Oregon) Region to the US East (N. Virginia) Region. It also encrypts the replicated backups, using an AWS KMS key in the destination Region.

**Note**

If you encrypt the backups, you must also include the `--source-region` option. Specifying the source AWS Region autogenerates a presigned URL that is a valid request for the operation that can be executed in the source Region.

For more information on presigned URLs, see *Authenticating Requests: Using Query Parameters (AWS Signature Version 4)* in the *Amazon Simple Storage Service API Reference* and *Signature Version 4 signing process* in the *AWS General Reference*.

**To enable backup replication**

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```
  aws rds start-db-instance-automated-backups-replication \
  --region us-east-1 \
  --kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" \
  --source-region us-west-2 \
  --backup-retention-period 7
  ```

  For Windows:

  ```
  aws rds start-db-instance-automated-backups-replication ^
  --region us-east-1 ^
  --kms-key-id "arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE" ^
  --source-region us-west-2 ^
  --backup-retention-period 7
  ```
RDS API

Enable backup replication by using the `StartDBInstanceAutomatedBackupsReplication` RDS API operation with the following parameters:

- Region
- SourceDBInstanceArn
- BackupRetentionPeriod
- KmsKeyId (optional)
- PreSignedUrl (required if you use KmsKeyId)

**Note**

If you encrypt the backups, you must also include a presigned URL. For more information on presigned URLs, see [Authenticating Requests: Using Query Parameters (AWS Signature Version 4)](https://docs.aws.amazon.com/AmazonS3/latest/dev/using-presigned-url.html) in the [Amazon Simple Storage Service API Reference](https://docs.aws.amazon.com/AmazonS3/latest/API/referencedata.html) and [Signature Version 4 signing process](https://docs.aws.amazon.com/AmazonS3/latest/dev/sigv4-manual.html) in the [AWS General Reference](https://docs.aws.amazon.com/AmazonS3/latest/dev/signature-version-4.html).

Finding information about replicated backups

You can use the following CLI commands to find information about replicated backups:

- `describe-source-regions`
- `describe-db-instances`
- `describe-db-instance-automated-backups`

The following `describe-source-regions` example lists the source AWS Regions from which automated backups can be replicated to the US West (Oregon) destination Region.

**To show information about source Regions**

- Run the following command.

  ```bash
  aws rds describe-source-regions --region us-west-2
  ```

The output shows that backups can be replicated from US East (N. Virginia), but not from US East (Ohio) or US West (N. California), into US West (Oregon).

```json
{
  "SourceRegions": [
    ...
    {
      "RegionName": "us-east-1",
      "Endpoint": "https://rds.us-east-1.amazonaws.com",
      "Status": "available",
      "SupportsDBInstanceAutomatedBackupsReplication": true
    },
    {
      "RegionName": "us-east-2",
      "Endpoint": "https://rds.us-east-2.amazonaws.com",
      "Status": "available",
      "SupportsDBInstanceAutomatedBackupsReplication": false
    },
    "RegionName": "us-west-1",
    "Endpoint": "https://rds.us-west-1.amazonaws.com",
    "Status": "available",
    "SupportsDBInstanceAutomatedBackupsReplication": false
  ]
}
```
The following `describe-db-instances` example shows the automated backups for a DB instance.

### To show the replicated backups for a DB instance

- Run one of the following commands.

  For Linux, macOS, or Unix:
  ```bash
  aws rds describe-db-instances \
  --db-instance-identifier mydatabase
  ```

  For Windows:
  ```bash
  aws rds describe-db-instances ^
  --db-instance-identifier mydatabase
  ```

  The output includes the replicated backups.

  ```json
  {    "DBInstances": [      {        "StorageEncrypted": false,        "Endpoint": {          "HostedZoneId": "Z1PVIF0B656C1W",          "Port": 1521,          ...        },        "BackupRetentionPeriod": 7,        "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE"}]      }    ]  }
  ```

The following `describe-db-instance-automated-backups` example shows the automated backups for a DB instance.

### To show automated backups for a DB instance

- Run one of the following commands.

  For Linux, macOS, or Unix:
  ```bash
  aws rds describe-db-instance-automated-backups \
  --db-instance-identifier mydatabase
  ```

  For Windows:
  ```bash
  aws rds describe-db-instance-automated-backups ^
  --db-instance-identifier mydatabase
  ```
Finding information about replicated backups

The output shows the source DB instance and automated backups in US West (Oregon), with backups replicated to US East (N. Virginia).

```
{
   "DBInstanceAutomatedBackups": [
      {
         "DbiResourceId": "db-L2IJCEXJFP7XQ7HOJ4SIEXAMPLE",
         "BackupRetentionPeriod": 7,
         "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJFP7XQ7HOJ4SIEXAMPLE"},
         "Region": "us-west-2",
         "DBInstanceIdentifier": "mydatabase",
         "RestoreWindow": {"EarliestTime": "2020-10-26T01:09:07Z", "LatestTime": "2020-10-31T19:01:23Z"},
      }
   ]
}
```

The following `describe-db-instance-automated-backups` example uses the `--db-instance-automated-backups-arn` option to show the replicated backups in the destination Region.

**To show replicated backups**

- Run one of the following commands.
  
  For Linux, macOS, or Unix:

  ```bash
  aws rds describe-db-instance-automated-backups \
  --db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJFP7XQ7HOJ4SIEXAMPLE"
  ```

  For Windows:

  ```bash
  aws rds describe-db-instance-automated-backups ^
  --db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJFP7XQ7HOJ4SIEXAMPLE"
  ```

  The output shows the source DB instance in US West (Oregon), with replicated backups in US East (N. Virginia).

```
{
   "DBInstanceAutomatedBackups": [
      {
         "DbiResourceId": "db-L2IJCEXJFP7XQ7HOJ4SIEXAMPLE",
         "Region": "us-west-2",

}

**Restoring to a specified time from a replicated backup**

You can restore a DB instance to a specific point in time from a replicated backup using the Amazon RDS console. You can also use the `restore-db-instance-to-point-in-time` AWS CLI command or the `RestoreDBInstanceToPointInTime` RDS API operation.

For general information on point-in-time recovery (PITR), see Restoring a DB instance to a specified time (p. 480).

**Note**

On RDS for SQL Server, option groups aren't copied across AWS Regions when automated backups are replicated. If you've associated a custom option group with your RDS for SQL Server DB instance, you can re-create that option group in the destination Region. Then restore the DB instance in the destination Region and associate the custom option group with it. For more information, see Working with option groups (p. 262).

**Console**

**To restore a DB instance to a specified time from a replicated backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the destination Region (where backups are replicated to) from the Region selector.
3. In the navigation pane, choose Automated backups.
4. On the Replicated backups tab, choose the DB instance that you want to restore.
5. For Actions, choose Restore to point in time.
6. Choose Latest restorable time to restore to the latest possible time, or choose Custom to choose a time.

   If you chose Custom, enter the date and time that you want to restore the instance to.

   **Note**

   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

7. For DB instance identifier, enter the name of the target restored DB instance.
8. (Optional) Choose other options as needed, such as enabling autoscaling.
9. Choose Restore to point in time.

**AWS CLI**

Use the `restore-db-instance-to-point-in-time` AWS CLI command to create a new DB instance.

**To restore a DB instance to a specified time from a replicated backup**

- Run one of the following commands.
For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
--source-db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEXAMPLE" \
--target-db-instance-identifier mytargetdbinstance \
--restore-time 2020-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
--target-db-instance-identifier mytargetdbinstance ^
--restore-time 2020-10-14T23:45:00.000Z
```

**RDS API**

To restore a DB instance to a specified time, call the `RestoreDBInstanceToPointInTime` Amazon RDS API operation with the following parameters:

- `SourceDBInstanceAutomatedBackupsArn`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

**Stopping automated backup replication**

You can stop backup replication for DB instances using the Amazon RDS console. You can also use the `stop-db-instance-automated-backups-replication` AWS CLI command or the `StopDBInstanceAutomatedBackupsReplication` RDS API operation.

Replicated backups are retained, subject to the backup retention period set when they were created.

**Console**

Stop backup replication from the **Automated backups** page in the source Region.

**To stop backup replication to an AWS Region**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the source Region from the **Region selector**.
3. In the navigation pane, choose **Automated backups**.
4. On the **Current Region** tab, choose the DB instance for which you want to stop backup replication.
5. For **Actions**, choose **Manage cross-Region replication**.
6. Under **Backup replication**, clear the **Enable replication to another AWS Region** check box.
7. Choose **Save**.

Replicated backups are listed on the **Retained** tab of the **Automated backups** page in the destination Region.
AWS CLI

Stop backup replication by using the `stop-db-instance-automated-backups-replication` AWS CLI command.

The following CLI example stops automated backups of a DB instance from replicating in the US West (Oregon) Region.

**To stop backup replication**

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```bash
  ```

  For Windows:

  ```bash
  ```

RDS API

Stop backup replication by using the `StopDBInstanceAutomatedBackupsReplication` RDS API operation with the following parameters:

- Region
- SourceDBInstanceArn

Deleting replicated backups

You can delete replicated backups for DB instances using the Amazon RDS console. You can also use the `delete-db-instance-automated-backups` AWS CLI command or the `DeleteDBInstanceAutomatedBackup` RDS API operation.

**Console**

Delete replicated backups in the destination Region from the Automated backups page.

**To delete replicated backups**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose the destination Region from the Region selector.
3. In the navigation pane, choose Automated backups.
4. On the Replicated backups tab, choose the DB instance for which you want to delete the replicated backups.
5. For Actions, choose Delete.
6. On the confirmation page, enter delete me and choose Delete.
AWS CLI

Delete replicated backups by using the `delete-db-instance-automated-backup` AWS CLI command.

You can use the `describe-db-instances` CLI command to find the Amazon Resource Names (ARNs) of the replicated backups. For more information, see Finding information about replicated backups (p. 421).

To delete replicated backups

- Run one of the following commands.

  For Linux, macOS, or Unix:

  ```bash
  aws rds delete-db-instance-automated-backup \
  --db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJF7XQ7HOJ4SIEXAMPLE"
  ```

  For Windows:

  ```cmd
  aws rds delete-db-instance-automated-backup ^
  --db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJF7XQ7HOJ4SIEXAMPLE"
  ```

RDS API

Delete replicated backups by using the `DeleteDBInstanceAutomatedBackup` RDS API operation with the `DBInstanceAutomatedBackupsArn` parameter.
Creating a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. Creating this DB snapshot on a Single-AZ DB instance results in a brief I/O suspension that can last from a few seconds to a few minutes, depending on the size and class of your DB instance. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size your databases. Since the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

**Note**
For PostgreSQL DB instances, data in unlogged tables might not be restored from snapshots. For more information, see Best practices for working with PostgreSQL (p. 169).

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups of MariaDB, MySQL, and PostgreSQL data, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see Exporting DB snapshot data to Amazon S3 (p. 461).

You can create a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To create a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. In the list of DB instances, choose the DB instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

   The **Take DB snapshot** window appears.
5. Enter the name of the snapshot in the **Snapshot name** box.
6. Choose **Take snapshot**.
The **Snapshots** page appears, with the new DB snapshot's status shown as *Creating*. After its status is *Available*, you can see its creation time.

**AWS CLI**

When you create a DB snapshot using the AWS CLI, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the AWS CLI `create-db-snapshot` command with the following parameters:

- `--db-instance-identifier`
- `--db-snapshot-identifier`

In this example, you create a DB snapshot called `mydbsnapshot` for a DB instance called `mydbinstance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-snapshot \
  --db-instance-identifier mydbinstance \ 
  --db-snapshot-identifier mydbsnapshot
```

For Windows:

```bash
aws rds create-db-snapshot ^
  --db-instance-identifier mydbinstance ^
  --db-snapshot-identifier mydbsnapshot
```

**RDS API**

When you create a DB snapshot using the Amazon RDS API, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API `CreateDBSnapshot` command with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`
Creating a Multi-AZ DB cluster snapshot

When you create a Multi-AZ DB cluster snapshot, make sure to identify which Multi-AZ DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later.

You can create a Multi-AZ DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To create a DB cluster snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the list, choose the Multi-AZ DB cluster for which you want to take a snapshot.
4. For Actions, choose Take snapshot.

   The Take DB snapshot window appears.
5. For Snapshot name, enter the name of the snapshot.
6. Choose Take snapshot.

The Snapshots page appears, with the new Multi-AZ DB cluster snapshot's status shown as Creating. After its status is Available, you can see its creation time.

**AWS CLI**

You can create a Multi-AZ DB cluster snapshot by using the AWS CLI `create-db-cluster-snapshot` command with the following options:

- `--db-cluster-identifier`
- `--db-cluster-snapshot-identifier`

In this example, you create a Multi-AZ DB cluster snapshot called `mymultiazdbclustersnapshot` for a DB cluster called `mymultiazdbcluster`.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-snapshot \
    --db-cluster-identifier mymultiazdbcluster \
    --db-cluster-snapshot-identifier mymultiazdbclustersnapshot
```

For Windows:

```
aws rds create-db-cluster-snapshot ^
    --db-cluster-identifier mymultiazdbcluster ^
    --db-cluster.snapshot-identifier mymultiazdbclustersnapshot
```

**RDS API**

You can create a Multi-AZ DB cluster snapshot by using the Amazon RDS API `CreateDBClusterSnapshot` operation with the following parameters:
- `DBClusterIdentifier`
- `DBClusterSnapshotIdentifier`
Restoring from a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. You can create a new DB instance by restoring from a DB snapshot. You provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that is created from the restore. You can’t restore from a DB snapshot to an existing DB instance; a new DB instance is created when you restore.

You can use the restored DB instance as soon as its status is available. The DB instance continues to load data in the background. This is known as lazy loading.

If you access data that hasn't been loaded yet, the DB instance immediately downloads the requested data from Amazon S3, and then continues loading the rest of the data in the background. For more information, see Amazon EBS snapshots.

To help mitigate the effects of lazy loading on tables to which you require quick access, you can perform operations that involve full-table scans, such as `SELECT *`. This allows Amazon RDS to download all of the backed-up table data from S3.

You can restore a DB instance and use a different storage type than the source DB snapshot. In this case, the restoration process is slower because of the additional work required to migrate the data to the new storage type. If you restore to or from magnetic storage, the migration process is the slowest. That's because magnetic storage doesn't have the IOPS capability of Provisioned IOPS or General Purpose (SSD) storage.

You can use AWS CloudFormation to restore a DB instance from a DB instance snapshot. For more information, see AWS::RDS::DBInstance in the AWS CloudFormation User Guide.

**Note**

You can’t restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy. For more information, see Copying a snapshot (p. 438).

Parameter group considerations

We recommend that you retain the DB parameter group for any DB snapshots you create, so that you can associate your restored DB instance with the correct parameter group.

The default DB parameter group is associated with the restored instance, unless you choose a different one. No custom parameter settings are available in the default parameter group.

You can specify the parameter group when you restore the DB instance.

For more information about DB parameter groups and DB cluster parameter groups, see Working with parameter groups (p. 278).

Security group considerations

When you restore a DB instance, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the instance or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the instance by including the `--vpc-security-group-ids` option in the `restore-db-instance-from-db-snapshot` command.
• If you're using the Amazon RDS API, you can include the VpcSecurityGroupIds.VpcSecurityGroupId.N parameter in the RestoreDBInstanceFromDBSnapshot action.

As soon as the restore is complete and your new DB instance is available, you can also change the VPC settings by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Option group considerations

When you restore a DB instance, the default DB option group is associated with the restored DB instance in most cases.

The exception is when the source DB instance is associated with an option group that contains a persistent or permanent option. For example, if the source DB instance uses Oracle Transparent Data Encryption (TDE), the restored DB instance must use an option group that has the TDE option.

If you restore a DB instance into a different VPC, you must do one of the following to assign a DB option group:

• Assign the default option group for that VPC group to the instance.
• Assign another option group that is linked to that VPC.
• Create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option.

For more information about DB option groups, see Working with option groups (p. 262).

Resource tagging considerations

When you restore a DB instance from a DB snapshot, RDS checks whether you specify new tags. If yes, the new tags are added to the restored DB instance. If there are no new tags, RDS looks for the tags from the source DB instance for the DB snapshot, and then adds those tags to the restored DB instance.

For more information, see Copying tags to DB instance snapshots (p. 379).

Microsoft SQL Server considerations

When you restore an RDS for Microsoft SQL Server DB snapshot to a new instance, you can always restore to the same edition as your snapshot. In some cases, you can also change the edition of the DB instance. The following limitations apply when you change editions:

• The DB snapshot must have enough storage allocated for the new edition.
• Only the following edition changes are supported:
  • From Standard Edition to Enterprise Edition
  • From Web Edition to Standard Edition or Enterprise Edition

If you want to change from one edition to a new edition that isn't supported by restoring a snapshot, you can try using the native backup and restore feature. SQL Server verifies whether your database is compatible with the new edition based on what SQL Server features you have enabled on the database. For more information, see Importing and exporting SQL Server databases (p. 962).
Oracle Database considerations

If you use Oracle GoldenGate, always retain the parameter group with the compatible parameter. When you restore a DB instance from a DB snapshot, specify a parameter group that has a matching or greater compatible value.

If you restore a snapshot of a CDB instance, you can change the PDB name. You can't change the CDB name, which is always RDSCDB. This CDB name is the same for all RDS instances that use a single-tenant architecture. For more information, see Snapshots in a single-tenant architecture (p. 1306).

Before you restore a DB snapshot, you can upgrade it to a later release. For more information, see Upgrading an Oracle DB snapshot (p. 1556).

Restoring from a snapshot

You can restore a DB instance from a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To restore a DB instance from a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, for **DB instance identifier**, enter the name for your restored DB instance.
6. Choose **Restore DB instance**.

**AWS CLI**

To restore a DB instance from a DB snapshot, use the AWS CLI command `restore-db-instance-from-db-snapshot`.

In this example, you restore from a previously created DB snapshot named `mydbsnapshot`. You restore to a new DB instance named `mynewdbinstance`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-db-snapshot \
   --db-instance-identifier mynewdbinstance \
   --db-snapshot-identifier mydbsnapshot
```

For Windows:

```bash
aws rds restore-db-instance-from-db-snapshot ^
   --db-instance-identifier mynewdbinstance ^
   --db-snapshot-identifier mydbsnapshot
```
This command returns output similar to the following:

```
DBINSTANCE  mynewdbinstance  db.m3.large  MySQL     50    sa       creating 3 n
5.6.40  general-public-license
```

**RDS API**

To restore a DB instance from a DB snapshot, call the Amazon RDS API function `RestoreDBInstanceFromDBSnapshot` with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`
Restoring from a snapshot to a Multi-AZ DB cluster

You can restore a snapshot to a Multi-AZ DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can restore each of these types of snapshots to a Multi-AZ DB cluster:

- A snapshot of a single-AZ deployment
- A snapshot of a Multi-AZ DB instance deployment with a single DB instance
- A snapshot of a Multi-AZ DB cluster

**Tip**
You can migrate a single-AZ deployment or a Multi-AZ DB instance deployment to a Multi-AZ DB cluster deployment by restoring a snapshot.

**Console**

**To restore a snapshot to a Multi-AZ DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
5. On the Restore snapshot page, in Availability and durability, choose Multi-AZ DB cluster.

<table>
<thead>
<tr>
<th>Availability and durability</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deployment options</strong> info</td>
</tr>
<tr>
<td>The deployment options below are limited to those supported by the engine you selected above.</td>
</tr>
<tr>
<td><strong>Multi-AZ DB cluster</strong> Creates a DB cluster with a primary DB instance and two readable standby DB instances, with each DB instance in a different Availability Zone (AZ). Provides high availability, data redundancy and increases capacity to serve read workloads.</td>
</tr>
<tr>
<td><strong>Multi-AZ DB instance</strong> Creates a primary DB instance and a standby DB instance in a different AZ. Provides high availability and data redundancy, but the standby DB instance doesn't support connections for read workloads.</td>
</tr>
<tr>
<td><strong>Single DB instance</strong> Creates a single DB instance with no standby DB instances.</td>
</tr>
</tbody>
</table>

6. In **DB instance class**, choose a DB instance class.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see DB instance classes (p. 9).
7. For **DB cluster identifier**, enter the name for your restored Multi-AZ DB cluster.
8. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for creating Multi-AZ DB clusters (p. 199).
9. Choose Restore DB cluster.

**AWS CLI**

To restore a snapshot to a Multi-AZ DB cluster, use the AWS CLI command `restore-db-cluster-from-snapshot`. 

In the following example, you restore from a previously created snapshot named `mysnapshot`. You restore to a new Multi-AZ DB cluster named `mynewmultiazdbcluster`. You also specify the DB instance class used by the DB instances in the Multi-AZ DB cluster. Specify either `mysql` or `postgres` for the DB engine.

For the `--snapshot-identifier` option, you can use either the name or the Amazon Resource Name (ARN) to specify a DB cluster snapshot. However, you can use only the ARN to specify a DB snapshot.

Currently, Multi-AZ DB clusters only support `db.m6gd` and `db.r6gd` DB instance classes. For more information about DB instance classes, see `DB instance classes (p. 9)`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot \
  --db-cluster-identifier mynewmultiazdbcluster \
  --snapshot-identifier mysnapshot \
  --engine mysql|postgres \
  --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier mynewmultiazdbcluster ^
  --snapshot-identifier mysnapshot ^
  --engine mysql|postgres ^
  --db-cluster-instance-class db.r6gd.xlarge
```

After the DB cluster has been restored, make sure to add the Multi-AZ DB cluster to the security group used by the DB cluster or DB instance used to create the snapshot. Doing so provides the same functionality as that of the previous DB cluster or DB instance.

**RDS API**

To restore a snapshot to a Multi-AZ DB cluster, call the RDS API operation `RestoreDBClusterFromSnapshot` with the following parameters:

- DBClusterIdentifier
- SnapshotIdentifier
- Engine

You can also specify other optional parameters.

After the DB cluster has been restored, make sure to add the Multi-AZ DB cluster to the security group used by the DB cluster or DB instance used to create the snapshot. Doing so provides the same functionality as that of the previous DB cluster or DB instance.
Copying a snapshot

With Amazon RDS, you can copy automated backups or manual DB snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

Limitations

The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the China (Beijing) or China (Ningxia) Regions.
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these AWS GovCloud (US) Regions and commercial AWS Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of AVAILABLE before you delete a source snapshot.
- You can have up to five snapshot copy requests in progress to a single destination Region per account.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.

Snapshot retention

Amazon RDS deletes automated backups in several situations:

- At the end of their retention period.
- When you disable automated backups for a DB instance.
- When you delete a DB instance.

If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see Amazon RDS pricing.

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.

You can copy a shared DB snapshot across AWS Regions if the snapshot is unencrypted. However, if the shared DB snapshot is encrypted, you can only copy it in the same Region.

Note

Copying shared incremental snapshots in the same AWS Region is supported when they're unencrypted, or encrypted using the same KMS key as the initial full snapshot. If you use a
Handling encryption

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.

The source snapshot remains encrypted throughout the copy process. For more information, see Limitations of Amazon RDS encrypted DB instances (p. 1753).

You can also encrypt a copy of an unencrypted snapshot. This way, you can quickly add encryption to a previously unencrypted DB instance. To do this, you create a snapshot of your DB instance when you are ready to encrypt it. You then create a copy of that snapshot and specify a KMS key to encrypt that snapshot copy. You can then restore an encrypted DB instance from the encrypted snapshot.

Incremental snapshot copying

An incremental snapshot contains only the data that has changed after the most recent snapshot of the same DB instance. Incremental snapshot copying is faster and results in lower storage costs than full snapshot copying.

Note
When you copy a source snapshot that is a snapshot copy itself, the new copy isn't incremental. This is because the source snapshot copy doesn't include the required metadata for incremental copies.

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy.

If a copy is still pending when you start another copy, the second copy doesn't start until the first copy finishes.

When you copy a snapshot across AWS accounts, the copy is an incremental copy if the following conditions are met:

- A different snapshot of the same source DB instance was previously copied to the destination account.
- The most recent snapshot copy still exists in the destination account.
- All copies of the snapshot in the destination account are either unencrypted, or were encrypted using the same KMS key.

The following examples illustrate the difference between full and incremental snapshots. They apply to both shared and unshared snapshots.

<table>
<thead>
<tr>
<th>Snapshot</th>
<th>Encryption key</th>
<th>Full or incremental</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1</td>
<td>K1</td>
<td>Full</td>
</tr>
<tr>
<td>S2</td>
<td>K1</td>
<td>Incremental of S1</td>
</tr>
</tbody>
</table>
Cross-Region copying

<table>
<thead>
<tr>
<th>Snapshot</th>
<th>Encryption key</th>
<th>Full or incremental</th>
</tr>
</thead>
<tbody>
<tr>
<td>S3</td>
<td>K1</td>
<td>Incremental of S2</td>
</tr>
<tr>
<td>S4</td>
<td>K1</td>
<td>Incremental of S3</td>
</tr>
<tr>
<td>Copy of S1 (S1C)</td>
<td>K2</td>
<td>Full</td>
</tr>
<tr>
<td>Copy of S2 (S2C)</td>
<td>K3</td>
<td>Full</td>
</tr>
<tr>
<td>Copy of S3 (S3C)</td>
<td>K3</td>
<td>Incremental of S2C</td>
</tr>
<tr>
<td>Copy of S4 (S4C)</td>
<td>K3</td>
<td>Incremental of S3C</td>
</tr>
<tr>
<td>Copy 2 of S4 (S4C2)</td>
<td>K4</td>
<td>Full</td>
</tr>
</tbody>
</table>

**Note**

In these examples, snapshots S2, S3, and S4 are incremental only if the previous snapshot still exists. The same applies to copies. Snapshot copies S3C and S4C are incremental only if the previous copy still exists.

For information on copying incremental snapshots across AWS Regions, see Full and incremental copies (p. 443).

**Cross-Region snapshot copying**

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

**Requesting a cross-Region DB snapshot copy**

To communicate with the source Region to request a cross-Region DB snapshot copy, the requester (IAM role or IAM user) must have access to the source DB snapshot and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that you're copying the DB snapshot from US East (Ohio) to US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```json
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
  "StringEquals": {
    "aws:RequestedRegion": "us-east-1"
  }
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```json
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
  "StringEquals": {
    "aws:SourceRegion": "us-east-1",
    "aws:TargetRegion": "us-east-2"
  }
}
```

Note

In these examples, snapshots S2, S3, and S4 are incremental only if the previous snapshot still exists. The same applies to copies. Snapshot copies S3C and S4C are incremental only if the previous copy still exists.
The requester's policy doesn't allow access to the source DB snapshot.

For a successful request, specify both the source and target snapshots.

The requester's policy denies aws:ViaAWSService.

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with aws:CalledVia in your policy to make the request succeed. For example, you can use aws:CalledVia with aws:SourceVpce as shown here:
For more information, see Policies and permissions in IAM in the IAM User Guide.

Authorizing the snapshot copy

After a cross-Region DB snapshot copy request returns success, RDS starts the copy in the background. An authorization for RDS to access the source snapshot is created. This authorization links the source DB snapshot to the target DB snapshot, and allows RDS to copy only to the specified target snapshot.

The authorization is verified by RDS using the rds:CrossRegionCommunication permission in the service-linked IAM role. If the copy is authorized, RDS communicates with the source Region and completes the copy.

RDS doesn't have access to DB snapshots that weren't authorized previously by a CopyDBSnapshot request. The authorization is revoked when copying completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the copy process, the copy fails.

For more information, see Using service-linked roles in the IAM User Guide.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the assumeRole API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to Valid in all AWS Regions in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

Latency and multiple copy requests

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that
source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

**Full and incremental copies**

When you copy a snapshot to a different AWS Region from the source snapshot, the first copy is a full snapshot copy, even if you copy an incremental snapshot. A full snapshot copy contains all of the data and metadata required to restore the DB instance. After the first snapshot copy, you can copy incremental snapshots of the same DB instance to the same destination Region within the same AWS account. For more information on incremental snapshots, see Incremental snapshot copying (p. 439).

Incremental snapshot copying across AWS Regions is supported for both unencrypted and encrypted snapshots.

When you copy a snapshot across AWS Regions, the copy is an incremental copy if the following conditions are met:

- The snapshot was previously copied to the destination Region.
- The most recent snapshot copy still exists in the destination Region.
- All copies of the snapshot in the destination Region are either unencrypted, or were encrypted using the same KMS key.

**Option group considerations**

Option groups are specific to the AWS Region that they are created in, and you can't use an option group from one AWS Region in another AWS Region.

When you copy a snapshot across Regions, you can specify a new option group for the snapshot. We recommend that you prepare the new option group before you copy the snapshot. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.

In some cases, you might copy a snapshot and not specify a new option group for the snapshot. In these cases, when you restore the snapshot the DB instance gets the default option group. To give the new DB instance the same options as the original, do the following:

1. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing option group from the previous step.

**Parameter group considerations**

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB instance. When you restore a snapshot to create a new DB instance, that DB instance gets the default parameter group for the AWS Region it is created in. To give the new DB instance the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB parameter group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing parameter group from the previous step.
Copying a DB snapshot

Use the procedures in this topic to copy a DB snapshot. For an overview of copying a snapshot, see Copying a snapshot (p. 438)

For each AWS account, you can copy up to five DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see Amazon RDS pricing.

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

The following procedure copies an encrypted or unencrypted DB snapshot, in the same AWS Region or across Regions, by using the AWS Management Console.

To copy a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the DB snapshot that you want to copy.
4. For Actions, choose Copy snapshot.
   The Copy snapshot page appears.
5. (Optional) To copy the DB snapshot to a different AWS Region, for **Destination Region**, choose the new AWS Region.
Note
The destination AWS Region must have the same database engine version available as the source AWS Region.

6. For **New DB Snapshot Identifier**, type the name of the DB snapshot copy.

You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

7. (Optional) For **Target Option Group**, choose a new option group.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see [Option group considerations](#).

8. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.

9. (Optional) For **Encryption**, do the following:

   a. Choose **Enable Encryption** if the DB snapshot isn't encrypted but you want to encrypt the copy.

      **Note**
      If the DB snapshot is encrypted, you must encrypt the copy, so the check box is already selected.

   b. For **AWS KMS key**, specify the KMS key identifier to use to encrypt the DB snapshot copy.

10. Choose **Copy snapshot**.

**AWS CLI**

You can copy a DB snapshot by using the AWS CLI command `copy-db-snapshot`. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region.

The following options are used to copy a DB snapshot. Not all options are required for all scenarios. Use the descriptions and the examples that follow to determine which options to use.

- `--source-db-snapshot-identifier` – The identifier for the source DB snapshot.
  - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
  - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.

- `--target-db-snapshot-identifier` – The identifier for the new copy of the encrypted DB snapshot.

- `--copy-tags` – Include the copy tags option to copy tags and values from the snapshot to the copy of the snapshot.

- `--option-group-name` – The option group to associate with the copy of the snapshot.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.
If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see Option group considerations (p. 443).

- `--kms-key-id` – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.

- If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.

- If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.

- If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.

- If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.

- `--source-region` – The ID of the AWS Region of the source DB snapshot. If you copy an encrypted snapshot to a different AWS Region, then you must specify this option.

**Example from unencrypted, to the same Region**

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot
   --source-db-snapshot-identifier mysql-instance1-snapshot-20130805
   --target-db-snapshot-identifier mydbsnapshotcopy
   --copy-tags
```

For Windows:

```
aws rds copy-db-snapshot ^
   --source-db-snapshot-identifier mysql-instance1-snapshot-20130805 ^
   --target-db-snapshot-identifier mydbsnapshotcopy ^
   --copy-tags
```

**Example from unencrypted, across Regions**

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the AWS Region in which the command is run.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot
   --target-db-snapshot-identifier mydbsnapshotcopy
```

For Windows:

```
aws rds copy-db-snapshot ^
```
Copying a DB snapshot

Example from encrypted, across Regions

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region in the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot
  --target-db-snapshot-identifier mydbsnapshotcopy
  --source-region us-west-2
  --kms-key-id my-us-east-1-key
  --option-group-name custom-option-group-name
```

For Windows:

```
aws rds copy-db-snapshot ^
  --target-db-snapshot-identifier mydbsnapshotcopy ^
  --source-region us-west-2 ^
  --kms-key-id my-us-east-1-key ^
  --option-group-name custom-option-group-name
```

RDS API

You can copy a DB snapshot by using the Amazon RDS API operation `CopyDBSnapshot`. If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region.

The following parameters are used to copy a DB snapshot. Not all parameters are required for all scenarios. Use the descriptions and the examples that follow to determine which parameters to use.

- **SourceDBSnapshotIdentifier** – The identifier for the source DB snapshot.
  - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
  - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
  - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.

- **TargetDBSnapshotIdentifier** – The identifier for the new copy of the encrypted DB snapshot.

- **CopyTags** – Set this parameter to `true` to copy tags and values from the snapshot to the copy of the snapshot. The default is `false`.

- **OptionGroupName** – The option group to associate with the copy of the snapshot.

Specify this parameter if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this parameter when copying across Regions. For more information, see Option group considerations (p. 443).
• **KmsKeyId** – The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  
  • If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new KMS key. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same KMS key as the source DB snapshot.
  
  • If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
  
  • If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
  
  • If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.
  
• **PreSignedUrl** – The URL that contains a Signature Version 4 signed request for the CopyDBSnapshot API operation in the source AWS Region that contains the source DB snapshot to copy.

Specify this parameter when you copy an encrypted DB snapshot from another AWS Region by using the Amazon RDS API. You can specify the source Region option instead of this parameter when you copy an encrypted DB snapshot from another AWS Region by using the AWS CLI.

The presigned URL must be a valid request for the CopyDBSnapshot API operation that can be run in the source AWS Region containing the encrypted DB snapshot to be copied. The presigned URL request must contain the following parameter values:

• **DestinationRegion** – The AWS Region that the encrypted DB snapshot will be copied to. This AWS Region is the same one where the CopyDBSnapshot operation is called that contains this presigned URL.

For example, suppose that you copy an encrypted DB snapshot from the us-west-2 Region to the us-east-1 Region. You then call the CopyDBSnapshot operation in the us-east-1 Region and provide a presigned URL that contains a call to the CopyDBSnapshot operation in the us-west-2 Region. For this example, the DestinationRegion in the presigned URL must be set to the us-east-1 Region.

• **KmsKeyId** – The KMS key identifier for the key to use to encrypt the copy of the DB snapshot in the destination AWS Region. This is the same identifier for both the CopyDBSnapshot operation that is called in the destination AWS Region, and the operation contained in the presigned URL.

• **SourceDBSnapshotIdentifier** – The DB snapshot identifier for the encrypted snapshot to be copied. This identifier must be in the Amazon Resource Name (ARN) format for the source AWS Region. For example, if you are copying an encrypted DB snapshot from the us-west-2 Region, then your SourceDBSnapshotIdentifier looks like the following example: `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20161115`.

For more information on Signature Version 4 signed requests, see the following:

• [Authenticating requests: Using query parameters (AWS signature version 4) in the Amazon Simple Storage Service API Reference](https://docs.aws.amazon.com/AmazonS3/latest/API/sig-v4-query-string-auth.html)

• [Signature version 4 signing process in the AWS General Reference](https://docs.aws.amazon.com/general/latest/gr/signing.html)

### Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

```sql
https://rds.us-west-1.amazonaws.com/?Action=CopyDBSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
```
Copying a DB snapshot

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the US West (N. California) Region.

```
https://rds.us-west-1.amazonaws.com/
?Action=CopyDBSnapshot
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBSnapshotIdentifier=arn%3Aaws%3Ards%3Aus-east-1%3A123456789012%3Asnapshot%3Amysql-instance1-snapshot-20130805
&TargetDBSnapshotIdentifier=mydbsnapshotcopy
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e87441cb7ef62f3cea29d0b448b9e0e7c53b288ddfed2
```

Example from encrypted, across Regions

The following code creates a copy of a snapshot, with the new name mydbsnapshotcopy, in the US East (N. Virginia) Region.

```
https://rds.us-east-1.amazonaws.com/
?Action=CopyDBSnapshot
&KmsKeyId=my-us-east-1-key
&OptionGroupName=custom-option-group-name
&PreSignedUrl=https%3A%2F%2Frds.us-west-2.amazonaws.com%2F%252FAction%253DCopyDBSnapshot%2526DestinationRegion%253Dus-east-1%2526KmsKeyId%253Dmy-us-east-1-key%2526SourceDBSnapshotIdentifier%253Darn%25253Aaws%25253Ards%25253Aus-west-2%25253A123456789012%25253Asnapshot%25253Amysql-instance1-snapshot-20161115%2526SignatureMethod%253DHmacSHA256%2526SignatureVersion%253D2014-10-31%2526Version%253D252F20161117T215409Z%252F%2526X-Amz-Algorithm%253DAWS4-HMAC-SHA256%2526X-Amz-Credential%253DAKIADQKE4SARGYLE%252F20161117%252Fus-east-1%252Frds%252Faws4_request%2526X-Amz-Content-Sha256%2526X-Amz-Expires%2526X-Amz-SignedHeaders%253Dcontent-type%253Bhost%253Buser-agent%253Bx-amz-content-sha256%253Bx-amz-date%2526X-Amz-Signature=255a0f17b4e717d3b67f9d163c3ec26573b882c03a65523522cf890a67fca613%2526SourceDBSnapshotIdentifier%253Darn%25253Aaws%25253Ards%25253Aus-west-2%25253A123456789012%25253Asnapshot%3Amsysql-instance1-snapshot-20161115%2526TargetDBSnapshotIdentifier%253Dmydbsnapshotcopy%2526Version=2014-10-31%2526X-Amz-Algorithm%253DAWS4-HMAC-SHA256%2526X-Amz-Credential%253DAKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
```
Sharing a DB snapshot

Using Amazon RDS, you can share a manual DB snapshot in the following ways:

- Sharing a manual DB snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing an unencrypted manual DB snapshot enables authorized AWS accounts to directly restore a DB instance from the snapshot instead of taking a copy of it and restoring from that. However, you can’t restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy.

**Note**

To share an automated DB snapshot, create a manual DB snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup–generated resources.

For more information on copying a snapshot, see Copying a snapshot (p. 438). For more information on restoring a DB instance from a DB snapshot, see Restoring from a DB snapshot (p. 432).

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitations apply when sharing manual snapshots with other AWS accounts:

- When you restore a DB instance from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.
- You can’t share a DB snapshot that uses an option group with permanent or persistent options, except for Oracle DB instances that have the `Timezone` or `OLS` option (or both).

A *permanent option* can't be removed from an option group. Option groups with persistent options can't be removed from a DB instance once the option group has been assigned to the DB instance.

The following table lists permanent and persistent options and their related DB engines.

<table>
<thead>
<tr>
<th>Option name</th>
<th>Persistent</th>
<th>Permanent</th>
<th>DB engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>TDE</td>
<td>Yes</td>
<td>No</td>
<td>Microsoft SQL Server Enterprise Edition</td>
</tr>
<tr>
<td>TDE</td>
<td>Yes</td>
<td>Yes</td>
<td>Oracle Enterprise Edition</td>
</tr>
<tr>
<td>Timezone</td>
<td>Yes</td>
<td>Yes</td>
<td>Oracle Enterprise Edition</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Oracle Standard Edition</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Oracle Standard Edition One</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Oracle Standard Edition Two</td>
</tr>
</tbody>
</table>

For Oracle DB instances, you can copy shared DB snapshots that have the `Timezone` or `OLS` option (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see Oracle time zone (p. 1533) and Oracle Label Security (p. 1494).
Sharing public snapshots

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB instances from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB instance from a public snapshot, you're billed for that DB instance. For Amazon RDS pricing information, see the Amazon RDS product page.

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

Viewing public snapshots owned by other AWS accounts

You can view public snapshots owned by other accounts in a particular AWS Region on the Public tab of the Snapshots page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.

To view public snapshots

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the Public tab.

The public snapshots appear. You can see which account owns a public snapshot in the Owner column.

Note
You might have to modify the page preferences, by selecting the gear icon at the upper right of the Public snapshots list, to see this column.

Viewing your own public snapshots

You can use the following AWS CLI command (Unix only) to view the public snapshots owned by your AWS account in a particular AWS Region.

```
aws rds describe-db-snapshots --snapshot-type public --include-public | grep account_number
```

The output returned is similar to the following example if you have public snapshots.

```
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot1",
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot2",
```

Note
You might see duplicate entries for DBSnapshotIdentifier or SourceDBSnapshotIdentifier.
Sharing encrypted snapshots

You can share DB snapshots that have been encrypted "at rest" using the AES-256 encryption algorithm, as described in Encrypting Amazon RDS resources (p. 1750). To do this, take the following steps:

1. Share the AWS KMS key that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

   You can share KMS keys with another AWS account by adding the other account to the KMS key policy. For details on updating a key policy, see Key policies in the AWS KMS Developer Guide. For an example of creating a key policy, see Allowing access to an AWS KMS key (p. 454) later in this topic.

2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share Oracle or Microsoft SQL Server snapshots that are encrypted using Transparent Data Encryption (TDE).
- You can't share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

Allowing access to an AWS KMS key

For another AWS account to copy an encrypted DB snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS key that encrypted the snapshot.

To allow another AWS account access to a KMS key, update the key policy for the KMS key. You update it with the Amazon Resource Name (ARN) of the AWS account that you are sharing to as Principal in the KMS key policy. Then you allow the kms:CreateGrant action.

After you have given an AWS account access to your KMS key, to copy your encrypted snapshot that AWS account must create an AWS Identity and Access Management (IAM) role or user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM role or user that allows the role or user to copy an encrypted DB snapshot using your KMS key. The account must be an IAM user and cannot be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user 111122223333 is the owner of the KMS key, and user 444455556666 is the account that the key is being shared with. This updated key policy gives the AWS account access to the KMS key by including the ARN for the root AWS account identity for user 444455556666 as a Principal for the policy, and by allowing the kms:CreateGrant action.

```json
{
    "Id": "key-policy-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {"AWS": [
                "arn:aws:iam::111122223333:user/KeyUser",
                "arn:aws:iam::444455556666:root"
            ]},
            "Action": [
                "kms:CreateGrant",
            ]
        }
    ]
}
```
Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your KMS key, the owner of that AWS account can create a policy that allows an IAM user created for that account to copy an encrypted snapshot encrypted with that KMS key.

The following example shows a policy that can be attached to an IAM user for AWS account 444455556666 that enables the IAM user to copy a shared snapshot from AWS account 111122223333 that has been encrypted with the KMS key c989c1dd-a3f2-4a5d-8d96-e793d082ab26 in the us-west-2 region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowUseOfTheKey",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowAttachmentOfPersistentResources",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/KeyUser",
                    "arn:aws:iam::444455556666:root"
                ]
            },
            "Action": [
                "kms:CreateGrant",
                "kms:ListGrants",
                "kms:RevokeGrant"
            ],
            "Resource": "*",
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": true
                }
            }
        }
    ]
}
```
Sharing a snapshot

You can share a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

Using the Amazon RDS console, you can share a manual DB snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

To share a manual DB snapshot by using the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the manual snapshot that you want to share.
4. For Actions, choose Share Snapshot.
5. Choose one of the following options for DB snapshot visibility.

   - If the source is unencrypted, choose Public to permit all AWS accounts to restore a DB instance from your manual DB snapshot, or choose Private to permit only AWS accounts that you specify to restore a DB instance from your manual DB snapshot.

     Warning
     If you set DB snapshot visibility to Public, all AWS accounts can restore a DB instance from your manual DB snapshot and have access to your data. Do not share any manual DB snapshots that contain private information as Public.

   - If the source is encrypted, DB snapshot visibility is set as Private because encrypted snapshots can't be shared as public.

6. For AWS Account ID, type the AWS account identifier for an account that you want to permit to restore a DB instance from your manual snapshot, and then choose Add. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

   If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing Delete at the right of the incorrect AWS account identifier.
7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

**To stop sharing a manual DB snapshot with an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to stop sharing.
4. Choose **Actions**, and then choose **Share Snapshot**.
5. To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.
6. Choose **Save** to save your changes.

**AWS CLI**

To share a DB snapshot, use the `aws rds modify-db-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

**Example of sharing a snapshot with a single account**

The following example enables AWS account identifier `123456789012` to restore the DB snapshot named `db7-snapshot`.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
  --db-snapshot-identifier db7-snapshot \
  --attribute-name restore \
  --values-to-add 123456789012
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
  --db-snapshot-identifier db7-snapshot ^
  --attribute-name restore ^
  --values-to-add 123456789012
```
Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB snapshot named manual-snapshot1.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot-attribute \\n--db-snapshot-identifier manual-snapshot1 \\n--attribute-name restore \\n--values-to-add {"111122223333","444455556666"}
```

For Windows:

```bash
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-add ["111122223333","444455556666"]
```

Note
When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the --values-to-remove parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot-attribute \\n--db-snapshot-identifier manual-snapshot1 \\n--attribute-name restore \\n--values-to-remove 444455556666
```

For Windows:

```bash
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the describe-db-snapshot-attributes AWS CLI command.

RDS API

You can also share a manual DB snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the ModifyDBSnapshotAttribute operation. Specify restore for AttributeName, and use the ValuesToAdd parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value all. However, take care not to add the all value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify all for encrypted snapshots, because making such snapshots public isn't supported.
To remove sharing permission for an AWS account, use the `ModifyDBSnapshotAttribute` operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the `DescribeDBSnapshotAttributes` API operation.
Exporting DB snapshot data to Amazon S3

You can export DB snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn’t affect the performance of your active DB instance.

When you export a DB snapshot, Amazon RDS extracts data from the snapshot and stores it in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by the AWS Backup service. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see Parquet SerDe in the Amazon Athena User Guide. For more information on using Redshift Spectrum to read Parquet data, see COPY from columnar data formats in the Amazon Redshift Database Developer Guide.

Amazon RDS supports exporting snapshots in all AWS Regions except the following:

- Asia Pacific (Jakarta)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

The following table shows the engine versions that are supported for exporting snapshot data to Amazon S3.

<table>
<thead>
<tr>
<th>MariaDB</th>
<th>MySQL</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>8.0.13 and higher</td>
<td>All 12 and 13 versions</td>
</tr>
<tr>
<td>10.2.12 and higher</td>
<td>5.7.24 and higher</td>
<td>11.2 and higher</td>
</tr>
<tr>
<td>5.6.40 and higher</td>
<td></td>
<td>10.7 and higher</td>
</tr>
<tr>
<td></td>
<td></td>
<td>9.6.6–9.6.9, 9.6.12 and higher</td>
</tr>
</tbody>
</table>

For complete lists of engine versions supported by Amazon RDS, see the following:

- MariaDB on Amazon RDS versions (p. 838)
- MySQL on Amazon RDS versions (p. 1133)
- Available PostgreSQL database versions (p. 1595)

Topics

- Limitations (p. 462)
- Overview of exporting snapshot data (p. 462)
- Setting up access to an Amazon S3 bucket (p. 463)
- Using a cross-account AWS KMS key for encrypting Amazon S3 exports (p. 465)
- Exporting a snapshot to an Amazon S3 bucket (p. 466)
- Monitoring snapshot exports (p. 469)
- Canceling a snapshot export task (p. 470)
- Failure messages for Amazon S3 export tasks (p. 471)
Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- Exporting snapshots from DB instances that use magnetic storage isn't supported.
- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
  - Latin letters (A–Z)
  - Digits (0–9)
  - Dollar symbol ($)
  - Underscore (_)
- Spaces ( ) and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:
  
  `, ; { } ( ) \n \t = (space)

- If the data contains a large object such as a BLOB or CLOB, close to or greater than 500 MB, the export fails.
- If a table contains a large row close to or greater than 2 GB, the table is skipped during export.
- We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

  ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID xxxxx already exists.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.

   Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.

2. Set up access to the Amazon S3 bucket.

   A bucket is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:
   
   a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see Identifying the Amazon S3 bucket for export (p. 463).
   
   b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see Providing access to an Amazon S3 bucket using an IAM role (p. 463).

3. Create a symmetric AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. For more information, see Encrypting Amazon RDS resources (p. 1750).
The KMS key is also used for local disk encryption at rest on Amazon EC2. In addition, if you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal export.rds.amazonaws.com.

You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see Using a cross-account AWS KMS key for encrypting Amazon S3 exports (p. 465).

4. Export the snapshot to Amazon S3 using the console or the start-export-task CLI command. For more information, see Exporting a snapshot to an Amazon S3 bucket (p. 466).

5. To access your exported data in the Amazon S3 bucket, see Uploading, downloading, and managing objects in the Amazon Simple Storage Service User Guide.

**Setting up access to an Amazon S3 bucket**

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon RDS service to write to the Amazon S3 bucket.

**Topics**
- Identifying the Amazon S3 bucket for export (p. 463)
- Providing access to an Amazon S3 bucket using an IAM role (p. 463)
- Using a cross-account Amazon S3 bucket (p. 465)

**Identifying the Amazon S3 bucket for export**

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

**Note**
The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the Amazon Simple Storage Service User Guide:
- How do I view the properties for an S3 bucket?
- How do I enable default encryption for an Amazon S3 bucket?
- How do I create an S3 bucket?

**Providing access to an Amazon S3 bucket using an IAM role**

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To do this, create an IAM policy that provides access to the bucket. Then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

**Important**
If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see Exporting a snapshot to an Amazon S3 bucket (p. 466).

**To give DB snapshot tasks access to Amazon S3**

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.
Include in the policy the following required actions to allow the transfer of files from Amazon RDS to an S3 bucket:

- s3:PutObject*
- s3:GetObject*
- s3:ListBucket
- s3:DeleteObject*
- s3:GetBucketLocation

Include in the policy the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- arn:aws:s3:::your-s3-bucket
- arn:aws:s3:::your-s3-bucket/*

For more information on creating an IAM policy for Amazon RDS, see Creating and using an IAM policy for IAM database access (p. 1789). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

The following AWS CLI command creates an IAM policy named ExportPolicy with these options. It grants access to a bucket named your-s3-bucket.

Note
After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name ExportPolicy --policy-document '{
"Version": "2012-10-17",
"Statement": [
{
  "Sid": "ExportPolicy",
  "Effect": "Allow",
  "Action": [
    "s3:PutObject*",
    "s3:ListBucket",
    "s3:GetObject*",
    "s3:DeleteObject*",
    "s3:GetBucketLocation"
  ],
  "Resource": [
    "arn:aws:s3:::your-s3-bucket",
    "arn:aws:s3:::your-s3-bucket/*"
  ]
}
}
'
```

2. Create an IAM role. You do this so that Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

The following example shows using the AWS CLI command to create a role named rds-s3-export-role.

```
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{
"Version": "2012-10-17",
"Statement": [
```

464
3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```bash
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

### Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you’re using for the S3 exports. For more information, see Example 2: Bucket owner granting cross-account bucket permissions.

- Attach a bucket policy to your bucket, as shown in the following example.

```json
{
"Version": "2012-10-17",
"Statement": [
{
 "Effect": "Allow",
 "Principal": {
 "AWS": "arn:aws:iam::123456789012:role/Admin"
 },
 "Action": ["s3:PutObject*", "s3:ListBucket", "s3:GetObject*", "s3:DeleteObject*", "s3:GetBucketLocation"],
 "Resource": [
 "arn:aws:s3:::mycrossaccountbucket",
 "arn:aws:s3:::mycrossaccountbucket/*"
 ]
}
]
}
```

### Using a cross-account AWS KMS key for encrypting Amazon S3 exports

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account, then you add IAM policies in the external account. For more information, see Allowing users in other accounts to use a KMS key.
To use a cross-account KMS key

1. Add a key policy to the local account.

The following example gives ExampleRole and ExampleUser in the external account 444455556666 permissions in the local account 123456789012.

```
{
   "Sid": "Allow an external account to use this KMS key",
   "Effect": "Allow",
   "Principal": {
      "AWS": [ 
         "arn:aws:iam::444455556666:role/ExampleRole",
         "arn:aws:iam::444455556666:user/ExampleUser"
      ]
   },
   "Action": [
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:CreateGrant",
      "kms:DescribeKey",
      "kms:RetireGrant"
   ],
   "Resource": "*"
}
```

2. Add IAM policies to the external account.

The following example IAM policy allows the principal to use the KMS key in account 123456789012 for cryptographic operations. To give this permission to ExampleRole and ExampleUser in account 444455556666, attach the policy to them in that account.

```
{
   "Sid": "Allow use of KMS key in account 123456789012",
   "Effect": "Allow",
   "Action": [
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:CreateGrant",
      "kms:DescribeKey",
      "kms:RetireGrant"
   ],
   "Resource": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

Exporting a snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per account.

**Note**

Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**.
The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don’t contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export a snapshot, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see AWS Lambda permissions.

### Console

The **Export to Amazon S3** console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn’t supported for S3 export.
- The DB instance version isn’t supported for S3 export.
- S3 export isn’t supported in the AWS Region where the snapshot was created.

#### To export a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For **Actions**, choose **Export to Amazon S3**.

   The **Export to Amazon S3** window appears.

6. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:
   - Choose **All** to export all data in the snapshot.
   - Choose **Partial** to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for **Identifiers**, separated by spaces.

   Use the following format:

   ```plaintext
database[.schema][.table] database2[.schema2][.table2] ... databases[.schema]
   [.table]
```

   For example:

   ```plaintext
   mydatabase mydatabase2.myschema1 mydatabase2.myschema2.mytable1
   mydatabase2.myschema2.mytable2
   ```

8. For **S3 bucket**, choose the bucket to export to.

   To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

9. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.
• If you created a role by following the steps in Providing access to an Amazon S3 bucket using an IAM role (p. 463), choose that role.

• If you didn’t create a role that grants you write access to your chosen S3 bucket, choose Create a new role to create the role automatically. Next, enter a name for the role in IAM role name.

10. For AWS KMS key, enter the ARN for the key to use for encrypting the exported data.

11. Choose Export to Amazon S3.

AWS CLI

To export a DB snapshot to Amazon S3 using the AWS CLI, use the start-export-task command with the following required options:

• --export-task-identifier
• --source-arn
• --s3-bucket-name
• --iam-role-arn
• --kms-key-id

In the following examples, the snapshot export task is named my-snapshot-export, which exports a snapshot to an S3 bucket named my-export-bucket.

Example

For Linux, macOS, or Unix:

```
aws rds start-export-task \
    --export-task-identifier my-snapshot-export \
    --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot: snapshot-name \
    --s3-bucket-name my-export-bucket \
    --iam-role-arn iam-role \
    --kms-key-id my-key
```

For Windows:

```
aws rds start-export-task ^
    --export-task-identifier my-snapshot-export ^
    --s3-bucket-name my-export-bucket ^
    --iam-role-arn iam-role ^
    --kms-key-id my-key ^
```

Sample output follows.

```json
{
    "Status": "STARTING",
    "IamRoleArn": "iam-role",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "my-export-bucket",
    "PercentProgress": 0,
    "KmsKeyId": "my-key",
    "ExportTaskIdentifier": "my-snapshot-export",
    "TotalExtractedDataInGB": 0,
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot: snapshot-name"
}
```
To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the `start-export-task` command.

**RDS API**

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the `StartExportTask` operation with the following required parameters:

- `ExportTaskIdentifier`
- `SourceArn`
- `S3BucketName`
- `IamRoleArn`
- `KmsKeyId`

**Monitoring snapshot exports**

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To monitor DB snapshot exports**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

**AWS CLI**

To monitor DB snapshot exports using the AWS CLI, use the `describe-export-tasks` command.

The following example shows how to display current information about all of your snapshot exports.

**Example**

```bash
aws rds describe-export-tasks
{
  "ExportTasks": [
    {
      "Status": "CANCELED",
      "TaskEndTime": "2019-11-01T17:36:46.961Z",
      "S3Prefix": "something",
      "S3Bucket": "examplebucket",
      "PercentProgress": 0,
      "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
      "ExportTaskIdentifier": "anewtest",
      "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
      "TotalExtractedDataInGB": 0,
      "SourceArn": "arn:aws:rds:AWS_Regio...test"
    }
  ]
}
```
Canceling a snapshot export

To display information about a specific snapshot export, include the --export-task-identifier option with the describe-export-tasks command. To filter the output, include the --Filters option. For more options, see the describe-export-tasks command.

RDS API

To display information about DB snapshot exports using the Amazon RDS API, use the DescribeExportTasks operation.

To track completion of the export workflow or to trigger another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see Using Amazon RDS event notification (p. 623).

Canceling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

Note
Canceling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see How do I delete objects from an S3 bucket? To delete the data using the CLI, use the delete-object command.
**Console**

**To cancel a snapshot export task**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Exports in Amazon S3** tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose **Cancel**.
6. Choose **Cancel export task** on the confirmation page.

**AWS CLI**

To cancel a snapshot export task using the AWS CLI, use the `cancel-export-task` command. The command requires the `--export-task-identifier` option.

**Example**

```
aws rds cancel-export-task --export-task-identifier my_export
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "examplebucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
    "ExportTaskIdentifier": "my_export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTIme": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

**RDS API**

To cancel a snapshot export task using the Amazon RDS API, use the `CancelExportTask` operation with the `ExportTaskIdentifier` parameter.

**Failure messages for Amazon S3 export tasks**

The following table describes the messages that are returned when Amazon S3 export tasks fail.

<table>
<thead>
<tr>
<th>Failure message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>An unknown internal error occurred.</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
<tr>
<td>An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name].</td>
<td>The task has failed because of an unknown error, exception, or failure.</td>
</tr>
<tr>
<td>The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN].</td>
<td>The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.</td>
</tr>
</tbody>
</table>
Failure message | Description
--- | ---
The RDS export failed to write the export task’s metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code] | One or more permissions are missing, so the export task can’t access the S3 bucket. This failure message is raised when receiving one of the following:
- AWSSecurityTokenServiceException with the error code AccessDenied
- AmazonS3Exception with the error code NoSuchBucket, AccessDenied, KMS.KMSInvalidStateException, 403 Forbidden, or KMS.DisabledException

The IAM role [role ARN] isn’t authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export. | The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing. This causes the export task to fail.

KMS key check failed. Check the credentials on your KMS key and try again. | The KMS key credential check failed.

S3 credential check failed. Check the permissions on your S3 bucket and IAM policy. | The S3 credential check failed.

The S3 bucket [bucket name] isn’t valid. Either it isn’t located in the current AWS Region or it doesn’t exist. Review your S3 bucket name and retry the export. | The S3 bucket is invalid.

The S3 bucket [bucket name] isn’t located in the current AWS Region. Review your S3 bucket name and retry the export. | The S3 bucket is in the wrong AWS Region.

Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a PERMISSIONS_DO_NOT_EXIST error stating that certain tables were skipped. This is usually caused by the superuser, which you specify when creating the DB instance, not having permissions to access those tables.

To fix this error, run the following command:

```sql
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see Master user account privileges (p. 1835).

File naming convention

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```bash
export_identifier/database_name/schema_name.table_name/
```
For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named. The current convention is the following:

```
partition_index/part-00000-random_uuid.format-based_extension
```

For example:

1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
2/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
3/part-00000-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet

The older convention is the following:

```
part-partition_index-random_uuid.format-based_extension
```

For example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables we recommend that you read everything inside the base prefix for the table.

**Data conversion when exporting to an Amazon S3 bucket**

When you export a DB snapshot to an Amazon S3 bucket, Amazon RDS converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the [Apache Parquet website](https://parquet.apache.org).

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A `logical type` is implemented as an annotation with the data in a `LogicalType` metadata field. The logical type annotation explains how to interpret the primitive type.

When the `STRING` logical type annotates a `BYTE_ARRAY` type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon RDS notifies
you if any string conversion occurred. The underlying data exported is always the same as the data from
the source. However, due to the encoding difference in UTF-8, some characters might appear different
from the source when read in tools such as Athena.

For more information, see Parquet logical type definitions in the Parquet documentation.

- MySQL and MariaDB data type mapping to Parquet (p. 474)
- PostgreSQL data type mapping to Parquet (p. 476)

MySQL and MariaDB data type mapping to Parquet

The following table shows the mapping from MySQL and MariaDB data types to Parquet data types
when data is converted and exported to Amazon S3.

<table>
<thead>
<tr>
<th>Source data type</th>
<th>Parquet primitive type</th>
<th>Logical type annotation</th>
<th>Conversion notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric data types</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BIGINT</td>
<td>INT64</td>
<td></td>
<td></td>
</tr>
<tr>
<td>BIGINT UNSIGNED</td>
<td>FIXED_LEN_BYTE_ARRAY(9) DECIMAL(20,0)</td>
<td>Parquet supports only signed types, so the mapping requires an additional byte (8 plus 1) to store the BIGINT_UNSIGNED type.</td>
<td></td>
</tr>
<tr>
<td>BIT</td>
<td>BYTE_ARRAY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DECIMAL</td>
<td>INT32</td>
<td>DECIMAL(p,s)</td>
<td>If the source value is less than $2^{31}$, it's stored as INT32.</td>
</tr>
<tr>
<td></td>
<td>INT64</td>
<td>DECIMAL(p,s)</td>
<td>If the source value is $2^{31}$ or greater, but less than $2^{63}$, it's stored as INT64.</td>
</tr>
<tr>
<td></td>
<td>FIXED_LEN_BYTE_ARRAY(N) DECIMAL(p,s)</td>
<td>If the source value is $2^{63}$ or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>BYTE_ARRAY</td>
<td>STRING</td>
<td>Parquet doesn't support Decimal precision greater than 38. The Decimal value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>DOUBLE</td>
<td></td>
<td></td>

Restoring a DB instance to a specified time

You can restore a DB instance to a specific point in time, creating a new DB instance.

When you restore a DB instance to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB instance.

Restored DB instances are automatically associated with the default DB parameter and option groups. However, you can apply a custom parameter group and option group by specifying them during a restore.

RDS uploads transaction logs for DB instances to Amazon S3 every five minutes. To see the latest restorable time for a DB instance, use the AWS CLI `describe-db-instances` command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose Automated backups.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose Automated backups in the Amazon RDS console.

Note
We recommend that you restore to the same or similar DB instance size—and IOPS if using Provisioned IOPS storage—as the source DB instance. You might get an error if, for example, you choose a DB instance size with an incompatible IOPS value.

Some of the database engines used by Amazon RDS have special considerations when restoring from a point in time:

- When you restore an Oracle DB instance to a point in time, you can specify a different Oracle DB engine, license model, and DBName (SID) to be used by the new DB instance.
- When you restore a Microsoft SQL Server DB instance to a point in time, each database within that instance is restored to a point in time within 1 second of each other database within the instance. Transactions that span multiple databases within the instance might be restored inconsistently.
- For a SQL Server DB instance, the OFFLINE, EMERGENCY, and SINGLE_USER modes aren't supported. Setting any database into one of these modes causes the latest restorable time to stop moving ahead for the whole instance.
- Some actions, such as changing the recovery model of a SQL Server database, can break the sequence of logs that are used for point-in-time recovery. In some cases, Amazon RDS can detect this issue and the latest restorable time is prevented from moving forward. In other cases, such as when a SQL Server database uses the BULK_LOGGED recovery model, the break in log sequence isn't detected. It might not be possible to restore a SQL Server DB instance to a point in time if there is a break in the
log sequence. For these reasons, Amazon RDS doesn't support changing the recovery model of SQL Server databases.

You can also use AWS Backup to manage backups of Amazon RDS DB instances. If your DB instance is associated with a backup plan in AWS Backup, that backup plan is used for point-in-time recovery. Backups that were created with AWS Backup have names ending in `awsbackup:` followed by `AWS-Backup-job-number`. For information about AWS Backup, see the [AWS Backup Developer Guide](https://docs.aws.amazon.com/awsbackup/latest/devguide).

**Note**

Information in this topic applies to Amazon RDS. For information on restoring an Amazon Aurora DB cluster, see [Restoring a DB cluster to a specified time](#).

You can restore a DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To restore a DB instance to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.
   
   The automated backups are displayed on the **Current Region** tab.
3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.
   
   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.
6. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.
8. Choose **Restore to point in time**.

**AWS CLI**

To restore a DB instance to a specified time, use the AWS CLI command `restore-db-instance-to-point-in-time` to create a new DB instance. This example also enables storage autoscaling.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-to-point-in-time
   --source-db-instance-identifier mysourcedbinstance
   --target-db-instance-identifier mytargetdbinstance
   --restore-time 2017-10-14T23:45:00.000Z
```
For Windows:

```bash
aws rds restore-db-instance-to-point-in-time
  --source-db-instance-identifier mysourcedbinstance
  --target-db-instance-identifier mytargetdbinstance
  --restore-time 2017-10-14T23:45:00.000Z
  --max-allocated-storage 1000
```

**RDS API**

To restore a DB instance to a specified time, call the Amazon RDS API `RestoreDBInstanceToPointInTime` operation with the following parameters:

- `SourceDBInstanceIdentifier`
- `TargetDBInstanceIdentifier`
- `RestoreTime`
Restoring a Multi-AZ DB cluster to a specified time

You can restore a Multi-AZ DB cluster to a specific point in time, creating a new Multi-AZ DB cluster.

RDS uploads transaction logs for Multi-AZ DB clusters to Amazon S3 continuously. You can restore to any point in time within your backup retention period. To see the earliest restorable time for a Multi-AZ DB cluster, use the AWS CLI `describe-db-clusters` command. Look at the value returned in the `EarliestRestorableTime` field for the DB cluster. To see the latest restorable time for a Multi-AZ DB cluster, look at the value returned in the `LatestRestorableTime` field for the DB cluster.

When you restore a Multi-AZ DB cluster to a point in time, you can choose the default VPC security group for your Multi-AZ DB cluster. Or you can apply a custom VPC security group to your Multi-AZ DB cluster.

Restored Multi-AZ DB clusters are automatically associated with the default DB cluster parameter group. However, you can apply a customer DB cluster parameter group by specifying it during a restore.

**Note**
We recommend that you restore to the same or similar Multi-AZ DB cluster size as the source DB cluster. We also recommend that you restore with the same or similar IOPS value if you're using Provisioned IOPS storage. You might get an error if, for example, you choose a DB cluster size with an incompatible IOPS value.

You can restore a Multi-AZ DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To restore a Multi-AZ DB cluster to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Multi-AZ DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the Multi-AZ DB cluster.

   **Note**
   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB cluster identifier**, enter the name for your restored Multi-AZ DB cluster.
7. In **Availability and durability**, choose **Multi-AZ DB cluster**.
8. In **DB instance class**, choose a DB instance class. Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes](p. 9).

9. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for creating Multi-AZ DB clusters](p. 199).

10. Choose **Restore to point in time**.

### AWS CLI

To restore a Multi-AZ DB cluster to a specified time, use the AWS CLI command `restore-db-cluster-to-point-in-time` to create a new Multi-AZ DB cluster.

Currently, Multi-AZ DB clusters only support db.m6gd and db.r6gd DB instance classes. For more information about DB instance classes, see [DB instance classes](p. 9).

**Example**

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier mysourcemultiazdbcluster \
  --db-cluster-identifier mytargetmultiazdbcluster \
  --restore-to-time 2021-08-14T23:45:00.000Z \
  --db-cluster-instance-class db.r6gd.xlarge
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier mysourcemultiazdbcluster ^
  --db-cluster-identifier mytargetmultiazdbcluster ^
  --restore-to-time 2021-08-14T23:45:00.000Z ^
  --db-cluster-instance-class db.r6gd.xlarge
```

### RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API `RestoreDBClusterToPointInTime` operation with the following parameters:

- `SourceDBClusterIdentifier`
- `DBClusterIdentifier`
• RestoreToTime
Deleting a snapshot

You can delete DB snapshots managed by Amazon RDS when you no longer need them.

**Note**
To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the *AWS Backup Developer Guide*.

Deleting a DB snapshot

You can delete a manual, shared, or public DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

If you have automated DB snapshots that you want to delete without deleting the DB instance, change the backup retention period for the DB instance to 0. The automated snapshots are deleted when the change is applied. You can apply the change immediately if you don't want to wait until the next maintenance period. After the change is complete, you can then re-enable automatic backups by setting the backup retention period to a number greater than 0. For information about modifying a DB instance, see *Modifying an Amazon RDS DB instance* (p. 309).

If you deleted a DB instance, you can delete its automated DB snapshots by removing the automated backups for the DB instance. For information about automated backups, see *Working with backups* (p. 407).

**Console**

**To delete a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
   
   The **Manual snapshots** list appears.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete Snapshot**.
5. Choose **Delete** on the confirmation page.

**AWS CLI**

You can delete a DB snapshot by using the AWS CLI command `delete-db-snapshot`.

The following options are used to delete a DB snapshot.

- `--db-snapshot-identifier` – The identifier for the DB snapshot.

**Example**

The following code deletes the `mydbsnapshot` DB snapshot.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-snapshot \   
   --db-snapshot-identifier mydbsnapshot
```
For Windows:

```bash
aws rds delete-db-snapshot
    --db-snapshot-identifier mydbsnapshot
```

**RDS API**

You can delete a DB snapshot by using the Amazon RDS API operation `DeleteDBSnapshot`.

The following parameters are used to delete a DB snapshot.

- `DBSnapshotIdentifier` – The identifier for the DB snapshot.
Tutorial: Restore an Amazon RDS DB instance from a DB snapshot

A common scenario when working with Amazon RDS is to have a DB instance that you work with occasionally but that you don't need full time. For example, you might have a quarterly customer survey that uses an Amazon Elastic Compute Cloud (Amazon EC2) instance to host a customer survey website and a DB instance that is used to store the survey results. One way to save money on such a scenario is to take a DB snapshot of the DB instance after the survey is completed, delete the DB instance, and then restore the DB instance when you need to conduct the survey again.

When you restore the DB instance, you provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that's created from the restore operation.

For more detailed information on restoring DB instances from snapshots, see Restoring from a DB snapshot (p. 432).

### Restoring a DB instance from a DB snapshot

Use the following procedure to restore from a snapshot in the AWS Management Console.

**To restore a DB instance from a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the DB snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.

The Restore snapshot page appears.
5. Under **DB instance settings**, use the default settings for **DB engine** and **License model** (for Oracle or Microsoft SQL Server).

6. Under **Settings**, for **DB instance identifier** enter the unique name that you want to use for the restored DB instance, for example `mynewdbinstance`.

   If you're restoring from a DB instance that you deleted after you made the DB snapshot, you can use the name of that DB instance.

7. Under **Availability & durability**, for **Multi-AZ deployment** choose whether to create a standby instance in another Availability Zone.

   For this tutorial, use **No**, the default setting.

8. Under **Connectivity**, use the default settings for the following:

   - Virtual private cloud (VPC)
   - Subnet group
   - Public access
   - VPC security group

9. Choose the **DB instance class**.

   For this tutorial, choose **Burstable classes (includes t classes)**, and then choose `db.t3.small`.

10. For **Encryption**, use the default settings.

    If the source DB instance for the snapshot was encrypted, the restored DB instance is also encrypted. You can't make it unencrypted.

11. Expand **Additional configuration** at the bottom of the page.
12. Do the following under **Database options**: 
   
   a. Choose the **DB parameter group**.
      
      For this tutorial, use the default parameter group.
   
   b. Choose the **Option group**.
      
      For this tutorial, use the default option group.
   
      **Important**
      
      If you're restoring from a DB snapshot of a DB instance that uses a persistent or permanent option, you must choose an option group that uses the same option.
   
   c. For **Deletion protection**, choose the **Enable deletion protection** check box.

13. Choose **Restore DB instance**.

The **Databases** page displays the restored DB instance, with a status of **Creating**.
Monitoring metrics in an Amazon RDS instance

In the following sections, you can find an overview of Amazon RDS monitoring and an explanation about how to access metrics. To learn how to monitor events, logs, and database activity streams, see Monitoring events, logs, and streams in an Amazon RDS DB instance (p. 615).

Topics
- Overview of monitoring metrics in Amazon RDS (p. 492)
- Viewing instance status and recommendations (p. 496)
- Viewing metrics in the Amazon RDS console (p. 505)
- Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 508)
- Monitoring DB load with Performance Insights on Amazon RDS (p. 521)
- Monitoring OS metrics with Enhanced Monitoring (p. 582)
- Metrics reference for Amazon RDS (p. 591)
Overview of monitoring metrics in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. To more easily debug multi-point failures, we recommend that you collect monitoring data from all parts of your AWS solution.

Topics

- Monitoring plan (p. 492)
- Performance baseline (p. 492)
- Performance guidelines (p. 492)
- Monitoring tools (p. 493)

Monitoring plan

Before you start monitoring Amazon RDS, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon RDS environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon RDS. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- High CPU or RAM consumption – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.
• **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.

• **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.

• **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the `User Connections` parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see *Working with parameter groups* (p. 278).

• **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

**Monitoring tools**

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your other AWS solutions. AWS provides various monitoring tools to watch Amazon RDS, report when something is wrong, and take automatic actions when appropriate.

**Topics**

• Automated monitoring tools (p. 493)
• Manual monitoring tools (p. 494)

**Automated monitoring tools**

We recommend that you automate monitoring tasks as much as possible.

**Topics**

• *Amazon RDS instance status and recommendations* (p. 493)
• *Amazon CloudWatch metrics for Amazon RDS* (p. 494)
• *Amazon RDS Performance Insights and operating-system monitoring* (p. 494)
• *Integrated services* (p. 494)

**Amazon RDS instance status and recommendations**

You can use the following automated tools to watch Amazon RDS and report when something is wrong:

• **Amazon RDS instance status** — View details about the current status of your instance by using the Amazon RDS console, the AWS CLI, or the RDS API.

• **Amazon RDS recommendations** — Respond to automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. For more information, see *Viewing Amazon RDS recommendations* (p. 500).
Amazon CloudWatch metrics for Amazon RDS

Amazon RDS integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon RDS:
  - **Amazon CloudWatch metrics** – Amazon RDS automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 508).
  - **Amazon CloudWatch alarms** – You can watch a single Amazon RDS metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 508).

Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon RDS performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 521).
- **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582).

Integrated services

The following AWS services are integrated with Amazon RDS:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see Monitoring Amazon RDS events (p. 619).
- **Amazon CloudWatch Logs** lets you monitor, store, and access your log files from Amazon RDS instances, CloudTrail, and other sources. For more information, see Monitoring Amazon RDS log files (p. 646).
- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 686).
- **Database Activity Streams** is an Amazon RDS feature that provides a near-real-time stream of the activity in your Oracle DB instance. For more information, see Monitoring Amazon RDS for Oracle with Database Activity Streams (p. 690).

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don’t cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.

- From the Amazon RDS console, you can monitor the following items for your resources:
  - The number of connections to a DB instance
  - The amount of read and write operations to a DB instance
  - The amount of storage that a DB instance is currently using
  - The amount of memory and CPU being used for a DB instance
• The amount of network traffic to and from a DB instance
• From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault tolerance, and performance improvement checks:
  • Amazon RDS Idle DB Instances
  • Amazon RDS Security Group Access Risk
  • Amazon RDS Backups
  • Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).
• CloudWatch home page shows:
  • Current alarms and status
  • Graphs of alarms and resources
  • Service health status

In addition, you can use CloudWatch to do the following:
  • Create customized dashboards to monitor the services that you care about.
  • Graph metric data to troubleshoot issues and discover trends.
  • Search and browse all your AWS resource metrics.
  • Create and edit alarms to be notified of problems.
Viewing instance status and recommendations

Using the Amazon RDS console, you can quickly access the status of your DB instance and respond to Amazon RDS recommendations.

Topics
- Viewing Amazon RDS DB instance status (p. 497)
- Viewing Amazon RDS recommendations (p. 500)
Viewing Amazon RDS DB instance status

The status of a DB instance indicates the health of the DB instance. You can view the status of a DB instance by using the Amazon RDS console, the AWS CLI command `describe-db-instances`, or the API operation `DescribeDBInstances`.

**Note**

Amazon RDS also uses another status called `maintenance status`, which is shown in the `Maintenance` column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information on `maintenance status`, see Applying updates for a DB instance (p. 335).

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

<table>
<thead>
<tr>
<th>DB instance status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>available</td>
<td>Billed</td>
<td>The DB instance is healthy and available.</td>
</tr>
<tr>
<td>backing-up</td>
<td>Billed</td>
<td>The DB instance is currently being backed up.</td>
</tr>
<tr>
<td>configuring-enhanced-monitoring</td>
<td>Billed</td>
<td>Enhanced Monitoring is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>configuring-iam-database-auth</td>
<td>Billed</td>
<td>AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>configuring-log-exports</td>
<td>Billed</td>
<td>Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>converting-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.</td>
</tr>
<tr>
<td>creating</td>
<td>Not billed</td>
<td>The DB instance is being created. The DB instance is inaccessible while it is being created.</td>
</tr>
<tr>
<td>deleting</td>
<td>Not billed</td>
<td>The DB instance is being deleted.</td>
</tr>
<tr>
<td>failed</td>
<td>Not billed</td>
<td>The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.</td>
</tr>
<tr>
<td>inaccessible-encryption-credentials</td>
<td>Not billed</td>
<td>The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.</td>
</tr>
<tr>
<td>inaccessible-encryption-credentials-recoverable</td>
<td>Billed for storage</td>
<td>The KMS key used to encrypt or decrypt the DB instance can't be accessed. However, if the KMS key is active, restarting the DB instance can recover it. For more information, see Encrypting a DB instance (p. 1751).</td>
</tr>
<tr>
<td>incompatible-network</td>
<td>Not billed</td>
<td>Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur</td>
</tr>
<tr>
<td>DB instance status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>incompatible-option-group</td>
<td>Billed</td>
<td>Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.</td>
</tr>
<tr>
<td>incompatible-parameters</td>
<td>Billed</td>
<td>Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.</td>
</tr>
<tr>
<td>incompatible-restore</td>
<td>Not billed</td>
<td>Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables, using MyISAM tables with MySQL, or using Aria tables with MariaDB.</td>
</tr>
<tr>
<td>insufficient-capacity</td>
<td></td>
<td>Amazon RDS can't create your instance because sufficient capacity isn't currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.</td>
</tr>
<tr>
<td>maintenance</td>
<td>Billed</td>
<td>Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.</td>
</tr>
<tr>
<td>modifying</td>
<td>Billed</td>
<td>The DB instance is being modified because of a customer request to modify the DB instance.</td>
</tr>
<tr>
<td>moving-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).</td>
</tr>
<tr>
<td>rebooting</td>
<td>Billed</td>
<td>The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.</td>
</tr>
<tr>
<td>resetting-master-credentials</td>
<td>Billed</td>
<td>The master credentials for the DB instance are being reset because of a customer request to reset them.</td>
</tr>
<tr>
<td>renaming</td>
<td>Billed</td>
<td>The DB instance is being renamed because of a customer request to rename it.</td>
</tr>
<tr>
<td>restore-error</td>
<td>Billed</td>
<td>The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.</td>
</tr>
<tr>
<td>starting</td>
<td>Billed</td>
<td>The DB instance is starting.</td>
</tr>
<tr>
<td>stopped</td>
<td>Billed</td>
<td>The DB instance is stopped.</td>
</tr>
</tbody>
</table>
### DB instance status

<table>
<thead>
<tr>
<th>DB instance status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stopping</td>
<td>Billed for storage</td>
<td>The DB instance is being stopped.</td>
</tr>
<tr>
<td>storage-full</td>
<td>Billed</td>
<td>The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.</td>
</tr>
<tr>
<td>storage-optimization</td>
<td>Billed</td>
<td>Your DB instance is being modified to change the storage size or type. The DB instance is fully operational. However, while the status of your DB instance is storage-optimization, you can't request any changes to the storage of your DB instance. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.</td>
</tr>
<tr>
<td>upgrading</td>
<td>Billed</td>
<td>The database engine version is being upgraded.</td>
</tr>
</tbody>
</table>
### Viewing Amazon RDS recommendations

Amazon RDS provides automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine version outdated</td>
<td>Your DB instance is not running the latest minor engine version.</td>
<td>We recommend that you upgrade to the latest version because it contains the latest security fixes and other improvements.</td>
<td>Upgrading a DB instance engine version (p. 344)</td>
</tr>
<tr>
<td>Pending maintenance available</td>
<td>You have pending maintenance available on your DB instance.</td>
<td>We recommend that you perform the pending maintenance available on your DB instance. Updates to the operating system most often occur for security issues and should be done as soon as possible.</td>
<td>Maintaining a DB instance (p. 333)</td>
</tr>
<tr>
<td>Automated backups disabled</td>
<td>Your DB instance has automated backups disabled.</td>
<td>We recommend that you enable automated backups on your DB instance. Automated backups enable point-in-time recovery of your DB instance. You receive backup storage up to the storage size of your DB instance at no additional charge.</td>
<td>Working with backups (p. 407)</td>
</tr>
<tr>
<td>Magnetic volumes in use</td>
<td>Your DB instance is using magnetic storage.</td>
<td>Magnetic storage is not recommended for most DB instances. We recommend switching to General Purpose (SSD) storage or provisioned IOPS storage.</td>
<td>Amazon RDS DB instance storage (p. 53)</td>
</tr>
<tr>
<td>EC2-Classic platform in use</td>
<td>Your DB instance is using the legacy EC2-Classic platform.</td>
<td>We recommend moving your DB instance to the EC2-VPC platform for better network access control. Amazon VPC provides a virtual network that is logically isolated from other virtual networks in the AWS Cloud.</td>
<td>Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869)</td>
</tr>
<tr>
<td>Enhanced Monitoring disabled</td>
<td>Your DB instance doesn't have Enhanced Monitoring enabled.</td>
<td>We recommend enabling Enhanced Monitoring. Enhanced Monitoring provides real-time operating system metrics for monitoring and troubleshooting.</td>
<td>Monitoring OS metrics with Enhanced Monitoring (p. 582)</td>
</tr>
<tr>
<td>Encryption disabled</td>
<td>Your DB instance doesn't have encryption enabled.</td>
<td>We recommend enabling encryption. You can encrypt your existing Amazon RDS DB instances by restoring from an encrypted snapshot.</td>
<td>Encrypting Amazon RDS resources (p. 1750)</td>
</tr>
<tr>
<td>Previous generation</td>
<td>Your DB instance is running on a Previous-generation DB instance classes have been replaced by DB</td>
<td></td>
<td>DB instance classes (p. 9)</td>
</tr>
</tbody>
</table>
### Amazon RDS recommendations

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance class in use</td>
<td>previous-generation DB instance class.</td>
<td>instance classes with better price, better performance, or both. We recommend running your DB instance on a later generation DB instance class.</td>
<td></td>
</tr>
<tr>
<td>Huge pages not used for an Oracle DB instance</td>
<td>The use_large_pages parameter is not set to ONLY in the DB parameter group used by your DB instance.</td>
<td>For increased database scalability, we recommend setting use_large_pages to ONLY in the DB parameter group used by your DB instance.</td>
<td>Enabling HugePages for an Oracle DB instance (p. 1424)</td>
</tr>
<tr>
<td>Nondefault custom memory parameters</td>
<td>Your DB parameter group sets memory parameters that diverge too much from the default values.</td>
<td>Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.</td>
<td>Working with parameter groups (p. 278)</td>
</tr>
<tr>
<td>Change buffering enabled for a MySQL DB instance</td>
<td>Your DB parameter group has change buffering enabled.</td>
<td>Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Query cache enabled for a MySQL DB instance</td>
<td>Your DB parameter group has query cache parameter enabled.</td>
<td>The query cache can cause the DB instance to appear to stall when changes require the cache to be purged. Most workloads don’t benefit from a query cache. The query cache was removed from MySQL version 8.0. We recommend that you disable the query cache parameter.</td>

</tr>
<tr>
<td>Logging to table</td>
<td>Your DB parameter group sets logging output to TABLE.</td>
<td>Setting logging output to TABLE uses more storage than setting this parameter to FILE. To avoid reaching the storage limit, we recommend setting the logging output parameter to FILE.</td>
<td>MySQL database log files (p. 664)</td>
</tr>
</tbody>
</table>

Amazon RDS generates recommendations for a resource when the resource is created or modified. Amazon RDS also periodically scans your resources and generates recommendations.
Responding to Amazon RDS recommendations

You can find recommendations in the AWS Management Console. You can perform the recommended action immediately, schedule it for the next maintenance window, or dismiss it.

To respond to Amazon RDS recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Recommendations.

The Recommendations page appears.
3. On the **Recommendations** page, choose one of the following:

- **Active** – Shows the current recommendations that you can apply, dismiss, or schedule.
- **Dismissed** – Shows the recommendations that have been dismissed. When you choose **Dismissed**, you can apply these dismissed recommendations.
- **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.
- **Applied** – Shows the recommendations that are currently applied.

From any list of recommendations, you can open a section to view the recommendations in that section.

To configure preferences for displaying recommendations in each section, choose the **Preferences** icon.
Viewing Amazon RDS recommendations

From the Preferences window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. Manage your active recommendations:

   a. Choose Active and open one or more sections to view the recommendations in them.

   b. Choose one or more recommendations and choose Apply now (to apply them immediately), Schedule (to apply them in next maintenance window), or Dismiss.

   If the Apply now button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance status is available. For example, you can't apply recommendations immediately to the DB instance if its status is modifying. In this case, wait for the DB instance to be available and then apply the recommendation.

   If the Apply now button doesn't appear for a recommendation, you can't apply the recommendation using the Recommendations page. You can modify the DB instance to apply the recommendation manually.

   For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

   Note
   When you choose Apply now, a brief DB instance outage might result.
Viewing metrics in the Amazon RDS console

Amazon RDS integrates with Amazon CloudWatch to display a variety of RDS DB instance metrics in the RDS console. For descriptions of these metrics, see Metrics reference for Amazon RDS (p. 591).

The Monitoring tab for your RDS DB instance shows the following categories of metrics:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS (p. 591).

- **Enhanced monitoring** – Shows a summary of operating-system metrics when your RDS DB instance has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see Monitoring OS metrics with Enhanced Monitoring (p. 582). For a list of Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 606).

- **OS Process list** – Shows details for each process running in your DB instance.

- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance. For an overview of Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS (p. 521). For a list of Performance Insights metrics, see Amazon CloudWatch metrics for Performance Insights (p. 595).

To view metrics for your DB instance in the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that you want to monitor.

The database page appears. The following example shows an Oracle database named orclb.

4. Scroll down and choose Monitoring.

The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see Amazon CloudWatch metrics for Amazon RDS (p. 591).
5. Choose **Monitoring** to see the metric categories.

6. Choose the category of metrics that you want to see.

The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see **OS metrics in Enhanced Monitoring** (p. 606).
Tip
To choose the time range of the metrics represented by the graphs, you can use the time range list.
To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.
Monitoring Amazon RDS metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon RDS into readable, near real-time metrics. For a complete list of Amazon RDS metrics sent to CloudWatch, see Metrics reference for Amazon RDS.

By default, Amazon RDS automatically sends metric data to CloudWatch in 1-minute periods. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

For more information about CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide. For more information about CloudWatch metrics retention, see Metrics retention.

Note
If you are using Amazon RDS Performance Insights, additional metrics are available. For more information, see Amazon CloudWatch metrics for Performance Insights (p. 595).
• Viewing DB instance metrics in the CloudWatch console and CLI (p. 510)
• Creating CloudWatch alarms to monitor Amazon RDS (p. 513)
• Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag (p. 514)
Viewing DB instance metrics in the CloudWatch console and CLI

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see Monitoring OS metrics with Enhanced Monitoring (p. 582).

When you use Amazon RDS resources, Amazon RDS sends metrics and dimensions to Amazon CloudWatch every minute. You can use the following procedures to view the metrics for Amazon RDS in the CloudWatch console and CLI.

Console

To view metrics using the Amazon CloudWatch console

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see Regions and endpoints.
3. In the navigation pane, choose Metrics and then All metrics.

![Metrics Console](image)

4. Scroll down and choose the RDS metric namespace.

The page displays the Amazon RDS dimensions. For descriptions of these dimensions, see Amazon CloudWatch dimensions for Amazon RDS (p. 595).
5. Choose a metric dimension, for example **By Database Class**.

6. Do any of the following actions:
   - To sort the metrics, use the column heading.
   - To graph a metric, select the check box next to the metric.
   - To filter by resource, choose the resource ID, and then choose **Add to search**.
   - To filter by metric, choose the metric name, and then choose **Add to search**.

The following example filters on the **db.t3.medium** class and graphs the **CPUUtilization** metric.
To obtain metric information by using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the AWS/RDS namespace.

```bash
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric statistics, use the command `get-metric-statistics`. The following command gets `CPUUtilization` statistics for instance `my-instance` over the specific 24-hour period, with a 5-minute granularity.

**Example**

For Linux, macOS, or Unix:

```bash
aws cloudwatch get-metric-statistics --namespace AWS/RDS \
  --metric-name CPUUtilization \
  --start-time 2021-12-15T00:00:00Z \
  --end-time 2021-12-16T00:00:00Z \
  --period 360 \
  --statistics Minimum \
  --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

For Windows:

```bash
aws cloudwatch get-metric-statistics --namespace AWS/RDS ^
```
Creating CloudWatch alarms

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods. The following procedures show how to create alarms for Amazon RDS.

To set alarms using the CloudWatch console

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. Choose **Alarms, All alarms**.

   Choose **Create an alarm**.

   This action launches a wizard.

3. Choose **Select metric**.

4. In **Browse**, choose **RDS**.

Sample output appears as follows:

```
{
  "Datapoints": [
    {
      "Timestamp": "2021-12-15T18:00:00Z",
      "Minimum": 8.7,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2021-12-15T23:54:00Z",
      "Minimum": 8.12486458559024,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2021-12-15T17:24:00Z",
      "Minimum": 8.84166666666667,
      "Unit": "Percent"
    }, ...
    {
      "Timestamp": "2021-12-15T22:48:00Z",
      "Minimum": 8.366248354248954,
      "Unit": "Percent"
    }],
  "Label": "CPUUtilization"
}
```

For more information, see **Getting statistics for a metric** in the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/).
5. Search for the metric that you want to place an alarm on. For example, search for **CPUUtilization**. To display only Amazon RDS metrics, search for the identifier of your resource.

6. Choose the metric to create an alarm on. Then choose **Select metric**.

7. In **Conditions**, define the alarm condition. Then choose **Next**.

   For example, you can specify that the alarm should be set when CPU utilization is over 75%.

8. Choose your notification method. Then choose **Next**.

   For example, to configure CloudWatch to send you an email when the alarm state is reached, do the following:

   1. Choose **Create new topic** (if one doesn't exist).
   2. Enter a topic name.
   3. Enter the email endpoints.

   The email addresses must be verified before they receive notifications. Emails are only sent when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, the addresses don't receive a notification.

   4. Choose **Create topic**.
   5. Choose **Next**.

9. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.

10. Preview the alarm that you're about to create. Then choose **Create alarm**.

**To set an alarm using the AWS CLI**

- Call `put-metric-alarm`. For more information, see [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/cloudwatch/put-metric-alarm).

**To set an alarm using the CloudWatch API**

- Call `PutMetricAlarm`. For more information, see [Amazon CloudWatch API Reference](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_PutMetricAlarm.html).

For more information about setting up Amazon SNS topics and creating alarms, see [Using Amazon CloudWatch alarms](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/creating-alarm.html).

**Tutorial: Creating an Amazon CloudWatch alarm for Multi-AZ DB cluster replica lag**

You can create an Amazon CloudWatch alarm that sends an Amazon SNS message when replica lag for a Multi-AZ DB cluster has exceeded a threshold. An alarm watches the **ReplicaLag** metric over a time period that you specify. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

**To set a CloudWatch alarm for Multi-AZ DB cluster replica lag**

2. In the navigation pane, choose **Alarms**, All alarms.
3. Choose **Create alarm**.
4. On the **Specify metric and conditions** page, choose **Select metric**.
5. In the search box, enter the name of your Multi-AZ DB cluster and press Enter.

The following image shows the Select metric page with a Multi-AZ DB cluster named rds-cluster entered.

6. Choose RDS, Per-Database Metrics.
7. In the search box, enter ReplicaLag and press Enter, then select each DB instance in the DB cluster.

The following image shows the Select metric page with the DB instances selected for the ReplicaLag metric.
This alarm considers the replica lag for all three of the DB instances in the Multi-AZ DB cluster. The alarm responds when any DB instance exceeds the threshold. It uses a math expression that returns the maximum value of the three metrics. Start by sorting by metric name, and then choose all three \texttt{ReplicaLag} metrics.

8. From \textit{Add math}, choose \textbf{All functions, MAX}.

9. Choose the \textbf{Graphed metrics} tab, and edit the details for \textit{Expression1} to \texttt{MAX([m1, m2, m3])}.

10. For all three \texttt{ReplicaLag} metrics, change the \textit{Period} to \textit{1 minute}.

11. Clear selection from all metrics except for \textit{Expression1}.

The \textbf{Select metric} page should look similar to the following image.
12. Choose Select metric.

13. On the Specify metric and conditions page, change the label to a meaningful name, such as ClusterReplicaLag, and enter a number of seconds in Define the threshold value. For this tutorial, enter 1200 seconds (20 minutes). You can adjust this value for your workload requirements.

The Specify metric and conditions page should look similar to the following image.
14. Choose Next, and the Configure actions page appears.
15. Keep In alarm selected, choose Create new topic, and enter the topic name and a valid email address.
16. Choose Create topic, and then choose Next.

17. On the Add name and description page, enter the Alarm name and Alarm description, and then choose Next.
18. Preview the alarm that you're about to create on the **Preview and create** page, and then choose **Create alarm**.
Monitoring DB load with Performance Insights on Amazon RDS

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users.

Topics
- Overview of Performance Insights (p. 521)
- Turning Performance Insights on and off (p. 526)
- Enabling the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL (p. 529)
- Configuring access policies for Performance Insights (p. 532)
- Analyzing metrics with the Performance Insights dashboard (p. 535)
- Retrieving metrics with the Performance Insights API (p. 566)
- Logging Performance Insights calls using AWS CloudTrail (p. 580)

Overview of Performance Insights

By default, Performance Insights is enabled in the console create wizard for Amazon RDS engines. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights in the following video.

Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL

Important
The following topics describe using Amazon RDS Performance Insights with non-Aurora DB engines. For information about using Amazon RDS Performance Insights with Amazon Aurora, see Using Amazon RDS Performance Insights in the Amazon Aurora User Guide.

Topics
- Database load (p. 521)
- Maximum CPU (p. 525)
- Amazon RDS DB engine support for Performance Insights (p. 525)
- AWS Region support for Performance Insights (p. 526)
- Cost of Performance Insights (p. 526)

Database load

*Database load (DB load)* measures the level of activity in your database. The key metric in Performance Insights is *DBLoad*, which is collected every second.

Topics
- Active sessions (p. 522)
- Average active sessions (p. 522)
- Average active executions (p. 522)
- Dimensions (p. 523)
Active sessions

A database session represents an application's dialogue with a relational database. An active session is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The average active sessions (AAS) is the unit for the DBLoad metric in Performance Insights. To get the average active sessions, Performance Insights samples the number of sessions concurrently running a query. The AAS is the total number of sessions divided by the total number of samples for a specific time period. The following table shows 5 consecutive samples of a running query.

<table>
<thead>
<tr>
<th>Sample</th>
<th>Number of sessions running query</th>
<th>AAS</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2 sessions / 1 sample</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>2 sessions / 2 samples</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2</td>
<td>6 sessions / 3 samples</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>1.5</td>
<td>6 sessions / 4 samples</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>2</td>
<td>10 sessions / 5 samples</td>
</tr>
</tbody>
</table>

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at a time during the time period when the 5 samples were taken.

An analogy for DB load is activity in a warehouse. Suppose that the warehouse employs 100 workers. If 1 order comes in, 1 worker fulfills the order while the other workers are idle. If 100 orders come in, all 100 workers fulfill orders simultaneously. If you periodically sample how many workers are active over a given time period, you can calculate the average number of active workers. The calculation shows that, on average, N workers are busy fulfilling orders at any given time. If the average was 50 workers yesterday and 75 workers today, the activity level in the warehouse increased. In the same way, DB load increases as session activity increases.

Average active executions

The average active executions (AAE) per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.

<table>
<thead>
<tr>
<th>Elapsed time (sec)</th>
<th>Total execution time (sec)</th>
<th>AAE</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>120</td>
<td>2</td>
<td>120 execution seconds/60 elapsed seconds</td>
</tr>
<tr>
<td>120</td>
<td>120</td>
<td>1</td>
<td>120 execution seconds/120 elapsed seconds</td>
</tr>
</tbody>
</table>
Overview of Performance Insights

<table>
<thead>
<tr>
<th>Elapsed time (sec)</th>
<th>Total execution time (sec)</th>
<th>AAE</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>180</td>
<td>380</td>
<td>2.11</td>
<td>380 execution seconds/180 elapsed seconds</td>
</tr>
<tr>
<td>240</td>
<td>380</td>
<td>1.58</td>
<td>380 execution seconds/240 elapsed seconds</td>
</tr>
<tr>
<td>300</td>
<td>600</td>
<td>2</td>
<td>600 execution seconds/300 elapsed seconds</td>
</tr>
</tbody>
</table>

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

Dimensions

The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called dimensions. You can think of dimensions as "slice by" categories for the different characteristics of the `DBLoad` metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

**Topics**
- Wait events (p. 523)
- Top SQL (p. 524)
- Plans (p. 524)

For a complete list of dimensions for the Amazon RDS engines, see DB load sliced by dimensions (p. 539).

**Wait events**

A wait event causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.

Consider the analogy of a warehouse worker. An order comes in for a book. The worker might be delayed in fulfilling the order. For example, a different worker might be currently restocking the shelves, a trolley might not be available. Or the system used to enter the order status might be slow. The longer the worker waits, the longer it takes to fulfill the order. Waiting is a natural part of the warehouse workflow, but if wait time becomes excessive, productivity decreases. In the same way, repeated or lengthy session
waits can degrade database performance. For more information, see Tuning with wait events for Aurora PostgreSQL and Tuning with wait events for Aurora MySQL in the Amazon Aurora User Guide.

Wait events vary by DB engine:

- For information about all MariaDB and MySQL wait events, see Wait Event Summary Tables in the MySQL documentation.
- For information about all PostgreSQL wait events, see PostgreSQL Wait Events in the PostgreSQL documentation.
- For information about all Oracle wait events, see Descriptions of Wait Events in the Oracle documentation.
- For information about all SQL Server wait events, see Types of Waits in the SQL Server documentation.

**Note**

For Oracle, background processes sometimes do work without an associated SQL statement. In these cases, Performance Insights reports the type of background process concatenated with a colon and the wait class associated with that background process. Types of background process include LGWR, ARCO, PMON, and so on.

For example, when the archiver is performing I/O, the Performance Insights report for it is similar to ARCI:System I/O. Occasionally, the background process type is also missing, and Performance Insights only reports the wait class, for example :System I/O.

**Top SQL**

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

**Plans**

An execution plan, also called simply a plan, is a sequence of steps that access data. For example, a plan for joining tables t1 and t2 might loop through all rows in t1 and compare each row to a row in t2. In a relational database, an optimizer is built-in code that determines the most efficient plan for a SQL query.

For Oracle DB instances, Performance Insights collects execution plans automatically. To diagnose SQL performance problems, examine the captured plans for high-resource Oracle SQL queries. The plans show how Oracle Database has parsed and run queries.

To learn how to analyze DB load using plans, see Analyzing Oracle execution plans using the Performance Insights dashboard (p. 559).

**Plan capture**

Every five minutes, Performance Insights identifies the most resource-intensive Oracle queries and captures their plans. Thus, you don't need to manually collect and manage a huge number of plans. Instead, you can use the Top SQL tab to focus on the plans for the most problematic queries.

**Note**

Performance Insights doesn't capture plans for queries whose text exceeds the maximum collectable query text limit. For more information, see Accessing the text of SQL statements (p. 562).
The retention period for execution plans is the same as for all your Performance Insights data. The default is seven days in the free tier or two years for the long retention tier.

**Digest queries**

The Top SQL tab shows digest queries by default. A digest query doesn't itself have a plan, but all queries that use literal values have plans. For example, a digest query might include the text WHERE `email`=?.

The digest might contain two queries, one with the text WHERE email=user1@example.com and another with WHERE email=user2@example.com. Each of these literal queries might include multiple plans.

If you select a digest query, the console shows all plans for child statements of the selected digest. Thus, you don't need to look through all the child statements to find the plan. You might see plans that aren't in the displayed list of top 10 child statements. The console shows plans for all child queries for which plans have been collected, regardless of whether the queries are in the top 10.

**Maximum CPU**

In the dashboard, the Database load chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the Max vCPU line. The Max vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance.

If the DB load is often above the Max vCPU line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the Max vCPU line.

**Amazon RDS DB engine support for Performance Insights**

Following, you can find the Amazon RDS DB engines that support Performance Insights.

**Note**

For Amazon Aurora, see Amazon Aurora DB engine support for Performance Insights in Amazon Aurora User Guide.

<table>
<thead>
<tr>
<th>Amazon RDS DB engine</th>
<th>Supported engine versions</th>
<th>Instance class restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS for MariaDB</td>
<td>Performance Insights is supported for the following engine versions: • All 10.6 versions • All 10.5 versions • All 10.4 versions • 10.3.23 and higher 10.3 versions • 10.2.21 and higher 10.2 versions</td>
<td>Performance Insights isn't supported for the following instance classes: • db.t2.micro • db.t2.small • db.t3.micro • db.t3.small The db.t4g.micro and db.t4g.small instance classes require 10.6 and higher.</td>
</tr>
<tr>
<td>Amazon RDS for MySQL</td>
<td>Performance Insights is supported for the following engine versions: • 8.0.17 and higher 8 versions</td>
<td>Performance Insights isn't supported for the following instance classes: • db.t2.micro</td>
</tr>
</tbody>
</table>
Turning Performance Insights on and off

<table>
<thead>
<tr>
<th>Amazon RDS DB engine</th>
<th>Supported engine versions</th>
<th>Instance class restrictions</th>
</tr>
</thead>
</table>
|                      | • 5.7.22 and higher 5.7 versions  
• 5.6.41 and higher 5.6 versions | • db.t2.small  
• db.t3.micro  
• db.t3.small  
The db.t4g instance classes require 8.0.25 and higher 8 versions. |
| Amazon RDS for Microsoft SQL Server | Performance Insights is supported for all engine versions except SQL Server 2008. | N/A |
| Amazon RDS for PostgreSQL | Performance Insights is supported for versions 14, 13, 12, 11, and 10. | N/A |
| Amazon RDS for Oracle | Performance Insights is supported for all engine versions. | N/A |

**Note**
Aurora Serverless doesn't support Performance Insights.

**AWS Region support for Performance Insights**

Performance Insights for Amazon RDS is supported for all AWS Regions except the following:

• AWS GovCloud (US-East)
• AWS GovCloud (US-West)
• Asia Pacific (Jakarta)

The only exception is version 10.3.13 of Amazon RDS for MariaDB, which isn't supported in the Europe (Frankfurt) and Europe (Stockholm) Regions.

**Cost of Performance Insights**

For cost information, see Performance Insights Pricing.

**Turning Performance Insights on and off**

To use Performance Insights, turn it on for your DB instance or Multi-AZ DB cluster. If needed, you can turn it off later. Turning Performance Insights on and off doesn't cause downtime, a reboot, or a failover.

**Note**
Performance Schema is an optional performance tool used by Amazon RDS for MariaDB or MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see Enabling the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL (p. 529).

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.
### Console

In the console, you can turn Performance Insights on or off when you create or modify a DB instance or Multi-AZ DB cluster.

**Turning Performance Insights on or off when creating a DB instance or DB cluster**

When you create a new DB instance or Multi-AZ DB cluster, turn on Performance Insights by choosing Enable Performance Insights in the Performance Insights section. Or choose Disable Performance Insights.

To create a DB instance, follow the instructions for your DB engine in Creating an Amazon RDS DB instance (p. 175).

To create a Multi-AZ DB cluster, follow the instructions for your DB engine in Creating a Multi-AZ DB cluster (p. 195).

The following screenshot shows the Performance Insights section.

If you choose Enable Performance Insights, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. Choose either 7 days (the default) or 2 years.
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Configuring an AWS KMS policy for Performance Insights (p. 534).

**Turning Performance Insights on or off when modifying a DB instance or DB cluster**

In the console, you can modify a DB instance or Multi-AZ DB cluster to turn Performance Insights on or off using the console.

**To turn Performance Insights on or off for a DB instance using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose Databases.
3. Choose a DB instance or Multi-AZ DB cluster, and choose Modify.
4. In the Performance Insights section, choose either Enable Performance Insights or Disable Performance Insights.

If you choose Enable Performance Insights, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. Choose either 7 days (the default) or 2 years. If you chose Long Term Retention (2 years) when you turn on Performance Insights, All displays 2 years of data. If you chose Default (7 days) instead, All displays only the past week.
- **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Encrypting Amazon RDS resources (p. 1750).

5. Choose Continue.
6. For Scheduling of Modifications, choose Apply immediately. If you choose Apply during the next scheduled maintenance window, your instance ignores this setting and turns on Performance Insights immediately.
7. Choose Modify instance.

**AWS CLI**

You can also specify these values using the following AWS CLI commands:

- create-db-instance-read-replica
- modify-db-instance
- restore-db-instance-from-s3
- create-db-cluster (Multi-AZ DB cluster)
- modify-db-cluster (Multi-AZ DB cluster)

The following procedure describes how to turn Performance Insights on or off for a DB instance using the AWS CLI.

**To turn Performance Insights on or off for a DB instance using the AWS CLI**

- Call the modify-db-instance AWS CLI command and supply the following values:
  - `--db-instance-identifier` – The name of the DB instance.
  - `--enable-performance-insights` to turn on or `--no-enable-performance-insights` to turn off

The following example turns on Performance Insights for `sample-db-instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
  --enable-performance-insights
```
For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier sample-db-instance ^
   --enable-performance-insights
```

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `--performance-insights-retention-period` option. Valid values are 7 (the default) or 731 (2 years).

The following example turns on Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for two years.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier sample-db-instance \
   --enable-performance-insights \
   --performance-insights-retention-period 731
```

RDS API

When you create a new DB instance using the `CreateDBInstance` operation Amazon RDS API operation, turn on Performance Insights by setting `EnablePerformanceInsights` to `True`. To turn off Performance Insights, set `EnablePerformanceInsights` to `False`.

You can also specify the `EnablePerformanceInsights` value using the following API operations:

- ModifyDBInstance
- CreateDBInstanceReadReplica
- RestoreDBInstanceFromS3
- CreateDBCluster (Multi-AZ DB cluster)
- ModifyDBCluster (Multi-AZ DB cluster)

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `PerformanceInsightsRetentionPeriod` parameter. Valid values are 7 (the default) or 731 (2 years).

Enabling the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL

The Performance Schema is an optional feature for monitoring Amazon RDS for MariaDB or MySQL runtime performance at a low level. You can use Performance Insights with or without the Performance Schema. The Performance Schema is designed to have minimal impact on database performance.

Topics
Overview of the Performance Schema

The Performance Schema monitors server events. In this context, an event is a server action that consumes time. Performance Schema events are distinct from binlog events and scheduler events.

The `PERFORMANCE_SCHEMA` storage engine collects event data using instrumentation in the database source code. The engine stores collected events in tables in the `performance_schema` database. You can query `performance_schema` just as you can query any other tables. For more information, see MySQL Performance Schema in MySQL Reference Manual.

When the Performance Schema is enabled for Amazon RDS for MariaDB or MySQL, Performance Insights uses it to provide more detailed information. For example, Performance Insights displays DB load categorized by detailed wait events. You can use wait events to identify bottlenecks. Without the Performance Schema, Performance Insights reports user states such as inserting and sending, which don't help you identify bottlenecks.

Options for enabling Performance Schema

You have the following options for enabling the Performance Schema:

- Allow Performance Insights to manage required Performance Schema parameters automatically.

  When you create an Amazon RDS for MariaDB or MySQL DB instance or Multi-AZ DB cluster with Performance Insights enabled, the Performance Schema is also enabled. In this case, Performance Insights automatically manages your Performance Schema parameters.

  For automatic management, the `performance_schema` must be set to 0 and the `Source` must be set to a value other than 0. By default, `Source` is `engine-default`. If you change the `performance_schema` value manually, and then later want to revert to automatic management, see Configuring the Performance Schema for automatic management (p. 531).

  **Important**
  When Performance Insights enables the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the instances that are running. The only way to see the changed values is to run the `SHOW GLOBAL VARIABLES` command.

- Set the required Performance Schema parameters yourself.

  For Performance Insights to list wait events, set all Performance Schema parameters as shown in the following table.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>performance_schema</code></td>
<td>1 (the <code>Source</code> column has the value <code>engine-default</code>)</td>
</tr>
<tr>
<td><code>performance-schema-consumer-events-waits-current</code></td>
<td>ON</td>
</tr>
<tr>
<td><code>performance-schema-instrument</code></td>
<td><code>wait/%=ON</code></td>
</tr>
<tr>
<td><code>performance_schema_consumer_global_instrumentation</code></td>
<td>ON</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Parameter Value</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>performance_schema_consumer_thread_instrumentation</td>
<td>ON</td>
</tr>
</tbody>
</table>

**Note**
If you enable or disable the Performance Schema, you must reboot the database. If you enable or disable Performance Insights, you don't need to reboot the database.

For more information, see Performance Schema Command Options and Performance Schema Option and Variable Reference in the MySQL documentation.

**Configuring the Performance Schema for automatic management**

The following table shows the difference in settings when Performance Insights is and isn't managing the Performance Schema.

<table>
<thead>
<tr>
<th>Performance Insights isn't managing the Performance Schema</th>
<th>Performance Insights is managing the Performance Schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>performance_schema is 0 or 1</td>
<td>performance_schema is 0</td>
</tr>
<tr>
<td>The <strong>Source</strong> column is set to <strong>user</strong></td>
<td>The <strong>Source</strong> column is set to <strong>system</strong></td>
</tr>
</tbody>
</table>

**To let Performance Insights manage the Performance Schema automatically**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Parameter groups**.
3. Select the name of the parameter group for your DB instance or Multi-AZ DB cluster.
4. Enter **performance_schema** in the search bar.
5. Select the **performance_schema** parameter.

6. Check whether **Source** is **system** and **Values** is 0. If so, Performance Insights is managing the Performance Schema automatically. If not, proceed to the next step.

7. Choose **Edit parameters**.
8. In **Values**, choose 0.
9. Select **Reset**. When you reset, Amazon RDS sets **Source** to **system** and **Values** to 0.
The **Reset parameters in DB parameter group** page appears.

10. Select **Reset parameters**.

11. Reboot the DB instance or Multi-AZ DB cluster.

**Important**
Whenever you enable or disable the Performance Schema, you must reboot the DB instance or Multi-AZ DB cluster.

For more information about modifying instance parameters, see Modifying parameters in a DB parameter group (p. 282). For more information about the dashboard, see Analyzing metrics with the Performance Insights dashboard (p. 535). For more information about the MySQL performance schema, see MySQL 8.0 Reference Manual.

### Configuring access policies for Performance Insights

To access Performance Insights, you must have the appropriate permissions from AWS Identity and Access Management (IAM). You have the following options for granting access:

- Attach the **AmazonRDSFullAccess** managed policy to an IAM user or role.
- Create a custom IAM policy and attach it to an IAM user or role.

Also, if you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key.

### Attaching the AmazonRDSFullAccess policy to an IAM principal

**AmazonRDSFullAccess** is an AWS-managed policy that grants access to all of the Amazon RDS API operations. This policy does the following:

- Grants access to related services used by the Amazon RDS console. For example, this policy grants access to event notifications using Amazon SNS.
- Grants permissions needed for using Performance Insights.

If you attach **AmazonRDSFullAccess** to an IAM user or role, the recipient can use Performance Insights with other console features.

### Creating a custom IAM policy for Performance Insights

For users who don't have full access with the **AmazonRDSFullAccess** policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM user or role, the recipient can use Performance Insights.

**To create a custom policy**

2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the JSON tab.
5. Copy and paste the following text, replacing `us-east-1` with the name of your AWS Region and `111122223333` with your customer account number.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PolicyStatement",
      "Effect": "Allow",
      "Action": [
        "rds:*",
        "ec2:*",
        "sns:*",
        "kms:*",
        "logs:*"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```
Performance Insights policies

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "pi:*",
    },
    {
      "Effect": "Allow",
      "Action": "rds:DescribeDBInstances",
      "Resource": "*"
    }
  ]
}
```

6. Choose **Review policy**.
7. Provide a name for the policy and optionally a description, and then choose **Create policy**.

You can now attach the policy to an IAM user or role. The following procedure assumes that you already have an IAM user available for this purpose.

**To attach the policy to an IAM user**

2. In the navigation pane, choose **Users**.
3. Choose an existing user from the list.
4. On the Summary page, choose **Add permissions**.
5. Choose **Attach existing policies directly**. For Search, type the first few characters of your policy name, as shown following.

6. Choose your policy, and then choose **Next: Review**.
7. Choose **Add permissions**.

---

533
Configuring an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you have the following options:

- Choose the default AWS managed key.

  Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

- Choose a customer managed key.

  If you specify a customer managed key, users in your account that call the Performance Insights API need the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key. You can configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see Using key policies in AWS KMS.

Example

The following sample key policy shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```json
{
  "Version": "2012-10-17",
  "Id": "your-policy",
  "Statement": [
    //This represents a statement that currently exists in your policy.
  ],
  //Starting here, add new statement to your policy for Performance Insights.
  //We recommend that you add one new statement for every RDS instance.
  "Sid": "Allow viewing RDS Performance Insights",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      //One or more principals allowed to access Performance Insights
      "arn:aws:iam::444455556666:role/Role1"
    ]
  },
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      //Restrict access to only RDS APIs (including Performance Insights).
      //Replace region with your AWS Region.
      //For example, specify us-west-2.
      "kms:ViaService": "rds.region.amazonaws.com"
    },
    "ForAnyValue:StringEquals": {
      //Restrict access to only data encrypted by Performance Insights.
      "kms:EncryptionContext:aws:pi:service": "rds",
      "kms:EncryptionContext:service": "pi",
      //Restrict access to a specific RDS instance.
      //The value is a DbiResourceId.
      "kms:EncryptionContext:aws:rds:db-id": "db-AAAAABBBBCCCCDDDDDEEEE"
    }
  }
}
```
Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can “slice” DB load by dimensions such as wait events or SQL.

Performance Insights dashboard

- Overview of the Performance Insights dashboard (p. 535)
- Opening the Performance Insights dashboard (p. 542)
- Analyzing DB load by wait events (p. 543)
- Analyzing running queries using the Performance Insights dashboard (p. 544)
- Analyzing Oracle execution plans using the Performance Insights dashboard (p. 559)
- Accessing the text of SQL statements (p. 562)
- Zooming In on the DB Load chart (p. 565)

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance. By default, the Performance Insights dashboard shows data for the last hour.
The dashboard is divided into the following parts:

1. **Counter Metrics** – Shows data for specific performance counter metrics.
2. **DB Load Chart** – Shows how the DB load compares to DB instance capacity as represented by the Max vCPU line.
3. **Top items** – Shows the top dimensions contributing to DB load.

**Topics**
- Counter metrics chart (p. 536)
- Database load chart (p. 538)
- Top dimensions table (p. 541)

**Counter metrics chart**

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.
The **Counter metrics** chart displays data for performance counters. The default metrics depend on the DB engine:

- MySQL and MariaDB – `db.SQL.Innodb_rows_read.avg`
- Oracle – `db.User.user calls.avg`
- PostgreSQL – `db.Transactions.xact_commit.avg`

![Counter Metrics Chart]

To change the performance counters, choose **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.
For descriptions of the counter metrics that you can add for each DB engine, see Performance Insights counter metrics (p. 597).

**Database load chart**

The **Database load** chart shows how the database activity compares to DB instance capacity as represented by the **Max vCPU** line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.
You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Oracle</th>
<th>SQL Server</th>
<th>PostgreSQL</th>
<th>MySQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>SQL</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>User</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Waits</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Plans</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Application</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Database</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Session type</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

The following image shows the dimensions for a PostgreSQL DB instance.
DB load details for a dimension item

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

To see details for any item for the selected time period in the legend, hover over that item.
Analyzing metrics with the Performance Insights dashboard

Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, Top SQL shows the SQL statements that contribute the most to DB load.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Supported engines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top SQL</td>
<td>The SQL statements that are currently running</td>
<td>All</td>
</tr>
<tr>
<td>Top waits</td>
<td>The event for which the database backend is waiting</td>
<td>All</td>
</tr>
</tbody>
</table>
Analyzing metrics with the Performance Insights dashboard

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Supported engines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top hosts</td>
<td>The host name of the connected client</td>
<td>All</td>
</tr>
<tr>
<td>Top users</td>
<td>The user logged in to the database</td>
<td>All</td>
</tr>
<tr>
<td>Top databases</td>
<td>The name of the database to which the client is connected</td>
<td>PostgreSQL, MySQL, and MariaDB only</td>
</tr>
<tr>
<td>Top applications</td>
<td>The name of the application that is connected to the database</td>
<td>PostgreSQL only</td>
</tr>
<tr>
<td>Top session types</td>
<td>The type of the current session</td>
<td>PostgreSQL only</td>
</tr>
</tbody>
</table>

To learn how to analyze queries by using the Top SQL tab, see Overview of the Top SQL tab (p. 544).

Opening the Performance Insights dashboard

To see the Performance Insights dashboard, use the following procedure.

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.

For DB instances with Performance Insights enabled, you can also reach the dashboard by choosing the Sessions item in the list of DB instances. Under Current activity, the Sessions item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.

4. (Optional) Choose a different time interval by selecting a button in the upper right. For example, to change the interval to 5 hours, select 5h.

In the following screenshot, the DB load interval is 5 hours.
5. (Optional) To refresh your data automatically, enable **Auto refresh.**

The Performance Insight dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 5 seconds.
- 1 hour refreshes every minute.
- 5 hours refreshes every minute.
- 24 hours refreshes every 5 minutes.
- 1 week refreshes every hour.

**Analyzing DB load by wait events**

If the **Database load** chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the **Database load** chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits shows if there are any resource or concurrency bottlenecks in the database. In this case, the **SQL** tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the **Database load** chart and see if there are any incidents of database load exceeding the **Max CPU** line.
2. If there is, look at the **Database load** chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the **SQL** tab on the top load items table are contributing most to those wait states. You can identify these by the **DB Load by Wait** column.
4. Choose one of these digest queries in the **SQL** tab to expand it and see the child queries that it is composed of.
Analyzing metrics with the Performance Insights dashboard

For example, in the dashboard following, log file sync waits account for most of the DB load. The LGWR all worker groups wait is also high. The Top SQL chart shows what is causing the log file sync waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

Analyzing running queries using the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about running queries in the Top SQL tab in the Top dimensions table. You can use this information to tune your queries.

Note
RDS for SQL Server doesn't show SQL-level statistics.

Topics
- Overview of the Top SQL tab (p. 544)
- Analyzing running queries in MariaDB and MySQL (p. 549)
- Analyzing running queries in Oracle (p. 552)
- Analyzing running queries in PostgreSQL (p. 556)

Overview of the Top SQL tab

By default, the Top SQL tab shows the SQL queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text, statistics, and Support SQL ID. You can also choose the statistics that you want to appear in the Top SQL tab.

Topics
- SQL statistics (p. 545)
SQL statistics

SQL statistics are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

A SQL digest is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be `SELECT * FROM emp WHERE lname= ?`. This digest might include the following child queries:

```
SELECT * FROM emp WHERE lname = 'Miller'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

Every line in the Top SQL table shows relevant statistics for the SQL statement or digest, as shown in the following example.

To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following screenshot, the selected query is a digest.

**Note**

A SQL digest groups similar SQL statements, but does not redact sensitive information.

Load by waits (AAS)

In Top SQL, the Load by waits (AAS) column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the DB Load Chart.
For example, you might group the DB load chart by wait states. You examine SQL queries in the top load items table. In this case, the DB Load by Waits bar is sized, segmented, and color-coded to show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.

SQL information

In the Top SQL table, you can open a statement to view its information. The information appears in the bottom pane.
The following types of identifiers (IDs) that are associated with SQL statements:

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn’t have access to your actual SQL IDs and SQL text.

- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn’t have access to your actual digest IDs and SQL text.

**Preferences**

You can control the statistics displayed in the Top SQL tab by choosing the Preferences icon.
When you choose the Preferences icon, the Preferences window opens.

To enable the statistics that you want to appear in the Top SQL tab, use your mouse to scroll to the bottom of the window, and then choose Continue.
Analyzing running queries in MariaDB and MySQL

MariaDB and MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics
- Digest table in MariaDB and MySQL (p. 549)
- Per-second statistics for MariaDB and MySQL (p. 549)
- Per-call statistics for MariaDB and MySQL (p. 550)
- Viewing SQL statistics for MariaDB and MySQL (p. 550)

Digest table in MariaDB and MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

```
Performance Insights is unable to collect SQL Digest statistics on new queries because the table events_statements_summary_by_digest is full. Please truncate events_statements_summary_by_digest table to clear the issue. Check the User Guide for more details.
```

In this situation, MariaDB and MySQL don’t track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically. For automatic management, the `performance_schema` parameter must be set to 0 and the Source must not be set to user.

If Performance Insights isn't managing the Performance Schema automatically, see Enabling the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL (p. 529).

In the AWS CLI, check the source of a parameter value by running the `describe-db-parameters` command.

Per-second statistics for MariaDB and MySQL

The following SQL statistics are available for MariaDB and MySQL DB instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.count_star_per_sec</code></td>
<td>Calls per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_timer_wait_per_sec</code></td>
<td>Average active executions per second (AAE)</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_full_join_per_sec</code></td>
<td>Select full join per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_range_check_per_sec</code></td>
<td>Select range check per second</td>
</tr>
<tr>

Viewing SQL statistics for MariaDB and MySQL

The statistics are available in the Top SQL tab of the Database load chart.

To view the SQL statistics

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Go to the Performance Insights dashboard.
3. Choose the SQL tab and expand a query.

Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart.

The following screenshot shows the preferences for MariaDB and MySQL DB instances.
Analyzing running queries in Oracle

Amazon RDS for Oracle collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of \texttt{V$SQL.SQL_ID}. At the digest level, the ID column shows the value of \texttt{V$SQL.FORCE_MATCHING_SIGNATURE}.

If the ID is 0 at the digest level, Oracle Database has determined that this statement is not suitable for reuse. In this case, the child SQL statements could belong to different digests. However, the statements are grouped together under the \texttt{digest_text} for the first SQL statement collected.

Analyzing running queries in PostgreSQL

PostgreSQL collects SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics
- Digest statistics for RDS PostgreSQL (p. 556)
- Per-second digest statistics for PostgreSQL (p. 556)
- Per-call digest statistics for PostgreSQL (p. 557)
- Viewing SQL statistics for PostgreSQL (p. 557)

Digest statistics for RDS PostgreSQL

To view SQL digest statistics, PostgreSQL must load the `pg_stat_statements` library. For RDS PostgreSQL DB instances that are compatible with PostgreSQL 11 or later, the database loads this library by default. For PostgreSQL DB instances that are compatible with PostgreSQL 10 or earlier, enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see Working with parameter groups (p. 278).

Note
Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

Per-second digest statistics for PostgreSQL

The following SQL digest statistics are available for PostgreSQL DB instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.calls_per_sec</code></td>
<td>Calls per second</td>
</tr>
<tr>

<tr>
<td>db.sql_tokenized.stats.blk_write_time_per_sec</td>
<td>Average concurrent writes per second</td>
</tr>
</tbody>
</table>

**Per-call digest statistics for PostgreSQL**

The following metrics provide per call statistics for a SQL statement.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.sql_tokenized.stats.rows_per_call</td>
<td>Rows per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.avg_latency_per_call</td>
<td>Average latency per call (in ms)</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_hit_per_call</td>
<td>Block hits per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_read_per_call</td>
<td>Block reads per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_written_per_call</td>
<td>Block writes per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.shared_blks_dirtied_per_call</td>
<td>Blocks dirtied per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.local_blks_hit_per_call</td>
<td>Local block hits per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.local_blks_read_per_call</td>
<td>Local block reads per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.local_blks_dirtied_per_call</td>
<td>Local block dirty per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.local_blks_written_per_call</td>
<td>Local block writes per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.temp_blks_written_per_call</td>
<td>Temporary block writes per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.temp_blks_read_per_call</td>
<td>Temporary block reads per call</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.blk_read_time_per_call</td>
<td>Read time per call (in ms)</td>
</tr>
<tr>
<td>db.sql_tokenized.stats.blk_write_time_per_call</td>
<td>Write time per call (in ms)</td>
</tr>
</tbody>
</table>

For more information about these metrics, see pg_stat_statements in the PostgreSQL documentation.

**Viewing SQL statistics for PostgreSQL**

The statistics are available in the Top SQL tab of the Database load chart.

**To view the SQL statistics**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Go to the Performance Insights dashboard.
3. Choose the SQL tab.
4. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart. The following screenshot shows the preferences for PostgreSQL.
Analyzing Oracle execution plans using the Performance Insights dashboard

When analyzing DB load on an Oracle Database, you might want to know which plans are contributing the most to DB load. For example, the top SQL statements at a given time might be using the plans shown in the following table.

<table>
<thead>
<tr>
<th>Top SQL</th>
<th>Plan</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT SUM(amount_sold) FROM sales WHERE prod_id = 10</td>
<td>Plan A</td>
</tr>
<tr>
<td>SELECT SUM(amount_sold) FROM sales WHERE prod_id = 521</td>
<td>Plan B</td>
</tr>
<tr>
<td>SELECT SUM(s_total) FROM sales WHERE region = 10</td>
<td>Plan A</td>
</tr>
<tr>
<td>SELECT * FROM emp WHERE emp_id = 1000</td>
<td>Plan C</td>
</tr>
<tr>
<td>SELECT SUM(amount_sold) FROM sales WHERE prod_id = 72</td>
<td>Plan A</td>
</tr>
</tbody>
</table>
With the plan feature of Performance Insights, you can do the following:

- Find out which plans are used by the top SQL queries.
  
  For example, you might find out that most of the DB load is generated by queries using plan A and plan B, with only a small percentage using plan C.

- Compare different plans for the same query.
  
  In the preceding example, three queries are identical except for the product ID. Two queries use plan A, but one query uses plan B. To see the difference in the two plans, you can use Performance Insights.

- Find out when a query switched to a new plan.
  
  You might see that a query used plan A and then switched to plan B at a certain time. Was there a change in the database at this point? For example, if a table is empty, the optimizer might choose a full table scan. If the table is loaded with a million rows, the optimizer might switch to an index range scan.

- Drill down to the specific steps of a plan with the highest cost.
  
  For example, the for a long-running query might show a missing a join condition in an equijoin. This missing condition forces a Cartesian join, which joins all rows of two tables.

You can perform the preceding tasks by using the plan capture feature of Performance Insights. Just as you can slice Oracle queries by wait events and top SQL, you can slice them by the plan dimension.

**To analyze Oracle execution plans using the console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Performance Insights**.
3. Choose an Oracle DB instance. The Performance Insights dashboard is displayed for that DB instance.
4. In the **Database load (DB load)** section, choose **Plans** next to **Slice by**.

   The Average active sessions chart shows the plans used by your top SQL statements. The plan hash values appear to the right of the color-coded squares. Each hash value uniquely identifies a plan.

5. Scroll down to the **Top SQL** tab.
In the following example, the top SQL digest has two plans. You can tell that it’s a digest by the question mark in the statement.

6. Choose the digest to expand it into its component statements.

In the following example, the SELECT statement is a digest query. The component queries in the digest use two different plans. The colors of the plans correspond to the database load chart. The total number of plans in the digest is shown in the second column.

<table>
<thead>
<tr>
<th>Load by plans (AAS)</th>
<th>SQL statements</th>
<th>Execution...</th>
<th>Plans cou...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT */ samedigest */ count(col1) FROM tab1 WHERE col1=?</td>
<td>0.36</td>
<td>1611.28</td>
<td>2 plans</td>
</tr>
<tr>
<td>DECLARE _output NUMBER; BEGIN while true loop FOR 1, 2000 LOOP...</td>
<td>0.24</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>SELECT</td>
<td>0.02</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>Unknown</td>
<td>0.02</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>PL/SQL EXECUTE</td>
<td>0.01</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>PSPO</td>
<td>0.01</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>DIAO</td>
<td>0.00</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>CSPT</td>
<td>0.00</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>LGWR</td>
<td>0.00</td>
<td>0.00</td>
<td>0 plans</td>
</tr>
<tr>
<td>SELECT */ diffdigest1469 */ count(col1) FROM tab1 WHERE col1=?</td>
<td>7.74</td>
<td>1 plans</td>
<td></td>
</tr>
</tbody>
</table>

7. Scroll down and choose two Plans to compare from Plans for digest query list.

You can view either one or two plans for a query at a time. The following screenshot compares the two plans in the digest, with hash 2032253151 and hash 1117438016. In the following example, 62% of the average active sessions running this digest query are using the plan on the left, whereas 38% are using the plan on the right.
In this example, the plans differ in an important way. Step 2 in plan 2032253151 uses an index scan, whereas plan 1117438016 uses a full table scan. For a table with a large number of rows, a query of a single row is almost always faster with an index scan.

8. (Optional) Choose **Copy** to copy the plan to the clipboard, or **Download** to save the plan to your hard drive.

**Accessing the text of SQL statements**

By default, each row in the Top SQL table shows 500 bytes of SQL text for each SQL statement. When a SQL statement exceeds 500 bytes, you can view more text by opening the statement in the Performance Insights dashboard. In this case, the maximum length for the displayed query is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. If you view a child SQL statement, you can also choose **Download**.

**Topics**
- Text size limits for Amazon RDS engines (p. 562)
- Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances (p. 563)
- Viewing and downloading SQL text in the Performance Insights dashboard (p. 563)

**Text size limits for Amazon RDS engines**

When you download a SQL statement, the database engine determines the maximum length of the text. You can download text up to the following per-engine limits:

- Amazon RDS for MySQL and MariaDB – 1,024 bytes
• Amazon RDS for Microsoft SQL Server – 4,096 characters
• Amazon RDS for Oracle – 1,000 bytes

The Performance Insights console displays up to the maximum that the engine returns. For example, if MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view or download the query, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. DescribeDimensionKeys and GetResourceMetrics return at most 500 bytes. GetDimensionKeyDetails returns the full query, but the size is subject to the engine limit.

Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances

Amazon RDS for PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter track_activity_query_size. This parameter has the following characteristics:

Default text size

On Amazon RDS for PostgreSQL version 9.6, the default setting for the track_activity_query_size parameter is 1,024 bytes. On Amazon RDS for PostgreSQL version 10 or higher, the default is 4,096 bytes.

Maximum text size

The limit for track_activity_query_size is 102,400 bytes for Amazon RDS for PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.

If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the track_activity_query_size DB instance parameter, see Run-time Statistics in the PostgreSQL documentation.

To increase the SQL text size, increase the track_activity_query_size limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Amazon RDS for PostgreSQL DB instance.

To change the setting when the instance uses the default parameter group

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see Modifying parameters in a DB parameter group (p. 282).

Viewing and downloading SQL text in the Performance Insights dashboard

In the Performance Insights dashboard, you can view or download SQL text.

To view more SQL text in the Performance Insights dashboard

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance.

The Performance Insights dashboard is displayed for your DB instance.

4. Scroll down to the Top SQL tab.

5. Choose a SQL statement.

SQL statements with text larger than 500 bytes look similar to the following image.

6. Scroll down to the SQL text tab.

The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

7. (Optional) Choose Copy to copy the displayed SQL statement, or choose Download to download the SQL statement to view the SQL text up to the DB engine limit.

**Note**

To copy or download the SQL statement, disable pop-up blockers.
Zooming In on the DB Load chart

You can use other features of the Performance Insights user interface to help analyze performance data.

Click-and-Drag Zoom In

In the Performance Insights interface, you can choose a small portion of the load chart and zoom in on the detail.

To zoom in on a portion of the load chart, choose the start time and drag to the end of the time period you want. When you do this, the selected area is highlighted. When you release the mouse, the load chart zooms in on the selected AWS Region, and the Top items table is recalculated.
Retrieving metrics with the Performance Insights API

When Performance Insights is enabled, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as SQL, Wait-event, User, or Host, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon RDS DB instance so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:

- Offload data into a database
- Add Performance Insights data to existing monitoring dashboards
- Build monitoring tools

To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see Turning Performance Insights
The Performance Insights API provides the following operations.

<table>
<thead>
<tr>
<th>Performance Insights action</th>
<th>AWS CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribeDimensionKeys</td>
<td><code>aws pi describe-dimension-keys</code></td>
<td>Retrieves the top N dimension keys for a metric for a specific time period.</td>
</tr>
<tr>
<td>GetDimensionKeyDetails</td>
<td><code>aws pi get-dimension-key-details</code></td>
<td>Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, GetDimensionKeyDetails retrieves the full text of the dimension <code>db.sql.statement</code> associated with this ID. This operation is useful because GetResourceMetrics and DescribeDimensionKeys don't support retrieval of large SQL statement text.</td>
</tr>
<tr>
<td>GetResourceMetadata</td>
<td><code>aws pi get-resource-metadata</code></td>
<td>Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.</td>
</tr>
<tr>
<td>GetResourceMetrics</td>
<td><code>aws pi get-resource-metrics</code></td>
<td>Retrieves Performance Insights metrics for a set of data sources over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.</td>
</tr>
<tr>
<td>ListAvailableResourceDimensions</td>
<td><code>aws pi list-available-resource-dimensions</code></td>
<td>Retrieve the dimensions that can be queried for each specified metric type on a specified instance.</td>
</tr>
<tr>
<td>ListAvailableResourceMetrics</td>
<td><code>aws pi list-available-resource-metrics</code></td>
<td>Retrieve all available metrics of the specified metric types that can be queried for a specified DB instance.</td>
</tr>
</tbody>
</table>

AWS CLI for Performance Insights

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

```
aws pi help
```

If you don’t have the AWS CLI installed, see Installing the AWS Command Line Interface in the AWS CLI User Guide for information about installing it.

Retrieving time-series metrics

The GetResourceMetrics operation retrieves one or more time-series metrics from the Performance Insights data. GetResourceMetrics requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses GetResourceMetrics to populate the Counter Metrics chart and the Database Load chart, as seen in the following image.

All metrics returned by GetResourceMetrics are standard time-series metrics, with the exception of db.load. This metric is displayed in the Database Load chart. The db.load metric is different from the other time-series metrics because you can break it into subcomponents called dimensions. In the previous image, db.load is broken down and grouped by the waits states that make up the db.load.

**Note**

GetResourceMetrics can also return the db.sampleload metric, but the db.load metric is appropriate in most cases.

For information about the counter metrics returned by GetResourceMetrics, see Performance Insights counter metrics (p. 597).

The following calculations are supported for the metrics:

- **Average** – The average value for the metric over a period of time. Append .avg to the metric name.
- **Minimum** – The minimum value for the metric over a period of time. Append .min to the metric name.
• Maximum – The maximum value for the metric over a period of time. Append `.max` to the metric name.
• Sum – The sum of the metric values over a period of time. Append `.sum` to the metric name.
• Sample count – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

• Average – 3
• Minimum – 1
• Maximum – 5
• Sum – 15
• Sample count – 5

For information about using the `get-resource-metrics` AWS CLI command, see `get-resource-metrics`.

For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```json
{
  "Metric": "string",
  "GroupBy": {
    "Group": "string",
    "Dimensions": ["string", ...],
    "Limit": integer
  },
  "Filter": {"string": "string" ...}
}
```

AWS CLI examples for Performance Insights

The following examples show how to use the AWS CLI for Performance Insights.

**Topics**

- Retrieving counter metrics (p. 569)
- Retrieving the DB load average for top wait events (p. 572)
- Retrieving the DB load average for top SQL (p. 574)
- Retrieving the DB load average filtered by SQL (p. 576)
- Retrieving the full text of a SQL statement (p. 579)

**Retrieving counter metrics**

The following screenshot shows two counter metrics charts in the AWS Management Console.
The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics --service-type RDS --identifier db-ID --start-time 2018-10-30T00:00:00Z --end-time 2018-10-30T01:00:00Z --period-in-seconds 60 --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
{"Metric": "os.cpuUtilization.idle.avg"}]
```

For Windows:

```bash
aws pi get-resource-metrics ^ --service-type RDS ^ --identifier db-ID ^ --start-time 2018-10-30T00:00:00Z ^ --end-time 2018-10-30T01:00:00Z ^ --period-in-seconds 60 ^ --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
{"Metric": "os.cpuUtilization.idle.avg"}]
```

You can also make a command easier to read by specifying a file for the `--metrics-query` option. The following example uses a file called `query.json` for the option. The file has the following contents.

```json
[
    {
        "Metric": "os.cpuUtilization.user.avg"
    },
    {
        "Metric": "os.cpuUtilization.idle.avg"
    }
]
```

Run the following command to use the file.

For Linux, macOS, or Unix:
aws pi get-resource-metrics
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json

For Windows:
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json

The preceding example specifies the following values for the options:

- `--service-type` – RDS for Amazon RDS
- `--identifier` – The resource ID for the DB instance
- `--start-time` and `--end-time` – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- `--period-in-seconds` – 60 for a per-minute query
- `--metric-queries` – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is `avg` for each query. As with Amazon CloudWatch, the supported functions are `min`, `max`, `total`, and `avg`.

The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1540857600.0,
  "AlignedEndTime": 1540861200.0,
  "MetricList": [
    { //A list of key/datapoints
      "Key": {
        "Metric": "os.cpuUtilization.user.avg" //Metric1
      },
      "DataPoints": [
        //Each list of datapoints has the same timestamps and same number of items
        { "Timestamp": 1540857660.0, //Minute1
          "Value": 4.0
        },
        { "Timestamp": 1540857720.0, //Minute2
          "Value": 4.0
        },
        { "Timestamp": 1540857780.0, //Minute 3
          "Value": 10.0
```
The response has an Identifier, AlignedStartTime, and AlignedEndTime. By the --period-in-seconds value was 60, the start and end times have been aligned to the minute. If the --period-in-seconds was 3600, the start and end times would have been aligned to the hour.

The MetricList in the response has a number of entries, each with a Key and a DataPoints entry. Each DataPoint has a Timestamp and a Value. Each DataPoints list has 60 data points because the queries are for per-minute data over an hour, with Timestamp1/Minute1, Timestamp2/Minute2, and so on, up to Timestamp60/Minute60.

Because the query is for two different counter metrics, there are two elements in the response MetricList.

**Retrieving the DB load average for top wait events**

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the db.load.avg for the last hour with load divided according to the top seven wait events. The command is the same as the command in Retrieving counter metrics (p. 569). However, the query.json file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
  }
]
```

Run the following command.

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file:///query.json
```
For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The example specifies the metric of `db.load.avg` and a GroupBy of the top seven wait events. For details about valid values for this example, see DimensionGroup in the Performance Insights API Reference.

The response looks similar to the following.

```
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1540857600.0,
  "AlignedEndTime": 1540861200.0,
  "MetricList": [
    { //A list of key/datapoints
      "Key": {
        //A Metric with no dimensions. This is the total db.load.avg
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        //Each list of datapoints has the same timestamps and same number of items
        { "Timestamp": 1540857660.0, //Minute1
          "Value": 0.5166666666666667
        },
        { "Timestamp": 1540857720.0, //Minute2
          "Value": 0.38333333333333336
        },
        { "Timestamp": 1540857780.0, //Minute 3
          "Value": 0.26666666666666666
        }
      ]
    },
    { "Key": {
        //Another key. This is db.load.avg broken down by CPU
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.name": "CPU",
          "db.wait_event.type": "CPU"
        }
      },
      "DataPoints": [
        { "Timestamp": 1540857660.0, //Minute1
          "Value": 0.35
        },
        { "Timestamp": 1540857720.0, //Minute2
          "Value": 0.15
        }
      ]
    }
  ]
}
```
In this response, there are eight entries in the MetricList. There is one entry for the total `db.load.avg`, and seven entries each for the `db.load.avg` divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

Retrieving the DB load average for top SQL

The following example groups `db.wait_events` by the top 10 SQL statements. There are two different groups for SQL statements:

- `db.sql` – The full SQL statement, such as `select * from customers where customer_id = 123`
- `db.sql_tokenized` – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use `db.sql_tokenized` when querying. However, especially when you're interested in explain plans, sometimes it's more useful to examine full SQL statements with parameters, and query grouping by `db.sql`. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is the similar to the command in Retrieving the DB load average for top wait events (p. 572). However, the query.json file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.sql_tokenized",
      "Limit": 10
    }
  }
]
```

The following example uses `db.sql_tokenized`.

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics
  --service-type RDS
  --identifier db-ID
  --start-time 2018-10-29T00:00:00Z
  --end-time 2018-10-30T00:00:00Z
  --period-in-seconds 3600
  --metric-queries file://query.json
```

For Windows:

```bash
aws pi get-resource-metrics
  --service-type RDS
  --identifier db-ID
  --start-time 2018-10-29T00:00:00Z
  --end-time 2018-10-30T00:00:00Z
```

//... In total we have 8 key/datapoints entries, 1) total, 2-8) Top Wait Events
] //end of MetricList
} //end of response
This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of `db.load.avg` and a `GroupBy` of the top seven wait events. For details about valid values for this example, see `DimensionGroup` in the `Performance Insights API Reference`.

The response looks similar to the following.

```json
{
  "AlignedStartTime": 1540771200.0,
  "AlignedEndTime": 1540857600.0,
  "Identifier": "db-XXX",
  "MetricList": [ //11 entries in the MetricList
    { //First key is total
      "Key": { //First key is total
        "Metric": "db.load.avg"
      }
    } //Each DataPoints list has 24 per-hour Timestamps and a value
    { //Each DataPoints list has 24 per-hour Timestamps and a value
      "Value": 1.6964980544747081,
      "Timestamp": 1540774800.0
    },
    //... 24 datapoints
  ],
  "Key": { //Next key is the top tokenized SQL
    "Dimensions": {
      "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email) VALUES
(nextval(?),?,?,?)",
      "db.sql_tokenized.db_id": "pi-2372568224",
      "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
    }
  },
  "DataPoints": [ //... 24 datapoints
    
  ],
  // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
} //End of MetricList
} //End of response
```

This response has 11 entries in the `MetricList` (1 total, 10 top tokenized SQL), with each entry having 24 per-hour `DataPoints`.

For tokenized SQL, there are three entries in each dimensions list:

- `db.sql_tokenized.statement` – The tokenized SQL statement.
- `db.sql_tokenized.db_id` – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn't available. This example returns the `pi-2372568224` synthetic ID.
- `db.sql_tokenized.id` – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It's named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data.
the example preceding, both the tokenized.statement and the tokenized.db_id are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a Group in GroupBy. However, for finer-grained control over the data that’s returned, specify the list of dimensions. For example, if all that is needed is the db.sql_tokenized.statement, then a Dimensions attribute can be added to the query.json file.

```
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.sql_tokenized",
      "Dimensions": ["db.sql_tokenized.statement"],
      "Limit": 10
    }
  }
]
```

Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in Retrieving the DB load average for top SQL (p. 574). However, the query.json file has the following contents.

```
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.wait_event",
      "Limit": 5
    },
    "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }
  }
]
```
For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-\ ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds \ 60 \
  --metric-queries file://query.json
```

For Windows:

```bash
aws pi get-resource-metrics ^ \
  --service-type RDS ^ \
  --identifier db-\ ID ^ \
  --start-time 2018-10-30T00:00:00Z ^ \
  --end-time 2018-10-30T01:00:00Z ^ \
  --period-in-seconds 60 ^ \
  --metric-queries file://query.json
```

The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1556215200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.4878117913832196
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.192823803967328
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/aurora_redo_log_flush"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.1360544217687074
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.058051341890315
        }
      ]
    }
  ]
}
```
{ "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "io", "db.wait_event.name": "wait/io/table/sql/handler" } }, "DataPoints": [ { "Timestamp": 1556218800.0, "Value": 0.16241496598639457 }, { "Timestamp": 1556222400.0, "Value": 0.05163605606093349 } ] }, { "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "synch", "db.wait_event.name": "wait/synch/mutex/innodb/aurora_lock_thread_slot_futex" } }, "DataPoints": [ { "Timestamp": 1556218800.0, "Value": 0.11479591836734694 }, { "Timestamp": 1556222400.0, "Value": 0.013127187864644107 } ] }, { "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "CPU", "db.wait_event.name": "CPU" } }, "DataPoints": [ { "Timestamp": 1556218800.0, "Value": 0.05215419501133787 }, { "Timestamp": 1556222400.0, "Value": 0.05805134189031505 } ] }, { "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "synch", "db.wait_event.name": "wait/synch/mutex/innodb/lock_wait_mutex" } }, "DataPoints": [ ] }
In this response, all values are filtered according to the contribution of tokenized SQL
AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order
than a query without a filter, because it’s the top five wait events that affected the filtered SQL.

Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance
db-10BCD2EFGH1J3KL4M5NO6PQRS5. The --group is db.sql, and the --group-identifier is
db.sql.id. In this example, my-sql-id represents a SQL ID retrieved by invoking pi get-resource-
metrics or pi describe-dimension-keys.

Run the following command.

For Linux, macOS, or Unix:

```bash
aws pi get-dimension-key-details --service-type RDS --identifier db-10BCD2EFGH1J3KL4M5NO6PQRS5 --group db.sql --group-identifier my-sql-id --requested-dimensions statement
```

For Windows:

```bash
aws pi get-dimension-key-details --service-type RDS --identifier db-10BCD2EFGH1J3KL4M5NO6PQRS5 --group db.sql --group-identifier my-sql-id --requested-dimensions statement
```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of
the SQL statement, without truncating it.

```json
{
  "Dimensions": [
    {
      "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d
WHERE e.department_id=d.department_id",
      "Dimension": "db.sql.statement",
      "Status": "AVAILABLE"
    },
    ...
  ]
}
```
Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events in the CloudTrail console in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in AWS CloudTrail User Guide.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in AWS CloudTrail User Guide:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Performance Insights operations are logged by CloudTrail and are documented in the Performance Insights API Reference. For example, calls to the DescribeDimensionKeys and GetResourceMetrics operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.
Performance Insights log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the GetResourceMetrics operation.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T19:28:46Z",
    "eventSource": "pi.amazonaws.com",
    "eventName": "GetResourceMetrics",
    "awsRegion": "us-east-1",

```
Monitoring the OS with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics
- Overview of Enhanced Monitoring (p. 582)
- Setting up and enabling Enhanced Monitoring (p. 583)
- Viewing OS metrics in the RDS console (p. 587)
- Viewing OS metrics using CloudWatch Logs (p. 590)

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements.

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see Enhanced Monitoring in the Amazon RDS FAQs.

Topics
- Enhanced Monitoring availability (p. 582)
- Differences between CloudWatch and Enhanced Monitoring metrics (p. 582)
- Retention of Enhanced Monitoring metrics (p. 583)
- Cost of Enhanced Monitoring (p. 583)

Enhanced Monitoring availability

Enhanced Monitoring is available for the following database engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Enhanced Monitoring is available for all DB instance classes except for the db.m1.small instance class.

Differences between CloudWatch and Enhanced Monitoring metrics

A hypervisor creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU
utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

**Retention of Enhanced Monitoring metrics**

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.

To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the RDSOSMetrics log group in the CloudWatch console. For more information, see Change log data retention in CloudWatch logs in the Amazon CloudWatch Logs User Guide.

**Cost of Enhanced Monitoring**

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see Amazon CloudWatch pricing.

**Setting up and enabling Enhanced Monitoring**

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

**Topics**

- Creating an IAM role for Enhanced Monitoring (p. 583)
- Turning Enhanced Monitoring on and off (p. 584)
- Protecting against the confused deputy problem (p. 586)

**Creating an IAM role for Enhanced Monitoring**

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

**Topics**

- Creating the IAM role when you enable Enhanced Monitoring (p. 584)
Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named rds-monitoring-role. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in Turning Enhanced Monitoring on and off (p. 584).
2. Set Monitoring Role to Default in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the PassRole permission. For more information, see Example 2 in Granting a user permissions to pass a role to an AWS service in the IAM User Guide.

To create an IAM role for Amazon RDS enhanced monitoring

2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Choose the AWS service tab, and then choose RDS from the list of services.
5. Choose RDS - Enhanced Monitoring, and then choose Next: Permissions.
6. Ensure that the Attached permissions policy page shows AmazonRDSEnhancedMonitoringRole, and then choose Next: Tags.
7. On the Add tags page, choose Next: Review.
8. For Role Name, enter a name for your role. For example, enter emaccess.

The trusted entity for your role is the AWS service monitoring.rds.amazonaws.com.
9. Choose Create role.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

Console

You can turn on Enhanced Monitoring when you create a DB instance, Multi-AZ DB cluster, or read replica, or when you modify a DB instance or Multi-AZ DB cluster. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the Databases page:
• **Create a DB instance or Multi-AZ DB cluster** – Choose Create database.
• **Create a read replica** – Choose Actions, then Create read replica.
• **Modify a DB instance or Multi-AZ DB cluster** – Choose Modify.

**To turn Enhanced Monitoring on or off in the RDS console**

1. Scroll to Additional configuration.
2. In Monitoring, choose Enable Enhanced Monitoring for your DB instance or read replica. To turn Enhanced Monitoring off, choose Disable Enhanced Monitoring.
3. Set the Monitoring Role property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role.
4. Set the Granularity property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The Granularity property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.

The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

**AWS CLI**

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the --monitoring-interval option to a value other than 0 and set the --monitoring-role-arn option to the role you created in Creating an IAM role for Enhanced Monitoring (p. 583).

- create-db-instance
- create-db-instance-read-replica
- modify-db-instance
- create-db-cluster (Multi-AZ DB cluster)
- modify-db-cluster (Multi-AZ DB cluster)

The --monitoring-interval option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the AWS CLI, set the --monitoring-interval option to 0 in these commands.

**Example**

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \ 
  --db-instance-identifier mydbinstance \ 
  --monitoring-interval 30 \ 
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```bash
aws rds modify-db-instance ^
```
Example

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier mydbcluster --monitoring-interval 30 --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier mydbcluster --monitoring-interval 30 --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To turn on Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than 0 and set the `MonitoringRoleArn` parameter to the role you created in Creating an IAM role for Enhanced Monitoring (p. 583). Set these parameters in the following actions:

- CreateDBInstance
- CreateDBInstanceReadReplica
- ModifyDBInstance
- CreateDBCluster (Multi-AZ DB cluster)
- ModifyDBCluster (Multi-AZ DB cluster)

The `MonitoringInterval` parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the RDS API, set `MonitoringInterval` to 0.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem.

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.
The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. For Amazon RDS, set `aws:SourceArn` to `arn:aws:rds:Region:my-account-id:db:dbname`.

The following example uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy to prevent the confused deputy problem.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringLike": {
                    "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db:dbname"
                },
                "StringEquals": {
                    "aws:SourceAccount": "my-account-id"
                }
            }
        }
    ]
}
```

**Viewing OS metrics in the RDS console**

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring for Monitoring**.

The Enhanced Monitoring page is shown following.

Some DB instances use more than one disk for the DB instance's data storage volume. On those DB instances, the **Physical Devices** graphs show metrics for each one of the disks. For example, the following graph shows metrics for four disks.
**Note**
Currently, **Physical Devices** graphs are not available for Microsoft SQL Server DB instances.

When you are viewing aggregated **Disk I/O** and **File system** graphs, the `rdsdev` device relates to the `/rdsdbdata` file system, where all database files and logs are stored. The `filesystem` device relates to the `/` file system (also known as root), where files related to the operating system are stored.

If the DB instance is a Multi-AZ deployment, you can view the OS metrics for the primary DB instance and its Multi-AZ standby replica. In the **Enhanced monitoring** view, choose **primary** to view the OS metrics for the primary DB instance, or choose **secondary** to view the OS metrics for the standby replica.
For more information about Multi-AZ deployments, see Multi-AZ deployments for high availability (p. 65).

**Note**
Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB or Microsoft SQL Server DB instances.

If you want to see details for the processes running on your DB instance, choose **OS process list** for Monitoring.

The **Process List** view is shown following.

The Enhanced Monitoring metrics shown in the **Process list** view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example `mysqld` for MySQL DB instances. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.

- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.

- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.
The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see Viewing OS metrics using CloudWatch Logs (p. 590).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

**Viewing OS metrics using CloudWatch Logs**

After you have enabled Enhanced Monitoring for your DB instance or Multi-AZ DB cluster, you can view the metrics for it using CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored. The log stream identifier is the resource identifier (`DbiResourceId`) for the DB instance or DB cluster.

**To view Enhanced Monitoring log data**

2. If necessary, choose the AWS Region that your DB instance or Multi-AZ DB cluster is in. For more information, see Regions and endpoints in the Amazon Web Services General Reference.
3. Choose Logs in the navigation pane.
4. Choose `RDSOSMetrics` from the list of log groups.

   In a Multi-AZ DB instance deployment, log files with `-secondary` appended to the name are for the Multi-AZ standby replica.

5. Choose the log stream that you want to view from the list of log streams.
## Metrics reference for Amazon RDS

In this reference, you can find descriptions of Amazon RDS metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

### Topics
- Amazon CloudWatch metrics for Amazon RDS (p. 591)
- Amazon CloudWatch dimensions for Amazon RDS (p. 595)
- Amazon CloudWatch metrics for Performance Insights (p. 595)
- Performance Insights counter metrics (p. 597)
- OS metrics in Enhanced Monitoring (p. 606)

### Amazon CloudWatch metrics for Amazon RDS

The `AWS/RDS` namespace in Amazon CloudWatch includes the following metrics.

**Note**
The Amazon RDS console might display metrics in units that are different from the units sent to Amazon CloudWatch. For example, the Amazon RDS console might display a metric in megabytes (MB), while the metric is sent to Amazon CloudWatch in bytes.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Console name</th>
<th>Description</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>BinLogDiskUsage</td>
<td>Binary Log Disk Usage (MB)</td>
<td>The amount of disk space occupied by binary logs. If automatic backups are enabled for MySQL and MariaDB instances, including read replicas, binary logs are created.</td>
<td>Bytes</td>
</tr>
<tr>
<td>BurstBalance</td>
<td>Burst Balance (Percent)</td>
<td>The percent of General Purpose SSD (gp2) burst-bucket I/O credits available.</td>
<td>Percent</td>
</tr>
<tr>
<td>CPUUtilization</td>
<td>CPU Utilization (Percent)</td>
<td>The percentage of CPU utilization.</td>
<td>Percent</td>
</tr>
<tr>
<td>CPUCreditUsage</td>
<td>CPU Credit Usage (Count)</td>
<td>(T2 instances) The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100 percent utilization for one minute or an equivalent combination of vCPUs, utilization, and time. For example, you might have one vCPU running at 50 percent utilization for two minutes or two vCPUs running at 25 percent utilization for two minutes. CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.</td>
<td>Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>CPUCreditBalance</td>
<td>CPU Credit Balance (Count)</td>
<td>(T2 instances) The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 instances, the number of CPU credits that an instance has earned since it was launched or started.</td>
<td>Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
<td>Units</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits don't count towards the limit. The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the CPUCreditBalance don't expire. When the instance stops, the CPUCreditBalance does not persist, and all accrued credits are lost. CPU credit metrics are available at a five-minute frequency only.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DatabaseConnections</td>
<td>DB:Connections</td>
<td>The number of client network connections to the database instance. The number of database sessions can be higher than the metric value because the metric value doesn't include the following: • Sessions that no longer have a network connection but which the database hasn't cleaned up • Sessions created by the database engine for its own purposes • Sessions created by the database engine's parallel execution capabilities • Sessions created by the database engine job scheduler • Amazon RDS connections</td>
<td>Count</td>
</tr>
<tr>
<td>DiskQueueDepth</td>
<td>Queue Depth</td>
<td>The number of outstanding I/Os (read/write requests) waiting to access the disk.</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
<td>Units</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>EBSByteBalance %</td>
<td><strong>EBS Byte Balance</strong> (percent)</td>
<td>The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</td>
<td>Percent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in Amazon EC2 User Guide for Linux Instances. The Sum statistic is not applicable to this metric.</td>
<td></td>
</tr>
<tr>
<td>EBSI0Balance%</td>
<td><strong>EBS IO Balance</strong> (percent)</td>
<td>The percentage of I/O credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</td>
<td>Percent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in Amazon EC2 User Guide for Linux Instances. The Sum statistic is not applicable to this metric.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>This metric is different from BurstBalance. To learn how to use this metric, see Improving application performance and reducing costs with Amazon EBS-Optimized Instance burst capability.</td>
<td></td>
</tr>
<tr>
<td>FailedSQLServerJobs Count/Minute</td>
<td><strong>Failed SQL Server Agent Jobs Count</strong> (Count/Minute)</td>
<td>The number of failed Microsoft SQL Server Agent jobs during the last minute.</td>
<td>Count/Minute</td>
</tr>
<tr>
<td>FreeableMemory MB</td>
<td><strong>Freeable Memory</strong> (MB)</td>
<td>The amount of available random access memory.</td>
<td>Bytes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For MariaDB, MySQL, Oracle, and PostgreSQL DB instances, this metric reports the value of the MemAvailable field of /proc/meminfo.</td>
<td></td>
</tr>
<tr>
<td>FreeLocalStorage MB</td>
<td><strong>Free Local Storage</strong> (MB)</td>
<td>The amount of available local storage space. Only applies to Multi-AZ DB clusters.</td>
<td>Bytes</td>
</tr>
<tr>
<td>FreeStorageSpace MB</td>
<td><strong>Free Storage Space</strong> (MB)</td>
<td>The amount of available storage space.</td>
<td>Bytes</td>
</tr>
<tr>
<td>MaximumUsedTransactionIDs Count/Minute</td>
<td><strong>Maximum Used Transaction IDs</strong> (Count)</td>
<td>The maximum transaction IDs that have been used. Applies to PostgreSQL.</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
<td>Units</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>NetworkReceiveThroughput</td>
<td>Network Receive Throughput (MB/Second)</td>
<td>The incoming (receive) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.</td>
<td>Bytes/Second</td>
</tr>
<tr>
<td>NetworkTransmitThroughput</td>
<td>Network Transmit Throughput (MB/Second)</td>
<td>The outgoing (transmit) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.</td>
<td>Bytes/Second</td>
</tr>
<tr>
<td>OldestReplicationSlotLag</td>
<td>Oldest Replication Slot Lag (MB)</td>
<td>The lagging size of the replica lagging the most in terms of write-ahead log (WAL) data received. Applies to PostgreSQL.</td>
<td>Bytes</td>
</tr>
<tr>
<td>ReadIOPS</td>
<td>Read IOPS (Count/Second)</td>
<td>The average number of disk read I/O operations per second.</td>
<td>Count/Second</td>
</tr>
<tr>
<td>ReadIOPSLocalStorage</td>
<td>Read IOPS Local Storage (Count/Second)</td>
<td>The average number of disk read I/O operations to local storage per second. Only applies to Multi-AZ DB clusters.</td>
<td>Count/Second</td>
</tr>
<tr>
<td>ReadLatency</td>
<td>Read Latency (Milliseconds)</td>
<td>The average amount of time taken per disk I/O operation.</td>
<td>Seconds</td>
</tr>
<tr>
<td>ReadLatencyLocalStorage</td>
<td>Read Latency Local Storage (Milliseconds)</td>
<td>The average amount of time taken per disk I/O operation for local storage. Only applies to Multi-AZ DB clusters.</td>
<td>Seconds</td>
</tr>
<tr>
<td>ReadThroughput</td>
<td>Read Throughput (MB/Second)</td>
<td>The average number of bytes read from disk per second.</td>
<td>Bytes/Second</td>
</tr>
<tr>
<td>ReadThroughputLocalStorage</td>
<td>Read Throughput Local Storage (MB/Second)</td>
<td>The average number of bytes read from disk per second for local storage. Only applies to Multi-AZ DB clusters.</td>
<td>Bytes/Second</td>
</tr>
<tr>
<td>ReplicaLag</td>
<td>Replica Lag (Milliseconds)</td>
<td>For read replica configurations, the amount of time a read replica DB instance lags behind the source DB instance. Applies to MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL read replicas. For Multi-AZ DB clusters, the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance.</td>
<td>Seconds</td>
</tr>
<tr>
<td>ReplicationSlotDiskUsage</td>
<td>Replica Slot Disk Usage (MB)</td>
<td>The disk space used by replication slot files. Applies to PostgreSQL.</td>
<td>Bytes</td>
</tr>
<tr>
<td>SwapUsage</td>
<td>Swap Usage (MB)</td>
<td>The amount of swap space used on the DB instance. This metric is not available for SQL Server.</td>
<td>Bytes</td>
</tr>
<tr>
<td>TransactionLogsDiskUsage</td>
<td>Transaction Logs Disk Usage (MB)</td>
<td>The disk space used by transaction logs. Applies to PostgreSQL.</td>
<td>Bytes</td>
</tr>
</tbody>
</table>
### Amazon CloudWatch dimensions for Amazon RDS

You can filter Amazon RDS metrics data by using any dimension in the following table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Filters the requested data for . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBInstanceIdentifier</td>
<td>A specific DB instance.</td>
</tr>
<tr>
<td>DatabaseClass</td>
<td>All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class <code>db.r5.large</code>.</td>
</tr>
<tr>
<td>EngineName</td>
<td>The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name <code>mysql</code>.</td>
</tr>
<tr>
<td>SourceRegion</td>
<td>The specified Region only. For example, you can aggregate metrics for all DB instances in the <code>us-east-1</code> Region.</td>
</tr>
</tbody>
</table>

### Amazon CloudWatch metrics for Performance Insights

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.
## Amazon Relational Database Service User Guide

### CloudWatch metrics for Performance Insights

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBLoad</td>
<td>The number of active sessions for the DB engine. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as <code>db.load.avg</code>.</td>
</tr>
<tr>
<td>DBLoadCPU</td>
<td>The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as <code>db.load.avg</code>, filtered by the wait event type CPU.</td>
</tr>
<tr>
<td>DBLoadNonCPU</td>
<td>The number of active sessions where the wait event type is not CPU.</td>
</tr>
</tbody>
</table>

**Note**

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the `DBLoad` metric by running the `get-metric-statistics` command.

```bash
aws cloudwatch get-metric-statistics \
  --region us-west-2 \ 
  --namespace AWS/RDS \ 
  --metric-name DBLoad \ 
  --period 60 \ 
  --statistics Average \ 
  --start-time 1532035185 \ 
  --end-time 1532036185 \ 
  --dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```json
{
  "Datapoints": [
    {
      "Timestamp": "2021-07-19T21:30:00Z",
      "Unit": "None",
      "Average": 2.1
    },
    {

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load.

Topics
- Performance Insights counters for Amazon RDS for MariaDB and MySQL (p. 597)
- Performance Insights counters for Amazon RDS for Microsoft SQL Server (p. 601)
- Performance Insights counters for Amazon RDS for Oracle (p. 603)
- Performance Insights counters for Amazon RDS for PostgreSQL (p. 604)

Performance Insights counters for Amazon RDS for MariaDB and MySQL

The following database counters are available with Performance Insights for Amazon RDS for MariaDB and MySQL.

Topics
- Native counters for RDS for MariaDB and RDS for MySQL (p. 597)
- Non-native counters for Amazon RDS for MariaDB and MySQL (p. 599)

Native counters for RDS for MariaDB and RDS for MySQL

For definitions of these native metrics, see Server Status Variables in the MySQL documentation.

<td>SQL Statistics</td>
<td>Re-compilations per second</td>
<td>db.SQL Statistics.SQL Re-Compilations</td>
</tr>
</tbody>
</table>

### Performance Insights counters for Amazon RDS for Oracle

The following database counters are available with Performance Insights for RDS for Oracle.

#### Native counters for RDS for Oracle

You can find definitions for these native metrics in Statistics Descriptions in the Oracle documentation.

**Note**

For the **CPU used by this session** counter metric, the unit has been transformed from the native centiseconds to active sessions to make the value easier to use. For example, CPU send in the DB Load chart represents the demand for CPU. The counter metric **CPU used by this session** represents the amount of CPU used by Oracle sessions. You can compare CPU send to the **CPU used by this session** counter metric. When demand for CPU is higher than CPU used, sessions are waiting for CPU time.

<table>
<thead>
<tr>
<th>Counter</th>
<th>Type</th>
<th>Unit</th>
<th>Metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU used by this session</td>
<td>User</td>
<td>Active sessions</td>
<td>db.User.CPU used by this session</td>
</tr>
<tr>
<td>SQL*Net roundtrips to/from client</td>
<td>User</td>
<td>Roundtrips per second</td>

**Non-native counters for Amazon RDS for PostgreSQL**

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.
OS metrics in Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. The following tables list the OS metrics available using Amazon CloudWatch Logs.

Topics

- OS metrics for MariaDB, MySQL, Oracle, and PostgreSQL (p. 606)
- OS metrics for Microsoft SQL Server (p. 611)

OS metrics for MariaDB, MySQL, Oracle, and PostgreSQL

<table>
<thead>
<tr>
<th>Group</th>

</table>
Monitoring events, logs, and streams in an Amazon RDS DB instance

When you monitor your Amazon RDS databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance

Monitoring metrics in an Amazon RDS instance (p. 491) explains how to monitor your instance using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services and routes that data to targets such as AWS Lambda. This enables you to monitor events that happen in services, and build event-driven architectures. For more information, see the Amazon EventBridge User Guide.

- **Amazon CloudWatch Logs** lets you monitor, store, and access your log files from Amazon RDS instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

- **Database Activity Streams** is an Amazon RDS feature that provides a near-real-time stream of the activity in your Oracle DB instance. Amazon RDS pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Topics

- Viewing logs, events, and streams in the Amazon RDS console (p. 615)
- Monitoring Amazon RDS events (p. 619)
- Monitoring Amazon RDS log files (p. 646)
- Monitoring Amazon RDS API calls in AWS CloudTrail (p. 686)
- Monitoring Amazon RDS for Oracle with Database Activity Streams (p. 690)

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.
The **Logs & events** tab for your RDS DB instance shows the following information:

- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance. If you haven't configured alarms, you can create them in the RDS console. For more information, see [Monitoring Amazon RDS metrics with Amazon CloudWatch](p. 508).

- **Recent events** – Shows a summary of events (environment changes) for your RDS DB instance. For more information, see [Viewing Amazon RDS events](p. 622).

- **Logs** – Shows database log files generated by a DB instance. For more information, see [Monitoring Amazon RDS log files](p. 646).

The **Configuration** tab displays information about database activity streams.

**To view logs, events, and streams for your DB instance in the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to monitor.

The database page appears. The following example shows an Oracle database named **orclb**.

![Database Page Screenshot](image)

4. Choose **Logs & events**.

The Logs & events section appears.
5. Choose **Configuration**.

The following example shows the status of the database activity streams for your RDS for Oracle DB instance.
### Storage
- Encryption: Not enabled
- Storage type: General Purpose SSD (gp2)
- Provisioned IOPS: 0
- Storage: 98 GiB
- Storage autoscaling: Enabled
- Maximum storage threshold: 1000 GiB

### Performance Insights
- Performance Insights enabled: Yes
- AWS KMS key: aws/rds
- Retention period: 731 days

### Published logs
- CloudWatch Logs: Alert, Audit, Listener, Trace

### Database activity stream
- Status: Stopped
Monitoring Amazon RDS events

An event indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service.

Topics
- Overview of events for Amazon RDS (p. 619)
- Viewing Amazon RDS events (p. 622)
- Using Amazon RDS event notification (p. 623)
- Creating a rule that triggers on an Amazon RDS event (p. 642)

Overview of events for Amazon RDS

An RDS event indicates a change in the Amazon RDS environment. For example, Amazon RDS generates an event when the state of a DB instance changes from pending to running. Amazon RDS delivers events to CloudWatch Events and EventBridge in near-real time.

Note
Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to your DB instances, DB snapshots, and DB parameter groups. This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event

The following examples illustrate different types of Amazon RDS events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see Tutorial: log the state of an Amazon RDS instance using EventBridge (p. 643).

Topics
- Example of a DB instance event (p. 619)
- Example of a DB parameter group event (p. 620)
- Example of a DB snapshot event (p. 620)

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named my-db-instance. The event ID is RDS-EVENT-0049.

```json
{
  "version": "0",
  "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ff84e",
  "detail-type": "RDS DB Instance Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-09-27T22:36:43Z",
  "region": "us-east-1",
  "resources": [
```

619
Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is RDS-EVENT-0037.

```json
{
  "version": "0",
  "id": "b4e28571-85d4-695f-930-0153b71dcb42",
  "detail-type": "RDS DB Parameter Group Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
  ],
  "detail": {
    "EventCategories": ["configuration change"],
    "SourceType": "DB_PARAM",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "rds:my-db-param-group",
    "EventID": "RDS-EVENT-0037"
  }
}
```

Example of a DB snapshot event

The following is an example of a DB snapshot event in JSON format. The event shows the deletion of the snapshot named `my-db-snapshot`. The event ID is RDS-EVENT-0041.

```json
{
  "version": "0",
  "id": "b4e28571-85d4-695f-930-0153b71dcb42",
  "detail-type": "RDS DB Snapshot Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
  ],
  "detail": {
    "EventCategories": ["configuration change"],
    "SourceType": "DB_PARAM",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "rds:my-db-param-group",
    "EventID": "RDS-EVENT-0037"
  }
}
```
"detail": {
    "EventCategories": [
        "deletion"
    ],
    "SourceType": "SNAPSHOT",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Deleted manual snapshot",
    "SourceIdentifier": "rds:my-db-snapshot",
    "EventID": "RDS-EVENT-0041"
}
Viewing Amazon RDS events

You can retrieve events for your RDS resources through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events for your RDS resources by using the describe-events AWS CLI command, or the DescribeEvents RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

**Note**
If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see Creating a rule that triggers on an Amazon RDS event (p. 642)

**Console**

To view all Amazon RDS instance events for the past 24 hours

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Events. The available events appear in a list.
3. Enter a search term to filter your results. For example, the following screenshot shows a list of events filtered by the characters stopped.

![RDS Events Console Screenshot](image)

**AWS CLI**

You can view all Amazon RDS instance events for the past 10080 minutes (7 days) by calling the describe-events AWS CLI command and setting the --duration parameter to 10080.

```bash
aws rds describe-events --duration 10080
```

The following example shows the events in the specified time range for DB instance `my-inst`.

```bash
aws rds describe-events
  --source-identifier my-inst
  --source-type db-instance
  --start-time 2022-03-13T18:00Z
  --end-time 2022-03-13T19:00Z
```

**API**

You can view all Amazon RDS instance events for the past 14 days by calling the DescribeEvents RDS API operation and setting the Duration parameter to 20160.
Using Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics
- Overview of Amazon RDS event notification (p. 623)
- Amazon RDS event categories and event messages (p. 624)
- Subscribing to Amazon RDS event notification (p. 633)
- Listing Amazon RDS event notification subscriptions (p. 636)
- Modifying an Amazon RDS event notification subscription (p. 637)
- Adding a source identifier to an Amazon RDS event notification subscription (p. 638)
- Removing a source identifier from an Amazon RDS event notification subscription (p. 639)
- Listing the Amazon RDS event notification categories (p. 640)
- Deleting an Amazon RDS event notification subscription (p. 641)

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs. Amazon RDS event notification is only available for unencrypted SNS topics. If you specify an encrypted SNS topic, event notifications aren't sent for the topic.

RDS resources eligible for event subscription

You can subscribe to an event category for the following resources:
- DB instance
- DB snapshot
- DB parameter group
- DB security group
- RDS Proxy

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB security group, you're notified when the DB security group is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription receiving all event notifications and another subscription that includes only critical events for your production DB instances.

Basic process for subscribing to Amazon RDS event notifications

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.
2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription. To confirm your subscription, choose the link in the notification you were sent.

3. When you have confirmed the subscription, the status of your subscription is updated in the Amazon RDS console's **My Event Subscriptions** section.

4. You then begin to receive event notifications.

To learn about identity and access management when using Amazon SNS, see Identity and access management in Amazon SNS in the Amazon Simple Notification Service Developer Guide.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see Using AWS Lambda with Amazon RDS in the AWS Lambda Developer Guide.

**Delivery of RDS event notifications**

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. Event notifications might take up to five minutes to be delivered.

**Important**

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see Amazon SNS message and JSON formats in the Amazon Simple Notification Service Developer Guide.

You can configure SNS to notify you with text messages. For more information, see Mobile text messaging (SMS) in the Amazon Simple Notification Service Developer Guide.

To turn off notifications without deleting a subscription, choose No for Enabled in the Amazon RDS console. Or you can set the Enabled parameter to false using the AWS CLI or Amazon RDS API.

**Billing for Amazon RDS event notifications**

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see Amazon Simple Notification Service pricing.

**Amazon RDS event categories and event messages**

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API. Each category applies to a source type.

Topics

- DB instance events (p. 624)
- DB parameter group events (p. 631)
- DB security group events (p. 631)
- DB snapshot events (p. 632)
- RDS Proxy events (p. 633)

**DB instance events**

The following table shows the event category and a list of events when a DB instance is the source type.

<table>
<thead>
<tr>
<th>Category</th>

</table>

#### DB parameter group events

The following table shows the event category and a list of events when a DB parameter group is the source type.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration change</td>
<td>RDS-EVENT-0037</td>
<td>The parameter group was modified.</td>
</tr>
</tbody>
</table>

#### DB security group events

The following table shows the event category and a list of events when a DB security group is the source type.
### Category | RDS event ID | Description
--- | --- | ---
Configuration change | RDS-EVENT-0038 | The security group has been modified.
Failure | RDS-EVENT-0039 | The security group owned by [user] does not exist; authorization for the security group has been revoked.

### DB snapshot events

The following table shows the event category and a list of events when a DB snapshot is the source type.

### Category | RDS event ID | Description
--- | --- | ---
Creation | RDS-EVENT-0040 | A manual DB snapshot is being created.
Creation | RDS-EVENT-0042 | A manual DB snapshot has been created.
Creation | RDS-EVENT-0090 | An automated DB snapshot is being created.
Creation | RDS-EVENT-0091 | An automated DB snapshot has been created.
Deletion | RDS-EVENT-0041 | A DB snapshot has been deleted.
Notification | RDS-EVENT-0059 | Started copy of snapshot [DB snapshot name] from region [region name].
  |  | Note
  |  | This is a cross-Region snapshot copy.
  |  | Note
  |  | This is a cross-Region snapshot copy.
Notification | RDS-EVENT-0061 | Canceled snapshot copy request of [DB snapshot name] from region [region name].
  |  | Note
  |  | This is a cross-Region snapshot copy.
Notification | RDS-EVENT-0159 | DB snapshot export task failed.
Notification | RDS-EVENT-0160 | DB snapshot export task canceled.
Notification | RDS-EVENT-0161 | DB snapshot export task completed.
Notification | RDS-EVENT-0196 | Started copy of snapshot [DB snapshot name] in region [region name].
  |  | Note
  |  | This is a local snapshot copy.
Notification | RDS-EVENT-0197 | Finished copy of snapshot [DB snapshot name] in region [region name].
  |  | Note
  |  | This is a local snapshot copy.
Using Amazon RDS event notification

<tr>
<td>Restoration</td>
<td>RDS-EVENT-0043</td>
<td>Restored from snapshot [snapshot_name].</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A DB instance is being restored from a DB snapshot.</td>
</tr>
</tbody>
</table>

**RDS Proxy events**

The following table shows the event category and a list of events when an RDS Proxy is the source type.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0204</td>
<td>RDS modified the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>change</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0207</td>
<td>RDS modified the endpoint of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>change</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0213</td>
<td>RDS detected the addition of the DB instance and automatically added it to</td>
</tr>
<tr>
<td>change</td>
<td></td>
<td>the target group of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-0214</td>
<td>RDS detected the deletion of the DB instance and automatically removed it</td>
</tr>
<tr>
<td>change</td>
<td></td>
<td>from the target group of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Configuration</td>
<td>RDS-EVENT-XXXX</td>
<td>RDS detected the deletion of the DB cluster and automatically removed it</td>
</tr>
<tr>
<td>change</td>
<td></td>
<td>from the target group of the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Creation</td>
<td>RDS-EVENT-0203</td>
<td>RDS created the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Creation</td>
<td>RDS-EVENT-0206</td>
<td>RDS created the endpoint for the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Deletion</td>
<td>RDS-EVENT-0205</td>
<td>RDS deleted the DB proxy (RDS Proxy).</td>
</tr>
<tr>
<td>Deletion</td>
<td>RDS-EVENT-0208</td>
<td>RDS deleted the endpoint of DB proxy (RDS Proxy).</td>
</tr>
</tbody>
</table>

**Subscribing to Amazon RDS event notification**

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see Getting started with Amazon SNS in the Amazon Simple Notification Service Developer Guide.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event. These are defined by the **Source Type** (type of source) and the **Source Identifier** (the Amazon RDS source generating the event). For example, **Source Type** might be **SourceType = db-instance**, **Source Identifier** might be **SourceIdentifier = db-instance-id**.
whereas SourceIdentifier might be SourceIdentifier = myDBInstance1. The following table shows possible combinations.

<table>
<thead>
<tr>
<th>SourceType</th>
<th>SourceIdentifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specified</td>
<td>Specified</td>
<td>You receive notice of all DB instance events for the specified source.</td>
</tr>
<tr>
<td>Specified</td>
<td>Not specified</td>
<td>You receive notice of the events for that source type for all your Amazon RDS sources.</td>
</tr>
<tr>
<td>Not specified</td>
<td>Not specified</td>
<td>You receive notice of all events from all Amazon RDS sources belonging to your customer account.</td>
</tr>
</tbody>
</table>

**Console**

**To subscribe to RDS event notification**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In navigation pane, choose Event subscriptions.
3. In the Event subscriptions pane, choose Create event subscription.
4. In the Create event subscription dialog box, do the following:
   a. For Name, enter a name for the event notification subscription.
   b. For Send notifications to, choose an existing Amazon SNS ARN for an Amazon SNS topic, or choose create topic to enter the name of a topic and a list of recipients.
   c. For Source type, choose a source type.
   d. Choose Yes to enable the subscription. If you want to create the subscription but to not have notifications sent yet, choose No.
   e. Depending on the source type you selected, choose the event categories and sources that you want to receive event notifications for.
   f. Choose Create.

The Amazon RDS console indicates that the subscription is being created.

**AWS CLI**

To subscribe to RDS event notification, use the AWS CLI create-event-subscription command. Include the following required parameters:

- --subscription-name
- --sns-topic-arn
Example

For Linux, macOS, or Unix:

```bash
aws rds create-event-subscription
   --subscription-name myeventsubscription
   --sns-topic-arn arn:aws:sns:us-east-1:802#########:myawsuser-RDS
   --enabled
```

For Windows:

```bash
aws rds create-event-subscription ^
   --subscription-name myeventsubscription ^
   --sns-topic-arn arn:aws:sns:us-east-1:802#########:myawsuser-RDS ^
   --enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function `CreateEventSubscription`. Include the following required parameters:

- SubscriptionName
- SnsTopicArn
Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

**Console**

**To list your current Amazon RDS event notification subscriptions**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.

**AWS CLI**

To list your current Amazon RDS event notification subscriptions, use the AWS CLI `describe-event-subscriptions` command.

**Example**

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the `myfirsteventsubscription`.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

**API**

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API `DescribeEventSubscriptions` action.
Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

**Console**

**To modify an Amazon RDS event notification subscription**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Event subscriptions.
3. In the Event subscriptions pane, choose the subscription that you want to modify and choose Edit.
4. Make your changes to the subscription in either the Target or Source section.
5. Choose Edit. The Amazon RDS console indicates that the subscription is being modified.

**AWS CLI**

To modify an Amazon RDS event notification subscription, use the AWS CLI `modify-event-subscription` command. Include the following required parameter:

- `--subscription-name`

**Example**

The following code enables `myeventsubscription`.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
  --subscription-name myeventsubscription \
  --enabled
```

For Windows:

```
aws rds modify-event-subscription ^
  --subscription-name myeventsubscription ^
  --enabled
```

**API**

To modify an Amazon RDS event, call the Amazon RDS API operation `ModifyEventSubscription`. Include the following required parameter:

- `SubscriptionName`
Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription (p. 637).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI add-source-identifier-to-subscription command. Include the following required parameters:

• --subscription-name
• --source-identifier

Example

The following example adds the source identifier mysql to the myrdsnotificationsubscription subscription.

For Linux, macOS, or Unix:

```
aws rds add-source-identifier-to-subscription \
    --subscription-name myrdsnotificationsubscription \
    --source-identifier mysql
```

For Windows:

```
aws rds add-source-identifier-to-subscription ^
    --subscription-name myrdsnotificationsubscription ^
    --source-identifier mysql
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API AddSourceIdentifierToSubscription. Include the following required parameters:

• SubscriptionName
• SourceIdentifier
Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription (p. 637).

AWS CLI

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI remove-source-identifier-from-subscription command. Include the following required parameters:

- --subscription-name
- --source-identifier

Example

The following example removes the source identifier mysql from the myrdseventsubscription subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription \
   --subscription-name myrdseventsubscription \
   --source-identifier mysql
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
   --subscription-name myrdseventsubscription ^
   --source-identifier mysql
```

API

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API RemoveSourceIdentifierFromSubscription command. Include the following required parameters:

- SubscriptionName
- SourceIdentifier
Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

Console

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see Modifying an Amazon RDS event notification subscription (p. 637).

AWS CLI

To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

Example

```
aws rds describe-event-categories
```

API

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.
Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI `delete-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following example deletes the subscription `myrdssubscription`.

```bash
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API `DeleteEventSubscription` command. Include the following required parameter:

- `SubscriptionName`
Creating a rule that triggers on an Amazon RDS event

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics
- Creating rules to send Amazon RDS events to CloudWatch Events (p. 642)
- Tutorial: log the state of an Amazon RDS instance using EventBridge (p. 643)

Creating rules to send Amazon RDS events to CloudWatch Events

You can write simple rules to indicate which Amazon RDS events interest you and which automated actions to take when an event matches a rule. You can set a variety of targets, such as an AWS Lambda function or an Amazon SNS topic, which receive events in JSON format. For example, you can configure Amazon RDS to send events to CloudWatch Events or Amazon EventBridge whenever a DB instance is created or deleted. For more information, see the Amazon CloudWatch Events User Guide and the Amazon EventBridge User Guide.

Use the following steps to create a CloudWatch Events rule that triggers on an event emitted by an AWS service.

To create a rule that triggers on an event:
2. Under Events in the navigation pane, choose Rules.
3. Choose Create rule.
4. For Event Source, do the following:
   a. Choose Event Pattern.
   b. For Service Name, choose Relational Database Service (RDS).
   c. For Event Type, choose the type of Amazon RDS resource that triggers the event. For example, if a DB instance triggers the event, choose RDS DB Instance Event.
5. For Targets, choose Add Target and choose the AWS service that is to act when an event of the selected type is detected.
6. In the other fields in this section, enter information specific to this target type, if any is needed.
7. For many target types, CloudWatch Events needs permissions to send events to the target. In these cases, CloudWatch Events can create the IAM role needed for your event to run:
   - To create an IAM role automatically, choose Create a new role for this specific resource.
   - To use an IAM role that you created before, choose Use existing role.
8. Optionally, repeat steps 5-7 to add another target for this rule.
9. Choose Configure details. For Rule definition, type a name and description for the rule.
   - The rule name must be unique within this Region.
10. Choose Create rule.

For more information, see Creating a CloudWatch Events Rule That Triggers on an Event in the Amazon CloudWatch User Guide.
Tutorial: log the state of an Amazon RDS instance using EventBridge

You can create an AWS Lambda function that logs the state changes for an Amazon RDS instance. You can choose to create a rule that runs the function whenever there is a state transition or a transition to one or more states that are of interest.

In this tutorial, you log any state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

**Important**
Don't perform this tutorial on a running production instance.

**Step 1: Create an AWS Lambda Function**

Create a Lambda function to log the state change events. You specify this function when you create your rule.

**To create a Lambda function**

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. If you're new to Lambda, you see a welcome page. Choose Get Started Now. Otherwise, choose Create function.
3. Choose Author from scratch.
4. On the Create function page, do the following:
   a. Enter a name and description for the Lambda function. For example, name the function RDSInstanceStateChange.
   b. In Runtime, select Node.js 14x.
   c. In Execution role, choose Create a new role with basic Lambda permissions. For Existing role, select your basic execution role. Otherwise, create a basic execution role.
   d. Choose Create function.
5. On the RDSInstanceStateChange page, do the following:
   a. In Code source, select index.js.
   b. Right-click index.js, and choose Open.
   c. In the index.js pane, delete the existing code.
   d. Enter the following code:

```
console.log('Loading function');
exports.handler = async (event, context) => {
    console.log('Received event:', JSON.stringify(event));
};
```
   e. Choose Deploy.

**Step 2: Create a Rule**

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

**To create the EventBridge rule**

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose Rules.
3. Choose **Create rule**.
4. Enter a name and description for the rule. For example, enter **RDSInstanceStateChangeRule**.
5. For **Define pattern**, do the following:
   a. Choose **Event pattern**.
   b. Choose **Pre-defined pattern by service**.
   c. For **Service provider**, choose **AWS**.
   d. For **Service Name**, choose **Relational Database Service (RDS)**.
   e. For **Event type**, choose **RDS DB Instance Event**.
6. For **Select event bus**, choose **AWS default event bus**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
7. For **Target**, choose **Lambda function**.
8. For **Function**, select the Lambda function that you created.
9. Choose **Create**.

**Step 3: Test the Rule**

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

**To test your rule by stopping a DB instance**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Metrics for the rule**.
   You are redirected to the Amazon CloudWatch console.
6. In **All metrics**, choose the name of the rule that you created.
   The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.
8. Choose the name of the log group for your Lambda function (**/aws/lambda/function-name**).
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```json
{
    "version": "0",
    "id": "12a345b6-78c9-01d2-34e5-123f4ghij6k",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "111111111111",
    "time": "2021-03-19T19:34:09Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:111111111111:db:testdb"
    ],
    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "DB_INSTANCE",
        "Detail": {
            "DBInstanceIdentifier": "testdb",
            "DBInstanceStatus": "creating"
        }
    }
}
```
"Date": "2021-03-19T19:34:09.293Z",
"Message": "DB instance stopped",
"SourceIdentifier": "testdb",
"EventID": "RDS-EVENT-0087"
}
}

For more examples of RDS events in JSON format, see Overview of events for Amazon RDS (p. 619).

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.
Monitoring Amazon RDS log files

You can view, download, and watch database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. Viewing, downloading, or watching transaction logs isn't supported.

Topics
- Viewing and listing database log files (p. 646)
- Downloading a database log file (p. 647)
- Watching a database log file (p. 648)
- Publishing database logs to Amazon CloudWatch Logs (p. 648)
- Reading log file contents using REST (p. 649)
- MariaDB database log files (p. 651)
- Microsoft SQL Server database log files (p. 660)
- MySQL database log files (p. 664)
- Oracle database log files (p. 673)
- PostgreSQL database log files (p. 680)

Viewing and listing database log files

You can view database log files for your DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

**Note**
If you can't view the list of log files for an existing Oracle DB instance, reboot the instance to view the list.

**Console**

**To view a database log file**
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. Scroll down to the Logs section.
6. In the Logs section, choose the log that you want to view, and then choose View.

**AWS CLI**

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

**Example**

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```
RDS API

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFile` action.

Downloading a database log file

You can use the AWS Management Console, AWS CLI or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. Scroll down to the Logs section.
6. In the Logs section, choose the button next to the log that you want to download, and then choose Download.
7. Open the context (right-click) menu for the link provided, and then choose Save Link As. Enter the location where you want the log file to be saved, and then choose Save.

AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called `log/ERROR.4` and store it in a local file called `errorlog.txt`.

Example

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
  --db-instance-identifier myexampledb \
  --starting-token 0 --output text
```
Watching a database log file

You can monitor the contents of a log file by using the AWS Management Console.

Console

To watch a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. In the Logs section, choose a log file, and then choose Watch.

Publishing database logs to Amazon CloudWatch Logs

In addition to viewing and downloading DB instance logs, you can publish logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, store the data in highly durable storage, and manage the data with the CloudWatch Logs Agent. AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see Change log data retention in CloudWatch Logs.

Topics

- Configuring CloudWatch log integration (p. 648)
- Engine-specific log information (p. 649)

Configuring CloudWatch log integration

Before you enable log data publishing, make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see Using service-linked roles for Amazon RDS (p. 1837).

To publish your database log files to CloudWatch Logs, choose which logs to publish. Make this choice in the Advanced Settings section when you create a new DB instance. You can also modify an existing DB instance to begin publishing.
After you have enabled publishing, Amazon RDS continuously streams all of the DB instance log records to a log group. For example, you have a log group `/aws/rds/instance/instance_name/log_type` for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

After you have published log records, you can use CloudWatch Logs to search and filter the records. For more information about searching and filtering logs, see Searching and filtering log data. For a tutorial explaining how to monitor RDS logs, see Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS.

**Engine-specific log information**

For engine-specific information, see the following:

- the section called “Publishing MariaDB logs to Amazon CloudWatch Logs” (p. 653)
- the section called “Publishing MySQL logs to Amazon CloudWatch Logs” (p. 666)
- the section called “Publishing Oracle logs to Amazon CloudWatch Logs” (p. 676)
- the section called “Publishing PostgreSQL logs to Amazon CloudWatch Logs” (p. 683)
- the section called “Publishing SQL Server logs to Amazon CloudWatch Logs” (p. 660)

**Reading log file contents using REST**

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- `DBInstanceIdentifier`—the name of the DB instance that contains the log file you want to download.
• **LogFileName**—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named *log/ERROR.6* for the DB instance named *sample-sql* in the *us-west-2* region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH/////////
wEa0AIXLhngC5zp9CyB1R6abWkrXHVR5efnAVN3XvR71wqKYalFSn6UyJuEFTft9n0bglx4QJ+GXI9cpACkEtq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorith: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-SignedHeaders: host
X-Amz-Signature: 353a4f14b3f2501d9afcc34f9f9948154d46ce7d4ec091d0cdaa86e8b4c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

• **DBInstanceNotFound**— *DBInstanceIdentifier* does not refer to an existing DB instance. (HTTP status code: 404)
MariaDB database log files

You can monitor the MariaDB error log, slow query log, and the general log. The MariaDB error log is generated by default; you can generate the slow query and general logs by setting parameters in your DB parameter group. Amazon RDS rotates all of the MariaDB log files; the intervals for each type are given following.

You can monitor the MariaDB logs directly through the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs. You can also access MariaDB logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 646).

Topics
- Accessing MariaDB error logs (p. 651)
- Accessing the MariaDB slow query and general logs (p. 651)
- Publishing MariaDB logs to Amazon CloudWatch Logs (p. 653)
- Log file size (p. 655)
- Managing table-based MariaDB logs (p. 655)
- Binary logging format (p. 656)
- Accessing MariaDB binary logs (p. 656)
- Binary log annotation (p. 657)

Accessing MariaDB error logs

The MariaDB error log is written to the `<host-name>.err` file. You can view this file by using the Amazon RDS console or by retrieving the log using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs. The `<host-name>.err` file is flushed every 5 minutes, and its contents are appended to `mysql-error-running.log`. The `mysql-error-running.log` file is then rotated every hour and the hourly files generated during the last 24 hours are retained. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MariaDB writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that resulted in a log entry.

Accessing the MariaDB slow query and general logs

The MariaDB slow query log and the general log can be written to a file or a database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Working with parameter groups (p. 278). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, AWS CLI, or AWS SDKs.

You can control MariaDB logging by using the parameters in this list:
- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds;
minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose run time exceeds the long_query_time value are logged. For example, setting long_query_time to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.

- **log_queries_not_using_indexes**: To log all queries that do not use an index to the slow query log, set this parameter to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the long_query_time parameter.

- **log_output option**: You can specify one of the following options for the log_output parameter:
  - **TABLE** (default)– Write general queries to the mysql.general_log table, and slow queries to the mysql.slow_log table.
  - **FILE**– Write both general and slow query logs to the file system. Log files are rotated hourly.
  - **NONE**– Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. FILE and TABLE logging approach rotation and deletion as follows:

- When FILE logging is enabled, log files are examined every hour and log files older than 24 hours are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.

- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space or the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space or the size of all logs combined is greater than 5 GB.

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

You can rotate the mysql.general_log table by calling the mysql.rds_rotate_general_log procedure. You can rotate the mysql.slow_log table by calling the mysql.rds_rotate_slow_log procedure.

Table logs are rotated during a database version upgrade.

Amazon RDS records both TABLE and FILE log rotation in an Amazon RDS event and sends you a notification.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the log_output parameter to FILE. Like the MariaDB error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained.

For more information about the slow query and general logs, go to the following topics in the MariaDB documentation:

- **Slow query log**
- **General query log**
Publishing MariaDB logs to Amazon CloudWatch Logs

You can configure your MariaDB DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MariaDB database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the /aws/rds/instance/my_instance/slowquery log group.

The error log is enabled by default. The following table summarizes the requirements for the other MariaDB logs.

<table>
<thead>
<tr>
<th>Log</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit log</td>
<td>The DB instance must use a custom option group with the MARIADB_AUDIT_PLUGIN option.</td>
</tr>
<tr>
<td>General log</td>
<td>The DB instance must use a custom parameter group with the parameter setting general_log = 1 to enable the general log.</td>
</tr>
<tr>
<td>Slow query log</td>
<td>The DB instance must use a custom parameter group with the parameter setting slow_query_log = 1 to enable the slow query log.</td>
</tr>
<tr>
<td>Log output</td>
<td>The DB instance must use a custom parameter group with the parameter setting log_output = FILE to write logs to the file system and publish them to CloudWatch Logs.</td>
</tr>
</tbody>
</table>

**Console**

**To publish MariaDB logs to CloudWatch Logs from the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

**AWS CLI**

You can publish a MariaDB logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`
Note
A change to the --cloudwatch-logs-export-configuration option is always applied to the DB instance immediately. Therefore, the --apply-immediately and --no-apply-immediately options have no effect.

You can also publish MariaDB logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example
The following example modifies an existing MariaDB DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is EnableLogTypes, and its value is an array of strings with any combination of audit, error, general, and slowquery.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
  --db-instance-identifier mydbinstance
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}''
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}''
```

Example
The following command creates a MariaDB DB instance and publishes log files to CloudWatch Logs. The --enable-cloudwatch-logs-exports value is a JSON array of strings. The strings can be any combination of audit, error, general, and slowquery.

For Linux, macOS, or Unix:

```
aws rds create-db-instance
  --db-instance-identifier mydbinstance
  --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]'
  --db-instance-class `db.m4.large`
  --engine mariadb
```

```
```
For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --enable-cloudwatch-logs-exports \["audit","error","general","slowquery"]\ ^
  --db-instance-class db.m4.large ^
  --engine mariadb
```

---

**RDS API**

You can publish MariaDB logs with the RDS API. You can call the `ModifyDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

**Note**

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MariaDB logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

**Log file size**

The MariaDB slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour and log files older than 24 hours are removed. If the combined log file size exceeds the threshold after removing old log files, then the largest log files are deleted until the log file size no longer exceeds the threshold.

**Managing table-based MariaDB logs**

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.
Both the general log and the slow query logs are disabled by default. In order to enable logging to
tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate
parameter to 0. A large amount of data often accumulates over time, which can use up a considerable
percentage of your allocated storage space. Amazon RDS does not allow you to truncate the log tables,
but you can move their contents. Rotating a table saves its contents to a backup table and then creates
a new empty log table. You can manually rotate the log tables with the following command line
procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in
succession.

### Binary logging format

MariaDB on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats.
The default binary logging format is *mixed*. For details on the different MariaDB binary log formats, see
Binary log formats in the MariaDB documentation.

If you plan to use replication, the binary logging format is important because it determines the record of
data changes that is recorded in the source and sent to the replication targets. For information about the
advantages and disadvantages of different binary logging formats for replication, see Advantages and
disadvantages of statement-based and row-based replication in the MySQL documentation.

**Important**

Setting the binary logging format to row-based can result in very large binary log files. Large
binary log files reduce the amount of storage available for a DB instance and can increase the
amount of time to perform a restore operation of a DB instance.

Statement-based replication can cause inconsistencies between the source DB instance and a
read replica. For more information, see Unsafe statements for statement-based replication in
the MariaDB documentation.

### To set the MariaDB binary logging format

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
   console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group that is used by the DB instance that you want to modify.

   You can't modify a default parameter group. If the DB instance is using a default parameter group,
   create a new parameter group and associate it with the DB instance.

   For more information on DB parameter groups, see Working with parameter groups (p. 278).
4. For Parameter group actions, choose Edit.
5. Set the `binlog_format` parameter to the binary logging format of your choice (ROW, STATEMENT,
or MIXED).
6. Choose Save changes to save the updates to the DB parameter group.

### Accessing MariaDB binary logs

You can use the mysqlbinlog utility to download binary logs in text format from MariaDB DB instances.
The binary log is downloaded to your local computer. For more information about using the mysqlbinlog
utility, go to Using mysqlbinlog in the MariaDB documentation.
To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MariaDB user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so the utility prompts you for a password.
- `--result-file`: Specify the local file that receives the output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.

For more information about mysqlbinlog options, go to `mysqlbinlog options` in the MariaDB documentation.

The following is an example:

For Linux, macOS, or Unix:

```bash
call mysqlbinlog
  --read-from-remote-server
  --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com
  --port=3306
  --user=ReplUser
  --password <password>
  --result-file=/tmp/binlog.txt
```

For Windows:

```bash
call mysqlbinlog
  --read-from-remote-server
  --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com
  --port=3306
  --user=ReplUser
  --password <password>
  --result-file=/tmp/binlog.txt
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs do not take up too much storage.

The following example sets the retention period to 1 day:

```sql
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure:

```sql
call mysql.rds_show_configuration;
```

**Binary log annotation**

In a MariaDB DB instance, you can use the `Annotate_rows` event to annotate a row event with a copy of the SQL query that caused the row event. This approach provides similar functionality to enabling the `binlog_rows_query_log_events` parameter on a DB instance on MySQL version 5.6 or later.
You can enable binary log annotations globally by creating a custom parameter group and setting the `binlog_annotate_row_events` parameter to 1. You can also enable annotations at the session level, by calling `SET SESSION binlog_annotate_row_events = 1`. Use the `replicate_anotate_row_events` to replicate binary log annotations to the replica instance if binary logging is enabled on it. No special privileges are required to use these settings.

The following is an example of a row-based transaction in MariaDB. The use of row-based logging is triggered by setting the transaction isolation level to read-committed.

```sql
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
BEGIN
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
```

Without annotations, the binary log entries for the transaction look like the following:

```
BEGIN /*!*/;
# at 1163
# at 1209
#150922 7:55:57 server id 1855786460 end_log_pos 1209 Table_map: `test`.`square`
mapped to number 76
#150922 7:55:57 server id 1855786460 end_log_pos 1247 Write_rows: table id 76
   flags: STMT_END_F
   ### INSERT INTO `test`.`square`
   ### SET
   ###   @1=5
   ###   @2=25
   # at 1247
#150922 7:56:01 server id 1855786460 end_log_pos 1274 Xid = 62
COMMIT/*!*/;
```

The following statement enables session-level annotations for this same transaction, and disables them after committing the transaction:

```sql
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
SET SESSION binlog_annotate_row_events = 1;
BEGIN;
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
SET SESSION binlog_annotate_row_events = 0;
```

With annotations, the binary log entries for the transaction look like the following:

```
BEGIN /*!*/;
# at 423
# at 483
# at 529
#150922 8:04:24 server id 1855786460 end_log_pos 483 Annotate_rows:
#Q> INSERT INTO square(x, y) VALUES(5, 5 * 5)
#150922 8:04:24 server id 1855786460 end_log_pos 529 Table_map: `test`.`square` mapped
to number 76
#150922 8:04:24 server id 1855786460 end_log_pos 567 Write_rows: table id 76 flags:
   STMT_END_F
```
### INSERT INTO `test`.`square`
### SET
### @1=5
### @2=25
# at 567
#150922 8:04:26 server id 1855786460 end_log_pos 594 Xid = 88
COMMIT/*!*/;
Microsoft SQL Server database log files

You can access Microsoft SQL Server error logs, agent logs, trace files, and dump files by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 646).

Topics

• Retention schedule (p. 660)
• Viewing the SQL Server error log by using the rds_read_error_log procedure (p. 660)
• Publishing SQL Server logs to Amazon CloudWatch Logs (p. 660)

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for Microsoft SQL Server logs on Amazon RDS.

<table>
<thead>
<tr>
<th>Log type</th>
<th>Retention schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error logs</td>
<td>A maximum of 30 error logs are retained. Amazon RDS might delete error logs older than 7 days.</td>
</tr>
<tr>
<td>Agent logs</td>
<td>A maximum of 10 agent logs are retained. Amazon RDS might delete agent logs older than 7 days.</td>
</tr>
<tr>
<td>Trace files</td>
<td>Trace files are retained according to the trace file retention period of your DB instance. The default trace file retention period is 7 days. To modify the trace file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 1130).</td>
</tr>
<tr>
<td>Dump files</td>
<td>Dump files are retained according to the dump file retention period of your DB instance. The default dump file retention period is 7 days. To modify the dump file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 1130).</td>
</tr>
</tbody>
</table>

Viewing the SQL Server error log by using the rds_read_error_log procedure

You can use the Amazon RDS stored procedure rds_read_error_log to view error logs and agent logs. For more information, see Viewing error and agent logs (p. 1129).

Publishing SQL Server logs to Amazon CloudWatch Logs

With Amazon RDS for SQL Server, you can publish error and agent log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

• Store logs in highly durable storage space with a retention period that you define.
• Search and filter log data.
• Share log data between accounts.
• Export logs to Amazon S3.
• Stream data to Amazon OpenSearch Service.
• Process log data in real time with Amazon Kinesis Data Streams. For more information, see Working with Amazon CloudWatch Logs in the Amazon Kinesis Data Analytics for SQL Applications Developer Guide.

Amazon RDS publishes each SQL Server database log as a separate database stream in the log group. For example, if you publish error logs, error data is stored in an error log stream in the /aws/rds/instance/my_instance/error log group.

Note
Publishing SQL Server logs to CloudWatch Logs isn't enabled by default. Publishing trace and dump files isn't supported. Publishing SQL Server logs to CloudWatch Logs is supported in all regions, except for Asia Pacific (Hong Kong).

Console

To publish SQL Server DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
   You can choose Agent log, Error log, or both.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

AWS CLI

To publish SQL Server logs, you can use the modify-db-instance command with the following parameters:

• --db-instance-identifier
• --cloudwatch-logs-export-configuration

Note
A change to the --cloudwatch-logs-export-configuration option is always applied to the DB instance immediately. Therefore, the --apply-immediately and --no-apply-immediately options have no effect.

You can also publish SQL Server logs using the following commands:

• create-db-instance
• restore-db-instance-from-db-snapshot
• restore-db-instance-to-point-in-time

Example

The following example creates an SQL Server DB instance with CloudWatch Logs publishing enabled. The --enable-cloudwatch-logs-exports value is a JSON array of strings that can include error, agent, or both.

For Linux, macOS, or Unix:
Amazon Relational Database Service User Guide
Microsoft SQL Server database log ﬁles

aws rds create-db-instance \
--db-instance-identifier mydbinstance \
--enable-cloudwatch-logs-exports '["error","agent"]' \
--db-instance-class db.m4.large \
--engine sqlserver-se

For Windows:
aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--enable-cloudwatch-logs-exports "[\"error\",\"agent\"]" ^
--db-instance-class db.m4.large ^
--engine sqlserver-se

Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by
preﬁxing them with a backslash (\).

Example
The following example modiﬁes an existing SQL Server DB instance to publish log ﬁles to CloudWatch
Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this
object is EnableLogTypes, and its value is an array of strings that can include error, agent, or both.
For Linux, macOS, or Unix:
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["error","agent"]}'

For Windows:
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{\"EnableLogTypes\":[\"error\",\"agent\"]}"

Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by
preﬁxing them with a backslash (\).

Example
The following example modiﬁes an existing SQL Server DB instance to disable publishing agent log ﬁles
to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The
key for this object is DisableLogTypes, and its value is an array of strings that can include error,
agent, or both.
For Linux, macOS, or Unix:
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"DisableLogTypes":["agent"]}'

For Windows:
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^

662


--cloudwatch-logs-export-configuration "{"DisableLogTypes":["agent"]}"

**Note**
When using the Windows command prompt, you must escape double quotes (""") in JSON code by prefixing them with a backslash (\).
MySQL database log files

You can monitor the MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 646).

Topics
• Overview of MySQL database logs (p. 664)
• Publishing MySQL logs to Amazon CloudWatch Logs (p. 666)
• Managing table-based MySQL logs (p. 669)
• Configuring MySQL binary logging (p. 669)
• Accessing MySQL binary logs (p. 671)

Overview of MySQL database logs

You can monitor the following types of MySQL log files:

• Error log
• Slow query log
• General log
• The audit log

The MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics
• MySQL error logs (p. 664)
• MySQL slow query and general logs (p. 665)
• MySQL audit log (p. 666)
• Log rotation and retention (p. 666)
• Size limits on BLOBs (p. 666)

MySQL error logs

MySQL writes errors in the mysql-error.log file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that would result in a log entry.

MySQL writes mysql-error.log to disk every 5 minutes. MySQL appends the contents of the log to mysql-error-running.log.

MySQL rotates the mysql-error-running.log file every hour. RDS for MySQL retains the logs generated during the last two weeks.

Note
The log retention period is different between Amazon RDS and Aurora.
MySQL slow query and general logs

The MySQL slow query log and the general log can be written to a file or a database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Working with parameter groups (p. 278). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control MySQL logging by using the parameters in this list:

- **slow_query_log**: To create the slow query log, set to 1. The default is 0.
- **general_log**: To create the general log, set to 1. The default is 0.
- **long_query_time**: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose run time exceeds the long_query_time value are logged. For example, setting long_query_time to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- **log_queries_not_using_indexes**: To log all queries that do not use an index to the slow query log, set to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the long_query_time parameter.
- **log_output option**: You can specify one of the following options for the log_output parameter.
  - **TABLE** (default) – Write general queries to the mysql.general_log table, and slow queries to the mysql.slow_log table.
  - **FILE** – Write both general and slow query logs to the file system. Log files are rotated hourly.
  - **NONE** – Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. FILE and TABLE logging approach rotation and deletion as follows:

- When FILE logging is enabled, log files are examined every hour and log files more than two weeks old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space or the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space or the size of all logs combined is greater than 5 GB. You can subscribe to the low_free_storage event to be notified when log tables are rotated to free up space. For more information, see Using Amazon RDS event notification (p. 623).

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

You can rotate the mysql.general_log table by calling the mysql.rds_rotate_general_log procedure. You can rotate the mysql.slow_log table by calling the mysql.rds_rotate_slow_log procedure.
Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to `FILE`. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous two weeks are retained. Note that the retention period is different between Amazon RDS and Aurora.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- The slow query log
- The general query log

**MySQL audit log**

To access the audit log, the DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option. For more information, see MariaDB Audit Plugin support (p. 1235).

**Log rotation and retention**

The MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. MySQL removes log files more than two weeks old. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.

**Size limits on BLOBs**

For MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the `innodb_log_file_size` parameter for your MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (`VARCHAR`, `VARBINARY`, `TEXT`) in the same tables. For information on how to set parameter values, see Working with parameter groups (p. 278). For information on the redo log BLOB size limit, go to Changes in MySQL 5.6.20.

**Publishing MySQL logs to Amazon CloudWatch Logs**

You can configure your MySQL DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MySQL database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MySQL logs.

<table>
<thead>
<tr>
<th>Log</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit log</td>
<td>The DB instance must use a custom option group with the <code>MARIADB_AUDIT_PLUGIN</code> option.</td>
</tr>
</tbody>
</table>
### Log

<table>
<thead>
<tr>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>The DB instance must use a custom parameter group with the parameter setting <code>general_log = 1</code> to enable the general log.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>The DB instance must use a custom parameter group with the parameter setting <code>slow_query_log = 1</code> to enable the slow query log.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>The DB instance must use a custom parameter group with the parameter setting <code>log_output = FILE</code> to write logs to the file system and publish them to CloudWatch Logs.</td>
</tr>
</tbody>
</table>

**Note**
Publishing log files to CloudWatch Logs is only supported for MySQL versions 5.6, 5.7, and 8.0.

**Console**

**To publish MySQL logs to CloudWatch Logs using the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

**AWS CLI**

You can publish MySQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

**Note**
A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MySQL logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
MySQL database log files

- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

**Example**

The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["audit","error","general","slowquery"]}'
```

**Example**

The following example creates a MySQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' \
    --db-instance-class db.m4.large \
    --engine MySQL
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' ^
    --db-instance-class db.m4.large ^
    --engine MySQL
```

**RDS API**

You can publish MySQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:
DBInstanceIdentifier
CloudwatchLogsExportConfiguration

Note
A change to the CloudwatchLogsExportConfiguration parameter is always applied to the DB instance immediately. Therefore, the ApplyImmediately parameter has no effect.

You can also publish MySQL logs by calling the following RDS API operations:

- CreateDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime

Run one of these RDS API operations with the following parameters:

- DBInstanceIdentifier
- EnableCloudwatchLogsExports
- Engine
- DBInstanceClass

Other parameters might be required depending on the AWS CLI command you run.

Managing table-based MySQL logs

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the log_output server parameter to TABLE. General queries are then logged to the mysql.general_log table, and slow queries are logged to the mysql.slow_log table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the general_log and slow_query_log server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by PROMPT>:

PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Configuring MySQL binary logging

The binary log is a set of log files that contain information about data modifications made to an MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
MySQL database log files

- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn’t

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see The Binary Log and Binary Log Overview in the MySQL documentation.

The automated backups feature determines whether binary logging is turned on or off for MySQL. You have the following options:

Turn binary logging on

- Set the backup retention period to a positive nonzero value.

Turn binary logging off

- Set the backup retention period to zero.

For more information, see Enabling automated backups (p. 409).

MySQL on Amazon RDS supports the row-based, statement-based, and mixed binary logging formats for MySQL version 5.6 and later. The default binary logging format is mixed. For details on the different MySQL binary log formats, see Binary logging formats in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

**Important**
Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance and can increase the amount of time to perform a restore operation of a DB instance. Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

**To set the MySQL binary logging format**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group used by the DB instance you want to modify.
   - You can’t modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.
   - For more information on parameter groups, see Working with parameter groups (p. 278).
4. From Parameter group actions, choose Edit.
5. Set the binlog_format parameter to the binary logging format of your choice (ROW, STATEMENT, or MIXED). You can also use the value OFF to turn off binary logging.
6. Choose Save changes to save the updates to the DB parameter group.

**Important**
Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MySQL DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups
identify different logging formats. Assign the appropriate DB parameter group to the each DB instance.

Accessing MySQL binary logs

You can use the mysqlbinlog utility to download or stream binary logs from Amazon RDS instances running MySQL 5.6 or later. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the mysql utility. For more information about using the mysqlbinlog utility, go to Using mysqlbinlog to back up binary log files.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- Specify the --read-from-remote-server option.
- --host: Specify the DNS name from the endpoint of the instance.
- --port: Specify the port used by the instance.
- --user: Specify a MySQL user that has been granted the replication slave permission.
- --password: Specify the password for the user, or omit a password value so that the utility prompts you for a password.
- To have the file downloaded in binary format, specify the --raw option.
- --result-file: Specify the local file to receive the raw output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command SHOW BINARY LOGS.
- To stream the binary log files, specify the --stop-never option.

For more information about mysqlbinlog options, go to mysqlbinlog - utility for processing binary log files.

For example, see the following.

For Linux, macOS, or Unix:

```bash
mysqlbinlog \
  --read-from-remote-server \
  --host=MySQL56Instance1.cg034hpkmjt.region.rds.amazonaws.com \
  --port=3306 \
  --user ReplUser \
  --password \
  --raw \
  --result-file=/tmp/ \
  binlog.00098
```

For Windows:

```bash
mysqlbinlog ^
  --read-from-remote-server ^
  --host=MySQL56Instance1.cg034hpkmjt.region.rds.amazonaws.com ^
  --port=3306 ^
  --user ReplUser ^
  --password ^
  --raw ^
  --result-file=/tmp/ ^
  binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the mysql.rds_set_configuration stored procedure and specify a period with enough
time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

**Note**
The `mysql.rds_set_configuration` stored procedure is only available for MySQL version 5.6 or later.

The following example sets the retention period to 1 day.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```sql
CALL mysql.rds_show_configuration;
```
Oracle database log files

You can access Oracle alert logs, audit files, and trace files by using the Amazon RDS console or API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files (p. 646).

The Oracle audit files provided are the standard Oracle auditing files. Amazon RDS supports the Oracle fine-grained auditing (FGA) feature. However, log access doesn’t provide access to FGA events that are stored in the SYS.FGA_LOG$ table and that are accessible through the DBA_FGA_AUDIT_TRAIL view.

The DescribeDBLogFiles API operation that lists the Oracle log files that are available for a DB instance ignores the MaxRecords parameter and returns up to 1,000 records. The call returns LastWritten as a POSIX date in milliseconds.

Topics

- Retention schedule (p. 673)
- Working with Oracle trace files (p. 673)
- Publishing Oracle logs to Amazon CloudWatch Logs (p. 676)
- Previous methods for accessing alert logs and listener logs (p. 679)

Retention schedule

The Oracle database engine might rotate log files if they get very large. To retain audit or trace files, download them. If you store the files locally, you reduce your Amazon RDS storage costs and make more space available for your data.

The following table shows the retention schedule for Oracle alert logs, audit files, and trace files on Amazon RDS.

<table>
<thead>
<tr>
<th>Log type</th>
<th>Retention schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert logs</td>
<td>The text alert log is rotated daily with 30-day retention managed by Amazon RDS. The XML alert log is retained for at least seven days. You can access this log by using the ALERTLOG view.</td>
</tr>
<tr>
<td>Audit files</td>
<td>The default retention period for audit files is seven days. Amazon RDS might delete audit files older than seven days.</td>
</tr>
<tr>
<td>Trace files</td>
<td>The default retention period for trace files is seven days. Amazon RDS might delete trace files older than seven days.</td>
</tr>
<tr>
<td>Listener logs</td>
<td>The default retention period for the listener logs is seven days. Amazon RDS might delete listener logs older than seven days.</td>
</tr>
</tbody>
</table>

**Note**

Audit files and trace files share the same retention configuration.

Working with Oracle trace files

Following, you can find descriptions of Amazon RDS procedures to create, refresh, access, and delete trace files.

Topics

673
• Listing files (p. 674)
• Generating trace files and tracing a session (p. 674)
• Retrieving trace files (p. 675)
• Purging trace files (p. 675)

Listing files

You can use either of two procedures to allow access to any file in the `background_dump_dest` path. The first procedure refreshes a view containing a listing of all files currently in `background_dump_dest`.

```sql
EXEC rdsadmin.manage_tracefiles.refresh_tracefile_listing;
```

After the view is refreshed, query the following view to access the results.

```sql
SELECT * FROM rdsadmin.tracefile_listing;
```

An alternative to the previous process is to use `FROM table` to stream nonrelational data in a table-like format to list database directory contents.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('BDUMP'));
```

The following query shows the text of a log file.

```sql
SELECT text FROM
    TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','alert_algorithm.log.date'));
```

On a read replica, get the name of the BDUMP directory by querying `V$DATABASE.DB_UNIQUE_NAME`. If the unique name is `DATABASE_B`, then the BDUMP directory is `BDUMP_B`. The following example queries the BDUMP name on a replica and then uses this name to query the contents of `alert_DATABASE.log.2020-06-23`.

```sql
SELECT 'BDUMP' || (SELECT regexp_replace(DB_UNIQUE_NAME,'.*(_[A-Z])', '\1') FROM V$DATABASE) AS BDUMP_VARIABLE FROM DUAL;

BDUMP_VARIABLE
--------------
BDUMP_B

SELECT TEXT FROM
    table(rdsadmin.rds_file_util.read_text_file('BDUMP_B','alert_DATABASE.log.2020-06-23'));
```

Generating trace files and tracing a session

Because there are no restrictions on `ALTER SESSION`, many standard methods to generate trace files in Oracle remain available to an Amazon RDS DB instance. The following procedures are provided for trace files that require greater access.

<table>
<thead>
<tr>
<th>Oracle method</th>
<th>Amazon RDS method</th>
</tr>
</thead>
<tbody>
<tr>
<td>oradebug hanganalyze 3</td>
<td>EXEC rdsadmin.manage_tracefiles.hanganalyze;</td>
</tr>
<tr>
<td>oradebug dump systemstate 266</td>
<td>EXEC rdsadmin.manage_tracefiles.dump_systemstate;</td>
</tr>
</tbody>
</table>
You can use many standard methods to trace individual sessions connected to an Oracle DB instance in Amazon RDS. To enable tracing for a session, you can run subprograms in PL/SQL packages supplied by Oracle, such as DBMS_SESSION and DBMS_MONITOR. For more information, see Enabling tracing for a session in the Oracle documentation.

Retrieving trace files

You can retrieve any trace file in background_dump_dest using a standard SQL query on an Amazon RDS–managed external table. To use this method, you must execute the procedure to set the location for this table to the specific trace file.

For example, you can use the rdsadmin.tracefile_listing view mentioned preceding to list all of the trace files on the system. You can then set the tracefile_table view to point to the intended trace file using the following procedure.

```sql
EXEC
rdsadmin.manage_tracefiles.set_tracefile_table_location('CUST01_ora_3260_SYSTEMSTATE.trc');
```

The following example creates an external table in the current schema with the location set to the file provided. You can retrieve the contents into a local file using a SQL query.

```sql
SPOOL /tmp/tracefile.txt
SELECT * FROM tracefile_table;
SPOOL OFF;
```

Purging trace files

Trace files can accumulate and consume disk space. Amazon RDS purges trace files by default and log files that are older than seven days. You can view and set the trace file retention period using the show_configuration procedure. You should run the command SET SERVEROUTPUT ON so that you can view the configuration results.

The following example shows the current trace file retention period, and then sets a new trace file retention period.

```sql
# Show the current tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:10080
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in bdump are automatically deleted.

# Set the tracefile retention to 24 hours:
SQL> EXEC rdsadmin.rdsadmin_util.set_configuration('tracefile retention',1440);
SQL> commit;

#show the new tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:1440
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in bdump are automatically deleted.
```

In addition to the periodic purge process, you can manually remove files from the background_dump_dest. The following example shows how to purge all files older than five minutes.

```sql
EXEC rdsadmin.manage_tracefiles.purge_tracefiles(5);
```
You can also purge all files that match a specific pattern (if you do, don't include the file extension, such as .trc). The following example shows how to purge all files that start with SCHPOC1_ora_5935.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles('SCHPOC1_ora_5935');
```

### Publishing Oracle logs to Amazon CloudWatch Logs

You can configure your Amazon RDS for Oracle DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can analyze the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each Oracle database log as a separate database stream in the log group. For example, if you configure the export function to include the audit log, audit data is stored in an audit log stream in the /aws/rds/instance/my_instance/audit log group. RDS for Oracle supports the following logs:

- Alert log
- Trace log
- Audit log
- Listener log
- Oracle Management Agent log

This Oracle Management Agent log consists of the log streams shown in the following table.

<table>
<thead>
<tr>
<th>Log name</th>
<th>CloudWatch log stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>emctl.log</td>
<td>oemagent-emctl</td>
</tr>
<tr>
<td>emdctlj.log</td>
<td>oemagent-emdctlj</td>
</tr>
<tr>
<td>gcagent.log</td>
<td>oemagent-gcagent</td>
</tr>
<tr>
<td>gcagent_errors.log</td>
<td>oemagent-gcagent-errors</td>
</tr>
<tr>
<td>emagent.nohup</td>
<td>oemagent-emagent-nohup</td>
</tr>
<tr>
<td>secure.log</td>
<td>oemagent-secure</td>
</tr>
</tbody>
</table>

For more information, see [Locating Management Agent Log and Trace Files](#) in the Oracle documentation.

#### Console

**To publish Oracle DB logs to CloudWatch Logs from the AWS Management Console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.
AWS CLI

To publish Oracle logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

**Note**
A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish Oracle logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

**Example**

The following example creates an Oracle DB instance with CloudWatch Logs publishing enabled. The `--cloudwatch-logs-export-configuration` value is a JSON array of strings. The strings can be any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration \\
  ['"trace","audit","alert","listener","oemagent"]' \
  --db-instance-class db.m5.large \
  --allocated-storage 20 \
  --engine oracle-ee \
  --engine-version 12.1.0.2.v18 \
  --license-model bring-your-own-license \
  --master-username myadmin \
  --master-user-password mypassword
```

For Windows:

```bash
aws rds create-db-instance ^ \
  --db-instance-identifier mydbinstance ^ \
  --cloudwatch-logs-export-configuration trace alert audit listener oemagent ^ \
  --db-instance-class db.m5.large ^ \
  --allocated-storage 20 ^ \
  --engine oracle-ee ^ \
  --engine-version 12.1.0.2.v18 ^ \
  --license-model bring-your-own-license ^ \
  --master-username myadmin ^ \
  --master-user-password mypassword
```

**Example**

The following example modifies an existing Oracle DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this
object is `EnableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["trace","alert","audit","listener","oemagent"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration EnableLogTypes="trace","alert","audit","listener","oemagent""
```

**Example**

The following example modifies an existing Oracle DB instance to disable publishing audit and listener log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"DisableLogTypes": ["audit","listener"]}'
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration DisableLogTypes="audit","listener"
```

**RDS API**

You can publish Oracle DB logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

**Note**

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish Oracle logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`
Run one of these RDS API operations with the following parameters:

- DBInstanceIdentifier
- EnableCloudwatchLogsExports
- Engine
- DBInstanceClass

Other parameters might be required depending on the RDS operation that you run.

**Previous methods for accessing alert logs and listener logs**

You can view the alert log using the Amazon RDS console. You can also use the following SQL statement to access the alert log.

```
SELECT message_text FROM alertlog;
```

The `listenerlog` view contains entries for Oracle Database version 12.1.0.2 and earlier. To access the listener log for these database versions, use the following query.

```
SELECT message_text FROM listenerlog;
```

For Oracle Database versions 12.2.0.1 and later, access the listener log using Amazon CloudWatch Logs.

**Note**

Oracle rotates the alert and listener logs when they exceed 10 MB, at which point they are unavailable from Amazon RDS views.
PostgreSQL database log files

RDS for PostgreSQL generates query and error logs. You can use log messages to troubleshoot performance and auditing issues while using the database.

To view, download, and watch file-based database logs, see Monitoring Amazon RDS log files (p. 646).

Topics
- Overview of PostgreSQL logs (p. 680)
- Setting the log retention period (p. 681)
- Setting the message format (p. 681)
- Enabling query logging (p. 681)
- Publishing PostgreSQL logs to Amazon CloudWatch Logs (p. 683)

Overview of PostgreSQL logs

PostgreSQL generates event log files that contain useful information for DBAs.

Log contents

The default logging level captures errors that affect your server. By default, Amazon RDS PostgreSQL logging parameters capture all server errors, including the following:

- Query failures
- Login failures
- Fatal server errors
- Deadlocks

To identify application issues, you can use the preceding error messages. For example, if you converted a legacy application from Oracle to Amazon RDS PostgreSQL, some queries may not convert correctly. These incorrectly formatted queries generate error messages in the logs, which you can use to identify the problematic code.

You can modify PostgreSQL logging parameters to capture additional information, including the following:

- Connections and disconnections
- Checkpoints
- Schema modification queries
- Queries waiting for locks
- Queries consuming temporary disk storage
- Backend autovacuum process consuming resources

The preceding log information can help troubleshoot potential performance and auditing issues. For more information, see Error reporting and logging in the PostgreSQL documentation. For a useful AWS blog about PostgreSQL logging, see Working with RDS and Aurora PostgreSQL logs: Part 1 and Working with RDS and Aurora PostgreSQL logs: Part 2.

Parameter groups

Each Amazon RDS PostgreSQL instance is associated with a parameter group that contains the engine specific configurations. The engine configurations also include several parameters that control
PostgreSQL logging behavior. AWS provides the parameter groups with default configuration settings to use for your instances. However, to change the default settings, you must create a clone of the default parameter group, modify it, and attach it to your instance.

To set logging parameters for a DB instance, set the parameters in a DB parameter group and associate that parameter group with the DB instance. For more information, see Working with parameter groups (p. 278).

Setting the log retention period

To set the retention period for system logs, use the rds.log_retention_period parameter. You can find rds.log_retention_period in the DB parameter group associated with your DB instance. The unit for this parameter is minutes. For example, a setting of 1,440 retains logs for one day. The default value is 4,320 (three days). The maximum value is 10,080 (seven days). Your instance must have enough allocated storage to contain the retained log files.

To retain older logs, publish them to Amazon CloudWatch Logs. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs (p. 683).

Setting the message format

By default, Amazon RDS PostgreSQL generates logs in standard error (stderr) format. In this format, each log message is prefixed with the information specified by the parameter log_line_prefix. Amazon RDS only allows the following value for log_line_prefix:

%t:%r:%u%@%d:[%p]:t

The preceding value maps to the following code:

log-time : remote-host : user-name @ db-name : [ process-id ]

For example, the following error message results from querying a column using the wrong name.

```
2019-03-10 03:54:59 UTC:10.0.0.123(52834):postgres@tstdb:[20175]:ERROR: column "wrong" does not exist at character 8
```

To specify the format for output logs, use the parameter log_destination. To make the instance generate both standard and CSV output files, set log_destination to csvlog in your instance parameter group. For a discussion of PostgreSQL logs, see Working with RDS and Aurora PostgreSQL logs: Part 1.

Enabling query logging

To enable query logging for your PostgreSQL DB instance, set two parameters in the DB parameter group associated with your DB instance: log_statement and log_min_duration_statement.

The log_statement parameter controls which SQL statements are logged. The default value is none. We recommend that when you debug issues in your DB instance, set this parameter to all to log all statements. To log all data definition language (DDL) statements (CREATE, ALTER, DROP, and so on), set this value to ddl. To log all DDL and data modification language (DML) statements (INSERT, UPDATE, DELETE, and so on), set the value to mod.

**Warning**

Sensitive information such as passwords can be exposed if you set the log_statement parameter to ddl, mod, or all. To avoid this risk, set the log_statement to none. Also consider the following solutions:
• Encrypt the sensitive information on the client side and use the ENCRYPTED and UNENCRYPTED options of the CREATE and ALTER statements.
• Restrict access to the CloudWatch logs.
• Use stronger authentication mechanisms such as IAM.

For auditing, you can use the PostgreSQL pgAudit extension because it redacts the sensitive information for CREATE and ALTER commands.

The log_min_duration_statement parameter sets the limit in milliseconds of a statement to be logged. All SQL statements that run longer than the parameter setting are logged. This parameter is disabled and set to -1 by default. Enabling this parameter can help you find unoptimized queries.

To set up query logging, take the following steps:

1. Set the log_statement parameter to all. The following example shows the information that is written to the postgresql.log file.

```
2013-11-05 16:48:56 UTC::@:[2952]:LOG:  received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@:[2952]:LOG:  parameter "log_statement" changed to "all"
```

Additional information is written to the postgresql.log file when you run a query. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:41:07 UTC::@:[2955]:LOG:  checkpoint starting: time
2013-11-05 16:41:07 UTC::@:[2955]:LOG:  checkpoint complete: wrote 1 buffers (0.3%); 0 transaction log file(s) added, 0 removed, 1 recycled; write=0.000 s, sync=0.003 s, 0.012 s; sync files=1, longest=0.003 s, average=0.003 s
2013-11-05 16:45:14 UTC:[local]:master@postgres:[8839]:LOG:  statement: SELECT d.datname as "Name",
                   pg_catalog.pg_get_userbyid(d.datdba) as "Owner",
                   pg_catalog.pg_encoding_to_char(d.encoding) as "Encoding",
                   d.datcollate as "Collate",
                   d.datctype as "Ctype",
                   pg_catalog.array_to_string(d.datacl, E'\n') AS "Access privileges"
FROM pg_catalog.pg_database d
ORDER BY 1;
2013-11-05 16:45:
```

2. Set the log_min_duration_statement parameter. The following example shows the information that is written to the postgresql.log file when the parameter is set to 1.

```
2013-11-05 16:48:56 UTC::@:[2952]:LOG:  received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@:[2952]:LOG:  parameter "log_min_duration_statement" changed to "1"
```

Additional information is written to the postgresql.log file when you run a query that exceeds the duration parameter setting. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG:  statement: SELECT c2.relname, i.indisprimary, i.indisunique, i.indisvalid, pg_catalog.pg_get_indexdef(i.indexrelid, 0, true), pg_catalog.pg_get_constraintdef(con.oid, true), contype, condeferrable, condeferred, c2.reltablespace
FROM pg_catalog.pg_class c, pg_catalog.pg_class c2, pg_catalog.pg_index i
LEFT JOIN pg_catalog.pg_constraint con ON (conrelid = i.indrelid AND conindid = i.indexrelid AND conindrelid = c2.oid)
WHERE c.oid = '1255' AND c.oid = i.indrelid AND i.indexrelid = c2.oid
```

682
ORDER BY i.indisprimary DESC, i.indisunique DESC, c2.relname;
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: duration: 3.367 ms

Publishing PostgreSQL logs to Amazon CloudWatch Logs

To store your PostgreSQL log records in highly durable storage, you can use Amazon CloudWatch Logs. With CloudWatch Logs, you can also perform real-time analysis of log data and use CloudWatch to view metrics and create alarms. For example, if you set log_statements to ddl, you can set up an alarm to alert whenever a DDL statement is executed.

To work with CloudWatch Logs, configure your RDS for PostgreSQL DB instance to publish log data to a log group.

**Note**
Publishing log files to CloudWatch Logs is supported only for PostgreSQL versions 9.6.6 and later and 10.4 and later.

You can publish the following log types to CloudWatch Logs for RDS for PostgreSQL:

- Postgresql log
- Upgrade log (not available for Aurora PostgreSQL)

After you complete the configuration, Amazon RDS publishes the log events to log streams within a CloudWatch log group. For example, the PostgreSQL log data is stored within the log group /aws/rds/instance/my_instance/postgresql. To view your logs, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

**Console**

**To publish PostgreSQL logs to CloudWatch Logs using the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify, and then choose Modify.
4. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
   
   The Log exports section is available only for PostgreSQL versions that support publishing to CloudWatch Logs.
5. Choose Continue, and then choose Modify DB Instance on the summary page.

**AWS CLI**

You can publish PostgreSQL logs with the AWS CLI. You can call the modify-db-instance command with the following parameters:

- --db-instance-identifier
• --cloudwatch-logs-export-configuration

**Note**
A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish PostgreSQL logs by calling the following CLI commands:

• `create-db-instance`
• `restore-db-instance-from-db-snapshot`
• `restore-db-instance-to-point-in-time`

Run one of these CLI commands with the following options:

• `--db-instance-identifier`
• `--enable-cloudwatch-logs-exports`
• `--db-instance-class`
• `--engine`

Other options might be required depending on the CLI command you run.

**Example Modify an instance to publish logs to CloudWatch Logs**

The following example modifies an existing PostgreSQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql", "upgrade"]}'
```

For Windows:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql", "upgrade"]}'
```

**Example Create an instance to publish logs to CloudWatch Logs**

The following example creates a PostgreSQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --enable-cloudwatch-logs-exports '["postgresql","upgrade"]' 
   --db-instance-class db.m4.large
```

For Windows:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --enable-cloudwatch-logs-exports '["postgresql","upgrade"]'
   --db-instance-class db.m4.large
```
--engine postgres

For Windows:

```bash
aws rds create-db-instance ^
   --db-instance-identifier mydbinstance ^
   --enable-cloudwatch-logs-exports '["postgresql","upgrade"]' ^
   --db-instance-class db.m4.large ^
   --engine postgres
```

**RDS API**

You can publish PostgreSQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

**Note**

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish PostgreSQL logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the operation that you run.
Monitoring Amazon RDS API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the AWS CloudTrail User Guide.

Topics

- CloudTrail integration with Amazon RDS (p. 686)
- Amazon RDS log file entries (p. 686)

CloudTrail integration with Amazon RDS

All Amazon RDS actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS.

CloudTrail events

CloudTrail captures API calls for Amazon RDS as events. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon RDS activity is recorded in a CloudTrail event in Event history. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon RDS, create a trail. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note

If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon RDS log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.
The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```json
{
    "eventVersion": "1.04",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/johndoe",
        "accountId": "123456789012",

  "name": "us-east-1a",
  "subnetIdentifier": "subnet-da327bf6",
  "subnetStatus": "Active"
  }
],
  
  "vpcId": "vpc-136a4c6a",
  "subnetGroupStatus": "Complete"
},
  
  "masterUsername": "myawsuser",
  "multiAZ": false,
  "autoMinorVersionUpgrade": true,
  "engine": "mysql",
  "cACertificateIdentifier": "rds-ca-2015",
  "dbInstanceIdentifier": "db-ETDZIIXHENV5N7GXC45H7S1A",
  "pendingModifiedValues": {
    "pendingCloudwatchLogsExports": {
      "logTypesToEnable": [
        "audit",
        "error",
        "general",
        "slowquery"
      ]
    },
    "masterUserPassword": "****",
    "pendingDbSecurityGroups": []
  }
},
  
  "dBInstanceStatus": "creating",
  "publiclyAccessible": true,
  "domainMemberships": [],
  "copyTagsToSnapshot": false,
  "dBInstanceIdentifier": "test-instance",
  "licenseModel": "general-public-license",
  "iAMDatabaseAuthenticationEnabled": false,
  "performanceInsightsEnabled": false,
  "vpcSecurityGroups": [
    {
      "status": "active",
      "vpcSecurityGroupId": "sg-f8396888"
    }
  ],
  
  "requestID": "daf2e3f5-96a3-4df7-a026-863f96db793e",
  "eventID": "797163d3-5726-441d-80a7-6eeb7464ac4d"
As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the CloudTrail `userIdentity` element. For more information about `CreateDBInstance` and other Amazon RDS actions, see the Amazon RDS API Reference.
Monitoring Amazon RDS for Oracle with Database Activity Streams

By using Database Activity Streams, you can monitor near-real-time streams of database activity.

Topics

- Overview of Database Activity Streams (p. 690)
- Configuring unified auditing for Oracle Database (p. 693)
- Starting a database activity stream (p. 694)
- Getting the status of a database activity stream (p. 695)
- Stopping a database activity stream (p. 696)
- Monitoring database activity streams (p. 697)
- Managing access to database activity streams (p. 711)

Overview of Database Activity Streams

As an RDS for Oracle database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your Oracle database.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. RDS for Oracle DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Topics

- How database activity streams work (p. 690)
- Unified auditing in Oracle Database (p. 691)
- Asynchronous mode for database activity streams (p. 692)
- Requirements for database activity streams (p. 692)
- Supported RDS for Oracle engine versions for database activity streams (p. 692)
- Supported DB instance classes for database activity streams (p. 692)
- Supported AWS Regions for database activity streams (p. 693)

How database activity streams work

Amazon RDS pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Important

Use of the Database Activity Streams feature in Amazon Aurora and Amazon RDS is free, but Amazon Kinesis charges for a data stream. For more information, see Amazon Kinesis Data Streams pricing.

Applications for compliance management can also consume database activity streams. These applications can use the stream to generate alerts and audit activity on your Oracle database.

Database Activity Streams
Unified auditing in Oracle Database

Amazon RDS for Oracle doesn't capture database activity by default. You create and manage audit policies in Oracle Database yourself.

Auditing is the monitoring and recording of configured database actions. In an Oracle database, a unified audit policy is a named group of audit settings that you can use to audit an aspect of user behavior. A policy can be as simple as auditing the activities of a single user. You can also create complex audit policies that use conditions.

An Oracle database writes audit records, including SYS audit records, to the unified audit trail. For example, if an error occurs during an INSERT statement, standard auditing indicates the error number and the SQL that was executed. The audit trail resides in a read-only table in the AUDSYS schema. To access these records, query the UNIFIED_AUDIT_TRAIL data dictionary view.

Typically, you configure database activity streams as follows:

1. Create an Oracle Database audit policy by using the CREATE AUDIT POLICY command. The Oracle Database generates audit records.
2. Enable the audit policy by using the AUDIT POLICY command.
3. Configure database activity streams.

   Only activities that match the Oracle Database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled, an Oracle database administrator can’t alter the audit policy or remove audit logs.

To learn more about unified audit policies, see About Auditing Activities with Unified Audit Policies and AUDIT in the Oracle Database Security Guide.

Topics

- Non-native audit fields (p. 691)
- DB parameter group override (p. 691)

Non-native audit fields

When you start a database activity stream, every database event generates a corresponding activity stream event. For example, a database user might run SELECT and INSERT statements. The database audits these events and sends them to an Amazon Kinesis data stream.

The events are represented in the stream as JSON objects. A JSON object contains a DatabaseActivityMonitoringRecord, which contains a databaseActivityEventList array. Predefined fields in the array include class, clientApplication, and command.

Most events in the unified audit trail for Oracle Database map to fields in the RDS data activity stream. For example, the UNIFIED_AUDIT_TRAIL.SQL_TEXT field in unified auditing maps to the commandText field in a database activity stream. However, Oracle Database audit fields such as OS_USERNAME don’t map to predefined fields in a database activity stream.

By default, an activity stream doesn't include engine-native audit fields. You can configure RDS for Oracle so that it includes these extra fields in the engineNativeAuditFields JSON object.

DB parameter group override

Typically, you turn on unified auditing in RDS for Oracle by attaching a parameter group. However, Database Activity Streams would require additional configuration. To improve your customer experience, Amazon RDS does the following
• If you enable an activity stream, RDS for Oracle ignores the auditing parameters in the parameter group.
• If you disable an activity stream, RDS for Oracle stops ignoring the auditing parameters.

Asynchronous mode for database activity streams

Activity streams in RDS for Oracle are always asynchronous. When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, the activity stream event is made a durable record. If an error occurs in the background task, Amazon RDS generates an event. This event indicates the beginning and end of any time windows where activity stream event records might have been lost. Asynchronous mode favors database performance over the accuracy of the activity stream.

Requirements for database activity streams

In RDS for Oracle, database activity streams have the following requirements and limitations.

Topics

• Oracle feature requirements (p. 692)
• Miscellaneous requirements (p. 692)

Oracle feature requirements

RDS for Oracle has the following requirements for database activity streams:
• CDBs aren't supported.
• Oracle read replicas aren't supported.
• In an RDS for Oracle DB instance, you create and manage audit policies yourself. Unlike Amazon Aurora, RDS for Oracle doesn't capture database activities by default.

Miscellaneous requirements

• Database activity streams require use of AWS Key Management Service (AWS KMS). AWS KMS is required because the activity streams are always encrypted.
• Database activity streams require use of Amazon Kinesis.

Supported RDS for Oracle engine versions for database activity streams

Supported DB instance classes for database activity streams

For Oracle for RDS, you can use database activity streams with the following DB instance classes:
• db.m4
• db.m5.*
- db.r4
- db.r5.*
- db.z1d

**Note**
The memory optimized db.r5 classes, which use the naming pattern db.r5.instance_size.threads_per_core.mem.ratio, aren't supported.

For more information about instance class types, see DB instance classes (p. 9).

### Supported AWS Regions for database activity streams

Database activity streams are supported in all AWS Regions except the following:

- China (Beijing) Region, cn-north-1
- China (Ningxia) Region, cn-northwest-1
- AWS GovCloud (US-East), us-gov-east-1
- AWS GovCloud (US-West), us-gov-west-1

### Configuring unified auditing for Oracle Database

When you configure unified auditing for use with database activity streams, the following situations are possible:

- Unified auditing isn't configured for your Oracle database.

  In this case, create new policies with the `CREATE AUDIT POLICY` command, and then enable them with the `AUDIT POLICY` command. The following example creates and enables a policy to monitor users with specific privileges and roles.

  ```sql
  CREATE AUDIT POLICY table_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ROLES emp_admin, sales_admin;
  AUDIT POLICY table_pol;
  ```

  For complete instructions, see Configuring Audit Policies in the Oracle Database documentation.

- Unified auditing is configured for your Oracle database.

  When you enable a database activity stream, RDS for Oracle automatically clears existing audit data. It also revokes audit trail privileges. RDS for Oracle can no longer do the following:

  - Purge unified audit trail records.
  - Add, delete, or modify the unified audit policy.
  - Update the last archived time stamp.

  **Important**
  We strongly recommend that you back up your audit data before enabling a database activity stream.

  For a description of the `UNIFIED_AUDIT_TRAIL` view, see `UNIFIED_AUDIT_TRAIL`. If you have an account with Oracle Support, see How To Purge The `UNIFIED_AUDIT_TRAIL`. 
Starting a database activity stream

When you start an activity stream for an Oracle DB instance, each database activity event, such as a change or access, generates an activity stream event. SQL commands such as `CONNECT` and `SELECT` generate access events. SQL commands such as `CREATE` and `INSERT` generate change events.

**Important**

Turning on an activity stream for an Oracle DB instance clears existing audit data. It also revokes audit trail privileges. When the stream is enabled, RDS for Oracle can no longer do the following:

- Purge unified audit trail records
- Add, delete, or modify the unified audit policy
- Update the last archived time stamp

**Console**

**To start a database activity stream**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the RDS instance for which you want to enable an activity stream.
4. For **Actions**, choose **Start activity stream**.

The **Start database activity stream: name** window appears, where **name** is your RDS instance.

5. Enter the following settings:

- For **AWS KMS key**, choose a key from the list of AWS KMS keys.
  
  RDS for Oracle uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see What is AWS Key Management Service? in the **AWS Key Management Service Developer Guide**.

  - For **Database activity events**, choose **Include Oracle native audit fields** to include Oracle-specific audit fields in the stream.
  - Choose **Immediately**.

  When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.

  When you're done entering settings, choose **Start database activity stream**.

  The status for the Oracle database shows that the activity stream is starting.

**AWS CLI**

To start database activity streams for an Oracle database, configure the database using the **start-activity-stream** AWS CLI command.

- **--kms-key-id key** – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.
- **--resource-arn arn** – Specifies the Amazon Resource Name (ARN) of the DB instance.
• `--region` – Identifies the AWS Region for the DB instance.
• `--engine-native-audit-fields-included` – Includes engine-specific unified auditing fields in the data stream. To exclude these fields, specify `--no-engine-native-audit-fields-included` (default).
• `--mode async` – Specifies asynchronous mode.
• `--apply-immediately` – Applies the change immediately. This parameter is optional. If you don't specify this parameter, the database activity stream starts at the next maintenance interval.

For Linux, macOS, or Unix:

```
aws rds --region my_region
    start-activity-stream
    --mode async
    --kms-key-id my_kms_key_arn
    --resource-arn my_db_arn
    --engine-native-audit-fields-included
    --apply-immediately
```

For Windows:

```
aws rds --region my_region
    start-activity-stream
    --mode async
    --kms-key-id my_kms_key_arn
    --resource-arn my_db_arn
    --engine-native-audit-fields-included
    --apply-immediately
```

**RDS API**

To start database activity streams for an Oracle database, configure the database using the `StartActivityStream` operation.

Call the action with the parameters below:

• Region
• EngineNativeAuditFieldsIncluded
• KmsKeyId
• ResourceArn
• Mode
• ApplyImmediately

**Getting the status of a database activity stream**

You can get the status of an activity stream for your Oracle DB using the console or AWS CLI.

**Console**

To get the status of a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance link.
3. Choose the **Configuration** tab, and check **Database activity stream** for status.

**AWS CLI**

You can get the activity stream configuration for a database as the response to a `describe-db-instances` CLI request. In the following example, see the values for `ActivityStreamKinesisStreamName`, `ActivityStreamStatus`, `ActivityStreamKmsKeyId`, and `ActivityStreamMode`.

The request is as follows.

```
aws rds --region MY_REGION describe-db-instances --db-instance-identifier my-db
```

The response includes the following items for a database activity stream.

The following example shows a JSON response.

```json
{
  "DBInstances": [
    {
      ...
      "Engine": "oracle-ee",
      ...
      "ActivityStreamStatus": "starting",
      "ActivityStreamKinesisStreamName": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
      "ActivityStreamKinesisStreamName": "aws-rds-das-db-AB1CDEFG23GHIJK4LMNOPQRST",
      "ActivityStreamMode": "async",
      "ActivityStreamEngineNativeAuditFieldsIncluded": true
    }
  ]
}
```

**RDS API**

You can get the activity stream configuration for a database as the response to a `DescribeDBInstances` operation.

**Stopping a database activity stream**

You can stop an activity stream using the console or AWS CLI.

If you delete Oracle database, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.

**Console**

**To turn off an activity stream**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose a database that you want to stop the database activity stream for.
4. For **Actions**, choose **Stop activity stream**. The **Database Activity Stream** window appears.
   a. Choose **Immediately**.

   When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.
b. Choose **Continue**.

**AWS CLI**

To stop database activity streams for your database, configure the DB instance using the AWS CLI command `stop-activity-stream`. Identify the AWS Region for the DB instance using the `--region` parameter. The `--apply-immediately` parameter is optional.

For Linux, macOS, or Unix:

```bash
aws rds --region MY_REGION \
  stop-activity-stream \
  --resource-arn MY_DB_ARN \
  --apply-immediately
```

For Windows:

```bash
aws rds --region MY_REGION ^
  stop-activity-stream ^
  --resource-arn MY_DB_ARN ^
  --apply-immediately
```

**RDS API**

To stop database activity streams for your database, configure the DB instance using the `StopActivityStream` operation. Identify the AWS Region for the DB instance using the `Region` parameter. The `ApplyImmediately` parameter is optional.

**Monitoring database activity streams**

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command `describe-db-instances` or the RDS API `DescribeDBInstances` operation.

Amazon RDS manages the Kinesis stream for you as follows:

- Amazon RDS creates the Kinesis stream automatically with a 24-hour retention period.
- Amazon RDS scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB instance, Amazon RDS deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.

- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. Database activity streams also monitor the bind variables and stored procedure parameters.

  **Important**

  The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Oracle can determine them from the context, such as in the following SQL statement.
ALTER ROLE role-name WITH password

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

**Topics**
- Accessing an activity stream from Kinesis (p. 698)
- Audit log contents and examples (p. 698)
- Processing a database activity stream using the AWS SDK (p. 711)

**Accessing an activity stream from Kinesis**

When you enable an activity stream for a database, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

**To access an activity stream from Kinesis**

2. Choose your activity stream from the list of Kinesis streams.
   
   An activity stream's name includes the prefix `aws-rds-das-db-` followed by the resource ID of the database. The following is an example.

   ```
   aws-rds-das-db-NHVOV4PCLWHGF52NP
   ```

   To use the Amazon RDS console to find the resource ID for the database, choose your DB instance from the list of databases, and then choose the **Configuration** tab.

   To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a `describe-db-instances` CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.
3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see What Is Amazon Kinesis Data Streams?.

**Audit log contents and examples**

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

**Topics**
- Examples of an audit log for an activity stream (p. 699)
- DatabaseActivityMonitoringRecords JSON object (p. 704)
- databaseActivityEvents JSON Object (p. 705)
Examples of an audit log for an activity stream

Following are sample decrypted JSON audit logs of activity event records.

**Example Activity event record of a CONNECT SQL statement**

Following is an activity event record of a login with the use of a `CONNECT` SQL statement (command) by a JDBC Thin Client (clientApplication).

```
{
    "class": "Standard",

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is DatabaseActivityMonitoringRecords.</td>
</tr>
<tr>
<td>version</td>
<td>string</td>
<td>The version of the database activity monitoring records. Oracle DB uses version 1.3. This version introduces the engineNativeAuditFields JSON object.</td>
</tr>
<tr>
<td>databaseActivityEvents</td>
<td>string[]</td>
<td>A JSON object containing the activity events.</td>
</tr>
<tr>
<td>key</td>
<td>string</td>
<td>An encryption key you use to decrypt the databaseActivityEventList (p. 706) databaseActivityEventList JSON array.</td>
</tr>
</tbody>
</table>
databaseActivityEvents JSON Object

The databaseActivityEvents JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

**type**

This field always has the value `DatabaseActivityMonitoringRecords`.

**version**

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

**databaseActivityEvents**

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

**key**

The encrypted data key used to encrypt the databaseActivityEvents string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```json
{
  "type":"DatabaseActivityMonitoringRecords",
  "version":"1.3",
  "databaseActivityEvents":"encrypted audit records",
  "key":"encrypted key"
}
```

Take the following steps to decrypt the contents of the databaseActivityEvents field:

1. Decrypt the value in the key JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the databaseActivityEvents JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
   - The encrypted payload is in the databaseActivityEvents field.
   - The databaseActivityEventList field contains an array of audit records. The type fields in the array can be record or heartbeat.

The audit log activity event record is a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is DatabaseActivityMonitoringRecord.</td>
</tr>
<tr>
<td>instanceId</td>
<td>string</td>
<td>The DB instance resource identifier. It corresponds to the DB instance attribute DbiResourceId.</td>
</tr>
</tbody>
</table>
### databaseActivityEventList JSON array

The audit log payload is an encrypted `databaseActivityEventList` JSON array. The following table lists alphabetically the fields for each activity event in the decrypted `DatabaseActivityEventList` array of an audit log.

When unified auditing is enabled in Oracle Database, the audit records are populated in this new audit trail. The `UNIFIED_AUDIT_TRAIL` view displays audit records in tabular form by retrieving the audit records from the audit trail. When you start a database activity stream, a column in `UNIFIED_AUDIT_TRAIL` maps to a field in the `databaseActivityEventList` array.

**Important**

The event structure is subject to change. Amazon RDS might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

### databaseActivityEventList fields for Amazon RDS for Oracle

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>string</td>
<td>The class of activity event. This corresponds to the <code>AUDIT_TYPE</code> column in the <code>UNIFIED_AUDIT_TRAIL</code> view. Valid values for Amazon RDS for Oracle are the following: • Standard • FineGrainedAudit • XS • Database Vault • Label Security • RMAN_AUDIT • Datapump • Direct path API For more information, see <code>UNIFIED_AUDIT_TRAIL</code> in the Oracle documentation.</td>
</tr>
<tr>
<td>clientApplication</td>
<td>string</td>
<td>The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null. A sample value is JDBC Thin Client.</td>
</tr>

### Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK.

### Managing access to database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB instance. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don’t provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about RDS for Oracle authentication, see Identity and access management in Amazon RDS (p. 1766). For more information about creating IAM policies, see Creating and using an IAM policy for IAM database access (p. 1789).

#### Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys `rds:StartActivityStream` and `rds:StopActivityStream` in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```json
{
    "Version":"2012-10-17",
    "Statement": [ 
    {
        "Sid":"ConfigureActivityStreams",
        "Effect":"Allow",
        "Action": [ 
            "rds:StartActivityStream",
            "rds:StopActivityStream"
        ],
        "Resource":"*",
    }
    ]
}
```
Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowStartActivityStreams",
            "Effect": "Allow",
            "Action": "rds:StartActivityStream",
            "Resource": "*"
        }
    ]
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowStopActivityStreams",
            "Effect": "Allow",
            "Action": "rds:StopActivityStream",
            "Resource": "*"
        }
    ]
}
```

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyStartActivityStreams",
            "Effect": "Deny",
            "Action": "rds:StartActivityStream",
            "Resource": "*"
        }
    ]
}
```

Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyStopActivityStreams",
            "Effect": "Deny",
            "Action": "rds:StopActivityStream",
            "Resource": "*"
        }
    ]
}
```
} ]

] }
Working with Amazon RDS Custom

Amazon RDS Custom automates database administration tasks and operations. RDS Custom makes it possible for you as a database administrator to access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications.

The following video is an overview of Amazon RDS Custom from AWS re:Invent 2021.

Topics

- Addressing the challenge of database customization (p. 714)
- Management model and benefits for Amazon RDS Custom (p. 715)
- Amazon RDS Custom architecture (p. 717)
- Requirements and limitations for Amazon RDS Custom (p. 722)
- Setting up your environment for Amazon RDS Custom for Oracle (p. 726)
- Setting up your environment for Amazon RDS Custom for SQL Server (p. 738)
- Working with custom engine versions for Amazon RDS Custom for Oracle (p. 748)
- Creating and connecting to a DB instance for Amazon RDS Custom for Oracle (p. 762)
- Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 770)
- Managing an Amazon RDS Custom DB instance (p. 778)
- Working with read replicas for RDS Custom for Oracle (p. 788)
- Backing up and restoring an Amazon RDS Custom DB instance (p. 791)
- Migrating an on-premises database to Amazon RDS Custom for SQL Server (p. 800)
- Upgrading a DB instance for Amazon RDS Custom for Oracle (p. 803)
- Upgrading a DB instance for Amazon RDS Custom for SQL Server (p. 807)
- Troubleshooting DB issues for Amazon RDS Custom (p. 808)

Addressing the challenge of database customization

Amazon RDS Custom brings the benefits of Amazon RDS to a market that can't easily move to a fully managed service because of customizations that are required with third-party applications. Amazon RDS Custom saves administrative time, is durable, and scales with your business.

If you need the entire database and operating system to be fully managed by AWS, we recommend Amazon RDS. If you need administrative rights to the database and underlying operating system to make dependent applications available, Amazon RDS Custom is the better choice. If you want full management responsibility and simply need a managed compute service, the best option is self-managing your commercial databases on Amazon EC2.

To deliver a managed service experience, Amazon RDS doesn't let you access the underlying host. Amazon RDS also restricts access to some procedures and objects that require high-level privileges.
However, for some applications, you might need to perform operations as a privileged operating system (OS) user.

For example, you might need to do the following:

- Install custom database and OS patches and packages.
- Configure specific database settings.
- Configure file systems to share files directly with their applications.

Previously, if you needed to customize your application, you had to deploy your database on-premises or on Amazon EC2. In this case, you bear most or all of the responsibility for database management, as summarized in the following table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>On-premises responsibility</th>
<th>Amazon EC2 responsibility</th>
<th>Amazon RDS responsibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application optimization</td>
<td>Customer</td>
<td>Customer</td>
<td>Customer</td>
</tr>
<tr>
<td>Scaling</td>
<td>Customer</td>
<td>Customer</td>

<tr>
<td>Power, network, and cooling</td>
<td>Customer</td>
<td>AWS</td>
<td>AWS</td>
</tr>
</tbody>
</table>

When you manage database software yourself, you gain more control, but you're also more prone to user errors. For example, when you make changes manually, you might accidentally cause application downtime. You might spend hours checking every change to identify and fix an issue. Ideally, you want a managed database service that automates common DBA tasks, but also supports privileged access to the database and underlying operating system.

### Management model and benefits for Amazon RDS Custom

Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. Amazon RDS Custom
automates setup, operation, and scaling of databases in the AWS Cloud while granting you access to the
database and underlying operating system. With this access, you can configure settings, install patches,
and enable native features to meet the dependent application's requirements. With RDS Custom, you can
run your database workload using the AWS Management Console or the AWS CLI.

Currently, Amazon RDS Custom supports only the Oracle Database and Microsoft SQL Server engines.

**Shared responsibility model**

With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibility of Amazon EC2.
By taking on additional database management responsibilities beyond what you do in Amazon RDS, you
can benefit from RDS automation and the deeper customization of EC2. To meet your application and
business requirements, you manage the host yourself.

In the shared responsibility model of RDS Custom, you get more control than in Amazon RDS but also
more responsibility. Shared responsibility has two meanings:

1. You own part of the process when using a feature.
2. You have full access to the feature, and it's your responsibility to make sure that any customizations
work with that feature.

The following table details the shared responsibility model for RDS Custom.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Amazon EC2 responsibility</th>
<th>Amazon RDS responsibility</th>
<th>RDS Custom for Oracle responsibility</th>
<th>RDS Custom for SQL Server responsibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application optimization</td>

</tbody>
</table>

You can create an RDS Custom DB instance using Oracle Database. In this case, you do the following:

- Manage your own media.
When using RDS Custom, you upload your own database installation files and patches. You create a custom engine version (CEV) from these files. Then you can create an RDS Custom DB instance by using this CEV.

- Manage your own licenses.

You bring your own Oracle Database licenses and manage licenses by yourself.

You can create an RDS Custom DB instance using Microsoft SQL Server. In this case:

- You don't manage your own media.
- You don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software.

**Key benefits of RDS Custom**

With RDS Custom, you can do the following:

- Automate many of the same administrative tasks as Amazon RDS, including the following:
  - Lifecycle management of databases
  - Automated backups and point-in-time recovery (PITR)
  - Monitoring the health of RDS Custom DB instances and observing changes to the infrastructure, operating system, and databases
  - Notification or taking action to fix issues depending on disruption to the DB instance
  - Install third-party applications.

  You can install software to run custom applications and agents. Because you have privileged access to the host, you can modify file systems to support legacy applications.

- Install custom patches.

  You can apply custom database patches or modify OS packages on your RDS Custom DB instances.

- Stage an on-premises database before moving it to a fully managed service.

  If you manage your own on-premises database, you can stage the database to RDS Custom as-is. After you familiarize yourself with the cloud environment, you can migrate your database to a fully managed Amazon RDS DB instance.

- Create your own automation.

  You can create, schedule, and run custom automation scripts for reporting, management, or diagnostic tools.

**Amazon RDS Custom architecture**

Amazon RDS Custom architecture is based on Amazon RDS, with important differences.

**Topics**

- RDS Custom for Oracle components (p. 718)
- RDS Custom for Oracle workflow (p. 719)
- RDS Custom for SQL Server components (p. 720)
- RDS Custom for SQL Server workflow (p. 721)
RDS Custom for Oracle components

The following diagram shows the most important components of the RDS Custom for Oracle architecture, listed and described after the diagram.

**Topics**
- VPC (p. 718)
- Amazon S3 (p. 718)

**VPC**

As in Amazon RDS, the RDS Custom DB instance resides in a virtual private cloud (VPC). The DB instance consists of the following main components:

- Amazon EC2 instance
- Operating system installed on the Amazon EC2 instance
- Amazon EBS storage, which contains any additional file systems
- Instance endpoint

**Amazon S3**

Amazon S3 provides the storage for your installation media. You use this media to create a custom engine version (CEV). A CEV is a binary volume snapshot of a database version and Amazon Machine Image (AMI). From the CEV, you create an RDS Custom instance.
RDS Custom for Oracle workflow

A typical workflow is as follows:

1. Upload your database software to your Amazon S3 bucket.
   
   For more information, see Uploading your installation files to Amazon S3 (p. 751).

2. Create an RDS Custom custom engine version (CEV) from your media.
   
   For more information, see Creating a CEV (p. 756).

3. Create an RDS Custom DB instance from a CEV.
   
   For more information, see Creating an RDS Custom for Oracle DB instance (p. 762).

4. Connect your application to the RDS Custom DB instance endpoint.
   
   For more information, see Connecting to your RDS Custom DB instance using SSH (p. 766) and Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 768).

5. (Optional) Access the host to customize your software.

RDS Custom monitors the DB instance and notifies you of any problems.

Database installation files

Your responsibility for media is a key difference between Amazon RDS and RDS Custom. Amazon RDS, which is a fully managed service, supplies the Amazon Machine Image (AMI) and database software. The Amazon RDS database software is preinstalled, so you need only choose a database engine and version, and create your database.

For RDS Custom, you supply your own media. When you create a custom engine version, RDS Custom installs the media that you provide. RDS Custom media contains your database installation files and patches. This service model is called Bring Your Own Media (BYOM).

Custom engine version

An RDS Custom custom engine version (CEV) is a binary volume snapshot of a database version and AMI. You store your database installation files in Amazon S3. When you create your CEV, you specify the files in a JSON document called a CEV manifest.

Name your CEV using a customer-specified string. The name format is the following, depending on your Oracle Database version:

- 12.1. customized_string
- 19. customized_string

You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might name your CEV 19.my_cev1. To learn how to create a CEV, see Working with custom engine versions for Amazon RDS Custom for Oracle (p. 748).

Creating a DB instance for RDS Custom for Oracle

After you create the CEV, it's available for use. You can create multiple CEVs, and you can create multiple RDS Custom for Oracle instances from any CEV. You can also change the status of a CEV to make it available or inactive.
To create your RDS Custom for Oracle DB instance, use the `create-db-instance` command. In this command, specify which CEV to use. The procedure is similar to creating an Amazon RDS instance. However, some of the parameters are different. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for Oracle (p. 762).

**Database connection**

Like an Amazon RDS DB instance, your RDS Custom DB instance resides in a VPC. Your application connects to the RDS Custom instance using an Oracle Listener, just as with RDS for Oracle.

**RDS Custom customization**

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming RDS Custom automation (p. 779).

**RDS Custom for SQL Server components**

The following diagram shows the most important components of the RDS Custom for SQL Server architecture, listed and described after the diagram.

As in Amazon RDS, the RDS Custom for SQL Server DB instance resides in a virtual private cloud (VPC). The DB instance consists of the following main components:

- Amazon EC2 instance
• Operating system installed on the Amazon EC2 instance
• Amazon EBS storage, which contains any additional file systems
• Instance endpoint

RDS Custom for SQL Server workflow

A typical workflow is as follows:

1. You create an RDS Custom for SQL Server DB instance from an engine version offered by RDS Custom. For more information, see Creating an RDS Custom for SQL Server DB instance (p. 770).
2. You connect your application to the RDS Custom DB instance endpoint. For more information, see Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 773) and Connecting to your RDS Custom DB instance using RDP (p. 775).
3. (Optional) You access the host to customize your software.

RDS Custom monitors the DB instance and notifies you of any problems.

Creating a DB instance for RDS Custom

You create your RDS Custom DB instance using the create-db-instance command. The procedure is similar to creating an Amazon RDS instance. However, some of the parameters are different. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 770).

Database connection

Like an Amazon RDS DB instance, your RDS Custom for SQL Server DB instance resides in a VPC. Your application connects to the RDS Custom instance using a client such as SQL Server Management Suite (SSMS), just as in RDS for SQL Server.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn’t perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming RDS Custom automation (p. 779).

RDS Custom automation and monitoring

RDS Custom has automation software that runs outside of the DB instance. This software communicates with agents on the DB instance and with other components within the overall RDS Custom environment.

Monitoring and recovery

The RDS Custom monitoring and recovery features offer similar functionality to Amazon RDS. By default, RDS Custom is in full automation mode. The automation software has the following primary responsibilities:

• Collect metrics and send notifications
• Perform automatic instance recovery
An important responsibility of RDS Custom automation is responding to problems with your Amazon EC2 instance. For various reasons, the host might become impaired or unreachable. RDS Custom resolves these problems by either rebooting or replacing the Amazon EC2 instance.

The automated replacement preserves all database data. On RDS Custom for SQL Server, host replacement doesn't preserve operating system customizations or data on the C: drive.

The only customer-visible change when a host is replaced is a new public IP address. For more information, see How Amazon RDS Custom replaces an impaired host (p. 816).

**Support perimeter**

RDS Custom provides additional monitoring capability called the *support perimeter*. This additional monitoring ensures that your RDS Custom instance uses a supported AWS infrastructure, operating system, and database. For more information about the support perimeter, see RDS Custom support perimeter and unsupported configurations (p. 809).

**Requirements and limitations for Amazon RDS Custom**

Following, you can find a summary of the Amazon RDS Custom requirements and limitations for quick reference. Requirements and limitations also appear in the relevant sections.

**Topics**

- General requirements for RDS Custom for Oracle (p. 722)
- General requirements for RDS Custom for SQL Server (p. 723)
- DB instance class support for RDS Custom (p. 723)
- AWS Region support for RDS Custom (p. 723)
- Limitations for RDS Custom for Oracle (p. 724)
- Limitations for RDS Custom for SQL Server (p. 724)

**General requirements for RDS Custom for Oracle**

Make sure to follow these requirements for Amazon RDS Custom for Oracle:

- Use Oracle Software Delivery Cloud to download Oracle installation and patch files. For more information, see Prerequisites for creating an RDS Custom for Oracle instance (p. 726).
- Use the Enterprise Edition of one of the following versions:
  - Oracle Database 12.1 with the January 2021 or later RU/RUR
  - Oracle Database 19c with the January 2021 or later RU/RUR
- Use the DB instance classes shown in DB instance class support for RDS Custom (p. 723). The instances must run Oracle Linux 7 Update 6. The only storage types supported are solid state drives (SSD) of types gp2 and io1. The maximum storage limit is 64 TiB.
- Make sure that you have an AWS KMS key to create an RDS Custom DB instance. For more information, see Make sure that you have a symmetric AWS KMS key (p. 726).
- Use only the approved database installation and patch files. For more information, see Downloading your database installation files and patches from Oracle (p. 748).
- Create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see Configuring IAM and your VPC (p. 727).
Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see Configuring IAM and your VPC (p. 727).

Make sure that the combined number of RDS Custom and Amazon RDS DB instances doesn’t exceed your quota limit. For example, if your quota for Amazon RDS is 40 DB instances, you can have 20 RDS Custom for Oracle DB instances and 20 Amazon RDS DB instances.

General requirements for RDS Custom for SQL Server

Make sure to follow these requirements for Amazon RDS Custom for SQL Server:

- Use the instance classes shown in DB instance class support for RDS Custom (p. 723). The only storage types supported are solid state drives (SSD) of types gp2 and io1. The maximum storage limit is 16 TiB.
- Make sure that you have a symmetric AWS KMS key to create an RDS Custom DB instance. For more information, see Make sure that you have a symmetric AWS KMS key (p. 738).
- Make sure that you create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see Creating your IAM role and instance profile manually (p. 740).
- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see Configuring IAM and your VPC (p. 739).
- The combined number of RDS Custom and Amazon RDS DB instances can’t exceed your quota limit. For example, if your quota is 40 DB instances, you can have 20 RDS Custom for SQL Server DB instances and 20 Amazon RDS DB instances.

DB instance class support for RDS Custom

RDS Custom for Oracle supports the following DB instance classes:

- db.m5.large–db.m5.24xlarge
- db.r5.large–db.r5.24xlarge

RDS Custom for SQL Server supports the DB instance classes shown in the following table.

<table>
<thead>
<tr>
<th>SQL Server edition</th>
<th>RDS Custom support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enterprise Edition</td>
<td>db.r5.xlarge–db.r5.24xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m5.xlarge–db.m5.24xlarge</td>
</tr>
<tr>
<td>Standard Edition</td>
<td>db.r5.large–db.r5.24xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m5.large–db.m5.24xlarge</td>
</tr>
<tr>
<td>Web Edition</td>
<td>db.r5.large–db.r5.4xlarge</td>
</tr>
<tr>
<td></td>
<td>db.m5.large–db.m5.4xlarge</td>
</tr>
</tbody>
</table>

AWS Region support for RDS Custom

RDS Custom is supported in the following AWS Regions:
Limitations for RDS Custom for Oracle

The following limitations apply to RDS Custom for Oracle:

- You can't provide your own AMI.
- Not all options are supported. For example, when you create an RDS Custom for Oracle DB instance, you can't do the following:
  - Change the number of CPU cores and threads per core on the DB instance class.
  - Turn on storage autoscaling.
  - Set backup retention to 0.
  - Configure Kerberos authentication.
  - Specify your own DB parameter group, option group, or character set.
  - Turn on Performance Insights.
  - Turn on automatic minor version upgrade.
- You can't change the DB instance class. For example, you can't change a db.m5.xlarge instance to db.m5.2xlarge. However, you can restore a DB snapshot to a different DB instance class.
- The maximum DB instance storage is 64 TiB.
- You can't use the Oracle Multitenant architecture.
- Only one database is supported on an RDS Custom for Oracle instance.

Limitations for RDS Custom for SQL Server

The following limitations apply to RDS Custom for SQL Server:

- You can't provide your own custom DB engine version.
- You can't provide your own AMI.
- You can't create read replicas in Amazon RDS for RDS Custom for SQL Server DB instances. However, you can configure high availability manually using Always On Availability Groups. For more information, see Working with high availability features for RDS Custom for SQL Server (p. 778).
- You can't modify the storage size after creating the DB instance. Migrate to a new DB instance with additional storage allocated to it.
- You can't modify the time zone of an existing RDS Custom for SQL Server DB instance.
- Changes to the Microsoft Windows operating system or C: drive don't persist when you replace an Amazon EC2 instance. However, you can redo those changes using automation.
- Not all options are supported. For example, when you create an RDS Custom for SQL Server DB instance, you can't do the following:
  - Change the number of CPU cores and threads per core on the DB instance class.
• Turn on storage autoscaling.
• Create a Multi-AZ deployment. However, you can configure high availability manually using Always On Availability Groups. For more information, see Working with high availability features for RDS Custom for SQL Server (p. 778).
• Configure Kerberos authentication using the AWS Management Console. However, you can configure Windows Authentication manually and use Kerberos.
• Specify your own DB parameter group, option group, or character set.
• Turn on Performance Insights.
• Turn on automatic minor version upgrade.
• The maximum DB instance storage is 16 TiB.
Setting up your environment for Amazon RDS Custom for Oracle

Before you create a DB instance based on Amazon RDS Custom for Oracle, perform the following tasks.

Topics

• Prerequisites for creating an RDS Custom for Oracle instance (p. 726)
• Make sure that you have a symmetric AWS KMS key (p. 726)
• Download and install the AWS CLI (p. 727)
• Configuring IAM and your VPC (p. 727)
• Grant required permissions to your IAM user (p. 735)

Prerequisites for creating an RDS Custom for Oracle instance

Before creating an RDS Custom for Oracle DB instance, make sure that you meet the following prerequisites:

• You have access to My Oracle Support and Oracle Software Delivery Cloud to download the supported list of installation files and patches for Oracle Database 12.1 or 19c Enterprise Edition. For example, you can use the April 2021 RU/RUR for 19c.

  If you use an unknown patch, custom engine version (CEV) creation fails. In this case, contact the RDS Custom support team and ask it to add the missing patch.

  For more information, see Downloading your database installation files and patches from Oracle (p. 748).

• You have access to Amazon S3 so that you can upload your Oracle installation files. You use the installation files when you create your RDS Custom CEV.

  For more information, see Uploading your installation files to Amazon S3 (p. 751) and Creating a CEV (p. 756).

• You supply your own virtual private cloud (VPC) and security group configuration. For more information, see Configuring IAM and your VPC (p. 727).

• The AWS Identity and Access Management (IAM) user that creates a CEV or RDS Custom DB instance has the required permissions for IAM, CloudTrail, and Amazon S3.

  For more information, see Grant required permissions to your IAM user (p. 735).

For each task, the following sections describe the requirements and limitations specific to the task. For example, when you create your RDS Custom DB for Oracle instance, use either the db.m5 or db.r5 instance classes running Oracle Linux 7 Update 6. For general requirements that apply to RDS Custom, see Requirements and limitations for Amazon RDS Custom (p. 722).

Make sure that you have a symmetric AWS KMS key

A symmetric AWS KMS key is required for RDS Custom. When you create an RDS Custom DB instance, you supply the KMS key identifier. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for Oracle (p. 762).

You have the following options:
• If you have an existing symmetric KMS key in your account, you can use it with RDS Custom. No further action is necessary.
• If you don’t already have a symmetric KMS key in your account, create one by following the instructions in Creating keys in the AWS Key Management Service Developer Guide.

You can choose the same symmetric key when you create a CEV and a DB instance, or choose different keys. RDS Custom doesn’t support AWS-managed KMS keys.

The symmetric key you wish to use must provide the IAM role in your IAM instance profile for RDS Custom with access to the kms:Decrypt and kms:GenerateDataKey operations. If you have created a new symmetric key in your account, no changes are required. Otherwise, make sure that your symmetric key’s policy can provide access to these operations.

For more information on configuring IAM for RDS Custom for Oracle, see Configuring IAM and your VPC (p. 727).

Download and install the AWS CLI

AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information on downloading and installing the AWS CLI, see Installing or updating the latest version of the AWS CLI.

If you plan to access RDS Custom only from the AWS Management Console, skip this step.

If you have already downloaded the AWS CLI for Amazon RDS or RDS Custom for SQL Server, skip this step.

Configuring IAM and your VPC

You can configure your IAM role and virtual private cloud (VPC) using either of the following techniques:

• Configuring IAM and your VPC using AWS CloudFormation (p. 727) (recommended)
• Following the procedures in Creating your IAM role and instance profile manually (p. 728) and Configuring your VPC manually (p. 732)

Configuring IAM and your VPC using AWS CloudFormation

To simplify setup, you can use the AWS CloudFormation template files to create CloudFormation stacks. To learn how to create stacks, see Creating a stack on the AWS CloudFormation console in AWS CloudFormation User Guide.

To download the template files
1. Open the context (right-click) menu for the link custom-oracle-iam.json and choose Save Link As.
2. Save the file to your computer.
3. Repeat the previous steps for the link custom-vpc.json.

If you already configured your VPC for RDS Custom for SQL Server, skip this step.

To configure IAM using CloudFormation
2. Start the Create Stack wizard, and choose **Create Stack**.

3. On the **Specify template** page, do the following:
   a. For **Template source**, choose **Upload a template file**.
   b. For **Choose file**, navigate to, then choose **custom-oracle-iam.json**.
   c. Choose **Next**.

4. On the **Specify stack details** page, do the following:
   a. For **Stack name**, enter **custom-oracle-iam**.
   b. Choose **Next**.

5. On the **Configure stack options page**, choose **Next**.

6. On the **Review custom-oracle-iam** page, do the following:
   a. For **Capabilities**, select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box.
   b. Choose **Create stack**.

CloudFormation creates the IAM roles that RDS Custom for Oracle requires.

**To configure your VPC using CloudFormation**

This procedure assumes that you've already used CloudFormation to create your IAM roles.

If you've already configured your VPC for RDS Custom for SQL Server, you can skip this step.

2. On the **Stacks** page, for **Create stack** choose **With new resources (standard)**.
3. On the **Specify template** page, do the following:
   a. For **Template source**, choose **Upload a template file**.
   b. For **Choose file**, go to and choose **custom-vpc.json**.
   c. Choose **Next**.

4. On the **Specify stack details** page, do the following:
   a. For **Stack name**, enter **custom-vpc**.
   b. For **Parameters**, choose the private subnets to use for RDS Custom DB instances.
   c. Choose the private VPC ID to use for RDS Custom DB instances.
   d. Enter the route table associated with the private subnets.
   e. Choose **Next**.

5. On the **Configure stack options page**, choose **Next**.

6. On the **Review custom-vpc** page, choose **Create stack**.

CloudFormation configures your VPC.

**Creating your IAM role and instance profile manually**

To use RDS Custom, you create an IAM instance profile named **AWSRDSCustomInstanceProfileForRdsCustomInstance**. You also create the IAM role **AWSRDSCustomInstanceRoleForRdsCustomInstance** for the instance profile. You then add **AWSRDSCustomInstanceRoleForRdsCustomInstance** to your instance profile.

The following section explains how to perform the task without using CloudFormation.
To create the RDS Custom instance profile and add the necessary role to it

1. Create the IAM role named AWSRDSCustomInstanceRoleForRdsCustomInstance with a trust policy that Amazon EC2 can use to assume this role.
2. Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
3. Create an IAM instance profile for RDS Custom named AWSRDSCustomInstanceProfileForRdsCustomInstance.
4. Add the AWSRDSCustomInstanceRoleForRdsCustomInstance IAM role to the instance profile.

Create the role AWSRDSCustomInstanceRoleForRdsCustomInstance

The following example creates the role AWSRDSCustomInstanceRoleForRdsCustomInstance. Using the trust policy, Amazon EC2 can assume the role.

```
aws iam create-role \
  --role-name AWSRDSCustomInstanceRoleForRdsCustomInstance \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Action": "sts:AssumeRole",
        "Effect": "Allow",
        "Principal": {
          "Service": "ec2.amazonaws.com"
        }
      }
    ]
  }'
```

Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance

When you embed an inline policy in an IAM role, the inline policy is used as part of the role's access (permissions) policy. You create the AWSRDSCustomIamRolePolicy policy that permits Amazon EC2 to send and receive messages and perform various actions.

The following example creates the access policy named AWSRDSCustomIamRolePolicy, and adds it to the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance. This example assumes that you have set the $REGION and $ACCOUNT_ID variables in the AWS CLI. This example also requires the Amazon Resource Name (ARN) of the AWS KMS key that you want to use for your RDS Custom DB instances.

To specify more than one KMS key, add it to the Resources section of statement ID (Sid) 11.

```
aws iam put-role-policy \
  --role-name AWSRDSCustomInstanceRoleForRdsCustomInstance \
  --policy-name AWSRDSCustomIamRolePolicy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "1",
        "Effect": "Allow",
        "Action": [
          "ssm:DescribeAssociation",
          "ssm:GetDeployablePatchSnapshotForInstance",
          "ssm:GetDocument",
          "ssm:DescribeDocument",
          "ssm:GetManifest",
```
"ssm:GetParameter",
"ssm:GetParameters",
"ssm:ListAssociations",
"ssm:ListInstanceAssociations",
"ssm:PutInventory",
"ssm:PutComplianceItems",
"ssm:PutConfigurePackageResult",
"ssm:UpdateAssociationStatus",
"ssm:UpdateInstanceAssociationStatus",
"ssm:UpdateInstanceInformation",
"ssm:GetConnectionStatus",
"ssm:DescribeInstanceInformation",
"ssmmessages:CreateControlChannel",
"ssmmessages:CreateDataChannel",
"ssmmessages:OpenControlChannel",
"ssmmessages:OpenDataChannel",
]
"Resource": [ 
"
],
"Effect": "Allow",
"Action": [ 
"ec2messages:AcknowledgeMessage",
"ec2messages:DeleteMessage",
"ec2messages:FailMessage",
"ec2messages:GetEndpoint",
"ec2messages:GetMessages",
"ec2messages:GetMessages",
"ec2messages:SendReply"
],
"Resource": [

  ],
  
  "Sid": "9",
  "Effect": "Allow",
  "Action": [  "ec2:CreateSnapshots",
  "Resource": [  "arn:aws:ec2:*:*:instance/**",
  "arn:aws:ec2:*:*:volume/**"
  ],
  "Condition": {  "StringEquals": {  "ec2:ResourceTag/AWSRDSCustom": "custom-oracle"
  }
  },
  
  "Sid": "10",
  "Effect": "Allow",
  "Action": [  "ec2:CreateSnapshots",
  "Resource": [  "arn:aws:ec2:*:*:snapshot/**"
  ]
}
Create your RDS Custom instance profile

Create your IAM instance profile as follows, naming it 
AWSRDSCustomInstanceProfileForRdsCustomInstance.

```bash
aws iam create-instance-profile \
   --instance-profile-name AWSRDSCustomInstanceProfileForRdsCustomInstance
```

Add AWSRDSCustomInstanceRoleForRdsCustomInstance to your RDS Custom instance profile

Add the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance to the profile 
AWSRDSCustomInstanceProfileForRdsCustomInstance.

```bash
aws iam add-role-to-instance-profile \
   --instance-profile-name AWSRDSCustomInstanceProfileForRdsCustomInstance \
   --role-name AWSRDSCustomInstanceRoleForRdsCustomInstance
```

Configuring your VPC manually

Your RDS Custom DB instance is in a VPC, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

RDS Custom sends communication from your DB instance to other AWS services. To make sure that RDS Custom can communicate, it validates network connectivity to these services.

If you have already configured a VPC for RDS Custom for SQL Server, you can reuse that VPC and skip this process.
Configure your instance security group

A security group acts as a virtual firewall for a VPC instance, controlling both inbound and outbound traffic. An RDS Custom DB instance has a default security group that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services.

To configure your security group for RDS Custom

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. Allow RDS Custom to use the default security group, or create your own security group.
   
   For detailed instructions, see Provide access to your DB instance in your VPC by creating a security group (p. 96).
3. If you have a private VPC and use VPC endpoints, make sure that your security group permits both inbound and outbound connections on port 443.
   
   RDS Custom needs port 443 to communicate with dependent AWS services. If incoming connections aren't allowed, the RDS Custom instance can't connect to the AWS Systems Manager and Amazon EC2 endpoints. For more information, see Create a Virtual Private Cloud endpoint.

For more information about security groups, see Security groups for your VPC in Amazon VPC Developer Guide.

Configure endpoints for dependent AWS services

Make sure that your VPC allows outbound traffic to the following AWS services:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that makes it possible for your VPC to communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

To configure endpoints for AWS services with which RDS Custom works

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose Endpoints. In the main pane, choose Create Endpoint.
4. For **Service category**, choose **AWS services**.
5. For **Service Name**, choose the endpoint shown in the table.
6. For **VPC**, choose your VPC.
7. For **Subnets**, choose a subnet from each Availability Zone to include.

   The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.
8. For **Security group**, choose or create a security group.

   You can use **security groups** to control access to your endpoint, much as you use a firewall.
9. Choose **Create endpoint**.

The following table explains how to find the list of endpoints that your VPC needs to use for outbound communications.

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint format</th>
<th>Notes and links</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Systems Manager</td>
<td>Use the following endpoint formats:</td>
<td>For the list of endpoints in each Region, see <a href="https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-config-iam.html">AWS Systems Manager endpoints and quotas</a> in the Amazon Web Services General Reference.</td>
</tr>
<tr>
<td></td>
<td>• ssm.REGION.amazonaws.com</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• ssmmessages.REGION.amazonaws.com</td>
<td></td>
</tr>
<tr>
<td>AWS Secrets Manager</td>
<td>Use the endpoint format</td>
<td>For the list of endpoints in each Region, see <a href="https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-config-iam.html">AWS Secrets Manager endpoints and quotas</a> in the Amazon Web Services General Reference.</td>
</tr>
<tr>
<td></td>
<td>secretsmanager.REGION.amazonaws.com</td>
<td></td>
</tr>
<tr>
<td>Amazon CloudWatch</td>
<td>Use the following endpoint formats:</td>
<td>For the list of endpoints in every Region, see:</td>
</tr>
<tr>
<td></td>
<td>• For CloudWatch metrics, use</td>

<td></td>
</tr>
<tr>
<td></td>
<td>logs.REGION.amazonaws.com</td>
<td></td>
</tr>
<tr>
<td>Amazon EC2</td>
<td>Use the following endpoint formats:</td>
<td>For the list of endpoints in each Region, see <a href="https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-config-iam.html">Amazon Elastic Compute Cloud endpoints and quotas</a> in the Amazon Web Services General Reference.</td>
</tr>
<tr>
<td></td>
<td>• ec2.REGION.amazonaws.com</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• ec2messages.REGION.amazonaws.com</td>
<td></td>
</tr>
<tr>
<td>Amazon S3</td>
<td>Use the endpoint format</td>
<td>For the list of endpoints in each Region, see <a href="https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-config-iam.html">Amazon Simple Storage Service endpoints and quotas</a> in the Amazon Web Services General Reference.</td>
</tr>
<tr>
<td></td>
<td>s3.REGION.amazonaws.com</td>
<td>To learn more about gateway endpoints for Amazon S3, see <a href="https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-config-iam.html">Endpoints for Amazon S3</a> in the Amazon VPC Developer Guide.</td>
</tr>
</tbody>
</table>
Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from http://169.254.169.254, the IMDSv2 link.

For more information on IMDSv2, see Use IMDSv2 in the Amazon EC2 User Guide for Linux Instances.

RDS Custom for Oracle automation uses IMDSv2 by default, by setting HttpTokens=enabled on the underlying Amazon EC2 instance. However, you can use IMDSv1 if you want. For more information, see Configure the instance metadata options in the Amazon EC2 User Guide for Linux Instances.

Grant required permissions to your IAM user

Make sure that the IAM principal that creates the CEV or DB instance has either of the following policies:

- The AdministratorAccess policy
- The AmazonRDSFullAccess policy with required permissions for Amazon S3 and AWS KMS (required for both CEV and DB creation), CEV creation, and DB instance creation.

Topics
- Permissions required for Amazon S3 and AWS KMS (p. 735)
- Permissions required for creating a CEV (p. 736)
- Permissions required for creating a DB instance from a CEV (p. 736)

Permissions required for Amazon S3 and AWS KMS

To create CEVs or RDS Custom for Oracle DB instances, the IAM principal needs to access Amazon S3 and AWS KMS. The following sample JSON policy grants the required permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ]
        }
    ]
}
```
Grant required permissions to your IAM user

"Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
},
{
   "Sid": "CreateKmsGrant",
   "Effect": "Allow",
   "Action": "kms:CreateGrant",
   "Resource": "*"
}
}

For more information on the kms:CreateGrant permission, see AWS KMS key management (p. 1754).

Permissions required for creating a CEV

To create a CEV, the IAM principal needs the following additional permissions:

s3:GetObjectAcl
s3:GetObject
s3:GetObjectTagging
s3:ListBucket
mediaimport:CreateDatabaseBinarySnapshot

The following sample JSON policy grants the additional permissions to bucket my-custom-installation-files and its contents.

{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AccessToS3MediaBucket",
         "Effect": "Allow",
         "Action": [
            "s3:GetObjectAcl",
            "s3:GetObject",
            "s3:GetObjectTagging",
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::my-custom-installation-files",
            "arn:aws:s3:::my-custom-installation-files/*"
         ]
      },
      {
         "Sid": "PermissionForByom",
         "Effect": "Allow",
         "Action": [
            "mediaimport:CreateDatabaseBinarySnapshot"
         ],
         "Resource": "*"
      }
   ]
}

You can grant similar permissions for Amazon S3 to caller accounts using an S3 bucket policy.

Permissions required for creating a DB instance from a CEV

To create a DB instance from an existing CEV, the IAM principal needs the following additional permissions:
Grant required permissions to your IAM user

iam:SimulatePrincipalPolicy
cloudtrail:CreateTrail
cloudtrail:StartLogging

The following sample JSON policy grants the required permissions.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "ValidateIamRole",
         "Effect": "Allow",
         "Action": "iam:SimulatePrincipalPolicy",
         "Resource": "*"
      },
      {
         "Sid": "CreateCloudTrail",
         "Effect": "Allow",
         "Action": [
            "cloudtrail:CreateTrail",
            "cloudtrail:StartLogging"
         ],
         "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
      }
   ]
}
```
Setting up your environment for Amazon RDS Custom for SQL Server

Before you create and manage a DB instance for Amazon RDS Custom for SQL Server DB instance, make sure to perform the following tasks.

Topics

- Prerequisites for setting up RDS Custom for SQL Server (p. 738)
- Make sure that you have a symmetric AWS KMS key (p. 738)
- Download and install the AWS CLI (p. 739)
- Configuring IAM and your VPC (p. 739)
- Grant required permissions to your IAM user (p. 747)

Prerequisites for setting up RDS Custom for SQL Server

Before creating an RDS Custom for SQL Server DB instance, make sure that you have your own virtual private cloud (VPC) and security group configuration. This network configuration must meet the requirements of RDS Custom.

For each task, RDS Custom topics describe the requirements and limitations specific to that task. For example, when you create your RDS Custom DB instance, use one of the SQL Server instances listed in DB instance class support for RDS Custom (p. 723).

For general requirements that apply to RDS Custom for SQL Server, see General requirements for RDS Custom for SQL Server (p. 723).

Make sure that you have a symmetric AWS KMS key

A symmetric AWS KMS key is required for RDS Custom. When you create an RDS Custom for SQL Server DB instance, you must supply the AWS KMS key identifier. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server (p. 770).

You have the following options:

- If you have an existing KMS key in your account, you can use it with RDS Custom. No further action is necessary.
- If you have already created a symmetric KMS key for RDS Custom for Oracle, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing symmetric KMS key in your account, create a KMS key by following the instructions in Creating keys in the AWS Key Management Service Developer Guide.

RDS Custom doesn't support AWS-managed KMS keys.

The symmetric key to use must provide the AWS Identity and Access Management (IAM) role in your IAM instance profile with access to the kms:Decrypt and kms:GenerateDataKey operations. If you have a new symmetric key in your account, no changes are required. Otherwise, make sure that your symmetric key's policy can provide access to these operations.

For more information on configuring IAM for RDS Custom for SQL Server, see Configuring IAM and your VPC (p. 739).
Download and install the AWS CLI

AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information on downloading and installing the AWS CLI, see [Installing or updating the latest version of the AWS CLI](#).

If you plan to access RDS Custom only from the AWS Management Console, skip this step.

If you have already downloaded the AWS CLI for Amazon RDS or RDS Custom for Oracle, skip this step.

Configuring IAM and your VPC

You can configure your IAM role and VPC by using the procedures in the following:

- Configuring IAM and your VPC using AWS CloudFormation (p. 739) (recommended)
- Following the procedures in [Creating your IAM role and instance profile manually (p. 740)](#)
  and [Configuring your VPC manually (p. 744)](#)

Configuring IAM and your VPC using AWS CloudFormation

To simplify setup, you can use the AWS CloudFormation template files to create CloudFormation stacks. To learn how to create stacks, see [Creating a stack on the AWS CloudFormation console](#) in AWS CloudFormation User Guide.

To download the template files

1. Open the context (right-click) menu for the link `custom-sqlserver-iam.json` and choose Save Link As.
2. Save the file to your computer.
3. Repeat the previous steps for the link `custom-vpc.json`.
   
   If you already configured your VPC for RDS Custom for Oracle, you can skip this step.

To configure IAM using CloudFormation

2. Start the Create Stack wizard, and choose Create Stack.
3. On the Specify template page, do the following:
   a. For Template source, choose Upload a template file.
   b. For Choose file, navigate to, then choose `custom-sqlserver-iam.json`.
   c. Choose Next.
4. On the Specify stack details page, do the following:
   a. For Stack name, enter `custom-sqlserver-iam`.
   b. Choose Next.
5. On the Configure stack options page, choose Next.
6. On the Review `custom-sqlserver-iam` page, do the following:
   a. For Capabilities, select the I acknowledge that AWS CloudFormation might create IAM resources with custom names check box.
b. Choose **Create stack**.

CloudFormation creates the IAM roles that RDS Custom for SQL Server requires.

**To configure your VPC using CloudFormation**

This procedure assumes that you already used CloudFormation to create your IAM roles.

If you already configured your VPC for RDS Custom for Oracle, you can skip this step.

2. On the **Stacks** page, for **Create stack** choose **With new resources (standard)**.
3. On the **Specify template** page, do the following:
   a. For **Template source**, choose **Upload a template file**.
   b. For **Choose file**, go to and choose `custom-vpc.json`.
   c. Choose **Next**.
4. On the **Specify stack details** page, do the following:
   a. For **Stack name**, enter `custom-vpc`.
   b. For **Parameters**, choose the private subnets to use for RDS Custom DB instances.
   c. Choose the private VPC ID to use for RDS Custom DB instances.
   d. Enter the route table associated with the private subnets.
   e. Choose **Next**.
5. On the **Configure stack options page**, choose **Next**.
6. On the **Review custom-vpc** page, choose **Create stack**.

CloudFormation configures your VPC.

**Creating your IAM role and instance profile manually**

To use RDS Custom for SQL Server, create an IAM instance profile and IAM role described in the following process.

**To create the RDS Custom for SQL Server IAM instance profile and IAM roles**

1. Create the IAM role named `AWSRDSCustomSQLServerInstanceRole` with a trust policy that lets Amazon EC2 assume this role.
2. Add an access policy to `AWSRDSCustomSQLServerInstanceRole`.
3. Create an IAM instance profile for RDS Custom for SQL Server named `AWSRDSCustomSQLServerInstanceProfile`.
4. Add `AWSRDSCustomSQLServerInstanceRole` to the instance profile.

**Create the AWSRDSCustomSQLServerInstanceRole IAM role**

The following example creates the `AWSRDSCustomSQLServerInstanceRole` role. The trust policy lets Amazon EC2 assume the role.

```
aws iam create-role
  --role-name AWSRDSCustomSQLServerInstanceRole
```
Add an access policy to AWSRDSCustomSQLServerInstanceRole

When you embed an inline policy in a role, the inline policy is used as part of the role's access (permissions) policy. You create the AWSRDSCustomSQLServerIamRolePolicy policy, which permits Amazon EC2 to get and receive messages and perform various actions.

The following example creates the access policy named AWSRDSCustomSQLServerIamRolePolicy, and adds it to the AWSRDSCustomSQLServerInstanceRole role. This example assumes that the '$REGION', '$ACCOUNT_ID', and '$CUSTOMER_KMS_KEY_ID' variables have been set.

```
aws iam put-role-policy
  --role-name AWSRDSCustomSQLServerInstanceRole
  --policy-name AWSRDSCustomSQLServerIamRolePolicy
  --policy-document '{

Create your RDS Custom for SQL Server instance profile

Create your instance profile as follows, naming it AWSRDSCustomSQLServerInstanceProfile.

```
aws iam create-instance-profile \
   --instance-profile-name AWSRDSCustomSQLServerInstanceProfile
```

Add AWSRDSCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile

Add the AWSRDSCustomInstanceRoleForRdsCustomInstance role to the AWSRDSCustomSQLServerInstanceProfile profile.

```
aws iam add-role-to-instance-profile \
   --instance-profile-name AWSRDSCustomSQLServerInstanceProfile \
   --role-name AWSRDSCustomSQLServerInstanceRole
```

Configuring your VPC manually

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just as an Amazon EC2 instance or Amazon RDS DB instance is. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.
RDS Custom sends communication from your DB instance to other AWS services. To make sure that RDS Custom can communicate, it validates network connectivity to these services.

If you have already configured a VPC for RDS Custom for Oracle, you can reuse that VPC and skip this process.

**Topics**
- Configure your VPC security group (p. 745)
- Configure endpoints for dependent AWS services (p. 745)
- Configure the instance metadata service (p. 747)

**Configure your VPC security group**

A *security group* acts as a virtual firewall for a VPC, controlling both inbound and outbound traffic. An RDS Custom DB instance has a default security group that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services.

**To configure your security group for RDS Custom**

2. Allow RDS Custom to use the default security group, or create your own security group. For detailed instructions, see *Provide access to your DB instance in your VPC by creating a security group* (p. 96).
3. If you have a private VPC and use VPC endpoints, make sure that your security group permits outbound connections on port 443. RDS Custom needs this port to communicate with dependent AWS services.

For more information about security groups, see *Security groups for your VPC* in *Amazon VPC Developer Guide*.

**Configure endpoints for dependent AWS services**

Make sure that your VPC allows outbound traffic to the following AWS services:

- Amazon CloudWatch
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- Amazon EC2
- Amazon EventBridge
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that lets your VPC communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

**To configure endpoints for AWS services with which RDS Custom works**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose **Endpoints**. In the main pane, choose **Create Endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Service Name**, choose the endpoint shown in the table.
6. For **VPC**, choose your VPC.
7. For **Subnets**, choose a subnet from each Availability Zone to include.

The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.
8. For **Security group**, choose or create a security group.

You can use security groups to control access to your endpoint, much as you use a firewall. For more information about security groups, see Security groups for your VPC in the Amazon VPC User Guide.
9. Choose **Create endpoint**.

The following table explains how to find the list of endpoints that your VPC needs for outbound communications.

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint format</th>
<th>Notes and links</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Systems Manager</td>
<td>Use the following endpoint formats:</td>
<td>For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the Amazon Web Services General Reference.</td>

<td></td>
</tr>
</tbody>
</table>
### Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254` , the IMDSv2 link.

For more information, see Use IMDSv2 in the *Amazon EC2 User Guide for Linux Instances*.

### Grant required permissions to your IAM user

The IAM principal that creates the RDS Custom for SQL Server DB instance must have either of the following policies:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with the following additional permissions:

```
iam:SimulatePrincipalPolicy
cloudtrail:CreateTrail
cloudtrail:StartLogging
s3:CreateBucket
s3:PutBucketPolicy
kms:CreateGrant
```

For more information on the `kms:CreateGrant` permission, see *AWS KMS key management* (p. 1754).

Working with custom engine versions for Amazon RDS Custom for Oracle

A custom engine version (CEV) for Amazon RDS Custom for Oracle is a binary volume snapshot of a database engine and specific Amazon Machine Image (AMI). You store your database installation files in Amazon S3. RDS Custom uses the installation files to create your CEV for you.

**Topics**
- Preparing to create a CEV (p. 748)
- Creating a CEV (p. 756)
- Modifying CEV status (p. 759)
- Deleting a CEV (p. 760)

**Preparing to create a CEV**

To create a CEV, access the installation files and patches for Oracle Database 12.1 or 19c Enterprise Edition that are stored in your Amazon S3 bucket. For example, you can use the April 2021 RU/RUR for 19c, or any valid combination of installation files and patches.

**Topics**
- Downloading your database installation files and patches from Oracle (p. 748)
- Uploading your installation files to Amazon S3 (p. 751)
- Creating the CEV manifest (p. 752)
- Validating the CEV manifest (p. 756)
- Adding necessary IAM permissions (p. 756)

**Downloading your database installation files and patches from Oracle**

The Oracle Database installation files and patches are hosted on Oracle Software Delivery Cloud.

To download the database installation files for 12.1

1. Go to [https://edelivery.oracle.com/](https://edelivery.oracle.com/) and sign in.
2. In the box, enter Oracle Database Enterprise Edition and choose Search.
4. Choose Continue.
5. Clear the Download Queue check box.
6. Choose Oracle Database 12.1.0.2.0.
7. Choose Linux x86-64 in Platform/Languages.
8. Choose Continue, and then sign the waiver.
9. Choose V46095-01_1of2.zip and V46095-01_2of2.zip, choose Download, and then save the files.

**Note**

The SHA-256 hash for V46095-01_1of2.zip is 31FDC2AF41687B4E547A3A18F796424D8C1AF36406D2160F65B0AF6A9CD47355.
The SHA-256 hash for V46095-01_2of2.zip is 03DA14F5E875304B28F0F3B02AF0EC33227885B99C9865DF70749D1E220ACCD.

10. Click the links in the following table to download the Oracle patches. All URLs are for updates.oracle.com or support.oracle.com.

Uploading your installation files to Amazon S3

Upload your Oracle installation and patch files to Amazon S3 using the AWS CLI. The S3 bucket that contains your installation files must be in the same AWS Region as your CEV.

Choose either of the following options:

- Use `aws s3 cp` to upload a single .zip file.
  - Upload each installation .zip file separately. Don't combine the .zip files into a single .zip file.
- Use `aws s3 sync` to upload a directory.

List your installation files using either the AWS Management Console or the AWS CLI.

Examples in this section use the following placeholders:

- `install-or-patch-file.zip` – Oracle installation media file. For example, `p32126828_190000_Linux-x86-64.zip` is a patch.
- `my-custom-installation-files` – Your Amazon S3 bucket designated for your uploaded installation files.
- `123456789012/cev1` – An optional prefix in your Amazon S3 bucket.
- `source-bucket` – An Amazon S3 bucket where you can optionally stage files.

The following example uploads `install-or-patch-file.zip` to the `123456789012/cev1` folder in the RDS Custom Amazon S3 bucket. Run a separate `aws s3` command for each .zip that you want to upload.

For Linux, macOS, or Unix:

```
aws s3 cp install-or-patch-file.zip \
    s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 cp install-or-patch-file.zip ^
```
Preparing to create a CEV

s3://my-custom-installation-files/123456789012/cev1/

Verify that your S3 bucket is in the AWS Region where you plan to run the `create-custom-db-engine-version` command.

```
aws s3 get-bucket-location --bucket my-custom-installation-files
```

List the files in your RDS Custom Amazon S3 bucket as follows.

```
aws s3 ls \
  s3://my-custom-installation-files/123456789012/cev1/
```

The following example uploads the files in your local `cev1` folder to the `123456789012/cev1` folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync cev1 \ 
  s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 sync cev1 ^ \
  s3://my-custom-installation-files/123456789012/cev1/
```

The following example uploads all files in `source-bucket` to the `123456789012/cev1` folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync s3://source-bucket/ \ 
  s3://my-custom-installation-files/123456789012/cev1/
```

For Windows:

```
aws s3 sync s3://source-bucket/ ^ \
  s3://my-custom-installation-files/123456789012/cev1/
```

Creating the CEV manifest

A CEV manifest is a JSON document that describes installation .zip files stored in Amazon S3.

Either save the CEV manifest as a file, or edit the template when creating the CEV using the console.

The following CEV manifest lists the files that you uploaded to Amazon S3. RDS Custom applies the patches in the order in which they're listed.

In the following example for the July 2021 PSU for Oracle Database 12c Release 1 (12.1), RDS Custom applies p32768233, then p32876425, then p16799735, and so on.

```json
{
    "mediaImportTemplateVersion":"2020-08-14",
    "databaseInstallationFileNames":[]
}
```
In the following example for Oracle Database 19c, RDS Custom applies p32126828, then p29213893, then p29782284, and so on.

```json
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [ "V982063-01.zip"
    ],
    "opatchFileNames": [ "p68808800_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [ "p32126828_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [ "p29213893_1910000DBRU_Generic.zip",
    "p29782284_1910000DBRU_Generic.zip",
    "p28730253_1910000DBRU_Linux-x86-64.zip",
    "p21171382_1910000DBRU_Linux-x86-64.zip",
    "p12091201_1910000DBRU_Linux-x86-64.zip",
    "p33013352_1910000DBRU_Linux-x86-64.zip",
    "p25031502_1910000DBRU_Linux-x86-64.zip",
    "p33113353_1910000DBRU_Generic.zip",
    "p19504946_1910000DBRU_Generic.zip"
    ]
}``
The following table describes the JSON fields in the manifest.

<table>
<thead>
<tr>
<th>JSON field</th>
<th>Description</th>
<th>Valid values for 12.1</th>
<th>Valid values for 19c</th>
</tr>
</thead>
<tbody>
<tr>
<td>MediaImportTemplateVersion</td>
<td>Version of the CEV manifest. The date is in the format YYYY-MM-DD.</td>
<td>2020-08-14</td>
<td>2020-08-14</td>
</tr>
<tr>
<td>databaseInstallationFileNames</td>

</tbody>
</table>
If you include a JSON field, it can't be empty. For example, the following manifest isn't valid because `otherPatchFileNames` is empty.

```
{
  "mediaImportTemplateVersion": "2020-08-14",
  "databaseInstallationFileNames": [ "V982063-01.zip"
  ],
  "opatchFileNames": [ "p6880880_190000_Linux-x86-64.zip"
  ],
  "psuRuPatchFileNames": [ "p32126828_190000_Linux-x86-64.zip"
  ]
}
```
Validating the CEV manifest

Optionally, verify that manifest is a valid JSON file by running the `json.tool` Python script.

For example, if you change into the directory containing a CEV manifest named `manifest.json`, run the following command.

```
python -m json.tool < manifest.json
```

Adding necessary IAM permissions

Make sure that the IAM principal that creates the CEV has the necessary policies described in Grant required permissions to your IAM user (p. 735).

Creating a CEV

You can create a CEV using the AWS Management Console or the AWS CLI. Typically, creating a CEV takes about two hours.

You can then use the CEV to create an RDS Custom instance. Make sure that the Amazon S3 bucket containing your installation files is in the same AWS Region as your CEV. Otherwise, the process to create a CEV fails.

For more information, see Creating an RDS Custom for Oracle DB instance (p. 762).

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
   - The **Custom engine versions** page shows all CEVs that currently exist. If you haven’t created any CEVs, the page is empty.
3. Choose **Create custom engine version**.
4. For **Engine type**, choose **Oracle**.
6. For **Major version**, choose the major engine version.
7. In **Version details**, enter a valid name in **Custom engine version name**.
   - The name format is `major-engine-version.customized_string`. You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might enter the name `19.my_cev1`.
   - Optionally, enter a description for your CEV.
8. For **S3 location of manifest files**, enter the location of the Amazon S3 bucket that you specified in Uploading your installation files to Amazon S3 (p. 751). For example, enter `s3://my-custom-installation-files/806242271698/cev1/`. 
9. In the RDS Custom encryption section, select Enter a key ARN to list the available AWS KMS keys. Then select your KMS key from the list. An AWS KMS key is required for RDS Custom. For more information, see Make sure that you have a symmetric AWS KMS key (p. 726).

10. Choose Create custom engine version.

If the CEV manifest has an invalid form, the console displays Error validating the CEV manifest. Fix the problems, and try again.

The Custom engine versions page appears. Your CEV is shown with the status Creating. The process to create the CEV takes approximately two hours.

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command. The following options are required:

- --engine custom-oracle-ee
- --engine-version major-engine-version.customized_string
- --kms-key-id
- --manifest manifest_string

Newline characters aren't permitted in manifest_string. Make sure to escape double quotes ("), in the JSON code by prefixing them with a backslash (\).

The following example shows the manifest_string for 19c from Creating the CEV manifest (p. 752). If you copy this string, remove all newline characters before pasting it into your command.

```
{"mediaImportTemplateVersion": "2020-08-14",
"databaseInstallationFileNames": ["V982063-01.zip"],
"opatchFileNames": ["p6880880_190000_Linux-x86-64.zip"],
"psuRuPatchFileNames": ["p32126828_190000_Linux-x86-64.zip"],
"otherPatchFileNames": ["p29213893_1910000DBRU_Generic.zip","p29782284_1910000DBRU_Generic.zip","p28730253_190000_Linux-x86-64.zip","p29374604_1910000DBRU_Linux-x86-64.zip","p28852325_190000_Linux-x86-64.zip","p31335037_190000_Linux-x86-64.zip","p31335142_190000_Generic.zip"]
```

- --database-installation-files-s3-bucket-name s3-bucket-name, where s3-bucket-name is the bucket name that you specified in Uploading your installation files to Amazon S3 (p. 751). The AWS Region in which you run create-custom-db-engine-version must be in the same AWS Region as the bucket.

You can also specify the following options:

- --description my-cev-description
- database-installation-files-s3-prefix prefix, where prefix is the folder name that you specified in Uploading your installation files to Amazon S3 (p. 751).

The following example creates a CEV named 19.my_cev1. Make sure that the name of your CEV starts with the major engine version number.

Example

For Linux, macOS, or Unix:
aws rds create-custom-db-engine-version \\  \\--engine custom-oracle-ee \\  \\--engine-version 19.my_cev1 \\  \\--database-installation-files-s3-bucket-name my-custom-installation-files \\  \\--database-installation-files-s3-prefix 123456789012/cev1 \\  \\--kms-key-id my-kms-key \\  \\--description "some text" \\  \\ --manifest manifest_string

For Windows:

aws rds create-custom-db-engine-version ^ \\ --engine custom-oracle-ee ^ \\ --engine-version 19.my_cev1 ^ \\ --database-installation-files-s3-bucket-name s3://my-custom-installation-files ^ \\ --database-installation-files-s3-prefix 123456789012/cev1 ^ \\ --kms-key-id my-kms-key ^ \\ --description "some text" ^ \\ --manifest manifest_string

Example

Get details about your CEV by using the describe-db-engine-versions command.

aws rds describe-db-engine-versions \\ --engine custom-oracle-ee \\ --include-all

The following partial output shows the engine, parameter groups, and other information.

"DBEngineVersions": [ 
  { 
    "Engine": "custom-oracle-ee", 
    "Status": "available", 
    "DBParameterGroupFamily": "custom-oracle-ee-19", 
    "DBEngineVersionArn": "arn:aws:rds:us-west-2:<my-account-id>:cev:custom-oracle-ee/19.my_cev1/0a123b45-6c78-901d-23e4-5678f901fg23", 
    "MajorEngineVersion": "19", 
    "SupportsReadReplica": false, 
    "SupportsLogExportsToCloudWatchLogs": false, 
    "EngineVersion": "19.my_cev1", 
    "DatabaseInstallationFilesS3BucketName": "my-custom-installation-files", 
    "DBEngineDescription": "Oracle Database server EE for RDS Custom", 
    "SupportedFeatureNames": [], 
    "KMSKeyId": "arn:aws:kms:us-east-2:<your-account-id>:key/<my-kms-key-id>", 
    "SupportsGlobalDatabases": false, 
    "SupportsParallelQuery": false, 
    "DatabaseInstallationFilesS3Prefix": "123456789012/cev1", 
    "DBEngineVersionDescription": "some text", 
    "ValidUpgradeTarget": [], 
    "CreateTime": "2021-06-23T20:00:34.782Z" 
  }
]

Failure to create a CEV

If the process to create a CEV fails, RDS Custom issues RDS-EVENT-0196 with the message Creation failed for custom engine version major-engine-version.cev_name, and includes details about the failure. For example, the event prints missing files.
You can't modify a failed CEV. You can only delete it, then try again to create a CEV after fixing the causes of the failure. For information on troubleshooting the reasons for CEV creation failure, see Troubleshooting custom engine version creation for RDS Custom for Oracle (p. 809).

Modifying CEV status

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- **available** – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- **inactive** – You can't create or upgrade an RDS Custom instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV from any supported status to any other supported status. You might change status to prevent the accidental use of a CEV or make a discontinued CEV eligible for use again. For example, you might change the status of your CEV from available to inactive, and from inactive back to available.

**Console**

**To modify a CEV**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.
3. Choose a CEV whose description or status you want to modify.
4. For Actions, choose Modify.
5. Make any of the following changes:
   - For CEV status settings, choose a new availability status.
   - For Version description, enter a new description.
6. Choose Modify CEV.

   If the CEV is in use, the console displays You can't modify the CEV status. Fix the problems, and try again.

The Custom engine versions page appears.

**AWS CLI**

To modify a CEV by using the AWS CLI, run the modify-custom-db-engine-version command. You can find CEVs to modify by running the describe-db-engine-versions command.

The following options are required:

- `--engine custom-oracle-ee`
- `--engine-version cev`, where `cev` is the name of the custom engine version that you want to modify
- `--status status`, where `status` is the availability status that you want to assign to the CEV

The following example changes a CEV named `19.my_cev1` from its current status to inactive.
Example

For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \\
--engine custom-oracle-ee \\
--engine-version 19.my_cev1 \\
--status inactive
```

For Windows:

```
aws rds modify-custom-db-engine-version ^
--engine custom-oracle-ee ^
--engine-version 19.my_cev1 ^
--status inactive
```

Deleting a CEV

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, deletion takes a few minutes.

To delete a CEV, it can't be in use by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

Console

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Custom engine versions.
3. Choose a CEV whose description or status you want to delete.
4. For Actions, choose Delete.
   - The Delete cev_name? dialog box appears.
5. Enter delete me, and then choose Delete.
   - In the Custom engine versions page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the delete-custom-db-engine-version command.

The following options are required:

- --engine custom-oracle-ee
- --engine-version cev, where cev is the name of the custom engine version to be deleted

The following example deletes a CEV named 19.my_cev1.
Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
  --engine custom-oracle-ee \
  --engine-version 19.my_cev1
```

For Windows:

```
aws rds delete-custom-db-engine-version ^
  --engine custom-oracle-ee ^
  --engine-version 19.my_cev1
```
Creating and connecting to a DB instance for Amazon RDS Custom for Oracle

You can create an RDS Custom DB instance, and then connect to it using Secure Shell (SSH) or AWS Systems Manager.

**Important**
Before you can create or connect to an RDS Custom DB instance, make sure to complete the tasks in Setting up your environment for Amazon RDS Custom for Oracle (p. 726).

You can tag RDS Custom DB instances when you create them, but don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. For more information, see Tagging RDS Custom resources (p. 786).

The first time that you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

**Topics**
- Creating an RDS Custom for Oracle DB instance (p. 762)
- RDS Custom service-linked role (p. 765)
- Connecting to your RDS Custom DB instance using SSH (p. 766)
- Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 768)

**Creating an RDS Custom for Oracle DB instance**

Create an Amazon RDS Custom for Oracle DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance.

For more information, see Creating an Amazon RDS DB instance (p. 175).

**Console**

**To create an RDS Custom for Oracle DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose Create database.
4. In Choose a database creation method, select Standard create.
5. In Engine options, choose Oracle for the DB engine type. Oracle Database is the only supported DB engine.
6. For Database management type, choose Amazon RDS Custom.
8. For Database version, choose the RDS Custom custom engine version (CEV) that you previously created. The CEV has the following format: major-engine-version.customized_string. An example identifier is 19.my_cev1.
9. In Templates, choose Production.
10. In Settings, enter a unique name for the DB instance identifier.
11. Enter your master password by doing the following:
    a. In the Settings section, open Credential Settings.
    b. Clear the Auto generate a password check box.
c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new RDS Custom DB instance uses an automatically generated password for the master user.

12. In **DB instance size**, choose a **DB instance class**.

   For supported classes, see [DB instance class support for RDS Custom](p. 723).

13. Choose **Storage** settings.

14. For **RDS Custom security**, do the following:

   a. For **IAM instance profile**, choose the instance profile for your RDS Custom for Oracle DB instance.

      The IAM instance profile must begin with `AWSRDSCustom`, for example `AWSRDSCustomInstanceProfileForRdsCustomInstance`.

   b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

      An AWS KMS key is required for RDS Custom. For more information, see [Make sure that you have a symmetric AWS KMS key](p. 726).

15. (Optional) In **Additional configuration**, enter an **Initial database name** if you want.

   The default database name is **ORCL**.

16. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see [Settings for DB instances](p. 178). The following settings don't appear in the console and aren't supported:

   - Processor features
   - Storage autoscaling
   - Availability & durability
   - **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
   - **Database options** group in **Additional configuration**
   - Performance Insights
   - Log exports
   - Enable auto minor version upgrade
   - Deletion protection

   **Backup retention period** is supported, but you can't choose 0 days.

17. Choose **Create database**.

    The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the RDS Custom DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see [Managing an Amazon RDS Custom DB instance](p. 778).
18. Choose **Databases** to view the list of RDS Custom DB instances.
19. Choose the RDS Custom DB instance that you just created.

On the RDS console, the details for the new RDS Custom DB instance appear:

- The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
- **Role** has the value **Instance (RDS Custom)**.
- **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

**AWS CLI**

You create an RDS Custom DB instance by using the `create-db-instance` AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see DB instance class support for RDS Custom (p. 723))
- `--engine custom-oracle-ee`
- `--engine-version cev` (where `cev` is the name of the custom engine version that you specified in Creating a CEV (p. 756))
- `--kms-key-id`
- `--no-auto-minor-version-upgrade`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom DB instance named `my-custom-instance`. The backup retention period is three days.

**Example**

For Linux, macOS, or Unix:

```bash
aws create-db-instance \
  --engine custom-oracle-ee \
  --db-instance-identifier my-custom-instance \
  --engine-version 19.my_cev1 \
  --allocated-storage 250 \
  --db-instance-class db.m5.xlarge \
  --db-subnet-group mydbsubnetgroup \
  --master-username myawsuser \
  --master-user-password mypassword \
  --backup-retention-period 3 \
  --no-multi-az \
  --port 8200 \
  --license-model bring-your-own-license \
  --kms-key-id my-kms-key \
  --no-auto-minor-version-upgrade \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```bash
aws rds create-db-instance
```

764
RDS Custom service-linked role

A service-linked role gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don’t have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can’t be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don’t already exist) and used. For more information, see Using service-linked roles for Amazon RDS (p. 1837).
Connecting to your RDS Custom DB instance using SSH

The first time that you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

After you create your RDS Custom DB instance, you can connect to this instance using an SSH client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see Connecting to your Linux instance using SSH.

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair on your behalf. The pair name uses the prefix do-not-delete-rds-custom-ssh-privatekey-db-. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. Configure your DB instance to allow SSH connections (p. 766)
2. Retrieve your secret key (p. 766)
3. Connect to your EC2 instance using the ssh utility (p. 768)

Configure your DB instance to allow SSH connections

Make sure that your DB instance security group permits inbound connections on port 22 for TCP. To learn how to configure your instance security group, see Configure your instance security group (p. 733).

Retrieve your secret key

Retrieve the secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose Configuration.
4. Note the Resource ID value. For example, the resource ID might be db-ABCDEFGHJKLMNOPQRS0123456.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose Instances.
7. Find the name of your EC2 instance, and choose the instance ID associated with it. For example, the EC2 instance ID might be i-abcdefghijklm01234.
8. In Details, find Key pair name. The pair name includes the resource ID. For example, the pair name might be do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHJKLMNOPQR0123456-0d726c.
9. In the instance summary, find Public IPv4 DNS. For example, the public Domain Name System (DNS) address might be ec2-12-345-678-901.us-east-2.compute.amazonaws.com.
11. Choose the secret that has the same name as your key pair.
12. Choose **Retrieve secret value**.
13. Copy the private key into a text file, and then save the file with the `.pem` extension. For example, save the file as `/tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456-0d726c.pem`.

### AWS CLI

To retrieve the private key, use the AWS CLI.

**Example**

To find the DB resource ID of your RDS Custom DB instance, use `aws rds describe-db-instances`.

```bash
aws rds describe-db-instances \
  --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
  --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

`db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456`

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456` for the resource ID.

```bash
aws ec2 describe-instances \
  --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456" \
  --output text \
  --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

`i-abcdefghijklm01234`

To find the key name, specify the EC2 instance ID.

```bash
aws ec2 describe-instances \
  --instance-ids i-0bdc4219e66944afa \
  --output text \
  --query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the prefix `do-not-delete-rds-custom-ssh-privatekey-`.

`do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456-0d726c`

To save the private key in a `.pem` file named after the key, use `aws secretsmanager`. The following example saves the file in your `/tmp` directory.

```bash
aws secretsmanager get-secret-value \
  --secret-id do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456-0d726c \
  --query SecretString \
  --output text >/tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456-0d726c.pem
```
Connect to your EC2 instance using the ssh utility

The following example assumes that you created a .pem file that contains your private key.

Change to the directory that contains your .pem file. Using chmod, set the permissions to 400.

```
cd /tmp
chmod 400 do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456-0d726c.pem
```

To obtain your public DNS name, use the command `ec2 describe-instances`.

```
aws ec2 describe-instances
   --instance-ids i-abcdefghijklm01234
   --output text
   --query 'Reservations[*].Instances[*].PublicDnsName'
```

The following sample output shows the public DNS name.

```
ec2-12-345-678-901.us-east-2.compute.amazonaws.com
```

In the ssh utility, specify the .pem file and the public DNS name of the instance.

```
ssh -i
   "do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456-0d726c.pem"
   ec2-user@ec2-12-345-678-901.us-east-2.compute.amazonaws.com
```

Connecting to your RDS Custom DB instance using AWS Systems Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is an Systems Manager capability that you can use to manage Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose Configuration.
4. Note the Resource ID for your DB instance. For example, the resource ID might be db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose Instances.
7. Look for the name of your EC2 instance, and then click the instance ID associated with it. For example, the instance ID might be i-abcdefghijklm01234.
8. Choose Connect.
9. Choose Session Manager.
10. Choose Connect.
A window opens for your session.

**AWS CLI**

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
  --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
  --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456` for the resource ID.

```
aws ec2 describe-instances \
  --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456" \
  --output text \
  --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefghijklmnopqr0123456"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklmnopqr123456
[ssm-user@ip-123-45-67-89 bin]$
```
Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server

You can create an RDS Custom DB instance, and then connect to it using AWS Systems Manager or Remote Desktop Protocol (RDP).

**Important**
Before you can create or connect to an RDS Custom for SQL Server DB instance, make sure to complete the tasks in Setting up your environment for Amazon RDS Custom for SQL Server (p. 738).
You can tag RDS Custom DB instances when you create them, but don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. For more information, see Tagging RDS Custom resources (p. 786).
The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

**Topics**
- Creating an RDS Custom for SQL Server DB instance (p. 770)
- RDS Custom service-linked role (p. 773)
- Connecting to your RDS Custom DB instance using AWS Systems Manager (p. 773)
- Connecting to your RDS Custom DB instance using RDP (p. 775)

## Creating an RDS Custom for SQL Server DB instance

Create an Amazon RDS Custom for SQL Server DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance.

For more information, see Creating an Amazon RDS DB instance (p. 175).

**Console**

To create an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose Create database.
4. Choose Standard create for the database creation method.
5. For Engine options, choose Microsoft SQL Server for the engine type.
6. For Database management type, choose Amazon RDS Custom.
7. In the Edition section, choose the DB engine edition that you want to use. For RDS Custom for SQL Server, the choices are Enterprise, Standard, and Web.
8. For Database version, keep the SQL Server 2019 default value.
9. For Templates, choose Production.
10. In the Settings section, enter a unique name for the DB instance identifier.
11. To enter your master password, do the following:
    a. In the Settings section, open Credential Settings.
    b. Clear the Auto generate a password check box.
c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new RDS Custom DB instance uses an automatically generated password for the master user.

12. In the **DB instance size** section, choose a value for **DB instance class**.

For supported classes, see [DB instance class support for RDS Custom](#). (p. 723)

13. Choose **Storage** settings.

14. For **RDS Custom security**, do the following:

   a. For **IAM instance profile**, choose the instance profile for your RDS Custom for SQL Server DB instance.

      The IAM instance profile must begin with `AWSRDSCustom`, for example `AWSRDSCustomInstanceProfileForRdsCustomInstance`.

   b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

      An AWS KMS key is required for RDS Custom. For more information, see [Make sure that you have a symmetric AWS KMS key](#). (p. 738)

15. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see [Settings for DB instances](#) (p. 178). The following settings don't appear in the console and aren't supported:

   - Processor features
   - Storage autoscaling
   - Availability & durability
   - **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
   - **Database options** group in **Additional configuration**
   - **Performance Insights**
   - **Log exports**
   - **Enable auto minor version upgrade**
   - **Deletion protection**

   **Backup retention period** is supported, but you can't choose **0 days**.

16. Choose **Create database**.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**

You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, modify the DB instance. For more information about modifying a DB instance, see [Managing an Amazon RDS Custom DB instance](#) (p. 778).

17. Choose **Databases** to view the list of RDS Custom DB instances.

18. Choose the RDS Custom DB instance that you just created.
On the RDS console, the details for the new RDS Custom DB instance appear:

- The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
- **Role** has the value **Instance (RDS Custom)**.
- **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

**AWS CLI**

You create an RDS Custom DB instance by using the `create-db-instance` AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see [DB instance class support for RDS Custom](#))
- `--engine (custom-sqlserver-ee, custom-sqlserver-se, or custom-sqlserver-web)`
- `--kms-key-id`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom for SQL Server DB instance named *my-custom-instance*. The backup retention period is 3 days.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
   --engine custom-sqlserver-ee \
   --engine-version 15.00.4073.23.v1 \
   --db-instance-identifier my-custom-instance \
   --db-instance-class db.m5.xlarge \
   --allocated-storage 20 \
   --db-subnet-group mydbsubnetgroup \
   --master-username myuser \
   --master-user-password mypassword \
   --backup-retention-period 3 \
   --no-multi-az \
   --port 8200 \
   --license-model license-included \
   --kms-key-id mykmskey \
   --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```bash
aws rds create-db-instance ^
   --engine custom-sqlserver-ee ^
   --engine-version 15.00.4073.23.v1 ^
   --db-instance-identifier my-custom-instance ^
   --db-instance-class db.m5.xlarge ^
   --allocated-storage 20 ^
   --db-subnet-group mydbsubnetgroup ^
   --master-username myuser ^
```

772
Get details about your instance by using the `describe-db-instances` command.

```bash
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The following partial output shows the engine, parameter groups, and other information.

```json
{
  "DBInstances": [
    {
      "PendingModifiedValues": {},
      "Engine": "custom-sqlserver-ee",
      "MultiAZ": false,
      "DBSecurityGroups": [],
      "DBParameterGroups": [
        {
          "DBParameterGroupName": "default.custom-sqlserver-ee-15",
          "ParameterApplyStatus": "in-sync"
        }
      ],
      "AutomationMode": "full",
      "DBInstanceIdentifier": "my-custom-instance",
      "TagList": []
    }
  ]
}
```

### RDS Custom service-linked role

A service-linked role gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS (p. 1837).

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

### Connecting to your RDS Custom DB instance using AWS Systems Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is a Systems Manager capability that you can use to manage Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.
**Console**

**To connect to your DB instance using Session Manager**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose Configuration.
4. Note the Resource ID value for your DB instance. For example, the resource ID might be `db-ABCDEFHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose Instances.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it. For example, the instance ID might be `i-abcdefghijklm01234`.
8. Choose Connect.
9. Choose Session Manager.
10. Choose Connect.

A window opens for your session.

**AWS CLI**

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `describe-db-instances`.

```bash
aws rds describe-db-instances \\   --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \\   --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFHIJKLMNOPQRS0123456` for the resource ID.

```bash
aws ec2 describe-instances \\   --filters "Name=tag:Name,Values=db-ABCDEFHIJKLMNOPQRS0123456" \\   --output text \\   --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the --target parameter.

```bash
aws ssm start-session --target "i-abcdefghijklm01234"
```
A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

## Connecting to your RDS Custom DB instance using RDP

After you create your RDS Custom DB instance, you can connect to this instance using an RDP client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see [Connect to your Windows instance](#).

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair for you. The pair name uses the prefix `do-not-delete-rds-custom-DBInstanceIdentifier`. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. Configure your DB instance to allow RDP connections (p. 775).
2. Retrieve your secret key (p. 776).
3. Connect to your EC2 instance using the RDP utility (p. 777).

### Configure your DB instance to allow RDP connections

To allow RDP connections, configure your VPC security group and set a firewall rule on the host.

#### Configure your VPC security group

Make sure that the VPC security group associated with your DB instance permits inbound connections on port 3389 for Transmission Control Protocol (TCP). To learn how to configure your VPC security group, see [Configure your VPC security group](#).

#### Set the firewall rule on the host

To permit inbound connections on port 3389 for TCP, set a firewall rule on the host. The following examples show how to do this.

We recommend that you use the specific `-Profile` value: Public, Private, or Domain. Using `Any` refers to all three values. You can also specify a combination of values separated by a comma. For more information on setting firewall rules, see `Set-NetFirewallRule` in the Microsoft documentation.

**To use Systems Manager Session Manager to set a firewall rule**

1. Connect to Session Manager as shown in [Connecting to your RDS Custom DB instance using AWS Systems Manager](#).
2. Run the following command.

```powershell
Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction Inbound -LocalAddress Any -Profile Any
```

**To use Systems Manager CLI commands to set a firewall rule**

1. Use the following command to open RDP on the host.

```powershell
Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction Inbound -LocalAddress Any -Profile Any
```
OPEN_RDP_COMMAND_ID=$(aws ssm send-command --region $AWS_REGION
--instance-ids $RDS_CUSTOM_INSTANCE_EC2_ID
--document-name "AWS-RunPowerShellScript"
--parameters '{"commands": ["Set-NetFirewallRule -DisplayName "Remote Desktop -
User Mode (TCP-In)" -Direction Inbound -LocalAddress Any -Profile Any"],
--comment "Open RDP port"} | jq -r ".Command.CommandId"

2. Use the command ID returned in the output to get the status of the previous command. To use the
following query to return the command ID, make sure that you have the jq plug-in installed.

aws ssm list-commands \
--region $AWS_REGION \
--command-id #OPEN_RDP_COMMAND_ID

Retrieve your secret key

Retrieve your secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance to which
you want to connect.
3. Choose the Configuration tab.
4. Note the DB instance ID for your DB instance, for example, my-custom-instance.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose Instances.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it.

In this example, the instance ID is i-abcdedffghijklm01234.
8. In Details, find Key pair name. The pair name includes the DB identifier. In this example, the pair
name is do-not-delete-rds-custom-my-custom-instance-0d726c.
9. In the instance summary, find Public IPv4 DNS. For the example, the public DNS might be
ec2-12-345-678-901.us-east-2.compute.amazonaws.com.
11. Choose the secret that has the same name as your key pair.
12. Choose Retrieve secret value.

AWS CLI

To retrieve the private key

1. Get the list of your RDS Custom DB instances by calling the aws rds describe-db-instances
command.

aws rds describe-db-instances \
--query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
--output text
2. Choose the DB instance identifier from the sample output, for example `do-not-delete-rds-custom-my-custom-instance`.

3. Find the EC2 instance ID of your DB instance by calling the `aws ec2 describe-instances` command. The following example uses the EC2 instance name to describe the DB instance.

   ```
   aws ec2 describe-instances \
   --filters "Name=tag:Name,Values=do-not-delete-rds-custom-my-custom-instance" \
   --output text \ 
   --query 'Reservations[*].Instances[*].InstanceId'
   ```

   The following sample output shows the EC2 instance ID.

   ```
   i-abcdefghijklm01234
   ```

4. Find the key name by specifying the EC2 instance ID, as shown in the following example.

   ```
   aws ec2 describe-instances \
   --instance-ids i-abcdefghijklm01234 \
   --output text \ 
   --query 'Reservations[*].Instances[*].KeyName'
   ```

   The following sample output shows the key name, which uses the prefix `do-not-delete-rds-custom-DBInstanceIdentifier`.

   ```
   do-not-delete-rds-custom-my-custom-instance-0d726c
   ```

**Connect to your EC2 instance using the RDP utility**

Follow the procedure in [Connect to your Windows instance using RDP](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_RDP.html) in the *Amazon EC2 User Guide for Windows Instances*. This procedure assumes that you created a .pem file that contains your private key.
Managing an Amazon RDS Custom DB instance

Amazon RDS Custom supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom management tasks using the AWS Management Console and the AWS CLI.

Topics
- Working with high availability features for RDS Custom for Oracle (p. 778)
- Working with high availability features for RDS Custom for SQL Server (p. 778)
- Pausing and resuming RDS Custom automation (p. 779)
- Modifying an RDS Custom for SQL Server DB instance (p. 782)
- Modifying the storage for an RDS Custom for Oracle DB instance (p. 783)
- Changing the time zone of an RDS Custom for Oracle DB instance (p. 785)
- Support for Transparent Data Encryption (p. 786)
- Tagging RDS Custom resources (p. 786)
- Deleting an RDS Custom DB instance (p. 786)

Working with high availability features for RDS Custom for Oracle

To support replication between RDS Custom for Oracle instances, you can configure high availability (HA) with Oracle Data Guard. The primary DB instance automatically synchronizes data to the standby instances.

You can configure your high availability environment in the following ways:

- Configure standby instances in different Availability Zones (AZs) to be resilient to AZ failures.
- Place your standby databases in mounted or read-only mode.
- Fail over or switch over from the primary database to a standby database with no data loss.
- Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom standby database.

To learn how to configure high availability, see the whitepaper Enabling high availability with Data Guard on Amazon RDS Custom for Oracle. You can perform the following tasks:

- Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn’t configured automatically by RDS Custom.
- Configure Oracle Fast-Failover Observer (FSFO) to monitor your high availability instances.
- Allow the observer to perform automatic failover when necessary conditions are met.

Working with high availability features for RDS Custom for SQL Server

To support replication between RDS Custom for SQL Server instances, you can configure high availability (HA) with Always On Availability Groups (AGs). The primary DB instance automatically synchronizes data to the standby instances.

You can configure your high availability environment in the following ways:
• Configure standby instances in different Availability Zones (AZs) to be resilient to AZ failures.
• Place your standby databases in mounted or read-only mode.
• Fail over or switch over from the primary database to a standby database with no data loss.
• Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom standby database.

To learn how to configure high availability, see the blog post Configure high availability with Always On Availability Groups on Amazon RDS Custom for SQL Server. You can perform the following tasks:

• Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn't configured automatically by RDS Custom.
• Configure Always On AGs to monitor your high availability instances.
• Allow the observer to perform automatic failover when necessary conditions are met.

You can also use other encryption technology, such as Secure Sockets Layer (SSL), to encrypt data in transit.

You're responsible for configuring VPC flow logs and CloudWatch alarms to monitor traffic mirroring to prevent data leakage.

Pausing and resuming RDS Custom automation

RDS Custom automatically provides monitoring and instance recovery for an RDS Custom DB instance. If you need to customize the instance, do the following:

1. Pause RDS Custom automation for a specified period. The pause ensures that your customizations don't interfere with RDS Custom automation.
2. Customize the RDS Custom DB instance as needed.
3. Do either of the following:
   • Resume automation manually.
   • Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

   **Important**
   Pausing and resuming automation are the only supported automation tasks when modifying a DB instance.

Console

**To pause or resume RDS Custom automation**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance that you want to modify.
4. For **RDS Custom automation mode**, choose one of the following options:
   • **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
   • **Full automation** resumes automation.
5. Choose **Continue** to check the summary of modifications.
   
   A message indicates that RDS Custom will apply the changes immediately.

6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.
   
   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.

7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.
   
   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in num minutes**.

**AWS CLI**

To pause or resume RDS Custom automation, use the modify-db-instance AWS CLI command. Identify the DB instance using the required parameter **--db-instance-identifier**. Control the automation mode with the following parameters:

- **--automation-mode** specifies the pause state of the DB instance. Valid values are all-paused, which pauses automation, and full, which resumes it.
- **--resume-full-automation-mode-minutes** specifies the duration of the pause. The default value is 60 minutes.

**Note**

Regardless of whether you specify **--no-apply-immediately** or **--apply-immediately**, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, **ResumeFullAutomationModeTime** indicates the resume time as a UTC timestamp. When the automation mode is all-paused, you can use modify-db-instance to resume automation mode or extend the pause period. No other modify-db-instance options are supported.

The following example pauses automation for **my-custom-instance** for 90 minutes.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance  \
  --automation-mode all-paused  \
  --resume-full-automation-mode-minutes 90
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --automation-mode all-paused ^
  --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in **ResumeFullAutomationModeTime**.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode all-paused \
  --resume-full-automation-mode-minutes 120
```
aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode all-paused \
  --resume-full-automation-mode-minutes 30

For Windows:

aws rds modify-db-instance ^ 
  --db-instance-identifier my-custom-instance ^ 
  --automation-mode all-paused ^ 
  --resume-full-automation-mode-minutes 30

The following example resumes full automation for my-custom-instance.

Example

For Linux, macOS, or Unix:

aws rds modify-db-instance \
  --db-instance-identifier my-custom-instance \
  --automation-mode full

For Windows:

aws rds modify-db-instance ^ 
  --db-instance-identifier my-custom-instance ^ 
  --automation-mode full

In the following partial sample output, the pending AutomationMode value is full.

```json
{
  "DBInstance": {
    "PubliclyAccessible": true,
    "MasterUsername": "admin",
    "MonitoringInterval": 0,
    "LicenseModel": "bring-your-own-license",
    "VpcSecurityGroups": [
      {
        "Status": "active",
        "VpcSecurityGroupId": "0123456789abcdefg"
      }
    ],
    "InstanceCreateTime": "2020-11-07T19:50:06.193Z",
    "CopyTagsToSnapshot": false,
    "OptionGroupMemberships": [
      {
        "Status": "in-sync",
        "OptionGroupName": "default:custom-oracle-ee-19"
      }
    ],
    "PendingModifiedValues": {
      "AutomationMode": "full"
    },
    "Engine": "custom-oracle-ee",
    "MultiAZ": false,
    "DBSecurityGroups": [],
    "DBParameterGroups": []
  }
}
Modifying an RDS Custom for SQL Server DB instance

Modifying an RDS Custom for SQL Server DB instance is similar to doing this for Amazon RDS, but the changes that you can make are limited to the following:

- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window
- Upgrading the DB engine version when a new version becomes available

The following limitations apply to modifying an RDS Custom for SQL Server DB instance:

- Multi-AZ deployments aren't supported.
- Custom DB option and parameter groups aren't supported.
- You can't modify the allocated storage.
- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

For more information, see RDS Custom support perimeter and unsupported configurations (p. 809).
Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
4. Choose Modify.
5. Make the following changes as needed:
   a. For DB engine version, choose the new version.
   b. Change the value for DB instance class. For supported classes, see DB instance class support for RDS Custom (p. 723).
   c. Change the value for Backup retention period.
   d. For Backup window, set values for the Start time and Duration.
   e. For DB instance maintenance window, set values for the Start day, Start time, and Duration.
6. Choose Continue.
7. Choose Apply immediately or Apply during the next scheduled maintenance window.
8. Choose Modify DB instance.

AWS CLI

To modify an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- --db-instance-class – For supported classes, see DB instance class support for RDS Custom (p. 723).
- --engine-version – The version number of the database engine to which you're upgrading.
- --backup-retention-period – How long to retain automated backups, from 0–35 days.
- --preferred-backup-window – The daily time range during which automated backups are created.
- --preferred-maintenance-window – The weekly time range (in UTC) during which system maintenance can occur.
- --apply-immediately – Use --apply-immediately to apply the storage changes immediately.
- --no-apply-immediately – Use --no-apply-immediately (the default) to apply the changes during the next maintenance window.

Modifying the storage for an RDS Custom for Oracle DB instance

Modifying the storage for an RDS Custom for Oracle DB instance is similar to doing this for Amazon RDS, but the changes that you can make are limited to the following:

- Increasing the allocated storage
- Changing the storage type from io1 to gp2, or gp2 to io1
- Changing the Provisioned IOPS, if you're using the io1 storage type

The following limitations apply to modifying the storage for an RDS Custom for Oracle DB instance:
• The minimum allocated storage for RDS Custom for Oracle is 40 GiB, and the maximum is 64 TiB.
• As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon EBS volumes.
• Storage autoscaling isn't supported for RDS Custom DB instances.
• Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

For more information, see RDS Custom support perimeter and unsupported configurations (p. 809).
• Magnetic (standard) storage isn't supported for RDS Custom.

For more information about storage, see Amazon RDS DB instance storage (p. 53).

For general information on storage modification, see Working with storage for Amazon RDS DB instances (p. 393). The following procedures are specific to RDS Custom.

**Console**

**To modify the storage for an RDS Custom for Oracle DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance that you want to modify.
4. Choose Modify.
5. Make the following changes as needed:
   a. Enter a new value for Allocated storage. It must be greater than the current value, and from 40 GiB–64 TiB.
   b. Change the value for Storage type. You can use General Purpose (gp2) or Provisioned IOPS (io1) storage.
   c. If using io1 storage, you can change the Provisioned IOPS value.
6. Choose Continue.
7. Choose Apply immediately or Apply during the next scheduled maintenance window.
8. Choose Modify DB instance.

**AWS CLI**

To modify the storage for an RDS Custom for Oracle DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

• --allocated-storage – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 40–65,536 GiB.
• --storage-type – The storage type, gp2 or io1.
• --iops – Provisioned IOPS for the DB instance, if using the io1 storage type.
• --apply-immediately – Use --apply-immediately to apply the storage changes immediately.

Or use --no-apply-immediately (the default) to apply the changes during the next maintenance window.
Changing the time zone of an RDS Custom for Oracle DB instance

You change the time zone of an RDS Custom for Oracle DB instance manually, unlike RDS for Oracle where you use the `TIME_ZONE` option in a custom DB option group.

You can change time zones for RDS Custom for Oracle DB instances multiple times, but we recommend not changing them more than once every 48 hours. We also recommend changing them only when the latest restorable time is within the last 30 minutes.

If you don’t follow these recommendations, cleaning up redo logs might remove more logs than intended. Redo log timestamps might also be converted incorrectly to UTC, which can prevent the redo logs from being downloaded and replayed correctly. This in turn can prevent point-in-time recovery (PITR) from performing correctly.

Changing the time zone of an RDS Custom for Oracle DB instance has the following limitations:

- PITR is supported for recovery times before RDS Custom automation is paused, and after automation is resumed.
  
  For more information on PITR, see [Restoring an RDS Custom instance to a point in time](p. 793).
- Changing the time zone of an existing read replica causes downtime. We recommend changing the time zone of the DB instance before creating read replicas.

You can create a read replica from a DB instance with a modified time zone. For more information on read replicas, see [Working with read replicas for RDS Custom for Oracle](p. 788).

Use the following procedures to change the time zone of an RDS Custom for Oracle DB instance.

Make sure to follow these procedures. If they aren’t followed, it can result in these issues:

- Disruption of redo log download and replay
- Incorrect redo log timestamps
- Cleanup of redo logs on the host that doesn't use the redo log retention period

**To change the time zone for a primary DB instance**

1. Pause RDS Custom automation. For more information, see [Pausing and resuming RDS Custom automation](p. 779).
2. (Optional) Change the time zone of the DB instance, for example by using the following command.

   ```sql
   ALTER DATABASE SET TIME_ZONE = 'US/Pacific';
   ```
3. Shut down the DB instance.
4. Log in to the host and change the system time zone.
5. Start the DB instance.
6. Resume RDS Custom automation.

**To change the time zone for a primary DB instance and its read replicas**

1. Pause RDS Custom automation on the primary DB instance.
2. Pause RDS Custom automation on the read replicas.
3. (Optional) Change the time zone of the primary and read replicas, for example by using the following command.

```
ALTER DATABASE SET TIME_ZONE = 'US/Pacific';
```

4. Shut down the primary DB instance.
5. Shut down the read replicas.
6. Log in to the host and change the system time zone for the read replicas.
7. Change the system time zone for the primary DB instance.
8. Mount the read replicas.
9. Start the primary DB instance.
10. Resume RDS Custom automation on the primary DB instance and then on the read replicas.

**Support for Transparent Data Encryption**

RDS Custom supports Transparent Data Encryption (TDE) for RDS Custom for Oracle and RDS Custom for SQL Server DB instances.

However, you can't enable TDE using an option in a custom option group as you can in RDS for Oracle or RDS for SQL Server. You turn on TDE manually. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption in the Oracle documentation. For information about Transparent Data Encryption for SQL Server, see Transparent Data Encryption (TDE) in the Microsoft documentation.

**Tagging RDS Custom resources**

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the AWSRDSCustom tag that's required for RDS Custom automation. If you do, you might break the automation.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information on resource tagging, see Tagging Amazon RDS resources (p. 375).

**Deleting an RDS Custom DB instance**

To delete an RDS Custom DB instance, do the following:

- Provide the name of the DB instance.
- Clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete) and how much data is deleted.
Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance that you want to delete. RDS Custom DB instances show the role Instance (RDS Custom).
3. For Actions, choose Delete.
4. To retain automated backups, choose Retain automated backups.
5. Enter delete me in the box.
6. Choose Delete.

AWS CLI

You delete an RDS Custom DB instance by using the delete-db-instance AWS CLI command. Identify the DB instance using the required parameter --db-instance-identifier. The remaining parameters are the same as for an Amazon RDS DB instance, with the following exceptions:

- --skip-final-snapshot is required.
- --no-skip-final-snapshot isn't supported.
- --final-db-snapshot-identifier isn't supported.

The following example deletes the RDS Custom DB instance named my-custom-instance, and retains automated backups.

Example

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance \
  --db-instance-identifier my-custom-instance \
  --skip-final-snapshot \
  --no-delete-automated-backups
```

For Windows:

```bash
aws rds delete-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --skip-final-snapshot ^
  --no-delete-automated-backups
```
Working with read replicas for RDS Custom for Oracle

You can create read replicas for RDS Custom for Oracle DB instances. Read replica creation is similar to that in Amazon RDS, but with some important differences. For general information on creating and managing read replicas, see Working with read replicas (p. 354) and Working with Oracle replicas for Amazon RDS (p. 1443).

Not all options are supported when you create RDS Custom for Oracle read replicas. For example, you must specify the replica mode as mounted when you create the replica, which you can then change to read-only. For more information, see the documentation for the create-db-instance-read-replica AWS CLI command.

As with RDS for Oracle, you can have up to six managed read replicas. You can create your own manually configured (external) RDS Custom for Oracle read replicas, which don't count toward the limit, but they're outside the support perimeter. For more information on the support perimeter, see RDS Custom support perimeter and unsupported configurations (p. 809).

Read replicas are named after the database unique name, with letters appended sequentially: `DB_UNIQUE_NAME_X`, for example `ORCL_A`. The first six letters, `A–F`, are reserved for RDS Custom. Database parameters are copied from the primary DB instance to the replicas. For more information, see `DB_UNIQUE_NAME` in the Oracle documentation.

RDS Custom read replicas use the same backup retention period as the primary DB instance by default. You can modify the backup retention period. Backing up, restoring, and point-in-time recovery (PITR) are supported. For more information on backing up and restoring RDS Custom DB instances, see Backing up and restoring an Amazon RDS Custom DB instance (p. 791).

Network considerations

Make sure that your network configuration supports read replicas. Be aware of the following considerations:

- Make sure to enable port 1140 for both inbound and outbound communication within your virtual private cloud (VPC) for the primary DB instance and all of the replicas. This is required for Oracle Data Guard communication between the read replicas.
- There is a network validation step during read replica creation. If end-to-end network connectivity between the primary DB instance and the new replica isn't possible, read replica creation fails. The replica is put in the INCOMPATIBLE_NETWORK state.
- For external read replicas, such as those you create on Amazon EC2 or on-premises, use another port and listener for Oracle Data Guard replication. Trying to use port 1140 could cause conflicts with RDS Custom automation.

Considerations for the tnsnames.ora file

The `tnsnames.ora` file contains network service names mapped to listener protocol addresses. On RDS Custom for Oracle, this file is in the `/rdsdbdata/config` directory. Be aware of the following considerations:

- Entries in `tnsnames.ora` prefixed with `rds_custom_` are reserved for RDS Custom when handling read replica operations.

    When creating manual entries in `tnsnames.ora`, don't use this prefix.
• In some cases, you might want to switch over or fail over manually, or use failover technologies such as Fast-Start Failover (FSFO). If so, make sure to manually synchronize `tnsnames.ora` entries from the primary DB instance to all of the standby instances. This recommendation applies to both read replicas managed by RDS Custom and to external read replicas.

RDS Custom automation updates `tnsnames.ora` entries only on the primary DB instance. Make sure also to synchronize when you add or remove a read replica.

If you don’t synchronize the `tnsnames.ora` files and switch over or fail over manually, Oracle Data Guard on the primary DB instance might not be able to communicate with the read replicas.

**Limitations**

RDS Custom for Oracle read replicas have the following limitations:

• You must create RDS Custom for Oracle replicas in mounted mode. However, you can manually change the mode of mounted replicas to read-only, and from read-only back to mounted.

• Cross-Region read replicas aren’t supported.

• Deleting the primary DB instance for a read replica isn’t supported. Delete the read replicas first, then delete the primary.

• Promoting a read replica using the `promote-read-replica` AWS CLI command isn’t supported, but you can promote a read replica manually.

  For information on promoting read replicas manually, see the white paper [Enabling high availability with Data Guard on Amazon RDS Custom for Oracle](https://aws.amazon.com/rds/custom/oracle/).

• RDS Custom uses the `RDS_DATAGUARD` database user to administer the Oracle Data Guard configuration for the DB instance. This user is reserved for RDS Custom automation.

  Don’t modify the `RDS_DATAGUARD` user. Doing so can result in undesired outcomes, such as not being able to create read replicas for your RDS Custom DB instance.

• The Oracle Data Guard `CommunicationTimeout` parameter is set to 15 seconds for RDS Custom DB instances and can’t be changed.

• The replication user password is stored in AWS Secrets Manager, tagged with the DB resource ID. Each read replica has its own secret in Secrets Manager. This password is required to administer the Oracle Data Guard configuration on the host. The format for the secret is the following.

  ```
  do-not-delete-rds-custom-db-DB_resource_id-6-digit_UUID-dg
  ```

  Don’t change the password, because this might put your read replica outside the support perimeter. For more information, see RDS Custom support perimeter and unsupported configurations (p. 809).

• While RDS Custom is creating a read replica, RDS Custom automation temporarily pauses the cleanup of redo logs. It does this so that these logs can be applied to the new read replica when it's available.

• RDS Custom detects instance role changes upon manual failover, such as FSFO, for read replicas managed by RDS Custom, but not for external read replicas.

  The role change is noted in the event log. You can also see the new state by using the `describe-db-instances` AWS CLI command.

• RDS Custom detects high replication lag for RDS Custom–managed read replicas, but not for external read replicas.

  High replication lag produces the `Replication has stopped` event. You can also see the replication status by using the `describe-db-instances` AWS CLI command, but there might be a delay for it to be updated.
Back up and restore an Amazon RDS Custom DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics
- Creating an RDS Custom snapshot (p. 791)
- Restoring from an RDS Custom DB snapshot (p. 792)
- Restoring an RDS Custom instance to a point in time (p. 793)
- Deleting an RDS Custom snapshot (p. 797)
- Deleting RDS Custom automated backups (p. 798)

Creating an RDS Custom snapshot

RDS Custom creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create an RDS Custom snapshot, specify which RDS Custom DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DbiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot (p. 428).

Create an RDS Custom snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For Actions, choose Take snapshot.
   The Take DB snapshot window appears.
5. For Snapshot name, enter the name of the snapshot.
6. Choose **Take snapshot**.

**AWS CLI**

You create a snapshot of an RDS Custom DB instance by using the `create-db-snapshot` AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called `my-custom-snapshot` for an RDS Custom DB instance called `my-custom-instance`.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier my-custom-instance \
    --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier my-custom-instance ^
    --db-snapshot-identifier my-custom-snapshot
```

### Restoring from an RDS Custom DB snapshot

When you restore an RDS Custom DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom backs up existing configuration files. These files are available on the restored instance in the directory `/rdsdbdata/config/backup`. RDS Custom restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name. (For RDS Custom for Oracle, the default is `ORCL`).

**Console**

**To restore an RDS Custom DB instance from a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.
5. On the Restore DB instance page, for DB instance identifier, enter the name for your restored RDS Custom DB instance.
6. Choose Restore DB instance.

**AWS CLI**

You restore an RDS Custom DB snapshot by using the `restore-db-instance-from-db-snapshot` AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct `db-subnet-group-name` and `no-publicly-accessible`. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- `db-snapshot-identifier` – Identifies the snapshot from which to restore
- `db-instance-identifier` – Specifies the name of the RDS Custom DB instance to create from the DB snapshot

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

**Example**

For Linux, macOS, or Unix:

```
aws restore-db-instance-from-db-snapshot \\
  --db-snapshot-identifier my-custom-snapshot \\
  --db-instance-identifier my-custom-instance \\
  --no-publicly-accessible
```

For Windows:

```
aws restore-db-instance-from-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --no-publicly-accessible
```

**Restoring an RDS Custom instance to a point in time**

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI `describe-db-instances` command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose Automated backups.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose Automated backups in the Amazon RDS console.

For general information on PITR, see Restoring a DB instance to a specified time (p. 480).

**Topics**

- PITR considerations for RDS Custom for Oracle (p. 794)
PITR considerations for RDS Custom for Oracle

In RDS Custom for Oracle, PITR differs in the following important ways from PITR in Amazon RDS:

- The restored database has the same name as in the source DB instance. You can't specify a different name. The default is ORCL.
- AWSRDSCustomIamRolePolicy requires new permissions. For more information, see Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance (p. 729).
- All RDS Custom for Oracle DB instances must have backup retention set to a nonzero value.
- If you change the operating system or DB instance time zone, PITR might not work. For information on changing time zones, see Changing the time zone of an RDS Custom for Oracle DB instance (p. 785).
- If you set automation to ALL_PAUSED, RDS Custom pauses the upload of archived redo logs, including logs created before the latest restorable time (LRT). We recommend that you pause automation for a brief period.

To illustrate, assume that your LRT is 10 minutes ago. You pause automation. During the pause, RDS Custom doesn't upload archived redo logs. If your DB instance crashes, you can only recover to a time before the LRT that existed when you paused. When you resume automation, RDS Custom resumes uploading logs. The LRT advances. Normal PITR rules apply.

- In RDS Custom, you can manually specify an arbitrary number of hours to retain archived redo logs before RDS Custom deletes them after upload. In RDS Custom, make sure to specify the number of logs manually in the following file: /opt/aws/rdscustomagent/config/redo_logs_custom_configuration.json. The format is: `{ "archivedLogRetentionHours" : "num_of_hours" }`.
- We recommend that you don't customize database initialization parameters. For example, modifying the following parameters affects PITR:
  - CONTROL_FILE_RECORD_KEEP_TIME affects the rules for uploading and deleting logs.
  - LOG_ARCHIVE_DEST_n doesn't support multiple destinations.
  - ARCHIVE_LAG_TARGET affects the latest restorable time.
- If you customize database initialization parameters, we strongly recommend that you only customize the following:
  - COMPATIBLE
  - MAX_STRING_SIZE
  - DB_FILES
  - UNDO_TABLESPACE
  - ENABLE_PLUGGABLE_DATABASE
  - CONTROL_FILES
  - AUDIT_TRAIL
  - AUDIT_TRAIL_DEST

For all other initialization parameters, RDS Custom restores the default values. If you modify a parameter that isn't in the preceding list, it might have an adverse effect on PITR and lead to unpredictable results. For example, CONTROL_FILE_RECORD_KEEP_TIME affects the rules for uploading and deleting logs.

PITR considerations for RDS Custom for SQL Server

In RDS Custom for SQL Server, PITR differs in the following important ways from PITR in Amazon RDS:
• PITR only restores the databases in the DB instance. It doesn't restore the operating system or files on the C: drive.
• For an RDS Custom for SQL Server DB instance, a database is backed up automatically and is eligible for PITR only under the following conditions:
  • The database is online.
  • Its recovery model is set to FULL.
  • It's writable.
  • It has its physical files on the D: drive.
  • It's not listed in the rds_pitr_blocked_databases table. For more information, see Making databases ineligible for PITR (p. 795).
• RDS Custom for SQL Server allows up to 5,000 databases per DB instance. However, the maximum number of databases restored by a PITR operation for an RDS Custom for SQL Server DB instance is 100. The 100 databases are determined by the order of their database ID.
  Other databases that aren't part of PITR can be restored from DB snapshots, including the automated backups used for PITR.
• Adding a new database, renaming a database, or restoring a database that is eligible for PITR initiates a snapshot of the DB instance.
• Restored databases have the same name as in the source DB instance. You can't specify a different name.
• AWSRDSCustomSQLServerIamRolePolicy requires new permissions. For more information, see Add an access policy to AWSRDSCustomSQLServerInstanceRole (p. 741).
• Time zone changes aren't supported for RDS Custom for SQL Server. If you change the operating system or DB instance time zone, PITR (and other automation) doesn't work.

Making databases ineligible for PITR

You can specify that certain RDS Custom for SQL Server databases aren't part of automated backups and PITR. To do this, put their database_id values into a rds_pitr_blocked_databases table. Use the following SQL script to create the table.

To create the rds_pitr_blocked_databases table

• Run the following SQL script.

```sql
CREATE TABLE msdb..rds_pitr_blocked_databases
(
    database_id INT NOT NULL,
    database_name SYSNAME NOT NULL,
    db_entry_updated_date DATETIME NOT NULL DEFAULT GETDATE(),
    db_entry_updated_by SYSNAME NOT NULL DEFAULT CURRENT_USER,
    PRIMARY KEY (database_id)
);
```

For the list of eligible and ineligible databases, see the RI.End file in the RDSCustomForSQLServer/Instances/DB_instance_resource_ID/TransactionLogMetadata directory in the Amazon S3 bucket do-not-delete-rds-custom-$ACCOUNT_ID-$REGION-unique_identifier. For more information about the RI.End file, see Transaction logs in Amazon S3 (p. 795).

Transaction logs in Amazon S3

The backup retention period determines whether transaction logs for RDS Custom for SQL Server DB instances are automatically extracted and uploaded to Amazon S3. A nonzero value means that
automatic backups are created, and that the RDS Custom agent uploads the transaction logs to S3 every 5 minutes.

Transaction log files on S3 are encrypted at rest using the AWS KMS key that you provided when you created your DB instance. For more information, see Protecting data using server-side encryption in the Amazon Simple Storage Service User Guide.

The transaction logs for each database are uploaded to an S3 bucket named do-not-delete-rds-custom-$ACCOUNT_ID-$REGION-unique_identifier. The RDSCustomForSQLServer/Instances/DB_instance_resource_ID directory in the S3 bucket contains two subdirectories:

- **TransactionLogs** – Contains the transaction logs for each database and their respective metadata.

  The transaction log file name follows the pattern `yyyyMMddHHmm.database_id.timestamp`, for example:

  ```plaintext
  202110202230.11.1634769287
  ```

  The same file name with the suffix `_metadata` contains information about the transaction log such as log sequence numbers, database name, and RdsChunkCount. RdsChunkCount determines how many physical files represent a single transaction log file. You might see files with suffixes `_0001`, `_0002`, and so on, which mean the physical chunks of a transaction log file. If you want to use a chunked transaction log file, make sure to merge the chunks after downloading them.

  Consider a scenario where you have the following files:

  - `202110202230.11.1634769287`
  - `202110202230.11.1634769287_0001`
  - `202110202230.11.1634769287_0002`
  - `202110202230.11.1634769287_metadata`

  The RdsChunkCount is 3. The order for merging the files is the following:

  ```plaintext
  202110202230.11.1634769287, 202110202230.11.1634769287_0001, 202110202230.11.1634769287_0002
  ```

- **TransactionLogMetadata** – Contains metadata information about each iteration of transaction log extraction.

  The `RI.End` file contains information for all databases that had their transaction logs extracted, and all databases that exist but didn't have their transaction logs extracted. The `RI.End` file name follows the pattern `yyyyMMddHHmm.RI.End.timestamp`, for example:

  ```plaintext
  202110202230.RI.End.1634769281
  ```

### Restoring an RDS Custom instance to a point in time

You can restore an RDS Custom DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To restore an RDS Custom DB instance to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For Actions, choose Restore to point in time. The Restore to point in time window appears.
5. Choose Latest restorable time to restore to the latest possible time, or choose Custom to choose a time.

If you chose Custom, enter the date and time to which you want to restore the instance.

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For DB instance identifier, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose Restore to point in time.

AWS CLI

You restore a DB instance to a specified time by using the restore-db-instance-to-point-in-time AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- --source-db-instance-identifier mysourceinstance
- --source-db-instance-automated-backups-arn backupARN

The following command restores my-custom-instance to a new DB instance named my-restored-custom-instance, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
  --source-db-instance-identifier my-custom-instance \
  --target-db-instance-identifier my-restored-custom-instance \
  --restore-time 2021-07-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
  --source-db-instance-identifier my-custom-instance ^
  --target-db-instance-identifier my-restored-custom-instance ^
  --restore-time 2021-07-14T23:45:00.000Z
```

Deleting an RDS Custom snapshot

You can delete DB snapshots managed by RDS Custom when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom
Deleting RDS Custom automated backups

Snapshots. These EBS snapshots are automatically deleted after they’re no longer related to any existing RDS Custom resources (DB instances or backups).

**Console**

**To delete a snapshot of an RDS Custom DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

**AWS CLI**

To delete an RDS Custom snapshot, use the AWS CLI command `delete-db-snapshot`.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds delete-db-snapshot \
   --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```bash
aws rds delete-db-snapshot ^
   --db-snapshot-identifier my-custom-snapshot
```

**Deleting RDS Custom automated backups**

You can delete retained automated backups for RDS Custom when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

**Console**

**To delete a retained automated backup**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter `delete me` and choose **Delete**.
AWS CLI

You can delete a retained automated backup by using the AWS CLI command `delete-db-instance-automated-backup`.

The following option is used to delete a retained automated backup:

- `--dbi-resource-id` – The resource identifier for the source RDS Custom DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command `describe-db-instance-automated-backups`.

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance-automated-backup \
--dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```powershell
aws rds delete-db-instance-automated-backup ^
--dbi-resource-id custom-db-123ABCEXAMPLE
```
Migrating an on-premises database to Amazon RDS Custom for SQL Server

You can use the following process to migrate an on-premises Microsoft SQL Server database to Amazon RDS Custom for SQL Server using native backup and restore:

1. Take a full backup of the database on the on-premises DB instance.
2. Upload the backup file to Amazon S3.
3. Download the backup file from S3 to your RDS Custom for SQL Server DB instance.
4. Restore a database using the downloaded backup file on the RDS Custom for SQL Server DB instance.

This process explains the migration of a database from on-premises to RDS Custom for SQL Server, using native full backup and restore. To reduce the cutover time during the migration process, you might also consider using differential or log backups.

For general information on native backup and restore for RDS for SQL Server, see Importing and exporting SQL Server databases (p. 962).

Topics
- Prerequisites (p. 800)
- Backing up the on-premises database (p. 800)
- Uploading the backup file to Amazon S3 (p. 801)
- Downloading the backup file from Amazon S3 (p. 801)
- Restoring the backup file to the RDS Custom for SQL Server DB instance (p. 801)

Prerequisites

Perform the following tasks before migrating the database:

1. Configure Remote Desktop Connection (RDP) for your RDS Custom for SQL Server DB instance. For more information, see Connecting to your RDS Custom DB instance using RDP (p. 775).
2. Configure access to Amazon S3 so you can upload and download the database backup file. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1014).

Backing up the on-premises database

You use SQL Server native backup to take a full backup of the database on the on-premises DB instance.

The following example shows a backup of a database called mydatabase, with the COMPRESSION option specified to reduce the backup file size.

To back up the on-premises database

1. Using SQL Server Management Studio (SSMS), connect to the on-premises SQL Server instance.
2. Run the following T-SQL command.

```
backup database mydatabase to
disk = 'C:\Program Files\Microsoft SQL Server\MSSQL13.MSSQLSERVER\MSSQL\Backup\mydb-full-compressed.bak'
```
Uploading the backup file to Amazon S3

You use the AWS Management Console to upload the backup file mydb-full-compressed.bak to Amazon S3.

To upload the backup file to S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. For Buckets, choose the name of the bucket to which you want to upload your backup file.
3. Choose Upload.
4. In the Upload window, do one of the following:
   - Drag and drop mydb-full-compressed.bak to the Upload window.
   - Choose Add file, choose mydb-full-compressed.bak, and then choose Open.

Amazon S3 uploads your backup file as an S3 object. When the upload completes, you can see a success message on the Upload: status page.

Downloading the backup file from Amazon S3

You use the console to download the backup file from S3 to the RDS Custom for SQL Server DB instance.

To download the backup file from S3

1. Using RDP, connect to your RDS Custom for SQL Server DB instance.
2. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the Buckets list, choose the name of the bucket that contains your backup file.
4. Choose the backup file mydb-full-compressed.bak.
5. For Actions, choose Download as.
6. Open the context (right-click) menu for the link provided, then choose Save As.
7. Save mydb-full-compressed.bak to the D:\rdsdbdata\BACKUP directory.

Restoring the backup file to the RDS Custom for SQL Server DB instance

You use SQL Server native restore to restore the backup file to your RDS Custom for SQL Server DB instance.

In this example, the MOVE option is specified because the data and log file directories are different from the on-premises DB instance.

To restore the backup file

1. Using SSMS, connect to your RDS Custom for SQL Server DB instance.
2. Run the following T-SQL command.
restore database mydatabase from disk='D:\rdsdbdata\BACKUP\mydb-full-compressed.bak'
with move 'mydatabase' to 'D:\rdsdbdata\DATA\mydatabase.mdf',
move 'mydatabase_log' to 'D:\rdsdbdata\DATA\mydatabase_log.ldf';
Upgrading a DB instance for Amazon RDS Custom for Oracle

You can upgrade an Amazon RDS Custom DB instance by modifying it to use a new custom engine version (CEV). To do this, make sure that the new CEV already exists.

Only minor version upgrades are supported. For example, you can't upgrade from a version 12.1 CEV to a version 19c CEV.

Read replicas are upgraded after the primary DB instance is upgraded. You don't have to upgrade read replicas manually.

When you upgrade a CEV, data in the bin volume of your DB instance is deleted.

For general information on upgrading DB instances, see Upgrading a DB instance engine version (p. 344).

Topics

- Viewing valid upgrade targets for RDS Custom for Oracle DB instances (p. 803)
- Upgrading an RDS Custom DB instance (p. 804)
- Viewing pending upgrades for RDS Custom DB instances (p. 805)
- Upgrade failure for an RDS Custom DB instance (p. 805)

Viewing valid upgrade targets for RDS Custom for Oracle DB instances

You can see existing CEVs on the Custom engine versions page in the AWS Management Console.

You can also use the describe-db-engine-versions AWS CLI command to find valid upgrades for your DB instances, as shown in the following example. This example assumes that a DB instance was created using the version 19.my_cev1, and that the upgrade versions 19.my_cev2 and 19.my_cev3 exist.

```
aws rds describe-db-engine-versions --engine custom-oracle-ee --engine-version 19.my_cev1
```

The output resembles the following.

```json
{
   "DBEngineVersions": [
       {
           "Engine": "custom-oracle-ee",
           "EngineVersion": "19.my_cev2",
           "Description": "19.my_cev2 description",
           "AutoUpgrade": false,
           "IsMajorVersionUpgrade": false
       },
       {
           "Engine": "custom-oracle-ee",
           "EngineVersion": "19.my_cev3",
           "Description": "19.my_cev3 description",
           "AutoUpgrade": false,
           "IsMajorVersionUpgrade": false
       }
   ]
}
```
Upgrading an RDS Custom DB instance

To upgrade your RDS Custom DB instance, you modify it to use a new CEV. Read replicas managed by RDS Custom are automatically upgraded after the primary DB instance is upgraded.

Console

To upgrade an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the RDS Custom DB instance that you want to modify.
4. For DB engine version, choose the CEV to upgrade to, such as 19.my_cev3.
5. Choose Continue to check the summary of modifications.
   - Choose Apply immediately to apply the changes immediately.
6. If your changes are correct, choose Modify DB instance. Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To upgrade an RDS Custom DB instance, use the modify-db-instance AWS CLI command with the following parameters:

- `--db-instance-identifier` - The DB instance to be upgraded
- `--engine-version` - The new CEV
- `--no-apply-immediately | --apply-immediately` - Whether to perform the upgrade immediately or wait until the scheduled maintenance window

The following example upgrades my-custom-instance to version 19.my_cev3.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \   
  --db-instance-identifier my-custom-instance \   
  --engine-version 19.my_cev3 \   
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier my-custom-instance ^
  --engine-version 19.my_cev3 ^
  --apply-immediately
```
Viewing pending upgrades for RDS Custom DB instances

You can see pending upgrades for your Amazon RDS Custom DB instances by using the `describe-db-instances` or `describe-pending-maintenance-actions` AWS CLI command.

However, this approach doesn't work if you used the `--apply-immediately` option or if the upgrade is in progress.

The following `describe-db-instances` command shows pending upgrades for `my-custom-instance`.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{
    "DBInstances": [ 
        {
            "DBInstanceIdentifier": "my-custom-instance",
            "EngineVersion": "19.my_cev1",
            ...
            "PendingModifiedValues": {
                "EngineVersion": "19.my_cev3"
            }
        }
    ]
}
```

The following shows use of the `describe-pending-maintenance-actions` command.

```
aws rds describe-pending-maintenance-actions
```

The output resembles the following.

```
{
    "PendingMaintenanceActions": [ 
        {
            "PendingMaintenanceActionDetails": [ 
                {
                    "Action": "db-upgrade",
                    "Description": "Upgrade to 19.my_cev3"
                }
            ]
        }
    ]
}
```

Upgrade failure for an RDS Custom DB instance

If an RDS Custom DB instance upgrade fails, an RDS event is generated and the DB instance status becomes `upgrade-failed`.
You can see this status by using the `describe-db-instances` AWS CLI command, as shown in the following example.

```bash
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```json
{
    "DBInstances": [
        {
            "DBInstanceIdentifier": "my-custom-instance",
            "EngineVersion": "19.my_cev1",
            ...
            "PendingModifiedValues": {
                "EngineVersion": "19.my_cev3"
            ...
            }
            "DBInstanceStatus": "upgrade-failed"
        }
    ]
}
```

After an upgrade failure, all database actions are blocked except for modifying the DB instance to perform the following tasks:

- Retrying the same upgrade
- Pausing and resuming RDS Custom automation
- Point-in-time recovery (PITR)
- Deleting the DB instance

**Note**

If automation has been paused for the RDS Custom DB instance, you can't retry the upgrade until you resume automation.

The same actions apply to an upgrade failure for an RDS-managed read replica as for the primary.

For more information, see [Troubleshooting upgrade issues for RDS Custom for Oracle DB instances](p. 818).
Upgrading a DB instance for Amazon RDS Custom for SQL Server

You can upgrade an Amazon RDS Custom for SQL Server DB instance by modifying it to use a new DB engine version, the same as you do for Amazon RDS.

The same limitations for upgrading an RDS Custom for SQL Server DB instance apply as for modifying an RDS Custom for SQL Server DB instance in general. For more information, see Modifying an RDS Custom for SQL Server DB instance (p. 782).

For general information on upgrading DB instances, see Upgrading a DB instance engine version (p. 344).
Troubleshooting RDS Custom DB issues

You can learn how to troubleshoot issues with Amazon RDS Custom DB instances.

**Topics**
- Viewing RDS Custom events (p. 808)
- Subscribing to event notifications (p. 808)
- Troubleshooting custom engine version creation for RDS Custom for Oracle (p. 809)
- RDS Custom support perimeter and unsupported configurations (p. 809)
- Fixing unsupported configurations (p. 810)
- How Amazon RDS Custom replaces an impaired host (p. 816)
- Troubleshooting upgrade issues for RDS Custom for Oracle DB instances (p. 818)

**Viewing RDS Custom events**

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events (p. 622).

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages (p. 624).

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \\
  --source-identifier my-custom-instance \\
  --source-type db-instance
```

**Subscribing to event notifications**

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification (p. 633).

To subscribe to RDS Custom event notification using the CLI, use `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \\
  --subscription-name my-instance-events \\
  --source-type db-instance \\
  --event-categories ['"backup","recovery"]' \\
  --sns-topic-arn arn:aws:sns:us-east-1:123456789012:interesting-events
```
Troubleshooting custom engine version creation for RDS Custom for Oracle

When CEV creation fails, RDS Custom issues RDS-EVENT-0196 with the message Creation failed for custom engine version major-engine-version.cev_name, and includes details about the failure. For example, the event prints missing files.

CEV creation might fail because of the following issues:

- The Amazon S3 bucket containing your installation files isn't in the same AWS Region as your CEV.
- When you request CEV creation in an AWS Region for the first time, RDS Custom creates an S3 bucket for storing RDS Custom resources (such as CEV artifacts, AWS CloudTrail logs, and transaction logs).
- CEV creation fails if RDS Custom can't create the S3 bucket. Either the caller doesn't have S3 permissions as described in Grant required permissions to your IAM user (p. 735), or the number of S3 buckets has reached the limit.
- The caller doesn't have permissions to get files from your S3 bucket that contains the installation media files. These permissions are described in Adding necessary IAM permissions (p. 756).
- Your IAM policy has an aws:SourceIp condition. Make sure to follow the recommendations in AWS Denies access to AWS based on the source IP in the AWS Identity and Access Management User Guide. Also make sure that the caller has the S3 permissions described in Grant required permissions to your IAM user (p. 735).
- Installation media files listed in the CEV manifest aren't in your S3 bucket.
- The SHA-256 checksums of the installation files are unknown to RDS Custom.
- Confirm that the SHA-256 checksums of the provided files match the SHA-256 checksum on the Oracle website. If the checksums match, contact AWS Support and provide the failed CEV name, file name, and checksum.
- The OPatch version is incompatible with the patch files.
- The patches specified in the CEV manifest are in the wrong order.

You can view RDS events either on the RDS console (in the navigation pane, choose Events) or by using the describe-events AWS CLI command. The default duration is 60 minutes. If no events are returned, specify a longer duration, as shown in the following example.

```
aws rds describe-events --duration 360
```

Currently, the MediaImport service that imports files from Amazon S3 to create CEVs isn't integrated with AWS CloudTrail. Therefore, if you turn on data logging for Amazon RDS in CloudTrail, calls to the MediaImport service such as the CreateCustomDbEngineVersion event aren't logged.

However, you might see calls from the API gateway that accesses your Amazon S3 bucket. These calls come from the MediaImport service for the CreateCustomDbEngineVersion event.

RDS Custom support perimeter and unsupported configurations

RDS Custom provides monitoring capability called the support perimeter. The support perimeter ensures that your RDS Custom instance uses a supported AWS infrastructure, operating system, and database.

The support perimeter checks that the requirements listed in Fixing unsupported configurations (p. 810) are met. If any of these requirements aren't met, RDS Custom considers the DB instance to be outside of the support perimeter. RDS Custom then changes the DB instance status.
to unsupported-configuration, and sends event notifications. After you fix the configuration problems, RDS Custom changes the DB instance status to available.

**What happens in the unsupported-configuration state**

While the DB instance is in the unsupported-configuration state, the following is the case:

- You can't modify the DB instance.
- You can't take DB snapshots.
- Automated backups aren't created.
- RDS Custom automation doesn't replace the underlying Amazon EC2 instance if it becomes impaired.

However, the following RDS Custom automation continues to run:

- The RDS Custom agent monitors the DB instance and sends notifications to the support perimeter of further changes.
- The support perimeter continues to run and captures change events for the DB instance. This has two purposes:
  - When you fix the configuration that caused the DB instance to be in the unsupported-configuration state, the support perimeter can return the DB instance to the available state.
  - If you make other unsupported configurations, the support perimeter notifies you about them so that you can correct them.
- Redo logs are still archived and uploaded to Amazon S3 to facilitate point-in-time recovery (PITR). However, be aware of the following:
  - PITR can take a long time to completely restore to a new DB instance. This is because you can't take either automated or manual snapshots while the DB instance is in the unsupported-configuration state.
  - PITR has to replay more redo logs starting from the most recent snapshot taken before the instance entered the unsupported-configuration state.
  - In some cases, the DB instance is in the unsupported-configuration state because of changes you made that impacted redo log upload functionality. In these cases, PITR can't restore the DB instance to the latest restorable time.

**Fixing unsupported configurations**

It's your responsibility to fix configuration issues that put your RDS Custom DB instance into the unsupported-configuration state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

In the following table, you can find descriptions of the notifications that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to change.

<table>
<thead>
<tr>
<th>Notification</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database health: • You need to manually recover the database on EC2 instance [i-xxxxxxxxxxxxxxxxxxxxx]. • The DB instance restarted.</td>
<td>The support perimeter monitors the DB instance state. It also monitors how many restarts occurred during the previous hour and day.</td>
<td>Log in to the host and examine the database state. `ps -eo pid,state,command</td>
</tr>
</tbody>
</table>
### Notification

<table>
<thead>
<tr>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>You're notified when the instance is in a state where it still exists, but you can't interact with it.</td>
<td>Restart the DB instance if necessary to get it running again. Sometimes it's necessary to reboot the host. After the restart, the RDS Custom agent detects that the DB instance is no longer in an unresponsive state. It then notifies the support perimeter to reevaluate the DB instance state.</td>
</tr>
</tbody>
</table>

#### Database archive lag target (RDS Custom for Oracle only):

- The monitored Archive Lag Target database parameter on Amazon EC2 instance [i-xxxxxxxxxxxxxxxx] has changed from [300] to [0].
- The RDS Custom instance is using an unsupported configuration because of the following [1] issue(s): (1) The archive lag target database parameter on Amazon EC2 instance [i-xxxxxxxxxxxxxxxx] is out of desired range {"lowerbound":60,"upperbound":7200}. The support perimeter monitors the `ARCHIVE_LAG_TARGET` database parameter to verify that the DB instance's latest restorable time is within reasonable bounds.

Log in to the host, connect to the DB instance, and change the `ARCHIVE_LAG_TARGET` parameter to a value from 60–7200.

For example, use the following SQL command.

```
alter system set archive_lag_target=300 scope=both;
```

The DB instance becomes available within 30 minutes.

#### Database log mode (RDS Custom for Oracle only):

The monitored log mode of the database on Amazon EC2 instance [i-xxxxxxxxxxxxxxxx] has changed from [ARCHIVELOG] to [NOARCHIVELOG]. The DB instance log mode must be set to `ARCHIVELOG`.

Log in to the host and shut down the DB instance. You can use the following SQL command.

```
shutdown immediate;
```

The RDS Custom agent restarts the DB instance and sets the log mode to `ARCHIVELOG`.

The DB instance becomes available within 30 minutes.
<table>
<thead>
<tr>
<th>Notification</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
</table>
| **RDS Custom agent status (RDS Custom for Oracle):** The monitored state of the RDS Custom agent on EC2 instance [i-xxxxxxxxxxxxxxxxxx] has changed from RUNNING to STOPPED. | The RDS Custom agent must always be running. The agent publishes the IamAlive metric to Amazon CloudWatch every 30 seconds. An alarm is triggered if the metric hasn't been published for 30 seconds. The support perimeter also monitors the RDS Custom agent process state on the host every 30 minutes. On RDS Custom for Oracle, the DB instance goes outside the support perimeter if the RDS Custom agent stops. | Log in to the host and make sure that the RDS Custom agent is running. You can use the following commands to find the agent's status. 

```
ps -ef | grep RDSCustomAgent
pgrep java
```

When the RDS Custom agent is running again, the IamAlive metric is published to Amazon CloudWatch, and the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running. |
| **RDS Custom agent status (RDS Custom for SQL Server):** The RDS Custom instance is going out of perimeter because an unsupported configuration was used for RDS Custom agent. | The RDS Custom agent must always be running. The support perimeter monitors the RDS Custom agent process state on the host every 1 minute. On RDS Custom for SQL Server, a stopped agent is recovered by the monitoring service. The DB instance goes outside the support perimeter if the RDS Custom agent stops. | Log in to the host and make sure that the RDS Custom agent is running. You can use the following commands to find the agent's status. 

```
$name = "RDSCustomAgent"
$service = Get-Service $name
Write-Host $service.Status
```

If the status isn't Running, you can start the service with the following command: 

```
Start-Service $name
```
<p>|
| <strong>AWS Systems Manager agent (SSM agent) status (RDS Custom for Oracle):</strong> The AWS Systems Manager agent on EC2 instance [i-xxxxxxxxxxxxxxxxxx] is currently unreachable. Make sure you have correctly configured the network, agent, and IAM permissions. | The SSM agent must always be running. The RDS Custom agent is responsible for making sure that the Systems Manager agent is running. If the SSM agent was down and restarted, the RDS Custom agent publishes a metric to CloudWatch. The RDS Custom agent has an alarm on the metric set to trigger when there has been a restart in each of the previous three minutes. The support perimeter also monitors the SSM agent process state on the host every 30 minutes. | For more information, see Troubleshooting SSM Agent. When the SSM agent is running again, the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running. |</p>
<table>

## How Amazon RDS Custom replaces an impaired host

If the Amazon EC2 host becomes impaired, RDS Custom attempts to reboot it. If this effort fails, RDS Custom uses the same stop and start feature included in Amazon EC2.

### Topics
- Stopping and starting the host (p. 817)
- Effects of host replacement (p. 817)
- Best practices for Amazon EC2 hosts (p. 817)

### Notification | Description | Action
--- | --- | ---
Shared memory connections (RDS Custom for SQL Server only): The RDS Custom instance is going out of perimeter because an unsupported configuration was used for shared memory protocol. The RDS Custom agent on the EC2 host connects to SQL Server using the shared memory protocol. If this protocol is turned off (Enabled is set to No), then RDS Custom can't perform its management actions and places the DB instance outside the support perimeter. To bring the RDS Custom for SQL Server DB instance back within the support perimeter, turn on the shared memory protocol on the Protocol page of the Shared Memory Properties window by setting Enabled to Yes.

Restart SQL Server after enabling the protocol.

Database file locations (RDS Custom for SQL Server only):
The RDS Custom instance is going out of perimeter because an unsupported configuration was used for database files location. All SQL Server database files are stored on the D: drive by default, in the D:\rdsadbdata\DATA directory. If you create or alter the database file location to be anywhere other than the D: drive, then RDS Custom places the DB instance outside the support perimeter. We strongly recommend that you don't save any database files on the C: drive. You can lose data on the C: drive during certain operations, such as hardware failure. Storage on the C: drive doesn't offer the same durability as on the D: drive, which is an EBS volume.

Also, if database files can't be found, RDS Custom places the DB instance outside the support perimeter. Store all RDS Custom for SQL Server database files on the D: drive.
Stopping and starting the host

RDS Custom automatically takes the following steps, with no user intervention required:

1. Stops the Amazon EC2 host.

   The EC2 instance performs a normal shutdown and stops running. Any Amazon EBS volumes remain attached to the instance, and their data persists. Any data stored in the instance store volumes (not supported on RDS Custom) or RAM of the host computer is gone.

   For more information, see Stop and start your instance in the Amazon EC2 User Guide for Linux Instances.

2. Starts the Amazon EC2 host.

   The EC2 instance migrates to a new underlying host hardware. In some cases, the RDS Custom DB instance remains on the original host.

Effects of host replacement

In RDS Custom, you have full control over the root device volume and Amazon EBS storage volumes. The root volume can contain important data and configurations that you don't want to lose.

RDS Custom for Oracle retains all database and customer data after the operation, including root volume data. No user intervention is required. On RDS Custom for SQL Server, database data is retained, but any data on the C: drive, including operating system and customer data, is lost.

After the replacement process, the Amazon EC2 host has a new public IP address. The host retains the following:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- Instance metadata
- Data storage volume data
- Root volume data (on RDS Custom for Oracle)

Best practices for Amazon EC2 hosts

The Amazon EC2 host replacement feature covers the majority of Amazon EC2 impairment scenarios. We recommend that you adhere to the following best practices:

- Before you change your configuration or the operating system, back up your data. If the root volume or operating system becomes corrupt, host replacement can't repair it. Your only options are restoring from a DB snapshot or point-in-time recovery.
- Don't manually stop or terminate the physical Amazon EC2 host. Both actions result in the instance being put outside the RDS Custom support perimeter.
- (RDS Custom for SQL Server) If you attach additional volumes to the Amazon EC2 host, configure them to remount upon restart. If the host is impaired, RDS Custom might stop and start the host automatically.
Troubleshooting RDS Custom for Oracle DB instances

The shared responsibility model of RDS Custom provides OS shell-level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. Therefore, you might have to intervene if certain events occur, such as upgrade failure.

Following, you can find some important techniques, files, and commands that you can use during upgrades of RDS Custom DB for Oracle DB instances:

- Examine the following log files:
  - All upgrade output log files are kept in the /tmp directory on the DB instance.
  - These log files are named catupg*.log.
  - A master output file named /tmp/catupgrd0.log reports all errors, and the steps performed.
  - The alert.log file for the DB instance is located in the /rdsdbdata/log/trace directory. Examine this file regularly as a best practice.
  - Run the following grep command in the root directory to track the upgrade OS process. This command shows where the log files are being written and determine the state of the upgrade process.

```
ps -aux | grep upg
```

The output resembles the following.

```
root  18884  0.0  0.0 235428  8172 ?        S<   17:03   0:00 /usr/bin/sudo -u rdsdb /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb 18886  0.0  0.0 153968 12164 ?        S<   17:03   0:00 /usr/bin/perl -T -w /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb 18887  0.0  0.0 113196  3032 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb 18900  0.0  0.0 113196  1812 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb 18901  0.1  0.0 167652 20620 ?        S<   17:03   0:07 /rdsdbbin/oracle/perl/bin/perl catctl.pl -n 4 -d /rdsdbbin/oracle/rdbms/admin -l /tmp catupgrd.sql
root  29944  0.0  0.0 112724  2316 pts/0    S+   18:43   0:00 grep --color=auto upg
```

- Run the following SQL query to verify the current state of the components to find the database version and the options installed on the DB instance.

```
set linesize 180
column comp_id format a15
column comp_name format a40 trunc
column status format a15 trunc
select comp_id, comp_name, version, status from dba_registry order by 1;
```

The output resembles the following.

```
<table>
<thead>
<tr>
<th>COMP_NAME</th>
<th>STATUS</th>
<th>PROCEDURE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database Catalog Views</td>
<td>VALID</td>
<td></td>
</tr>
<tr>
<td>DBMS_REGISTRY_SYS.VALIDATE_CATALOG</td>
<td>VALID</td>
<td></td>
</tr>
<tr>
<td>Oracle Database Packages and Types</td>
<td>VALID</td>
<td></td>
</tr>
<tr>
<td>DBMS_REGISTRY_SYS.VALIDATE_CATPROC</td>

</tr>
<tr>
<td>Oracle Text</td>
<td>VALID</td>
<td>DBMS_REGXDB.VALIDATEXDB</td>
</tr>
<tr>
<td>Oracle XML Database</td>
<td>VALID</td>
<td></td>
</tr>
</tbody>
</table>
```

818
• Run the following SQL query to check for invalid objects that might interfere with the upgrade process.

```sql
set pages 1000 lines 2000
col OBJECT for a40
Select substr(owner,1,12) owner,
    substr(object_name,1,30) object,
    substr(object_type,1,30) type,
    status,
    created
from
    dba_objects where status <> 'VALID' and owner in ('SYS','SYSTEM','RDSADMIN','XDB');
```
Working with Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information about AWS Outposts, see AWS Outposts.

You use the same AWS Management Console, AWS CLI, and RDS API to provision and manage on-premises RDS on Outposts DB instances as you do for RDS DB instances running in the AWS Cloud. RDS on Outposts automates tasks, such as database provisioning, operating system and database patching, backup, and long-term archival in Amazon S3.

RDS on Outposts supports automated backups of DB instances. Network connectivity between your Outpost and your AWS Region is required to back up and restore DB instances. DB snapshots and transaction logs from an Outpost can be stored in your AWS Region or on your Outpost if you have Amazon S3 on Outposts configured. From your AWS Region, you can restore a DB instance from a DB snapshot to a different Outpost. For more information, see Working with backups (p. 407).

RDS on Outposts supports automated maintenance and upgrades of DB instances. For more information, see Maintaining a DB instance (p. 333).

RDS on Outposts uses encryption at rest for DB instances and DB snapshots using your AWS KMS key. For more information about encryption at rest, see Encrypting Amazon RDS resources (p. 1750).

By default, EC2 instances in Outposts subnets can use the Amazon Route 53 DNS Service to resolve domain names to IP addresses. You might encounter longer DNS resolution times with Route 53, depending on the path latency between your Outpost and the AWS Region. In such cases, you can use the DNS servers installed locally in your on-premises environment. For more information, see DNS in the AWS Outposts User Guide.

When network connectivity to the AWS Region isn't available, your DB instance continues to run locally. You can continue to access DB instances using DNS name resolution by configuring a local DNS server as a secondary server. However, you can't create new DB instances or take new actions on existing DB instances. Automatic backups don't occur when there is no connectivity. If there is a DB instance failure, the DB instance isn't automatically replaced until connectivity is restored. We recommend restoring network connectivity as soon as possible.

Topics
- Prerequisites for Amazon RDS on AWS Outposts (p. 820)
- Amazon RDS on AWS Outposts support for Amazon RDS features (p. 822)
- Supported DB instance classes for Amazon RDS on AWS Outposts (p. 825)
- Customer-owned IP addresses for RDS on Outposts (p. 827)
- Creating DB instances for Amazon RDS on AWS Outposts (p. 829)
- Considerations for restoring DB instances (p. 835)

Prerequisites for Amazon RDS on AWS Outposts

The following are prerequisites for using Amazon RDS on AWS Outposts:
• Install AWS Outposts in your on-premises data center. For more information about AWS Outposts, see AWS Outposts.
• Make sure that you have at least one subnet available for RDS on Outposts. You can use the same subnet for other workloads.
• Make sure that you have a reliable network connection between your Outpost and an AWS Region.
Amazon RDS on AWS Outposts support for Amazon RDS features

The following table describes the Amazon RDS features supported by Amazon RDS on AWS Outposts.

<table>

**Note**
RDS on Outposts doesn't support use cases that require all data to remain in your data center.

### Supported DB instance classes for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts supports the following DB instance classes:

- General purpose DB instance classes
  - db.m5.24xlarge
  - db.m5.12xlarge
  - db.m5.4xlarge
  - db.m5.2xlarge
  - db.m5.xlarge
  - db.m5.large
- Memory optimized DB instance classes
  - db.r5.24xlarge
  - db.r5.12xlarge
• **db.r5.4xlarge**
• **db.r5.2xlarge**
• **db.r5.xlarge**
• **db.r5.large**

Only general purpose SSD storage is supported for RDS on Outposts DB instances. For more information about DB instance classes, see [DB instance classes (p. 9)](#).

Amazon RDS manages maintenance and recovery for your DB instances and requires active capacity on the Outpost to do so. We recommend that you configure N+1 EC2 instances for each DB instance class in your production environments. RDS on Outposts can use the extra capacity of these EC2 instances for maintenance and repair operations. For example, if your production environments have 3 db.m5.large and 5 db.r5.xlarge DB instance classes, then we recommend that they have at least 4 m5.large EC2 instances and 6 r5.xlarge EC2 instances. For more information, see [Resilience in AWS Outposts](#) in the *AWS Outposts User Guide*. 
Customer-owned IP addresses for RDS on Outposts

AWS Outposts uses information that you provide about your on-premises network to create an address pool, known as a customer-owned IP address pool (CoIP pool). Customer-owned IP addresses (CoIPs) provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information about CoIPs, see Customer-owned IP addresses in the AWS Outposts User Guide.

Each RDS on Outposts DB instance has a private IP address for traffic inside its virtual private cloud (VPC). This private IP address isn't publicly accessible. You can use the Public option to designate whether the DB instance also has a public IP address in addition to the private IP address. Using the public IP address for connections routes them through the internet and can result in high latencies in some cases.

Instead of using these private and public IP addresses, RDS on Outposts supports enabling a CoIP for DB instances through their subnets. When you enable a CoIP for an RDS on Outposts DB instance, you connect to the DB instance with the DB instance endpoint. RDS on Outposts automatically uses the CoIP for all connections from both inside and outside of the VPC.

CoIPs can provide the following benefits for RDS on Outposts DB instances:

- Lower connection latency
- Enhanced security

You can enable or disable a CoIP for an RDS on Outposts DB instance using the AWS Management Console, the AWS CLI, or the RDS API:

- With the AWS Management Console, use the Customer-owned IP address (CoIP) setting in Access type to enable a CoIP. Use one of the other settings to disable it.

  ▼ Additional configuration

  Access type Info

  ○ Private
  
  RDS will not assign a public IP address to the database. Amazon EC2 instances and devices inside the VPC can connect to your database. EC2 instances and devices outside your VPC can't connect unless they use AWS Site-to-Site VPN or AWS Direct Connect.

  ○ Customer-owned IP address (CoIP)
  
  Devices on your on-premises network can connect to your database through a CoIP.

  ○ Public
  
  Amazon EC2 instances and devices outside the VPC can connect to your database. Choose one or more VPC security groups that specify which EC2 instances and devices can connect to the database.

  Database port
  
  TCP/IP port that the database will use for application connections.

  3306

- With the AWS CLI, use the --enable-customer-owned-ip | --no-enable-customer-owned-ip option.
Customer-owned IP addresses

- With the RDS API, use the `EnableCustomerOwnedIp` parameter.

You can enable or disable a CoIP when you perform any of the following actions:

- Create a DB instance
  
  For more information, see Creating DB instances for Amazon RDS on AWS Outposts (p. 829).

- Modify a DB instance
  
  For more information, see Modifying an Amazon RDS DB instance (p. 309).

- Restore a DB instance from a snapshot
  
  For more information, see Restoring from a DB snapshot (p. 432).

- Restore a DB instance to a specified time
  
  For more information, see Restoring a DB instance to a specified time (p. 480).

**Note**

If you enable a CoIP for a DB instance, but Amazon RDS is unable to allocate a CoIP for the DB instance, the DB instance status is changed to `incompatible-network`. For more information about the DB instance status, see Viewing Amazon RDS DB instance status (p. 497).

The following limitations apply to CoIP support for RDS on Outposts DB instances:

- When a CoIP is enabled for a DB instance, make sure that public accessibility is disabled for the DB instance.

- You can’t assign a CoIP from a CoIP pool to a DB instance. When you enable a CoIP for a DB instance, Amazon RDS automatically assigns a CoIP from a CoIP pool to the DB instance.

- You must use the AWS account that owns the Outpost resources (owner) or share the following resources with other AWS accounts (consumers) in the same organization.
  
  - The Outpost
  - The local gateway (LGW) route table for the DB instance's VPC
  - The CoIP pool or pools for the LGW route table

  For more information, see Working with shared AWS Outposts resources in the AWS Outposts User Guide.
Creating DB instances for Amazon RDS on AWS Outposts

Creating an Amazon RDS on AWS Outposts DB instance is similar to creating an Amazon RDS DB instance in the AWS Cloud. However, make sure that you specify a DB subnet group that is associated with your Outpost.

A virtual private cloud (VPC) based on the Amazon VPC service can span all of the Availability Zones in an AWS Region. You can extend any VPC in the AWS Region to your Outpost by adding an Outpost subnet. To add an Outpost subnet to a VPC, specify the Amazon Resource Name (ARN) of the Outpost when you create the subnet.

Before you create an RDS on Outposts DB instance, you can create a DB subnet group that includes one subnet that is associated with your Outpost. When you create an RDS on Outposts DB instance, specify this DB subnet group. You can also choose to create a new DB subnet group when you create your DB instance.

For information about configuring AWS Outposts, see the AWS Outposts User Guide.

Console

Creating a DB subnet group

Create a DB subnet group with one subnet that is associated with your Outpost.

You can also create a new DB subnet group for the Outpost when you create your DB instance. If you want to do so, then skip this procedure.

Note
To create a DB subnet group for the AWS Cloud, specify at least two subnets. However, for an Outpost DB subnet group, specify only one subnet.

To create a DB subnet group for your Outpost

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB subnet group.
3. Choose Subnet groups, and then choose Create DB Subnet Group.

The Create DB subnet group page appears.
4. For **Name**, choose the name of the DB subnet group.
5. For **Description**, choose a description for the DB subnet group.
6. For **VPC**, choose the VPC that you're creating the DB subnet group for.
7. For **Availability Zones**, choose the Availability Zone for your Outpost.
8. For **Subnets**, choose the subnet for use by RDS on Outposts.

   Your DB subnet group can have only one subnet.

9. Choose **Create** to create the DB subnet group.

**Creating the RDS on Outposts DB instance**

Create the DB instance, and choose the Outpost for your DB instance.
To create an RDS on Outposts DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.
3. In the navigation pane, choose Databases.
4. Choose Create database.

The AWS Management Console detects available Outposts that you have configured and presents the On-premises option in the Database location section.

**Note**
If you haven't configured any Outposts, either the Database location section doesn't appear or the RDS on Outposts option isn't available in the Choose an on-premises creation method section.

5. For Database location, choose On-premises.
6. For On-premises creation method, choose RDS on Outposts.
7. Specify your settings for Outposts Connectivity. These settings are for the Outpost that uses the VPC that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.
   a. For Virtual Private Cloud (VPC), choose the VPC that contains the DB subnet group for your DB instance.
   b. For VPC security group, choose the Amazon VPC security group for your DB instance.
   c. For Subnet group, choose the DB subnet group for your DB instance.

   You can choose an existing DB subnet group that is associated with the Outpost—for example, if you performed the procedure in Creating a DB subnet group (p. 829).

   You can also create a new DB subnet group for the Outpost. Only one subnet is allowed in this DB subnet group.

8. Under Backup, do the following:
   a. For Backup target, choose one of the following:
      • AWS Cloud to store automated backups and manual snapshots in the parent AWS Region.
      • Outposts (on-premises) to create local backups.
        **Note**
        To store backups on your Outpost, make sure that you have Amazon S3 on Outposts configured. For more information, see Amazon S3 on Outposts.
   b. Choose Enable automated backups to create point-in-time snapshots of your DB instance.

      If you enable automated backups, then you can choose the Backup retention period and Backup window, or leave the default values.

9. Specify other DB instance settings as needed.

   For information about each setting when creating a DB instance, see Settings for DB instances (p. 178).

10. Choose Create database.

    The Databases page appears. A banner tells you that your DB instance is being created, and displays the View credential details button.
Viewing DB instance details

After you create your DB instance, you can view credentials and other details for it.

**To view DB instance details**

1. To view the master user name and password for the DB instance, choose View credential details on the Databases page.

You can connect to the DB instance as the master user by using these credentials.

**Important**
You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the DB instance is available, modify the DB instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

2. Choose the name of the new DB instance on the Databases page.

On the RDS console, the details for the new DB instance appear. The DB instance has a status of Creating until the DB instance is created and ready for use. When the state changes to Available, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new DB instance to be available.

After the DB instance is available, you can manage it the same way that you manage RDS DB instances in the AWS Cloud.

### AWS CLI

Before you create a new DB instance in an Outpost with the AWS CLI, first create a DB subnet group for use by RDS on Outposts.

**To create a DB subnet group for your Outpost**

- Use the `create-db-subnet-group` command. For `--subnet-ids`, specify the subnet group in the Outpost for use by RDS on Outposts.
For Linux, macOS, or Unix:

```
aws rds create-db-subnet-group \
    --db-subnet-group-name myoutpostdbsubnetgr \
    --db-subnet-group-description "DB subnet group for RDS on Outposts" \
    --subnet-ids subnet-abc123
```

For Windows:

```
aws rds create-db-subnet-group ^
    --db-subnet-group-name myoutpostdbsubnetgr ^
    --db-subnet-group-description "DB subnet group for RDS on Outposts" ^
    --subnet-ids subnet-abc123
```

To create an RDS on Outposts DB instance using the AWS CLI

- Use the `create-db-instance` command. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost. You can include the following options:

  - `--db-instance-identifier`
  - `--db-instance-class`
  - `--engine` – The database engine. Use one of the following values:
    - MySQL – Specify `mysql`.
    - PostgreSQL – Specify `postgres`.
    - Microsoft SQL Server – Specify `sqlserver-ee`, `sqlserver-se`, `sqlserver-ex`, or `sqlserver-web`.
  - `--availability-zone`
  - `--vpc-security-group-ids`
  - `--db-subnet-group-name`
  - `--allocated-storage`
  - `--master-username`
  - `--master-user-password`
  - `--backup-retention-period` (Optional) Where to store automated backups and manual snapshots. Use one of the following values:
    - `outposts` – Store them locally on your Outpost.
    - `region` – Store them in the parent AWS Region. This is the default value.
  - `--storage-encrypted`
  - `--kms-key-id`

**Example**

The following example creates a MySQL DB instance named `myoutpostdbinstance` with backups stored on your Outpost.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myoutpostdbinstance \
    --engine-version 8.0.17 \
```
For Windows:

```
aws rds create-db-instance 
    --db-instance-identifier myoutpostdbinstance 
    --engine-version 8.0.17 
    --db-instance-class db.m5.large 
    --engine mysql 
    --availability-zone us-east-1d 
    --vpc-security-group-ids outpost-sg 
    --db-subnet-group-name myoutpostdbsubnetgr 
    --allocated-storage 100 
    --master-username masterawsuser 
    --master-user-password masteruserpassword 
    --backup-retention-period 3 
    --backup-target outposts 
    --storage-encrypted 
    --kms-key-id mykey
```

For information about each setting when creating a DB instance, see Settings for DB instances (p. 178).

### RDS API

To create a new DB instance in an Outpost with the RDS API, first create a DB subnet group for use by RDS on Outposts by calling the `CreateDBSubnetGroup` operation. For `SubnetIds`, specify the subnet group in the Outpost for use by RDS on Outposts.

Next, call the `CreateDBInstance` operation with the parameters following. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost.

- `AllocatedStorage`
- `AvailabilityZone`
- `BackupRetentionPeriod`
- `BackupTarget`
- `DBInstanceClass`
- `DBInstanceIdentifier`
- `VpcSecurityGroupIds`
- `DBSubnetGroupName`
- `Engine`
- `EngineVersion`
- `MasterUsername`
- `MasterUserPassword`
- `StorageEncrypted`
Considerations for restoring DB instances

When you restore a DB instance in Amazon RDS on AWS Outposts, you can choose the storage location for automated backups and manual snapshots of the restored DB instance.

Restoring from a manual DB snapshot, you can store backups either in the parent AWS Region or locally on your Outpost.

Restoring from an automated backup (point-in-time recovery), you have fewer choices:

- If restoring from the parent AWS Region, you can store backups either in the AWS Region or on your Outpost.
- If restoring from your Outpost, you can store backups only on your Outpost.
MariaDB on Amazon RDS

Amazon RDS supports DB instances running several versions of MariaDB. You can use the following major versions:

- MariaDB 10.6
- MariaDB 10.5
- MariaDB 10.4
- MariaDB 10.3
- MariaDB 10.2

For more information about minor version support, see MariaDB on Amazon RDS versions (p. 838).

You first use the Amazon RDS management tools or interfaces to create a MariaDB DB instance. You can then use the Amazon RDS tools to perform management actions for the DB instance, such as reconfiguring or resizing the DB instance, authorizing connections to the DB instance, creating and restoring from backups or snapshots, creating Multi-AZ secondaries, creating read replicas, and monitoring the performance of the DB instance. You use standard MariaDB utilities and applications to store and access the data in the DB instance.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see Regions, Availability Zones, and Local Zones (p. 60).

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance. AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see Setting up for Amazon RDS (p. 93).

Common management tasks for MariaDB on Amazon RDS

The following are the common management tasks you perform with an Amazon RDS DB instance running MariaDB, with links to relevant documentation for each task.

<table>
<thead>
<tr>
<th>Task area</th>
<th>Relevant documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Instance Classes, Storage, and PIOPS</strong></td>
<td></td>
</tr>
</tbody>
</table>
| If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS. | DB instance classes (p. 9)  
Amazon RDS storage types (p. 53) |
| **Multi-AZ Deployments**         | Multi-AZ deployments for high availability (p. 65)         |
| Provide high availability with synchronous standby replication in a different Availability Zone, automatic failover, fault tolerance for DB instances using Multi-AZ deployments, and read replicas. |
## Task area

<table>
<thead>
<tr>
<th>Task area</th>
<th>Relevant documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Amazon Virtual Private Cloud (VPC)</strong></td>
<td>If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. If your account does not have a default VPC, and you want the DB instance in a VPC, you must create the VPC and subnet groups before you create the DB instance.</td>
</tr>
<tr>
<td><strong>Security Groups</strong></td>
<td>By default, DB instances are created with a firewall that prevents access to them. You therefore must create a security group with the correct IP addresses and network configuration to access the DB instance. The security group you create depends on what Amazon EC2 platform your DB instance is on, and whether you access your DB instance from an Amazon EC2 instance. In general, if your DB instance is on the EC2-Classic platform, you will need to create a DB security group; if your DB instance is on the EC2-VPC platform, you will need to create a VPC security group.</td>
</tr>
<tr>
<td><strong>Parameter Groups</strong></td>
<td>If your DB instance is going to require specific database parameters, you should create a parameter group before you create the DB instance.</td>
</tr>
<tr>
<td><strong>Importing and Exporting Data</strong></td>
<td>Establish procedures for importing or exporting data.</td>
</tr>
<tr>
<td><strong>Replication</strong></td>
<td>You can offload read traffic from your source MariaDB DB instance by creating read replicas.</td>
</tr>
<tr>
<td><strong>Connecting to Your DB Instance</strong></td>
<td>Connect to your DB instance using a standard SQL client application.</td>
</tr>
<tr>
<td><strong>Backup and Restore</strong></td>
<td>When you create your DB instance, you can configure it to take automated backups. You can also back up and restore your databases manually by using full backup files (.bak files).</td>
</tr>
<tr>
<td><strong>Monitoring</strong></td>
<td>Monitor your MariaDB DB instance by using Amazon CloudWatch RDS metrics, events, and Enhanced Monitoring. View log files for your MariaDB DB instance.</td>
</tr>
<tr>
<td><strong>Log Files</strong></td>
<td>You can access the log files for your MariaDB DB instance.</td>
</tr>
</tbody>
</table>
There are also advanced administrative tasks for working with DB instances running MariaDB. For more information, see the following documentation:

- Parameters for MariaDB (p. 910)
- MariaDB on Amazon RDS SQL reference (p. 916)

## MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.4 to 10.5. A version change is considered minor if only the minor version number changes, for example going from version 10.3.20 to 10.3.23.

Amazon RDS currently supports the following versions of MariaDB:

<table>
<thead>
<tr>
<th>Major version</th>
<th>Minor version</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB 10.6</td>
<td>10.6.7</td>
</tr>
<tr>
<td></td>
<td>10.6.5</td>
</tr>
<tr>
<td>MariaDB 10.5</td>
<td>10.5.15</td>
</tr>
<tr>
<td></td>
<td>10.5.13</td>
</tr>
<tr>
<td></td>
<td>10.5.12</td>
</tr>
<tr>
<td></td>
<td>10.5.9</td>
</tr>
<tr>
<td></td>
<td>10.5.8</td>
</tr>
<tr>
<td>MariaDB 10.4</td>
<td>10.4.24</td>
</tr>
<tr>
<td></td>
<td>10.4.22</td>
</tr>
<tr>
<td></td>
<td>10.4.21</td>
</tr>
<tr>
<td></td>
<td>10.4.18</td>
</tr>
<tr>
<td></td>
<td>10.4.13</td>
</tr>
<tr>
<td>MariaDB 10.3</td>
<td>10.3.34</td>
</tr>
<tr>
<td></td>
<td>10.3.32</td>
</tr>
<tr>
<td></td>
<td>10.3.31</td>
</tr>
<tr>
<td></td>
<td>10.3.28</td>
</tr>
<tr>
<td></td>
<td>10.3.23</td>
</tr>
<tr>
<td></td>
<td>10.3.20</td>
</tr>
<tr>
<td></td>
<td>10.3.13</td>
</tr>
<tr>
<td></td>
<td>10.3.8</td>
</tr>
<tr>
<td>MariaDB 10.2</td>
<td>10.2.43</td>
</tr>
<tr>
<td></td>
<td>10.2.41</td>
</tr>
<tr>
<td></td>
<td>10.2.40</td>
</tr>
<tr>
<td></td>
<td>10.2.39</td>
</tr>
<tr>
<td></td>
<td>10.2.37</td>
</tr>
<tr>
<td></td>
<td>10.2.32</td>
</tr>
<tr>
<td></td>
<td>10.2.21</td>
</tr>
<tr>
<td></td>
<td>10.2.15</td>
</tr>
</tbody>
</table>
You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```bash
```

Replace `major-engine-version` with the major engine version, and replace `region` with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.5 major version and the US West (Oregon) AWS Region (us-west-2):

```bash
```

### MariaDB feature support on Amazon RDS

In the following sections, find MariaDB feature support on Amazon RDS for MariaDB major versions:

**Topics**
- MariaDB 10.6 support on Amazon RDS (p. 839)
- MariaDB 10.5 support on Amazon RDS (p. 840)
- MariaDB 10.4 support on Amazon RDS (p. 841)
- MariaDB 10.3 support on Amazon RDS (p. 841)
- MariaDB 10.2 support on Amazon RDS (p. 842)

For information about supported minor versions of Amazon RDS for MariaDB, see MariaDB on Amazon RDS versions (p. 838).

### MariaDB 10.6 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.6 or later:

- **MyRocks storage engine** – You can use the MyRocks storage engine with RDS for MariaDB to optimize storage consumption of your write-intensive, high-performance web applications. For more information, see Supported storage engines for MariaDB on Amazon RDS (p. 843) and MyRocks.
- **IAM DB authentication** – You can use IAM DB authentication for better security and central management of connections to your MariaDB DB instances. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).
• **Upgrade options** – You can now upgrade to RDS for MariaDB version 10.6 from any prior major release (10.2, 10.3, 10.4, 10.5). You can also take a snapshot of an existing MySQL 5.6 or 5.7 DB instance and restore the snapshot to a MariaDB 10.6 instance. For more information, see Upgrading the MariaDB DB engine (p. 861).

• **Delayed replication** – You can now set a configurable time period for which a read replica lags behind the source database. In a standard MariaDB replication configuration, there is minimal replication delay between the source and the replica. With delayed replication, you can set an intentional delay as a strategy for disaster recovery. For more information, see Configuring delayed replication with MariaDB (p. 893).

• **Oracle PL/SQL compatibility** – By using RDS for MariaDB version 10.6, you can more easily migrate your legacy Oracle applications to Amazon RDS. For more information, see SQL_MODE=ORACLE.

• **Atomic DDL** – Your dynamic data language (DDL) statements can be relatively crash-safe with RDS for MariaDB version 10.6. CREATE TABLE, ALTER TABLE, RENAME TABLE, DROP TABLE, DROP DATABASE and related DDL statements are now atomic. Either the statement succeeds, or it's completely reversed. For more information, see Atomic DDL.

• **Other enhancements** – These enhancements include a JSON_TABLE function for transforming JSON data to relational format within SQL, and faster empty table data load with InnoDB. They also include new sys_schema for analysis and troubleshooting, optimizer enhancement for ignoring unused indexes, and performance improvements. For more information, see JSON_TABLE.

• **New default values for parameters** – The following parameters have new default values for MariaDB version 10.6 DB instances:

  - The default value for the following parameters has changed from utf8 to utf8mb3:
    - character_set_client
    - character_set_connection
    - character_set_results
    - character_set_system

  Although the default values have changed for these parameters, there is no functional change. For more information, see Supported Character Sets and Collations.

  - The default value of the collation_connection parameter has changed from utf8_general_ci to utf8mb4_general_ci. Although the default value has changed for this parameter, there is no functional change.

  - The default value of the old_mode parameter has changed from unset to UTF8_IS_UTF8MB3. Although the default value has changed for this parameter, there is no functional change.

For a list of all MariaDB 10.6 features and their documentation, see Changes and improvements in MariaDB 10.6 and Release notes - MariaDB 10.6 series on the MariaDB website.

For a list of unsupported features, see Features not supported (p. 842).

### MariaDB 10.5 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

• **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see InnoDB: Performance Improvements etc..

• **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables.

• **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the innodb_log_files_in_group parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.
If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the `innodb_log_file_size` parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the `innodb_log_file_size` parameter. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 282).

- **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, the equivalent `SHOW REPLICA STATUS` command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

  Instead of using the `SHOW REPLICA STATUS` command, run the new `mysql.rds_replica_status` stored procedure to return similar information. For more information, see `mysql.rds_replica_status` (p. 916).

- **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the `SHOW RELAYLOG EVENTS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, this command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:
  - The default value of the `max_connections` parameter has changed to `LEAST({DBInstanceClassMemory/25165760},12000)`. For information about the `LEAST` parameter function, see DB parameter functions (p. 300).
  - The default value of the `innodb_adaptive_hash_index` parameter has changed to `OFF (0)`. The default value of the `innodb_checksum_algorithm` parameter has changed to `full_crc32`
  - The default value of the `innodb_log_file_size` parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see Changes and improvements in MariaDB 10.5 and Release notes - MariaDB 10.5 series on the MariaDB website.

For a list of unsupported features, see Features not supported (p. 842).

**MariaDB 10.4 support on Amazon RDS**

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

- **User account security enhancements** – Password expiration and account locking improvements
- **Optimizer enhancements** – Optimizer trace feature
- **InnoDB enhancements** – Instant DROP COLUMN support and instant VARCHAR extension for `ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPACT`
- **New parameters** – Including `tcp_nodedelay`, `tls_version`, and `gtid_cleanup_batch_size`

For a list of all MariaDB 10.4 features and their documentation, see Changes and improvements in MariaDB 10.4 and Release notes - MariaDB 10.4 series on the MariaDB website.

For a list of unsupported features, see Features not supported (p. 842).

**MariaDB 10.3 support on Amazon RDS**

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.3 or later:
• **Oracle compatibility** – PL/SQL compatibility parser, sequences, INTERSECT and EXCEPT to complement UNION, new TYPE OF and ROW TYPE OF declarations, and invisible columns

• **Temporal data processing** – System versioned tables for querying of past and present states of the database

• **Flexibility** – User-defined aggregates, storage-independent column compression, and proxy protocol support to relay the client IP address to the server

• **Manageability** – Instant ADD COLUMN operations and fast-fail data definition language (DDL) operations

For a list of all MariaDB 10.3 features and their documentation, see Changes & improvements in MariaDB 10.3 and Release notes - MariaDB 10.3 series on the MariaDB website.

For a list of unsupported features, see Features not supported (p. 842).

### MariaDB 10.2 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.2 or later:

• ALTER USER

• Common Table Expressions

• Compressing Events to Reduce Size of the Binary Log

• CREATE USER — new options for limiting resource usage and TLS/SSL

• EXECUTE IMMEDIATE

• Flashback

• InnoDB — now the default storage engine instead of XtraDB

• InnoDB — set the buffer pool size dynamically

• JSON Functions

• Window Functions

• WITH

For a list of all MariaDB 10.2 features and their documentation, see Changes & improvements in MariaDB 10.2 and Release notes - MariaDB 10.2 series on the MariaDB website.

For a list of unsupported features, see Features not supported (p. 842).

### Features not supported

The following MariaDB features are not supported on Amazon RDS:

• S3 storage engine

• Authentication plugin – GSSAPI

• Authentication plugin – Unix Socket

• AWS Key Management encryption plugin

• Delayed replication for MariaDB versions lower than 10.6

• Native MariaDB encryption at rest for InnoDB and Aria.

You can enable encryption at rest for a MariaDB DB instance by following the instructions in Encrypting Amazon RDS resources (p. 1750).
• HandlerSocket
• JSON table type for MariaDB versions lower than 10.6
• MariaDB ColumnStore
• MariaDB Galera Cluster
• Multisource replication
• MyRocks storage engine for MariaDB versions lower than 10.6
• Password validation plugin, simple_password_check, and cracklib_password_check
• Spider storage engine
• Sphinx storage engine
• TokuDB storage engine
• Storage engine-specific object attributes, as described in Engine-defined new Table/Field/Index attributes in the MariaDB documentation
• Table and tablespace encryption

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.

Supported storage engines for MariaDB on Amazon RDS

RDS for MariaDB supports the following storage engines.

Topics
• The InnoDB storage engine (p. 843)
• The MyRocks storage engine (p. 843)

Other storage engines aren't currently supported by RDS for MariaDB.

The InnoDB storage engine

Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB is the recommended storage engine for MariaDB DB instances on Amazon RDS. Amazon RDS features such as point-in-time restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version.

For more information, see InnoDB.

The MyRocks storage engine

The MyRocks storage engine is available in RDS for MariaDB version 10.6 and higher. Before using the MyRocks storage engine in a production database, we recommend that you perform thorough benchmarking and testing to verify any potential benefits over InnoDB for your use case.
The default parameter group for MariaDB version 10.6 includes MyRocks parameters. For more information, see Parameters for MariaDB (p. 910) and Working with parameter groups (p. 278).

To create a table that uses the MyRocks storage engine, specify ENGINE=RocksDB in the CREATE TABLE statement. The following example creates a table that uses the MyRocks storage engine.

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=RocksDB;
```

We strongly recommend that you don't run transactions that span both InnoDB and MyRocks tables. MariaDB doesn't guarantee ACID (atomicity, consistency, isolation, durability) for transactions across storage engines. Although it is possible to have both InnoDB and MyRocks tables in a DB instance, we don't recommend this approach except during a migration from one storage engine to the other. When both InnoDB and MyRocks tables exist in a DB instance, each storage engine has its own buffer pool, which might cause performance to degrade.

MyRocks doesn't support SERIALIZABLE isolation or gap locks. So, generally you can't use MyRocks with statement-based replication. For more information, see MyRocks and Replication.

Currently, you can modify only the following MyRocks parameters:

- `rocksdb_block_cache_size`
- `rocksdb_bulk_load`
- `rocksdb_bulk_load_size`
- `rocksdb_deadlock_detect`
- `rocksdb_deadlock_detect_depth`
- `rocksdb_max_latest_deadlocks`

The MyRocks storage engine and the InnoDB storage engine can compete for memory based on the settings for the `rocksdb_block_cache_size` and `innodb_buffer_pool_size` parameters. In some cases, you might only intend to use the MyRocks storage engine on a particular DB instance. If so, we recommend setting the `innodb_buffer_pool_size` minimal parameter to a minimal value and setting the `rocksdb_block_cache_size` as high as possible.

You can access MyRocks log files by using the DescribeDBLogFiles and DownloadDBLogFilePortion operations.

For more information about MyRocks, see MyRocks on the MariaDB website.

**MariaDB file size limits in Amazon RDS**

For MariaDB DB instances, the maximum size of a table is 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) are set by default for MariaDB DB instances. This limit isn't related to the maximum storage limit for MariaDB DB instances. For more information about the storage limit, see Amazon RDS DB instance storage (p. 53).

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.
One option that you can use for breaking a large table up into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn’t need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

To determine the file size of a table

Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning. To update table statistics, issue an ANALYZE TABLE command on each table. For more information, see ANALYZE TABLE statement in the MySQL documentation.

```
SELECT TABLE_SCHEMA, TABLE_NAME,
      round(((DATA_LENGTH + INDEX_LENGTH) / 1024 / 1024), 2) As "Approximate size (MB)",
      DATA_FREE
FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema');
```

To enable InnoDB file-per-table tablespaces

- To enable InnoDB file-per-table tablespaces, set the innodb_file_per_table parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- To disable InnoDB file-per-table tablespaces, set the innodb_file_per_table parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see Working with parameter groups (p. 278).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command. You can use this command to move a table from the global tablespace to its own tablespace. Or you can move a table from its own tablespace to the global tablespace. Following is an example.

```
ALTER TABLE table_name ENGINE=InnoDB, ALGORITHM=COPY;
```

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management in Amazon RDS (p. 1766).

- When you create a DB instance, you use either a VPC security group or a DB security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Socket Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.

- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in stand-alone databases, as does directly modifying database schema tables.
When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
- create temporary tables
- create user
- create view
- delete
- drop
- event
- execute
- grant option
- index
- insert
- lock tables
- process
- references
- reload

This privilege is limited on MariaDB DB instances. It doesn't grant access to the FLUSH LOGS or FLUSH TABLES WITH READ LOCK operations.

- replication client
- replication slave
- select
- show databases
- show view
- trigger
- update

For more information about these privileges, see User account management in the MariaDB documentation.

**Note**

Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the ModifyDBInstance API or the modify-db-instance AWS CLI and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the rdsadmin user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the rdsadmin account results in an error.

To allow management of the DB instance, the standard kill and kill_query commands have been restricted. The Amazon RDS commands mysql.rds_kill, mysql.rds_kill_query, and mysql.rds_kill_query_id are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.
Using SSL with a MariaDB DB instance

Amazon RDS supports Secure Sockets Layer (SSL) connections with DB instances running the MariaDB database engine. MariaDB uses OpenSSL for secure connections.

Amazon RDS creates an SSL certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. The following table shows the TLS support for MySQL versions.

<table>
<thead>
<tr>
<th>MariaDB version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
<th>TLS 1.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB 10.6</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MariaDB 10.5</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MariaDB 10.4</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MariaDB 10.3</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MariaDB 10.2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

**Important**
The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql  Ver 15.1 Distrib 10.5.9-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, as shown in the examples following.

The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

```
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com
--ssl-ca=[full path]global-bundle.pem --ssl-mode=REQUIRED
```

The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

```
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com
--ssl-ca=[full path]global-bundle.pem --ssl
```
For information about downloading certificate bundles, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

You can require SSL connections for specific users accounts. For example, you can use one of the following statements, depending on your MariaDB version, to require SSL connections on the user account encrypted_user.

Use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL connections with MariaDB, see SSL overview in the MariaDB documentation.

**Cache warming**

InnoDB cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see Dumping and restoring the buffer pool in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.2 and higher DB instances. To enable it, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see Working with parameter groups (p. 278).

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don't commonly see a significant performance benefit.

**Important**

If your MariaDB DB instance doesn't shut down normally, such as during a failover, then the buffer pool state isn't saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool before the restart. To ensure that you have a recent state of the buffer pool available to warm the cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand.

You can create an event to dump the buffer pool automatically and at a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
  ON SCHEDULE EVERY 1 HOUR
  DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see Events in the MariaDB documentation.

**Dumping and loading the buffer pool on demand**

You can save and load the cache on demand using the following stored procedures:
• To dump the current state of the buffer pool to disk, call the 
  mysql.rds_innodb_buffer_pool_dump_now (p. 1283) stored procedure.

• To load the saved state of the buffer pool from disk, call the 
  mysql.rds_innodb_buffer_pool_load_now (p. 1284) stored procedure.

• To cancel a load operation in progress, call the mysql.rds_innodb_buffer_pool_load_abort (p. 1284)
  stored procedure.

Database parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For more information on the parameters available for the RDS for MariaDB DB engine, see Parameters for MariaDB (p. 910).

Common DBA tasks for MariaDB

Ending sessions or queries, skipping replication errors, working with InnoDB tablespaces to improve crash recovery times, and managing the global status history are common DBA tasks you might perform in a MariaDB DB instance. You can handle these tasks just as in a MySQL DB instance, as described in Common DBA tasks for MySQL DB instances (p. 1245). The crash recovery instructions there refer to the MySQL InnoDB engine, but they are applicable to a MariaDB DB instance running InnoDB as well.

Local time zone for MariaDB DB instances

By default, the time zone for a MariaDB DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the time_zone parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the time_zone parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Working with parameter groups (p. 278).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the time_zone parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the time_zone parameter in the instance’s and read replica’s parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.
You can set your local time zone to one of the following values.

<table>
<thead>
<tr>
<th>Time Zone</th>
<th>Time Zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Africa/Cairo</td>
<td>Asia/Riyadh</td>

</table>
InnoDB reserved word

InnoDB is a reserved word for RDS for MariaDB. You can't use this name for a MariaDB database.

Deprecated versions for Amazon RDS for MariaDB

Amazon RDS for MariaDB version 10.0 and 10.1 are deprecated.

For more information, see Announcement: Extending end-of-life Process for Amazon RDS for MariaDB 10.0 and 10.1.

For information about the Amazon RDS deprecation policy for MariaDB, see Amazon RDS FAQs.

Connecting to a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql command-line client in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the Download heidi page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on most RPM-based Linux distributions, including Amazon Linux 2, run the following command:
yum install mariadb

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

apt-get install mariadb-client

To check the version of your MySQL command-line client, run the following command:

mysql --version

To read the MySQL documentation for your current client version, run the following command:

man mysql

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1880).

You can use SSL encryption on connections to a MariaDB DB instance. For information, see Using SSL with a MariaDB DB instance (p. 847).

Topics

• Finding the connection information for a MariaDB DB instance (p. 852)
• Connecting from the MySQL command-line client (unencrypted) (p. 855)
• Connecting from the MySQL command-line client with SSL (encrypted) (p. 856)
• Troubleshooting connections to your MariaDB DB instance (p. 856)

Finding the connection information for a MariaDB DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is mydb.123456789012.us-east-1.rds.amazonaws.com. In this case, the port value is 3306, and the database user is admin. Given this information, you specify the following values in a connection string:

• For host or host name or DNS name, specify mydb.123456789012.us-east-1.rds.amazonaws.com.
• For port, specify 3306.
• For user, specify admin.

To connect to a DB instance, use any client for the MariaDB DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.
Finding the connection information

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Databases to display a list of your DB instances.

3. Choose the name of the MariaDB DB instance to display its details.

4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

AWS CLI

To find the connection information for a MariaDB DB instance by using the AWS CLI, call the describe-db-instances command. In the call, query for the DB instance ID, endpoint, port, and master user name.
For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances
   --filters "Name=engine,Values=mariadb"
   --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```bash
aws rds describe-db-instances ^
   --filters "Name=engine,Values=mariadb" ^
   --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```json
[
[    
   "mydb1",
   "mydb1.123456789012.us-east-1.rds.amazonaws.com",
   3306,
   "admin"
],
[    
   "mydb2",
   "mydb2.123456789012.us-east-1.rds.amazonaws.com",
   3306,
   "admin"
]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the MySQL command-line client (unencrypted)

**Important**

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL (encrypted) (p. 856).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for your DB instance for `<endpoint>` and the master user name that you used for `<mymasteruser>`. Provide the master password that you used when prompted for a password.

```bash
mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g. 
Your MariaDB connection id is 31 
Server version: 10.5.8-MariaDB-log Source distribution
```
Connecting from the MySQL command-line client with SSL (encrypted)

Amazon RDS creates an SSL certificate for your DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks. To connect to your DB instance using SSL, follow these steps:

To connect to a DB instance with SSL using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

2. Enter the following command at a command prompt to connect to a DB instance with SSL using the mysql utility. For the \-h parameter, substitute the DNS name for your DB instance. For the --ssl-ca parameter, substitute the SSL certificate file name as appropriate.

   ```
   mysql -h mariadb-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem -p
   ```

3. Include the --ssl-verify-server-cert parameter so that the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate. For example:

   ```
   mysql -h mariadb-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-verify-server-cert -p
   ```

4. Enter the master user password when prompted.

You should see output similar to the following.

```
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.5.8-MariaDB-log Source distribution
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
MariaDB [(none)]>
```

Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. If the DB instance was
created in an Amazon VPC, it must have a VPC security group that authorizes the connections. For more information, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

You can add or edit an inbound rule in the security group. For Source, choose My IP. This allows access to the DB instance from the IP address detected in your browser.

If the DB instance was created outside of a VPC, it must have a DB security group that authorizes the connections.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can’t connect to Amazon RDS DB instance (p. 1880).
Updating applications to connect to MariaDB DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

Note
Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.
You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and still connects successfully. We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 1757). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). For information about using SSL/TLS with MariaDB DB instances, see Using SSL with a MariaDB DB instance (p. 847).

Topics
- Determining whether a client requires certificate verification in order to connect (p. 858)
- Updating your application trust store (p. 859)
- Example Java code for establishing SSL connections (p. 860)

Determining whether a client requires certificate verification in order to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application’s JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have sslMode set to VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
```
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);

Note
If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL
The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the --ssl-mode option you specify VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the --ssl-verify-server-cert option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see Using TLS/SSL with MariaDB Connector/J in the MariaDB documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1764).

Note
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```
When you start the application, set the following properties.

```java
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

## Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```java
private static final String DB_USER = "admin";
private static final String DB_USER = "user name";
private static final String DB_PASSWORD = "password";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void main(String[] args) throws Exception {
    Class.forName("org.mariadb.jdbc.Driver");
    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

    Properties properties = new Properties();
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);

    Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-public.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306?useSSL=true", properties);
    Statement stmt=connection.createStatement();
    ResultSet rs=stmt.executeQuery("SELECT 1 from dual");
    return;
}
```

### Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 1757).
Upgrading the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in [Major version upgrades for MariaDB](p. 862).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see [Upgrading a DB instance engine version](p. 344).

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see [MariaDB on Amazon RDS versions](p. 838).

**Note**

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

**Topics**

- [Overview of upgrading](p. 861)
- [Major version upgrades for MariaDB](p. 862)
- [Upgrading a MariaDB DB instance](p. 863)
- [Automatic minor version upgrades for MariaDB](p. 863)

**Overview of upgrading**

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
  --engine mariadb
  --engine-version version-number
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine mariadb ^
  --engine-version version-number ^
```

861
For example, to identify the valid upgrade targets for a MariaDB version 10.3.13 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:
```bash
aws rds describe-db-engine-versions \
  --engine mariadb \
  --engine-version 10.3.13 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:
```bash
aws rds describe-db-engine-versions ^
  --engine mariadb ^
  --engine-version 10.3.13 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

**Note**
Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 309).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

### Major version upgrades for MariaDB

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:

- Any MariaDB version to MariaDB 10.6
For information about manually or automatically upgrading a MariaDB DB instance, see Upgrading a DB instance engine version (p. 344).

Automatic minor version upgrades for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The Auto minor version upgrade setting is enabled.
- The Backup retention period setting is greater than 0.

In the AWS Management Console, these settings are under Additional configuration. The following image shows the Auto minor version upgrade setting.
For more information about these settings, see Settings for DB instances (p. 310).

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MariaDB community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^ \
--engine mariadb ^ \
--engine-version minor-version ^ \
--region region ^ \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^ \
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.3.8 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version 10.3.8 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^ \
--engine mariadb ^ \
--engine-version 10.3.8 ^ \
--region us-east-2 ^ \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^ \
--output table
```

864
In this example, the `AutoUpgrade` value is `True` for MariaDB version 10.3.23. So, the automatic minor upgrade target is MariaDB version 10.3.23, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](p. 346).
# Importing data into a MariaDB DB instance

You can use several different techniques to import data into an RDS for MariaDB DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Find techniques to import data into an RDS for MariaDB DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Applicatio downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing MariaDB DB instance</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.</td>
<td>Working with read replicas (p. 354)</td>
</tr>
<tr>
<td>Existing MariaDB or MySQL database</td>
<td>Small</td>
<td>One time</td>
<td>Some</td>
<td>Copy the data directly to your MySQL DB instance using a command-line utility.</td>
<td>Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 867)</td>
</tr>
<tr>
<td>Data not stored in an existing database</td>
<td>Medium</td>
<td>One time</td>
<td>Some</td>
<td>Create flat files and import them using the <code>mysqlimport</code> utility.</td>
<td>Importing data from any source to a MariaDB or MySQL DB instance (p. 882)</td>
</tr>
<tr>
<td>Existing MariaDB or MySQL database on premises or on Amazon EC2</td>
<td>Any</td>
<td>Ongoing</td>
<td>Minimal</td>
<td>Configure replication with an existing MariaDB or MySQL database as the replication source.</td>
<td>Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 899)</td>
</tr>
</tbody>
</table>

You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or higher, or using binary log coordinates for MySQL instances or MariaDB instances on earlier versions than 10.0.24. MariaDB GTIDs are implemented differently than MySQL GTIDs, which aren’t supported by Amazon RDS.
## Importing data from an external database

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Application downtime</th>
<th>Technique</th>
<th>More information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any existing database</td>
<td>Any</td>
<td>One time or ongoing</td>
<td>Minimal</td>
<td>Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.</td>
<td>to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 869)</td>
</tr>
</tbody>
</table>

**Note**

The mysql system database contains authentication and authorization information required to log into your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the mysql database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, the DB instance can be restored from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` or recovered using `restore-db-instance-to-point-in-time` commands.

### Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with `mysqldump` and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.
Note
If you are using a MySQL DB instance and your scenario supports it, it’s easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1178).

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
   --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \
   -p local_password | mysql -u RDS_user \
   --port=port_number \
   --host=host_name \
   -p RDS_password
```

Important
Make sure not to leave a space between the `-p` option and the entered password.

Make sure that you’re aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups (p. 1822).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-p local_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-p RDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.
Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
  --databases world \
  --single-transaction \
  --compress \
  --order-by-primary \
  --routines=0 \
  --triggers=0 \
  --events=0 \
  -p localpassword | mysql -u rdsuser \
    --port=3306 \
    --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
    -p rdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking Command Prompt on the Windows programs menu and choosing Run as administrator:

```
mysqldump -u localuser ^
  --databases world ^
  --single-transaction ^
  --compress ^
  --order-by-primary ^
  --routines=0 ^
  --triggers=0 ^
  --events=0 ^
  -p localpassword | mysql -u rdsuser ^
    --port=3306 ^
    --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
    -p rdspassword
```

Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB or MySQL DB instance. In these cases, you can use the following procedure to minimize the impact on application availability. This procedure can also help if you are working with a very large database. Here, the procedure helps because you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS DB instance. You then use replication to bring the Amazon RDS DB instance up-to-date with your live external instance, before redirecting your application to the Amazon RDS DB instance. You configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, you configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it due to its enhanced crash-safety features. For more information, see Global transaction ID in the MariaDB documentation.
Note
If you want to import data into a MySQL DB instance and your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1178).

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an Amazon RDS MariaDB or MySQL DB instance with minimal downtime is to create a copy of the source data.

Note
We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5, due to potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.
You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a nonproduction environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see Using mysqldump for backups in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

**Note**

Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.

**To set replication options**

1. Edit the `my.cnf` file (this file is usually under `/etc`).

```
sudo vi /etc/my.cnf
```
Add the log_bin and server_id options to the [mysqld] section. The log_bin option provides a file name identifier for binary log files. The server_id option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated [mysqld] section of a my.cnf file.

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see the MySQL documentation.

2. Restart the mysql service.

```
sudo service mysqld restart
```

## To create a backup copy of your existing database

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the mysqldump documentation.

To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of mysqldump.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with mysqldump. For more information, see Creating a data snapshot using mysqldump in the MySQL documentation.

Use chmod if necessary to make sure that the directory where the backup file is being created is writeable.

**Important**

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \
   --databases database_name \
   --master-data=2 \ 
   --single-transaction \ 
   --order-by-primary \ 
   -r backup.sql \ 
   -u local_user \ 
   -p password
```

For Windows:

```
mysqldump ^
   --databases database_name ^
   --master-data=2 ^
   --single-transaction ^
   --order-by-primary ^
   -r backup.sql ^
```
To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump --tab=target_directory --fields-terminated-by ',' --fields-enclosed-by '"' --lines-terminated-by 0x0d0a database_name --master-data=2 --single-transaction --order-by-primary -p password
```

For Windows:

```
mysqldump --tab=target_directory --fields-terminated-by ',' --fields-enclosed-by '"' --lines-terminated-by 0x0d0a database_name --master-data=2 --single-transaction --order-by-primary -p password
```

**Note**

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command:

```
--routines=0 --triggers=0 --events=0.
```

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.
3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS DB instance. Take note of the size of the backup file; you need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL DB instance. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS DB instance also reduces network latency during the import.

To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS DB instance to run your MySQL database engine, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. This can be a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.
2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS DB instance. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS DB instance from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose Security Groups in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the Amazon VPC User Guide.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.

   ```bash
   $ scp -r -i key_pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
   ```

   **Important**
   Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

   ```bash
   sudo yum update -y
   sudo yum install mysql -y
   ```

   For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

   **Important**
   This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or RedHat Enterprise Linux, this example doesn't work. For information about installing MySQL, see Installing and Upgrading MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

   • To decompress SQL output, use the following command.

   ```bash
   gzip backup.sql.gz -d
   ```

   • To decompress delimited-text output, use the following command.

   ```bash
   tar xzvf backup.tar.gz
   ```
Create a MySQL or MariaDB DB instance and import data from your Amazon EC2 instance

By creating a MariaDB or MySQL DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.

To create a MariaDB or MySQL DB instance and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS DB instance. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes (p. 9).

2. Determine if Amazon RDS provisioned I/O operations per second (IOPS) is required to support the workloads. Provisioned IOPS storage delivers fast throughput for online transaction processing (OLTP) workloads, which are I/O intensive. For more information, see Provisioned IOPS SSD storage (p. 55).

3. Open the Amazon RDS console. In the upper-right corner, choose the AWS Region that contains your Amazon EC2 instance.

4. In the navigation pane, choose Databases.

5. Choose Create database, and then go through the steps to choose options for your DB instance:
   a. Make sure that Standard Create is chosen.
   b. In the Engine options section, choose MySQL or MariaDB, as appropriate.
   c. For Version, choose the version that is compatible with your source MySQL instance, as follows:
      - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL 5.5.x or greater.
      - If your source instance is MySQL 5.6.x, the Amazon RDS DB instance must be MySQL 5.6.x or MariaDB.
      - If your source instance is MySQL 5.7.x, the Amazon RDS DB instance must be MySQL 5.7.x, 5.6.x, or MariaDB.
Importing data to a DB instance with reduced downtime

- If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
- If your source instance is MariaDB 5.5 or greater, the Amazon RDS DB instance must be MariaDB.

d. In the Templates section, choose Dev/Test to skip configuring Multi-AZ deployment and provisioned IOPS storage.

e. In the Settings section, specify the requested DB instance identifier and user information.

f. In the DB instance class and Storage sections, specify the DB instance class and allocated storage size that you want.

g. In the Availability & durability section, choose Do not create a standby instance for Multi-AZ deployment.

h. In the Connectivity section, choose the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Set Publicly accessible to Yes. To set up replication with your source database as described later, your DB instance must be publicly accessible.

Use the default values for the other settings in this section.

In the Backup section, set the backup retention period to 0 days.

Use the default values for the other settings in this section.

i. Open the Additional configuration section, and specify an Initial database name.

Set the Backup retention period to 0 days

Use the default values for the other settings in this section.

j. Choose Create database.

Your new DB instance appears in the Databases list with the status Creating. Wait for the Status of your new DB instance to show as Available.

Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is done, you can set Multi-AZ and backup retention the way that you want them for the production instance. For a detailed walkthrough of creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

6. Review the default configuration options for the Amazon RDS DB instance. In the RDS console navigation pane, choose Parameter groups, and then choose the magnifying glass icon next to the default.mysqlx.x or default.mariadbxe parameter group. If this parameter group doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups (p. 278).

To use a different parameter group than the default, associate it with your Amazon RDS DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

7. Connect to the new Amazon RDS DB instance as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The host name for the Amazon RDS DB instance is the Endpoint value for this instance without including the port number. An example is mysampledb.claxc2oy9ak1.us-west-2.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

8. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

9. Connect to your Amazon RDS DB instance as a remote host from your Amazon EC2 instance using the mysql command. The following is an example.
The host name is the DNS name from the Amazon RDS DB instance endpoint.

10. At the mysql prompt, run the source command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

- For SQL format, use the following command.

  ```
  mysql> source backup.sql;
  ```

- For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS DB instance.

  ```
  mysql> create database database_name;
  $ mysql> use database_name;
  ```

  Then create the tables.

  ```
  mysql> source table1.sql
  $ mysql> source table2.sql
  etc...
  ```

  Then import the data.

  ```
  mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
  $ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
  etc...
  ```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables get created and then loaded at the same time.

**Note**
If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

11. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the Amazon EC2 User Guide.

**Replicate between your external database and new Amazon RDS DB instance**

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL DB instance. That being the case, you can use replication to bring the copied database up-to-date with the source database.
The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS mysql.rds_set_external_master (p. 1266) command or the mysql.rds_set_external_master_gtid (p. 917) command to configure replication, and the mysql.rds_start_replication (p. 1277) command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS DB instance as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance, so that it can communicate with your source instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

MySQL 5.5, 5.6, and 5.7

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```
MySQL 8.0

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `repl_user` user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

MySQL 8.0

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

`cat backup.sql`

The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with `mysqldump`. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS DB instance the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master` (p. 1266) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the `mysql.rds_set_external_master_gtid` (p. 917) command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic. The following is an example.
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306, 'ReplicationUser', 'password', 'GTID', 0);

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

6. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` (p. 1277) command to start replication.

```sql
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS DB instance, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

   **Note**
   Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

   For a MariaDB 10.5 or 10.6 DB instance, run the `mysql.rds_replica_status` (p. 916) procedure instead of the MySQL command.

8. After the Amazon RDS DB instance is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS DB instance using the Amazon RDS Management Console. For more information, see Working with backups (p. 407).

**Redirect your live application to your Amazon RDS instance**

After the MariaDB or MySQL DB instance is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.
To redirect your live application to your MariaDB or MySQL DB instance and stop replication

1. To add the VPC security group for the Amazon RDS DB instance, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   SHOW REPLICA STATUS;

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

For a MariaDB 10.5 or 10.6 DB instance, run the mysql.rds_replica_status (p. 916) procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS DB instance. This update typically involves changing the connection settings to identify the host name and port of the Amazon RDS DB instance, the user account and password to connect with, and the database to use.

5. Stop replication for the Amazon RDS instance using the mysql.rds_stop_replication (p. 1279) command.

   CALL mysql.rds_stop_replication;

6. Run the mysql.rds_reset_external_master (p. 1273) command on your Amazon RDS DB instance to reset the replication configuration so this instance is no longer identified as a replica.

   CALL mysql.rds_reset_external_master;

7. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Multi-AZ deployments for high availability (p. 65) and Working with read replicas (p. 354).

Importing data from any source to a MariaDB or MySQL DB instance

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with mysqlimport. The mysqlimport utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about mysqlimport, see mysqlimport - a data import program in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.
The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqlimport.
6. Enable automated backups again.

**Step 1: Create flat files containing the data to be loaded**

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name might be `sales.csv` or `sales.txt`, but not `sales_01.csv`.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (`-C 1024m`). The new files are named `sales.part_00`, `sales.part_01`, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

**Step 2: Stop any applications accessing the target DB instance**

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

**Step 3: Create a DB snapshot**

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:
aws rds create-db-snapshot
  --db-instance-identifier AcmeRDS
  --db-snapshot-identifier preload

For Windows:

aws rds create-db-snapshot ^
  --db-instance-identifier AcmeRDS ^
  --db-snapshot-identifier preload

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2" is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

aws rds restore-db-instance-from-db-snapshot
  --db-instance-identifier AcmeRDS-2
  --db-snapshot-identifier preload

For Windows:

aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS-2 ^
  --db-snapshot-identifier preload

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

aws rds delete-db-instance
  --db-instance-identifier AcmeRDS
  --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
  --db-instance-identifier AcmeRDS
  --db-snapshot-identifier preload

For Windows:

aws rds delete-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS ^
  --db-snapshot-identifier preload

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.
Step 4: Consider turning off Amazon RDS automated backups

**Warning**
Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
  --apply-immediately \
  --backup-retention-period 0
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --apply-immediately ^
  --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI `describe-db-instances` command. The following example displays the DB instance status of the AcmeRDS DB instance.

```bash
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "[*].
  (DBInstanceStatus:DBInstanceStatus)"
```

When the DB instance status is `available`, you're ready to proceed.

**Step 5: Load the data**

Use the `mysqlimport` utility to load the flat files into Amazon RDS. The following example tells `mysqlimport` to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example.

Use the `--compress` option to minimize network traffic. The `--fields-terminated-by='\''` option is used for CSV files, and the `--local` option specifies that the incoming data is located on the client. Without the `--local` option, the Amazon RDS DB instance looks for the data on the database host, so always specify the `--local` option. For the `--host` option, specify the DB instance endpoint of the RDS for MySQL DB instance.
For RDS for MySQL version 8.0.15 and higher, run the following statement before using the mysqlimport utility.

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO master_user;
```

Replace `master_user` with the master username for your DB instance.

For Linux, macOS, or Unix:

```
mysqlimport --local --compress --user=username --password --host=hostname --fields-terminated-by=',' Acme sales.part_*
```

For Windows:

```
mysqlimport --local ^ --compress ^ --user=username ^ --password ^ --host=hostname ^ --fields-terminated-by="," Acme sales.part_*
```

For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the `AcmeRDS` DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \    --db-instance-identifier AcmeRDS \    --backup-retention-period 1 \    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^    --db-instance-identifier AcmeRDS ^    --backup-retention-period 1 ^    --apply-immediately
```
Working with MariaDB replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 354). For specific information about working with read replicas on Amazon RDS for MariaDB, see Working with MariaDB read replicas (p. 887).

You can also configure replication based on binary log coordinates for a MariaDB DB instance. For MariaDB instances, you can also configure replication based on global transaction IDs (GTIDs), which provides better crash safety. For more information, see Using GTID-based replication into a MariaDB DB instance (p. 896).

The following are other replication options available with Amazon RDS for MariaDB:

- You can set up replication between an Amazon RDS for MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 899).
- You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 869) and Exporting data from a MySQL DB instance by using replication (p. 1229).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Binary logging format (p. 656).

- Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 899)

Working with MariaDB read replicas

This section contains specific information about working with read replicas on Amazon RDS for MariaDB. For general information about read replicas and instructions for using them, see Working with read replicas (p. 354).

Topics
- Read replica configuration with MariaDB (p. 888)
- Configuring replication filters with MariaDB (p. 888)
- Configuring delayed replication with MariaDB (p. 893)
- Read replica updates with MariaDB (p. 894)
- Multi-AZ read replica deployments with MariaDB (p. 894)
- Monitoring MariaDB read replicas (p. 895)
- Starting and stopping replication with MariaDB read replicas (p. 895)
- Troubleshooting a MariaDB read replica problem (p. 895)
Read replica configuration with MariaDB

Before a MariaDB DB instance can serve as a replication source, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica.

You can create up to five read replicas from one DB instance. For replication to operate effectively, each read replica should have as the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

If a read replica is running any version of MariaDB, you can specify it as the source DB instance for another read replica. For example, you can create ReadReplica1 from MyDBInstance, and then create ReadReplica2 from ReadReplica1. Updates made to MyDBInstance are replicated to ReadReplica1 and then replicated from ReadReplica1 to ReadReplica2. You can't have more than four instances involved in a replication chain. For example, you can create ReadReplica1 from MySourceDBInstance, and then create ReadReplica2 from ReadReplica1, and then create ReadReplica3 from ReadReplica2, but you can't create a ReadReplica4 from ReadReplica3.

If you promote a MariaDB read replica that is in turn replicating to other read replicas, those read replicas remain active. Consider an example where MyDBInstance1 replicates to MyDBInstance2, and MyDBInstance2 replicates to MyDBInstance3. If you promote MyDBInstance2, replication from MyDBInstance1 to MyDBInstance2 no longer occurs, but MyDBInstance2 still replicates to MyDBInstance3.

To enable automatic backups on a read replica for Amazon RDS for MariaDB, first create the read replica, then modify the read replica to enable automatic backups.

You can run multiple concurrent read replica create or delete actions that reference the same source DB instance, as long as you stay within the limit of five read replicas for the source instance.

Configuring replication filters with MariaDB

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

**Note**

You can also use replication filters to specify which databases and tables are replicated with a primary MariaDB DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222).

**Topics**

- Replication filtering parameters for Amazon RDS for MariaDB (p. 889)
- Replication filtering limitations for Amazon RDS for MariaDB (p. 889)
- Replication filtering examples for Amazon RDS for MariaDB (p. 890)
- Viewing the replication filters for a read replica (p. 892)
Replication filtering parameters for Amazon RDS for MariaDB

To configure replication filters, set the following replication filtering parameters on the read replica:

- **replicate-do-db** – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- **replicate-ignore-db** – Don't replicate changes to the specified databases. When the replicate-do-db parameter is set for a read replica, this parameter isn't evaluated.
- **replicate-do-table** – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the replicate-do-db or replicate-ignore-db parameter is set, the database that includes the specified tables must be included in replication with the read replica.
- **replicate-ignore-table** – Don't replicate changes to the specified tables. When the replicate-do-table parameter is set for a read replica, this parameter isn't evaluated.
- **replicate-wild-do-table** – Replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-db or replicate-ignore-db parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- **replicate-wild-ignore-table** – Don't replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the replicate-do-table or replicate-wild-do-table parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MariaDB documentation.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the replicate-wild-do-table and replicate-wild-ignore-table parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see Binary logging format (p. 656).

**Note**

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for Amazon RDS for MariaDB

The following limitations apply to replication filtering for Amazon RDS for MariaDB:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MariaDB `binlog_do_db` and `binlog_ignore_db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

- Replication filtering is supported for Amazon RDS for MariaDB version 10.3.13 and higher 10.3 versions, all 10.4 versions, all 10.5 versions, and all 10.6 versions.
- Replication filtering isn't supported for Amazon RDS for MariaDB version 10.2.
Replication filtering examples for Amazon RDS for MariaDB

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

**Note**
You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see [Working with parameter groups](p. 278).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see [Modifying parameters in a DB parameter group](p. 282).

When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Escaping wildcard characters in names
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

**Example Including databases in replication**

The following example includes the `mydb1` and `mydb2` databases in replication. When you set `replicate-do-db` for a read replica, only the databases specified in the parameter are replicated.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters 
   "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"}]"
```

For Windows:

```bash
aws rds modify-db-parameter-group 
   --db-parameter-group-name myparametergroup 
   --parameters 
   "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"}]"
```

**Example Including tables in replication**

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

```bash
aws rds modify-db-parameter-group
   --db-parameter-group-name myparametergroup
   --parameters 
   "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1", "ApplyMethod":"immediate"}]"
```
For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"
```

Example Escaping wildcard characters in names

The following example shows you how to use the escape character `\` to escape a wildcard character that is part of a name.

Assume that you have several table names in database `mydb1` that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table %", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table %", "ApplyMethod":"immediate"]"
```
Example Excluding databases from replication

The following example excludes the mydb1 and mydb2 databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^ 
  --db-parameter-group-name myparametergroup ^ 
  --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"]"
```

Example Excluding tables from replication

The following example excludes tables table1 and table2 in database mydb1 from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^ 
  --db-parameter-group-name myparametergroup ^ 
  --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with orders and returns in database mydb from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^ 
  --db-parameter-group-name myparametergroup ^ 
  --parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:
• Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

For instructions, see Viewing parameter values for a DB parameter group (p. 289).
• In a MariaDB client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

In the output, the following fields show the replication filters for the read replica:
• `Replicate_Do_DB`
• `Replicate_Ignore_DB`
• `Replicate_Do_Table`
• `Replicate_Ignore_Table`
• `Replicate_Wild_Do_Table`
• `Replicate_Wild_Ignore_Table`

For more information about these fields, see Checking Replication Status in the MySQL documentation.

**Note**
Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5, then use `SHOW SLAVE STATUS`.

### Configuring delayed replication with MariaDB

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

• Stop replication to the read replica before the change that caused the disaster is sent to it.

  To stop replication, use the `mysql.rds_stop_replication` stored procedure.

• Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 361).

  **Note**
  • Delayed replication is supported for MariaDB 10.6 and higher.
  • Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
  • You can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration.

**Topics**
• Configuring delayed replication during read replica creation (p. 893)
• Modifying delayed replication for an existing read replica (p. 894)
• Promoting a read replica (p. 894)

### Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the `mysql.rds_set_configuration` stored procedure with the `target_delay` parameter.
To configure delayed replication during read replica creation

1. Using a MariaDB client, connect to the MariaDB DB instance to be the source for read replicas as the master user.
2. Run the `mysql.rds_set_configuration (p. 1284)` stored procedure with the `target_delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```sql
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   **Note**

   After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay (p. 1276)` stored procedure.

To modify delayed replication for an existing read replica

1. Using a MariaDB client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication (p. 1279)` stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay (p. 1276)` stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```sql
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the `mysql.rds_start_replication (p. 1277)` stored procedure to start replication.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance (p. 361).

Read replica updates with MariaDB

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to speed the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica.

Multi-AZ read replica deployments with MariaDB

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Multi-AZ deployments for high availability (p. 65).
You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Monitoring MariaDB read replicas

For MariaDB read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the SHOW REPLICA STATUS command.

**Note**

Previous versions of MariaDB used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MariaDB version before 10.5, then use SHOW SLAVE STATUS.

Common causes for replication lag for MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the read_only parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MariaDB.

When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. ReplicaLag = -1 is equivalent to Seconds_Behind_Master = NULL.

Starting and stopping replication with MariaDB read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures mysql.rds_stop_replication (p. 1279) and mysql.rds_start_replication (p. 1277). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188) and Exporting data from a MySQL DB instance by using replication (p. 1229).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS ends replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is ended. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MariaDB read replica problem

The replication technologies for MariaDB are asynchronous. Because they are asynchronous, occasional BinLogDiskUsage increases on the source DB instance and ReplicaLag on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MariaDB documentation, go to Replication overview.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
• Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the max_allowed_packet parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MariaDB engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 630), RDS-EVENT-0046 (p. 630), and RDS-EVENT-0047 (p. 628). For more information about events and subscribing to events, see Using Amazon RDS event notification (p. 623). If a MariaDB error message is returned, review the error in the MariaDB error message documentation.

One common issue that can cause replication errors is when the value for the max_allowed_packet parameter for a read replica is less than the max_allowed_packet parameter for the source DB instance. The max_allowed_packet parameter is a custom parameter that you can set in a DB parameter group that is used to specify the maximum size of DML code that can be run on the database. In some cases, the max_allowed_packet parameter value in the DB parameter group associated with a source DB instance is smaller than the max_allowed_packet parameter value in the DB parameter group associated with the source's read replica. In these cases, the replication process can throw an error (Packet bigger than 'max_allowed_packet' bytes) and stop replication. You can fix the error by having the source and read replica use DB parameter groups with the same max_allowed_packet parameter values.

Other common situations that can cause replication errors include the following:

• Writing to tables on a read replica. If you are creating indexes on a read replica, you need to have the read_only parameter set to 0 to create the indexes. If you are writing to tables on the read replica, it might break replication.

• Using a non-transactional storage engine such as MyISAM. read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MariaDB.

• Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping the current replication error (p. 1245). Otherwise, you can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the Replication State changes to replicating.

For MariaDB DB instances, in some cases read replicas can’t be switched to the secondary if some binlog events aren’t flushed during the failure. In these cases, you must manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: sync_binlog=1 and innodb_flush_log_at_trx_commit=1. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

Using GTID-based replication into a MariaDB DB instance

You can set up replication based on global transaction identifiers (GTIDs) from an external MariaDB instance of version 10.0.24 or higher into a MariaDB DB instance. Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

• Monitor failover events for the Amazon RDS for MariaDB DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different
network address. For information on how to monitor failover events, see Using Amazon RDS event notification (p. 623).

- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance ensures that you can restore your source instance in the event of a failure.
- Turn on automated backups on your MariaDB DB instance on Amazon RDS. Turning on automated backups ensures that you can restore your replica to a particular point in time if you need to resynchronize your source instance and replica. For information on backups and Point-In-Time Restore, see Backing up and restoring an Amazon RDS DB instance (p. 406).

**Note**
The permissions required to start replication on a MariaDB DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS `mysql.rds_set_external_master_gtid` (p. 917) and `mysql.rds_start_replication` (p. 1277) commands to set up replication between your live database and your Amazon RDS for MariaDB database.

To start replication between an external source instance and a MariaDB DB instance on Amazon RDS, use the following procedure.

**To start replication**

1. Make the source MariaDB instance read-only:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Get the current GTID of the external MariaDB instance. You can do this by using `mysql` or the query editor of your choice to run `SELECT @@gtid_current_pos;`.

   The GTID is formatted as `<domain-id>-<server-id>-<sequence-id>`. A typical GTID looks something like `0-1234510749-1728`. For more information about GTIDs and their component parts, see Global transaction ID in the MariaDB documentation.

3. Copy the database from the external MariaDB instance to the MariaDB DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188).

   **Note**
   Make sure there is not a space between the `-p` option and the entered password.

   For Linux, macOS, or Unix:

   ```
   mysqldump \
   --databases <database_name> \
   --single-transaction \ 
   --compress \ 
   --order-by-primary \ 
   -u <local_user> \ 
   -p<local_password> | mysql \
   --host=hostname \ 
   --port=3306 \ 
   -u <RDS_user_name> \ 
   -p <RDS_password>
   ```

   For Windows:

   ```
   mysqldump ^
   --databases <database_name> ^
   --single-transaction ^
   ```
4. Make the source MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the external MariaDB database to the VPC security group for the MariaDB DB instance. For more information on modifying a VPC security group, go to Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your MariaDB DB instance, so that it can communicate with your external MariaDB instance. To find the IP address of the MariaDB DB instance, use the `host` command.

```
host <RDS_MariaDB_DB_host_name>
```

The host name is the DNS name from the MariaDB DB instance endpoint.

6. Using the client of your choice, connect to the external MariaDB instance and create a MariaDB user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY '<password>';
```

7. For the external MariaDB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.*
TO 'repl_user'@'mydomain.com'
IDENTIFIED BY '<password>';
```

8. Make the MariaDB DB instance the replica. Connect to the MariaDB DB instance as the master user and identify the external MariaDB database as the replication source instance by using the

```
--compress ^
--order-by-primary \
-u <local_user> \
-p<local_password> | mysql ^
--host=hostname ^
--port=3306 ^
-u <RDS_user_name> ^
-p <RDS_password>
```
mysql.rds_set_external_master_gtid (p. 917) command. Use the GTID that you determined in Step 2. The following is an example.

```sql
CALL mysql.rds_set_external_master_gtid ('mymasterserver.mydomain.com', 3306, 'repl_user', '<password>', '<GTID>', 0);
```

9. On the MariaDB DB instance, issue the mysql.rds_start_replication (p. 1277) command to start replication.

```sql
CALL mysql.rds_start_replication;
```

### Replication with a MariaDB or MySQL instance running external to Amazon RDS

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS.

**Topics**
- Before you begin (p. 899)
- Configuring binary log file position replication with an external source instance (p. 899)
- Configuring GTID-based replication with an external source instance (p. 902)

### Before you begin

You can configure replication using the binary log file position of replicated transactions. On RDS for MySQL 5.7.23 and higher MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions, you can also configure replication using global transaction identifiers (GTIDs).

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master (p. 1266) and mysql.rds_start_replication (p. 1277) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the binlog_format parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify binlog_format settings. We recommend that you use the default setting for binlog_format, which is MIXED. However, you can also set binlog_format to ROW or STATEMENT if you need a specific binlog format. Reboot your DB instance for the change to take effect.

For information about setting the binlog_format parameter, see Configuring MySQL binary logging (p. 669). For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

**Note**

Use the procedure in this topic to configure replication in all cases except when the external instance is MariaDB version 10.0.24 or higher and the Amazon RDS instance is MariaDB. In that case, use the procedure at Using GTID-based replication into a MariaDB DB instance (p. 896) to set up GTID-based replication.

### Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:
Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Using Amazon RDS event notification (p. 623).

Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.

Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up and restoring an Amazon RDS DB instance (p. 406).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>----------</td>
</tr>
</tbody>
</table>

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`.

   For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188).

   For Linux, macOS, or Unix:

   ```
   mysqldump --databases database_name
   --single-transaction
   --compress
   --order-by-primary
   -u local_user
   -p local_password | mysql
   --host=hostname
   --port=3306
   -u RDS_user_name
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump --databases database_name ^
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   -u local_user ^
   -plocal_password | mysql ^
   --host=hostname ^
   --port=3306 ^
   -u RDS_user_name ^
   -pRDS_password
   ```
Replication with an external database instance

Note
Make sure that there isn’t a space between the \(-p\) option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the \(\--host,\ --user \(-u\), \(\--port\) and \(-p\) options in the \texttt{mysql} command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

\begin{verbatim}
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
\end{verbatim}

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the host command.

\texttt{host db_instance_endpoint}

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication. and restrict it to your domain to improve security. The following is an example.

MySQL 5.5, 5.6, and 5.7

\begin{verbatim}
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
\end{verbatim}

MySQL 8.0

\begin{verbatim}
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
\end{verbatim}

7. For the external instance, grant \texttt{REPLICATION_CLIENT} and \texttt{REPLICATION_SLAVE} privileges to your replication user. For example, to grant the \texttt{REPLICATION_CLIENT} and \texttt{REPLICATION_SLAVE} privileges on all databases for the ‘\texttt{repl_user}’ user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';

MySQL 8.0

GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```sql
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

```sql
CALL mysql.rds_start_replication;
```

### Configuring GTID-based replication with an external source instance

When you set up an external source instance and a replica on Amazon RDS, monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Using Amazon RDS event notification (p. 623).

**Important**

GTID-based replication is only supported on RDS for MySQL version 5.7.23 and higher MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions. GTID-based replication isn't supported for RDS for MySQL 5.6.

To configure GTID-based replication with an external source instance

1. Prepare for GTID-based replication:
   a. Make sure that the external MySQL or MariaDB database has GTID-based replication enabled. To do so, make sure that the external database has the following parameters set to the specified values:

   ```
   gtid_mode = ON
   enforce_gtid_consistency = ON
   ```

   For more information, see Replication with global transaction identifiers in the MySQL documentation or Global transaction ID in the MariaDB documentation.
b. Make sure that the parameter group associated with the DB instance has the following parameter settings:

- gtid_mode – ON, ON_PERMISSIVE, or OFF_PERMISSIVE
- enforce_gtid_consistency – ON

For more information about parameter groups, see Working with parameter groups (p. 278).

c. If you changed the parameter group of the DB instance, reboot the DB instance. For more information, see Rebooting a DB instance (p. 350).

2. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`.
For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188).

For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

**Note**

Make sure that there isn’t a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the DNS name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```
For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the replication primary instance by using the mysql.rds_set_external_master_with_auto_position (p. 1271) command. The following is an example.

```
CALL mysql.rds_set_external_master_with_auto_position ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 0, 0);
```

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the mysql.rds_set_external_master_with_delay (p. 1268) stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to enable disaster recovery with the mysql.rds_start_replication_until_gtid (p. 1278) stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the mysql.rds_start_replication_until_gtid procedure.

9. On the Amazon RDS DB instance, issue the mysql.rds_start_replication (p. 1277) command to start replication.
CALL mysql.rds_start_replication;
Options for MariaDB database engine

This appendix describes options, or additional features, that are available for Amazon RDS instances running the MariaDB engine. To enable these options, you add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups (p. 262).

Amazon RDS supports the following options for MariaDB:

<table>
<thead>
<tr>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MARIADB_AUDIT_PLUGIN</td>
<td>MariaDB 10.2 and higher</td>
</tr>
</tbody>
</table>

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MariaDB database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 646) and MariaDB database log files (p. 651).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATE_SIZE</td>
<td>1–100000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see Log file size (p. 655).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save. For more information, see Log file size (p. 655) and Downloading a database log file (p. 647).</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, TABLE, QUERY DDL, QUERY DML, QUERY DML NO_SELECT, QUERY DCL</td>
<td>CONNECT, QUERY, TABLE, QUERY DDL, QUERY DML, QUERY DML NO_SELECT, QUERY DCL</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
</tbody>
</table>
  - CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database.
  - QUERY: Log the text of all queries run against the database.
  - TABLE: Log tables affected by queries when the queries are run against the database.
  - QUERY_DDL: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
  - QUERY_DML: Similar to the QUERY event, but returns only data manipulation language (DML)
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>queries (INSERT, UPDATE, and so on, and also SELECT).</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>• QUERY_DML_NO_SELECT:</strong> Similar to the QUERY_DML event, but doesn't log SELECT queries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The QUERY_DML_NO_SELECT setting is supported only for RDS for MariaDB 10.2.37 and higher 10.2 versions, 10.3.28 and higher 10.3 versions, 10.4.18 and higher 10.4 versions, all 10.5 versions, and all 10.6 versions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>• QUERY_DCL:</strong> Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).</td>
</tr>
<tr>
<td>SERVER_AUDIT_INCL_USERS</td>
<td>Multiple comma-separated values</td>
<td>None</td>
<td>Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.</td>
</tr>
<tr>
<td>SERVER_AUDIT_EXCL_USERS</td>
<td>Multiple comma-separated values</td>
<td>None</td>
<td>Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS.</td>
</tr>
<tr>
<td>SERVER_AUDIT_LOGGING</td>
<td>ON</td>
<td></td>
<td>Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 908).</td>
</tr>
<tr>
<td>SERVER_AUDIT_QUERY_LOG_LIMIT</td>
<td>0–2147483647</td>
<td>1024</td>
<td>The limit on the length of the query string in a record.</td>
</tr>
</tbody>
</table>
Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose mariadb for Engine, and choose 10.2 or higher for Major engine version. For more information, see Creating an option group (p. 264).
2. Add the MARIADB_AUDIT_PLUGIN option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 266). For more information about each setting, see Audit Plugin option settings (p. 906).
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the DB instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at /rdsdbdata/log/audit/. For information about viewing the log file in the console, see Viewing and listing database log files (p. 646). For information about downloading the log file, see Downloading a database log file (p. 647).

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify settings for the plugin. For more information about how to modify option settings, see Modifying an option setting (p. 271). For more information about each setting, see Audit Plugin option settings (p. 906).

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274)
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For information about working with parameter groups and setting parameters, see Working with parameter groups (p. 278).

Viewing MariaDB parameters

RDS for MariaDB parameters are set to the default values of the storage engine that you have selected. For more information about MariaDB parameters, see the MariaDB documentation. For more information about MariaDB storage engines, see Supported storage engines for MariaDB on Amazon RDS (p. 843).

You can view the parameters available for a specific RDS for MariaDB version using the RDS console or the AWS CLI. For information about viewing the parameters in a MariaDB parameter group in the RDS console, see Viewing parameter values for a DB parameter group (p. 289).

Using the AWS CLI, you can view the parameters for an RDS for MariaDB version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mariadb10.6
- mariadb10.5
- mariadb10.4
- mariadb10.3
- mariadb10.2

For example, to view the parameters for RDS for MariaDB version 10.6, run the following command.

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6
```

Your output looks similar to the following.

```json
{
  "EngineDefaults": {
    "Parameters": [
      {
        "ParameterName": "alter_algorithm",
        "Description": "Specify the alter table algorithm.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "string",
        "AllowedValues": "DEFAULT,COPY,INPLACE,NOCOPY,INSTANT",
        "IsModifiable": true
      },
      {
        "ParameterName": "analyze_sample_percentage",
        "Description": "Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "float",
        "AllowedValues": "0-100",
        "IsModifiable": true
      }
    ]
  }
}
```
MySQL parameters that aren't available

The following MySQL parameters are not available in MariaDB-specific DB parameter groups:

- bind_address
- binlog_error_action
- binlog_gtid_simple_recovery
- binlog_max_flush_queue_time
- binlog_order_commits
- binlog_row_image
- binlog_rows_query_log_events
- binlogging_impossible_mode
- block_encryption_mode
- core_file
- default_tmp_storage_engine
- div_precision_increment
- end_markers_in_json
- enforce_gtid_consistency
- eq_range_index_dive_limit
- explicit_defaults_for_timestamp
- gtid_executed
- gtid-mode
• gtid_next
• gtid_owned
• gtid_purged
• log_bin_basedname
• log_bin_index
• log_bin_use_v1_row_events
• log_slow_admin_statements
• log_slow_slave_statements

Migrating data from a MySQL DB snapshot to a MariaDB DB instance

You can migrate an RDS for MySQL DB snapshot to a new DB instance running MariaDB using the AWS Management Console, the AWS CLI, or Amazon RDS API. You must create the DB snapshot from an Amazon RDS DB instance running MySQL 5.6 or 5.7. To learn how to create an RDS for MySQL DB snapshot, see Creating a DB snapshot (p. 428).

Migrating the snapshot doesn't affect the original DB instance from which the snapshot was taken. You can test and validate the new DB instance before diverting traffic to it as a replacement for the original DB instance.

After you migrate from MySQL to MariaDB, the MariaDB DB instance is associated with the default DB parameter group and option group. After you restore the DB snapshot, you can associate a custom DB parameter group with the new DB instance. However, a MariaDB parameter group has a different set of configurable system variables. For information about the differences between MySQL and MariaDB system variables, see System Variable Differences between MariaDB and MySQL. To learn about DB parameter groups, see Working with parameter groups (p. 278). To learn about option groups, see Working with option groups (p. 262).

Performing the migration

You can migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To migrate a MySQL DB snapshot to a MariaDB DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots, and then select the MySQL DB snapshot you want to migrate.
3. For Actions, choose Migrate snapshot. The Migrate database page appears.
4. For Migrate to DB Engine, choose mariadb.

   Amazon RDS selects the DB engine version automatically. You can't change the DB engine version.
5. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances (p. 178).

6. Choose Migrate.

**AWS CLI**

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, use the AWS CLI `restore-db-instance-from-db-snapshot` command with the following parameters:

- `--db-instance-identifier` – Name of the DB instance to create from the DB snapshot.
- `--db-snapshot-identifier` – The identifier for the DB snapshot to restore from.
- `--engine` – The database engine to use for the new instance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier newmariadbinstance \
    --db-snapshot-identifier mysqlsnapshot \
    --engine mariadb
```

For Windows:

```bash
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier newmariadbinstance ^
    --db-snapshot-identifier mysqlsnapshot ^
    --engine mariadb
```
API

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, call the Amazon RDS API operation `RestoreDBInstanceFromDBSnapshot`.

Incompatibilities between MariaDB and MySQL

Incompatibilities between MySQL and MariaDB include the following:

- You can't migrate a DB snapshot created with MySQL 8.0 to MariaDB.
- If the source MySQL database uses a SHA256 password hash, make sure to reset user passwords that are SHA256 hashed before you connect to the MariaDB database. The following code shows how to reset a password that is SHA256 hashed.

```sql
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('new_password')
WHERE (User, Host) = ('master_user_name', %);
FLUSH PRIVILEGES;
```

- If your RDS master user account uses the SHA-256 password hash, make sure to reset the password using the AWS Management Console, the `modify-db-instance` AWS CLI command, or the `ModifyDBInstance` RDS API operation. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).
- MariaDB doesn't support the Memcached plugin. However, the data used by the Memcached plugin is stored as InnoDB tables. After you migrate a MySQL DB snapshot, you can access the data used by the Memcached plugin using SQL. For more information about the innodb_memcache database, see InnoDB memcached plugin internals.
MariaDB on Amazon RDS SQL reference

This appendix describes system stored procedures that are available for Amazon RDS instances running the MariaDB DB engine.

You can use the system stored procedures that are available for MySQL DB instances and MariaDB DB instances. These stored procedures are documented at MySQL on Amazon RDS SQL reference (p. 1264). MariaDB DB instances support all of the stored procedures, except for mysql.rds_start_replication_until and mysql.rds_start_replication_until_gtid.

Additionally, the following system stored procedures are supported only for Amazon RDS DB instances running MariaDB:

- mysql.rds_replica_status (p. 916)
- mysql.rds_set_external_master_gtid (p. 917)
- mysql.rds_kill_query_id (p. 919)

mysql.rds_replica_status

Shows the replication status of a MariaDB read replica.

Call this procedure on the read replica to show status information on essential parameters of the replica threads.

**Syntax**

```
CALL mysql.rds_replica_status;
```

**Usage notes**

This procedure is only supported for MariaDB DB instances running MariaDB version 10.5 and higher.

This procedure is the equivalent of the SHOW REPLICA STATUS command. This command isn't supported for MariaDB version 10.5 and higher DB instances.

In prior versions of MariaDB, the equivalent SHOW SLAVE STATUS command required the REPLICATION SLAVE privilege. In MariaDB version 10.5 and higher, it requires the REPLICATION REPLICA ADMIN privilege. To protect the RDS management of MariaDB 10.5 and higher DB instances, this new privilege isn't granted to the RDS master user.

**Examples**

The following example shows the status of a MariaDB read replica:

```
call mysql.rds_replica_status;
```

The response is similar to the following:

```
*************************** 1. row ***************************
Replica_IO_State: Waiting for master to send event
Source_Host: XX.XX.XX.XXX
Source_User: rdsrepladmin
Source_Port: 3306
```

916
mysql.rds_set_external_master_gtid

Configures GTID-based replication from a MariaDB instance running external to Amazon RDS to a MariaDB DB instance. This stored procedure is supported only where the external MariaDB instance is version 10.0.24 or higher. When setting up replication where one or both instances do not support MariaDB global transaction identifiers (GTIDs), use mysql.rds_set_external_master (p. 1266).

Using GTIDs for replication provides crash-safety features not offered by binary log replication, so we recommend it in cases where the replicating instances support it.
Syntax

```
CALL mysql.rds_set_external_master_gtid(
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    gtid,
    ssl_encryption
);
```

Parameters

**host_name**

String. The host name or IP address of the MariaDB instance running external to Amazon RDS that will become the source instance.

**host_port**

Integer. The port used by the MariaDB instance running external to Amazon RDS to be configured as the source instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

String. The ID of a user with `REPLICATION_SLAVE` permissions in the MariaDB DB instance to be configured as the read replica.

**replication_user_password**

String. The password of the user ID specified in `replication_user_name`.

**gtid**

String. The global transaction ID on the source instance that replication should start from.

You can use `@@gtid_current_pos` to get the current GTID if the source instance has been locked while you are configuring replication, so the binary log doesn't change between the points when you get the GTID and when replication starts.

Otherwise, if you are using `mysqldump` version 10.0.13 or greater to populate the replica instance prior to starting replication, you can get the GTID position in the output by using the `--master-data` or `--dump-slave` options. If you are not using `mysqldump` version 10.0.13 or greater, you can run the `SHOW MASTER STATUS` or use those same `mysqldump` options to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance:

```
SELECT BINLOG_GTID_POS('<binary log file name>', <binary log file position>);
```

For more information about the MariaDB implementation of GTIDs, go to Global transaction ID in the MariaDB documentation.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.
Usage notes

The `mysql.rds_set_external_master_gtid` procedure must be run by the master user. It must be run on the MariaDB DB instance that you are configuring as the replica of a MariaDB instance running external to Amazon RDS. Before running `mysql.rds_set_external_master_gtid`, you must have configured the instance of MariaDB running external to Amazon RDS as a source instance. For more information, see Importing data into a MariaDB DB instance (p. 866).

**Warning**

Do not use `mysql.rds_set_external_master_gtid` to manage replication between two Amazon RDS DB instances. Use it only when replicating with a MariaDB instance running external to RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas (p. 354).

After calling `mysql.rds_set_external_master_gtid` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When `mysql.rds_set_external_master_gtid` is called, Amazon RDS records the time, user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MariaDB DB instance, the following example configures it as the replica of an instance of MariaDB running external to Amazon RDS.

```sql
CALL mysql.rds_set_external_master_gtid
('Sourcedb.some.com',3306,'ReplicationUser','SomePassW0rd','0-123-456',0);
```

### mysql.rds_kill_query_id

Ends a query running against the MariaDB server.

**Syntax**

```sql
CALL mysql.rds_kill_query_id(queryID);
```

**Parameters**

`queryID`

- Integer. The identity of the query to be ended.

**Usage notes**

To stop a query running against the MariaDB server, use the `mysql.rds_kill_query_id` procedure and pass in the ID of that query. To obtain the query ID, query the MariaDB Information schema `PROCESSLIST` table, as shown following:

```sql
SELECT USER, HOST, COMMAND, TIME, STATE, INFO, QUERY_ID FROM
INFORMATION_SCHEMA.PROCESSLIST WHERE USER = '<user name>';
```

The connection to the MariaDB server is retained.
Examples

The following example ends a query with a query ID of 230040:

call mysql.rds_kill_query_id(230040);
Microsoft SQL Server on Amazon RDS

Amazon RDS supports DB instances running several versions and editions of Microsoft SQL Server. Following, you can find the most recent supported version of each major version. For the full list of supported versions, editions, and RDS engine versions, see Microsoft SQL Server versions on Amazon RDS (p. 928).

- SQL Server 2019 CU12 15.00.4153.1, released per KB5004524 on August 4, 2021.
- SQL Server 2016 SP2 CU16 13.00.5882.1, released per KB5000645 on February 11, 2021.
- SQL Server 2014 SP3 CU4 12.00.6329.1, released per KB4500181 on July 29, 2019.
- SQL Server 2012 SP4 GDR 11.0.7493.4, released per KB4532098 on February 11, 2020.
- SQL Server 2008: It's no longer possible to provision new instances in any Region. Amazon RDS is actively migrating existing instances off this version.

For information about licensing for SQL Server, see Licensing Microsoft SQL Server on Amazon RDS (p. 946). For information about SQL Server builds, see this Microsoft support article about the latest SQL Server builds.

With Amazon RDS, you can create DB instances and DB snapshots, point-in-time restores, and automated or manual backups. DB instances running SQL Server can be used inside a VPC. You can also use Secure Sockets Layer (SSL) to connect to a DB instance running SQL Server, and you can use transparent data encryption (TDE) to encrypt data at rest. Amazon RDS currently supports Multi-AZ deployments for SQL Server using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs) as a high-availability, failover solution.

To deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio. Amazon RDS does not allow direct host access to a DB instance via Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, the master user is assigned to the db_owner role for all user databases on that instance, and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see Setting up for Amazon RDS (p. 93).

Common management tasks for Microsoft SQL Server on Amazon RDS

The following are the common management tasks you perform with an Amazon RDS for SQL Server DB instance, with links to relevant documentation for each task.
<table>
<thead>

Limitations for Microsoft SQL Server DB instances

The Amazon RDS implementation of Microsoft SQL Server on a DB instance has some limitations that you should be aware of:

- The maximum number of databases supported on a DB instance depends on the instance class type and the availability mode—Single-AZ, Multi-AZ Database Mirroring (DBM), or Multi-AZ Availability Groups (AGs). The Microsoft SQL Server system databases don't count toward this limit.

The following table shows the maximum number of supported databases for each instance class type and availability mode. Use this table to help you decide if you can move from one instance class type to another, or from one availability mode to another. If your source DB instance has more databases than the target instance class type or availability mode can support, modifying the DB instance fails. You can see the status of your request in the Events pane.

<table>
<thead>
<tr>
<th>Instance class type</th>
<th>Single-AZ</th>
<th>Multi-AZ with DBM</th>
<th>Multi-AZ with Always On AGs</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.<em>.micro to db.</em>.medium</td>
<td>30</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>db.*.large</td>
<td>30</td>
<td>30</td>
<td>30</td>
</tr>
<tr>
<td>db.<em>.xlarge to db.</em>.16xlarge</td>
<td>100</td>
<td>50</td>
<td>75</td>
</tr>
<tr>
<td>db.*.24xlarge</td>
<td>100</td>
<td>50</td>
<td>100</td>
</tr>
</tbody>
</table>

* Represents the different instance class types.
For example, let’s say that your DB instance runs on a db.*.16xlarge with Single-AZ and that it has 76 databases. You modify the DB instance to upgrade to using Multi-AZ Always On AGs. This upgrade fails, because your DB instance contains more databases than your target configuration can support. If you upgrade your instance class type to db.*.24xlarge instead, the modification succeeds.

If the upgrade fails, you see events and messages similar to the following:
- Unable to modify database instance class. The instance has 76 databases, but after conversion it would only support 75.
- Unable to convert the DB instance to Multi-AZ: The instance has 76 databases, but after conversion it would only support 75.

If the point-in-time restore or snapshot restore fails, you see events and messages similar to the following:
- Database instance put into incompatible-restore. The instance has 76 databases, but after conversion it would only support 75.

Some ports are reserved for Amazon RDS, and you can’t use them when you create a DB instance.
- Client connections from IP addresses within the range 169.254.0.0/16 are not permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.
- SQL Server Standard Edition uses only a subset of the available processors if the DB instance has more processors than the software limits (24 cores, 4 sockets, and 128GB RAM). Examples of this are the db.m5.24xlarge and db.r5.24xlarge instance classes.

For more information, see the table of scale limits under Editions and supported features of SQL Server 2019 (15.x) in the Microsoft documentation.
- Amazon RDS for SQL Server doesn’t support importing data into the msdb database.
- You can’t rename databases on a DB instance in a SQL Server Multi-AZ deployment.
- Make sure that you use these guidelines when setting the following DB parameters on RDS for SQL Server:
  - max server memory (mb) >= 256 MB
  - max worker threads >= (number of logical CPUs * 7)

For more information on setting DB parameters, see Working with parameter groups (p. 278).
- The maximum storage size for SQL Server DB instances is the following:
  - General Purpose (SSD) storage – 16 TiB for all editions
  - Provisioned IOPS storage – 16 TiB for all editions
  - Magnetic storage – 1 TiB for all editions

If you have a scenario that requires a larger amount of storage, you can use sharding across multiple DB instances to get around the limit. This approach requires data-dependent routing logic in applications that connect to the sharded system. You can use an existing sharding framework, or you can write custom code to enable sharding. If you use an existing framework, the framework can’t install any components on the same server as the DB instance.
- The minimum storage size for SQL Server DB instances is the following:
  - General Purpose (SSD) storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Provisioned IOPS storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Magnetic storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Amazon RDS doesn’t support running these services on the same server as your RDS DB instance:
    - Data Quality Services
    - Master Data Services

To use these features, we recommend that you install SQL Server on an Amazon EC2 instance, or use an on-premises SQL Server instance. In these cases, the EC2 or SQL Server instance acts as the Master
Data Services server for your SQL Server DB instance on Amazon RDS. You can install SQL Server on an Amazon EC2 instance with Amazon EBS storage, pursuant to Microsoft licensing policies.

- Because of limitations in Microsoft SQL Server, restoring to a point in time before successfully running DROP DATABASE might not reflect the state of that database at that point in time. For example, the dropped database is typically restored to its state up to 5 minutes before the DROP DATABASE command was issued. This type of restore means that you can't restore the transactions made during those few minutes on your dropped database. To work around this, you can reissue the DROP DATABASE command after the restore operation is completed. Dropping a database removes the transaction logs for that database.

- For SQL Server, you create your databases after you create your DB instance. Database names follow the usual SQL Server naming rules with the following differences:
  - Database names can't start with rdsadmin.
  - They can't start or end with a space or a tab.
  - They can't contain any of the characters that create a new line.
  - They can't contain a single quote (').

### DB instance class support for Microsoft SQL Server

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements. For more information, see [DB instance classes (p. 9)](https://console.aws.amazon.com/rds/).

The following list of DB instance classes supported for Microsoft SQL Server is provided here for your convenience. For the most current list, see the RDS console: [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

<table>

</tbody>
</table>
Microsoft SQL Server security

The Microsoft SQL Server database engine uses role-based security. The master user name that you specify when you create a DB instance is a SQL Server Authentication login that is a member of the processadmin, public, and setupadmin fixed server roles.

Any user who creates a database is assigned to the db_owner role for that database and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

The following server-level roles aren't available in Amazon RDS for SQL Server:

- bulkadmin
- dbcreator
- diskadmin
- securityadmin
- serveradmin
- sysadmin

The following server-level permissions aren't available on RDS for SQL Server DB instances:

- ALTER ANY DATABASE
- ALTER ANY EVENT NOTIFICATION
- ALTER RESOURCES
- ALTER SETTINGS (you can use the DB parameter group API operations to modify parameters; for more information, see Working with parameter groups (p. 278))
- AUTHENTICATE SERVER
- CONTROL_SERVER
- CREATE DDL EVENT NOTIFICATION
- CREATE ENDPOINT
- CREATE SERVER ROLE
- CREATE TRACE EVENT NOTIFICATION
- DROP ANY DATABASE
- EXTERNAL ACCESS ASSEMBLY
- SHUTDOWN (You can use the RDS reboot option instead)
- UNSAFE ASSEMBLY
- ALTER ANY AVAILABILITY GROUP (SQL Server 2012 only)
- CREATE ANY AVAILABILITY GROUP (SQL Server 2012 only)

Compliance program support for Microsoft SQL Server DB instances

AWS Services in scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.
HIPAA support for Microsoft SQL Server DB instances

You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance.

Amazon RDS for SQL Server supports HIPAA for the following versions and editions:

- SQL Server 2019 Enterprise, Standard, and Web Editions
- SQL Server 2017 Enterprise, Standard, and Web Editions
- SQL Server 2016 Enterprise, Standard, and Web Editions
- SQL Server 2014 Enterprise, Standard, and Web Editions
- SQL Server 2012 Enterprise, Standard, and Web Editions

To enable HIPAA support on your DB instance, set up the following three components.

<table>
<thead>
<tr>
<th>Component</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auditing</td>
<td>To set up auditing, set the parameter <code>rds.sqlserver_audit</code> to the value <code>fedramp_hipaa</code>. If your DB instance is not already using a custom DB parameter group, you must create a custom parameter group and attach it to your DB instance before you can modify the <code>rds.sqlserver_audit</code> parameter. For more information, see Working with parameter groups (p. 278).</td>
</tr>
<tr>
<td>Transport encryption</td>
<td>To set up transport encryption, force all connections to your DB instance to use Secure Sockets Layer (SSL). For more information, see Forcing connections to your DB instance to use SSL (p. 996).</td>
</tr>
<tr>
<td>Encryption at rest</td>
<td>To set up encryption at rest, you have two options:</td>
</tr>
<tr>
<td></td>
<td>1. If you're running SQL Server 2012–2019 Enterprise Edition or 2019 Standard Edition, you can use Transparent Data Encryption (TDE) to achieve encryption at rest. For more information, see Support for Transparent Data Encryption in SQL Server (p. 1049).</td>
</tr>
<tr>
<td></td>
<td>2. You can set up encryption at rest by using AWS Key Management Service (AWS KMS) encryption keys. For more information, see Encrypting Amazon RDS resources (p. 1750).</td>
</tr>
</tbody>
</table>

SSL support for Microsoft SQL Server DB instances

You can use SSL to encrypt connections between your applications and your Amazon RDS DB instances running Microsoft SQL Server. You can also force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

SSL is supported in all AWS Regions and for all supported SQL Server editions. For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 996).

Microsoft SQL Server versions on Amazon RDS

You can specify any currently supported Microsoft SQL Server version when creating a new DB instance. You can specify the Microsoft SQL Server major version (such as Microsoft SQL Server 14.00), and any
supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

The following table shows the supported versions for all editions and all AWS Regions, except where noted. You can also use the describe-db-engine-versions AWS CLI command to see a list of supported versions, as well as defaults for newly created DB instances.

### SQL Server versions supported in RDS

<table>
<thead>
<tr>
<th>Major version</th>

</tbody>
</table>

### Version management in Amazon RDS

Amazon RDS includes flexible version management that enables you to control when and how your DB instance is patched or upgraded. This enables you to do the following for your DB engine:

- Maintain compatibility with database engine patch versions.
- Test new patch versions to verify that they work with your application before you deploy them in production.
- Plan and perform version upgrades to meet your service level agreements and timing requirements.
Microsoft SQL Server engine patching in Amazon RDS

Amazon RDS periodically aggregates official Microsoft SQL Server database patches into a DB instance engine version that's specific to Amazon RDS. For more information about the Microsoft SQL Server patches in each engine version, see Version and feature support on Amazon RDS.

Currently, you manually perform all engine upgrades on your DB instance. For more information, see Upgrading the Microsoft SQL Server DB engine (p. 957).

Deprecation schedule for major engine versions of Microsoft SQL Server on Amazon RDS

The following table displays the planned schedule of deprecations for major engine versions of Microsoft SQL Server.

<table>
<thead>
<tr>
<th>Date</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>July 12, 2022</td>
<td>Microsoft will stop critical patch updates for SQL Server 2012. For more information, see Microsoft SQL Server documentation.</td>
</tr>
<tr>
<td>June 1, 2022</td>
<td>Amazon RDS plans to end support of Microsoft SQL Server 2012 on RDS for SQL Server. Amazon RDS is scheduled to migrate to SQL Server 2014 (latest minor version available). For more information, see Announcement: Amazon RDS for SQL Server end of support for SQL Server 2012 major versions. To avoid an automatic upgrade from Microsoft SQL Server 2012, you can upgrade at a time that is convenient to you. For more information, see Upgrading a DB instance engine version (p. 344).</td>
</tr>
<tr>
<td>September 1, 2021</td>
<td>Amazon RDS is starting to disable the creation of new RDS for SQL Server DB instances using Microsoft SQL Server 2012. For more information, see Announcement: Amazon RDS for SQL Server end of support for SQL Server 2012 major versions.</td>
</tr>
<tr>
<td>July 12, 2019</td>
<td>The Amazon RDS team deprecated support for Microsoft SQL Server 2008 R2 in June 2019. Remaining instances of Microsoft SQL Server 2008 R2 are migrating to SQL Server 2012 (latest minor version available). To avoid an automatic upgrade from Microsoft SQL Server 2008 R2, you can upgrade at a time that is convenient to you. For more information, see Upgrading a DB instance engine version (p. 344).</td>
</tr>
<tr>
<td>April 25, 2019</td>
<td>Before the end of April 2019, you will no longer be able to create new Amazon RDS for SQL Server 2008R2.</td>
</tr>
</tbody>
</table>

Microsoft SQL Server features on Amazon RDS

The supported SQL Server versions on Amazon RDS include the following features. In general, a version also includes features from the previous versions, unless otherwise noted in the Microsoft documentation.

Topics
- Microsoft SQL Server 2019 features (p. 931)
- Microsoft SQL Server 2017 features (p. 931)
- Microsoft SQL Server 2016 features (p. 932)
- Microsoft SQL Server 2014 features (p. 932)
- Microsoft SQL Server 2012 features (p. 932)
- Microsoft SQL Server 2008 R2 deprecated on Amazon RDS (p. 933)
Microsoft SQL Server 2019 features

SQL Server 2019 includes many new features, such as the following:

- Accelerated database recovery (ADR) – Reduces crash recovery time after a restart or a long-running transaction rollback.
- Intelligent Query Processing (IQP):
  - Row mode memory grant feedback – Corrects excessive grants automatically, that would otherwise result in wasted memory and reduced concurrency.
  - Batch mode on rowstore – Enables batch mode execution for analytic workloads without requiring columnstore indexes.
  - Table variable deferred compilation – Improves plan quality and overall performance for queries that reference table variables.
- Intelligent performance:
  - OPTIMIZE_FOR_SEQUENTIAL_KEY index option – Improves throughput for high-concurrency inserts into indexes.
  - Improved indirect checkpoint scalability – Helps databases with heavy DML workloads.
  - Concurrent Page Free Space (PFS) updates – Enables handling as a shared latch rather than an exclusive latch.
- Monitoring improvements:
  - WAIT_ON_SYNC_STATISTICS_REFRESH wait type – Shows accumulated instance-level time spent on synchronous statistics refresh operations.
  - Database-scoped configurations – Include LIGHTWEIGHT_QUERY_PROFILING and LAST_QUERY_PLAN_STATS.
  - Dynamic management functions (DMFs) – Include sys.dm_exec_query_plan_stats and sys.dm_db_page_info.
  - Verbose truncation warnings – The data truncation error message defaults to include table and column names and the truncated value.
  - Resumable online index creation – In SQL Server 2017, only resumable online index rebuild is supported.

For the full list of SQL Server 2019 features, see What's new in SQL Server 2019 (15.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 933).

Microsoft SQL Server 2017 features

SQL Server 2017 includes many new features, such as the following:

- Adaptive query processing
- Automatic plan correction (an automatic tuning feature)
- GraphDB
- Resumable index rebuilds

For the full list of SQL Server 2017 features, see What's new in SQL Server 2017 in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 933).
Microsoft SQL Server 2016 features

Amazon RDS supports the following features of SQL Server 2016:

• Always Encrypted
• JSON Support
• Operational Analytics
• Query Store
• Temporal Tables

For the full list of SQL Server 2016 features, see What's new in SQL Server 2016 in the Microsoft documentation.

Microsoft SQL Server 2014 features

In addition to supported features of SQL Server 2012, Amazon RDS supports the new query optimizer available in SQL Server 2014, and also the delayed durability feature.

For a list of unsupported features, see Features not supported and features with limited support (p. 933).

SQL Server 2014 supports all the parameters from SQL Server 2012 and uses the same default values. SQL Server 2014 includes one new parameter, backup checksum default. For more information, see How to enable the CHECKSUM option if backup utilities do not expose the option in the Microsoft documentation.

Microsoft SQL Server 2012 features

In addition to supported features of SQL Server 2008 R2, Amazon RDS supports the following SQL Server 2012 features:

• Columnstore indexes (Enterprise Edition)
• Online Index Create, Rebuild and Drop for XML, varchar(max), nvarchar(max), and varbinary(max) data types (Enterprise Edition)
• Flexible Server Roles
• Service Broker is supported. Service Broker endpoints aren't supported.
• Partially Contained Databases
• Sequences
• Transparent Data Encryption (Enterprise Edition only)
• THROW statement
• New and enhanced spatial types
• UTF-16 Support
• ALTER ANY SERVER ROLE server-level permission
• Secondary (user-defined) filegroups

For more information about SQL Server 2012, see Features supported by the editions of SQL Server 2012 in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support (p. 933).

Some SQL Server parameters have changed in SQL Server 2012.
• The following parameters have been removed from SQL Server 2012: awe enabled, precompute rank, and sql mail xps. These parameters were not modifiable in SQL Server DB Instances and their removal should have no impact on your SQL Server use.

• A new contained database authentication parameter in SQL Server 2012 supports partially contained databases. When you enable this parameter and then create a partially contained database, an authorized user's user name and password is stored within the partially contained database instead of in the primary database. For more information about partially contained databases, see Contained databases in the Microsoft documentation.

Microsoft SQL Server 2008 R2 deprecated on Amazon RDS

We are upgrading all existing instances that are still using SQL Server 2008 R2 to the latest minor version of SQL Server 2012. For more information, see Version management in Amazon RDS (p. 929).

For more information about SQL Server 2008 R2, see Features supported by the editions of SQL Server 2008 R2 in the Microsoft documentation.

Change data capture support for Microsoft SQL Server DB instances

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables, and stores metadata about each change that you can access later. For more information, see Change data capture in the Microsoft documentation.

Amazon RDS supports CDC for the following SQL Server editions and versions:

• Microsoft SQL Server Enterprise Edition (All versions)
• Microsoft SQL Server Standard Edition:
  • 2019
  • 2017
  • 2016 version 13.00.4422.0 SP1 CU2 and later

To use CDC with your Amazon RDS DB instances, first enable or disable CDC at the database level by using RDS-provided stored procedures. After that, any user that has the db_owner role for that database can use the native Microsoft stored procedures to control CDC on that database. For more information, see Using change data capture (p. 1125).

You can use CDC and AWS Database Migration Service to enable ongoing replication from SQL Server DB instances.

Features not supported and features with limited support

The following Microsoft SQL Server features aren't supported on Amazon RDS:

• Backing up to Microsoft Azure Blob Storage
Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary replica so database operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the passive secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS manages failover by actively monitoring your Multi-AZ deployment and initiating a failover when a problem with your primary occurs. Failover doesn't occur unless the standby and primary are fully in sync. Amazon RDS actively maintains your Multi-AZ deployment by automatically repairing unhealthy DB instances and re-establishing synchronous replication. You don't have to manage anything.
Amazon RDS handles the primary, the witness, and the standby instance for you. When you set up SQL Server Multi-AZ, RDS configures passive secondary instances for all of the databases on the instance.

For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).

Using Transparent Data Encryption to encrypt data at rest

Amazon RDS supports Microsoft SQL Server Transparent Data Encryption (TDE), which transparently encrypts stored data. Amazon RDS uses option groups to enable and configure these features. For more information about the TDE option, see Support for Transparent Data Encryption in SQL Server (p. 1049).

Functions and stored procedures for Amazon RDS for Microsoft SQL Server

The following table lists Amazon RDS functions and stored procedures that help automate SQL Server tasks.

<table>
<thead>
<tr>
<th>Task type</th>

## Local time zone for Microsoft SQL Server DB instances

The time zone of an Amazon RDS DB instance running Microsoft SQL Server is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment (using SQL Server DBM or AGs), then when you fail over, your time zone remains the local time zone that you set. For more information, see Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups (p. 934).

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time (p. 480).
The following are limitations to setting the local time zone on your DB instance:

- You can't modify the time zone of an existing SQL Server DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases (p. 962).

## Supported time zones

You can set your local time zone to one of the values listed in the following table.

### Time zones supported for Amazon RDS on SQL Server

<table>
<thead>
<tr>
<th>Time zone</th>
<th>Standard time offset</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Afghanistan Standard Time</td>
<td>(UTC+04:30)</td>
<td>Kabul</td>

Licensing Microsoft SQL Server on Amazon RDS

When you set up an Amazon RDS DB instance for Microsoft SQL Server, the software license is included. This means that you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software. Amazon RDS pricing includes the software license, underlying hardware resources, and Amazon RDS management capabilities.

Amazon RDS supports the following Microsoft SQL Server editions:

- Enterprise
- Standard
- Web
- Express

Note: Licensing for SQL Server Web Edition supports only public and internet-accessible webpages, websites, web applications, and web services. This level of support is required for compliance with Microsoft's usage rights. For more information, see AWS service terms.

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). There are no additional licensing requirements for Multi-AZ deployments. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).

Restoring license-terminated DB instances

Amazon RDS takes snapshots of license-terminated DB instances. If your instance is terminated for licensing issues, you can restore it from the snapshot to a new DB instance. New DB instances have a license included.

For more information, see Restoring license-terminated DB instances (p. 1124).

Development and test

Because of licensing requirements, we can't offer SQL Server Developer Edition on Amazon RDS. You can use Express Edition for many development, testing, and other nonproduction needs. However, if you need the full feature capabilities of an enterprise-level installation of SQL Server for development, you can download and install SQL Server Developer Edition (and other MSDN products) on Amazon EC2. Dedicated infrastructure isn't required for Developer Edition. By using your own host, you also gain access to other programmability features that are not accessible on Amazon RDS. For more information on the difference between SQL Server editions, see Editions and supported features of SQL Server 2017 in the Microsoft documentation.
Connecting to a DB instance running the Microsoft SQL Server database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to your DB instance by using either Microsoft SQL Server Management Studio (SSMS) or SQL Workbench/J.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating a Microsoft SQL Server DB instance and connecting to it (p. 107).

Before you connect

Before you can connect to your DB instance, it has to be available and accessible.

1. Make sure that its status is available. You can check this on the details page for your instance in the AWS Management Console or by using the `describe-db-instances` AWS CLI command.

2. Make sure that it is publicly accessible. You can check this when you check the availability.

3. Make sure that the inbound rules of your VPC security group allow access to your DB instance. For more information, see Can't connect to Amazon RDS DB instance (p. 1880).

Finding the DB instance endpoint and port number

You need both the endpoint and the port number to connect to the DB instance.

To find the endpoint and port

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the Domain Name System (DNS) name (endpoint) and port number for your DB instance:
   a. Open the RDS console and choose **Databases** to display a list of your DB instances.
   b. Choose the SQL Server DB instance name to display its details.
   c. On the **Connectivity & security** tab, copy the endpoint.
   d. Note the port number.

### Connecting to your DB instance with Microsoft SQL Server Management Studio

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS). To download a standalone version of this utility, see [Download SQL Server Management Studio (SSMS)](https://docs.microsoft.com/en-us/sql-server/downloads/sql-server-downloads) in the Microsoft documentation.

**To connect to a DB instance using SSMS**

1. Start SQL Server Management Studio.
   
The **Connect to Server** dialog box appears.
2. Provide the information for your DB instance:
   a. For Server type, choose **Database Engine**.
   b. For Server name, enter the DNS name (endpoint) and port number of your DB instance, separated by a comma.
      
      **Important**
      Change the colon between the endpoint and port number to a comma.
      
      Your server name should look like the following example.
      
      database-2.cg034itsfake.us-east-1.rds.amazonaws.com,1433
   c. For Authentication, choose **SQL Server Authentication**.
   d. For Login, enter the master user name for your DB instance.
   e. For Password, enter the password for your DB instance.

3. Choose **Connect**.

   After a few moments, SSMS connects to your DB instance.

   If you can't connect to your DB instance, see Security group considerations (p. 952) and Troubleshooting connections to your SQL Server DB instance (p. 952).

4. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (**master**, **model**, **msdb**, and **tempdb**). To explore the system databases, do the following:
   a. In SSMS, on the View menu, choose **Object Explorer**.
   b. Expand your DB instance, expand **Databases**, and then expand **System Databases**.
5. Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks. For more information, see Common DBA tasks for Microsoft SQL Server (p. 1113).

6. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In SSMS, on the File menu point to New and then choose Query with Current Connection.
   b. Enter the following SQL query.

   ```sql
   select @@VERSION
   ```
   c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.

Connecting to your DB instance with SQL Workbench/J

This example shows how to connect to a DB instance running the Microsoft SQL Server database engine by using the SQL Workbench/J database tool. To download SQL Workbench/J, see SQL Workbench/J.

SQL Workbench/J uses JDBC to connect to your DB instance. You also need the JDBC driver for SQL Server. To download this driver, see Microsoft JDBC drivers 4.1 (preview) and 4.0 for SQL Server.
To connect to a DB instance using SQL Workbench/J

1. Open SQL Workbench/J. The Select Connection Profile dialog box appears, as shown following.

2. In the first box at the top of the dialog box, enter a name for the profile.
3. For Driver, choose SQL JDBC 4.0.
4. For URL, enter jdbc:sqlserver://, then enter the endpoint of your DB instance. For example, the URL value might be the following.
   ```
   ```
5. For Username, enter the master user name for the DB instance.
6. For Password, enter the password for the master user.
7. Choose the save icon in the dialog toolbar, as shown following.
8. Choose OK. After a few moments, SQL Workbench/J connects to your DB instance. If you can’t connect to your DB instance, see Security group considerations (p. 952) and Troubleshooting connections to your SQL Server DB instance (p. 952).
9. In the query pane, enter the following SQL query.
   ```
   select @@VERSION
   ```
10. Choose the Execute icon in the toolbar, as shown following.

The query returns the version information for your DB instance, similar to the following.

Microsoft SQL Server 2012 - 11.0.2100.60 (X64)
Security group considerations

To connect to your DB instance, your DB instance must be associated with a security group. This security group contains the IP addresses and network configuration that you use to access the DB instance. You might have associated your DB instance with an appropriate security group when you created your DB instance. If you assigned a default, no-configured security group when you created your DB instance, your DB instance firewall prevents connections.

In some cases, you might need to create a new security group to enable access. If so, the type of security group to create depends on what Amazon EC2 platform your DB instance is on. To determine your platform, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869). In general, if your DB instance is on the EC2-Classic platform, you create a DB security group. If your DB instance is on the VPC platform, you create a VPC security group.

For instructions on creating a new security group, see Controlling access with security groups (p. 1822). For a topic that walks you through the process of setting up rules for your VPC security group, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863).

After you have created the new security group, modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 996).

Troubleshooting connections to your SQL Server DB instance

The following table shows error messages that you might encounter when you attempt to connect to your SQL Server DB instance. For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 1880).

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Could not open a connection to SQL Server – Microsoft SQL Server, Error: 53</td>
<td>Make sure that you specified the server name correctly. For <strong>Server name</strong>, enter the DNS name and port number of your sample DB instance, separated by a comma.</td>
</tr>
<tr>
<td></td>
<td><strong>Important</strong></td>
</tr>
<tr>
<td></td>
<td>If you have a colon between the DNS name and port number, change the colon to a comma.</td>
</tr>
<tr>
<td></td>
<td>Your server name should look like the following example.</td>
</tr>
<tr>
<td></td>
<td>sample-instance.cg034itsfake.us-east-1.rds.amazonaws.com,1433</td>
</tr>
<tr>
<td>No connection could be made because the target machine actively refused it – Microsoft SQL Server, Error: 10061</td>
<td>You were able to reach the DB instance but the connection was refused. This issue is usually caused by specifying the user name or password incorrectly. Verify the user name and password, then retry.</td>
</tr>
<tr>
<td>A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found</td>
<td>The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.</td>
</tr>
</tbody>
</table>
## Issue

or was not accessible... The wait operation timed out – Microsoft SQL Server, Error: 258

## Troubleshooting suggestions

Your database instance must be publicly accessible. To connect to it from outside of the VPC, the instance must have a public IP address assigned.
Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

**Note**
Some applications are configured to connect to SQL Server DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 1757). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). For information about using SSL/TLS with Microsoft SQL Server DB instances, see Using SSL with a Microsoft SQL Server DB instance (p. 996).

**Topics**
- Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL (p. 954)
- Determining whether a client requires certificate verification in order to connect (p. 955)
- Updating your application trust store (p. 956)

Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL

Check the DB instance configuration for the value of the rds.force_ssl parameter. By default, the rds.force_ssl parameter is set to 0 (off). If the rds.force_ssl parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups (p. 278).

Run the following query to get the current encryption option for all the open connections to a DB instance. The column ENCRYPT_OPTION returns TRUE if the connection is encrypted.

```sql
select SESSION_ID,
       ENCRYPT_OPTION,
       NET_TRANSPORT,
       AUTH_SCHEME
from SYS.DM_EXEC_CONNECTIONS
```

This query shows only the current connections. It doesn't show whether applications that have connected and disconnected in the past have used SSL.
Determining whether a client requires certificate verification in order to connect

You can check whether different types of clients require certificate verification to connect.

**Note**
If you use connectors other than the ones listed, see the specific connector’s documentation for information about how it enforces encrypted connections. For more information, see Connection modules for Microsoft SQL databases in the Microsoft SQL Server documentation.

**SQL Server Management Studio**

Check whether encryption is enforced for SQL Server Management Studio connections:

1. Launch SQL Server Management Studio.
2. For **Connect to server**, enter the server information, login user name, and password.
3. Choose **Options**.
4. Check if **Encrypt connection** is selected in the connect page.

For more information about SQL Server Management Studio, see Use SQL Server Management Studio.

**Sqlcmd**

The following example with the sqlcmd client shows how to check a script's SQL Server connection to determine whether successful connections require a valid certificate. For more information, see Connecting with sqlcmd in the Microsoft SQL Server documentation.

When using sqlcmd, an SSL connection requires verification against the server certificate if you use the \-N command argument to encrypt connections, as in the following example.

```bash
$ sqlcmd -N -S dbinstance.rds.amazon.com -d ExampleDB
```

**Note**
If sqlcmd is invoked with the \-C option, it trusts the server certificate, even if that doesn’t match the client-side trust store.

**ADO.NET**

In the following example, the application connects using SSL, and the server certificate must be verified.

```csharp
using SQLC = Microsoft.Data.SqlClient;
...

    static public void Main()
    {
        using (var connection = new SQLC.SqlConnection(
            "Server=tcp:dbinstance.rds.amazon.com;" +
            "Database=ExampleDB;User ID=LOGIN_NAME;" +
            "Password=YOUR_PASSWORD;" +
            "Encrypt=True;TrustServerCertificate=False;"
        ))
    }
```
Java

In the following example, the application connects using SSL, and the server certificate must be verified.

```java
connection.Open();
...
}
```

String connectionUrl =
    "jdbc:sqlserver://dbinstance.rds.amazon.com;"
    +
    "databaseName=ExampleDB;integratedSecurity=true;"
    +
    "encrypt=true;trustServerCertificate=false";

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS certificate to the Java CA certificate store. For instructions, see Configuring the client for encryption in the Microsoft SQL Server documentation. You can also provide the trusted CA certificate file name directly by appending `trustStore=path-to-certificate-trust-store-file` to the connection string.

**Note**

If you use `TrustServerCertificate=true` (or its equivalent) in the connection string, the connection process skips the trust chain validation. In this case, the application connects even if the certificate can't be verified. Using `TrustServerCertificate=false` enforces certificate validation and is a best practice.

**Updating your application trust store**

You can update the trust store for applications that use Microsoft SQL Server. For instructions, see Encrypting specific connections (p. 997). Also, see Configuring the client for encryption in the Microsoft SQL Server documentation.

If you are using an operating system other than Microsoft Windows, see the software distribution documentation for SSL/TLS implementation for information about adding a new root CA certificate. For example, OpenSSL and GnuTLS are popular options. Use the implementation method to add trust to the RDS root CA certificate. Microsoft provides instructions for configuring certificates on some systems.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1764).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.
Upgrading the Microsoft SQL Server DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for SQL Server DB instances: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you test the upgrade by following the steps described in Testing an upgrade (p. 960).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Alternatively, you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. You can confirm whether the minor version upgrade will be automatic by using the `describe-db-engine-versions` AWS CLI command. For example:

```bash
aws rds describe-db-engine-versions --engine sqlserver-se --engine-version 14.00.3049.1.v1
```

In the following example, the CLI command returns a response indicating that upgrades are automatic.

```json
...
"ValidUpgradeTarget": [  
    {  
      "Engine": "sqlserver-se",  
      "EngineVersion": "14.00.3192.2.v1",  
      "Description": "SQL Server 2017 14.00.3192.2.v1",  
      "AutoUpgrade": true,  
      "IsMajorVersionUpgrade": false  
    }  
...
```

For more information about performing upgrades, see Upgrading a SQL Server DB instance (p. 961). For information about what SQL Server versions are available on Amazon RDS, see Microsoft SQL Server on Amazon RDS (p. 921).

**Topics**
- Overview of upgrading (p. 958)
- Major version upgrades (p. 958)
- Multi-AZ and in-memory optimization considerations (p. 959)
- Option group considerations (p. 960)
- Parameter group considerations (p. 960)
- Testing an upgrade (p. 960)
- Upgrading a SQL Server DB instance (p. 961)
- Upgrading deprecated DB instances before support ends (p. 961)
Overview of upgrading

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. The second DB snapshot is taken after the upgrade finishes.

**Note**

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](p. 309).

After an upgrade is completed, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore from the DB snapshot that was taken before the upgrade to create a new DB instance.

During a minor or major version upgrade of SQL Server, the Free Storage Space and Disk Queue Depth metrics will display −1. After the upgrade is completed, both metrics will return to normal.

Major version upgrades

Amazon RDS currently supports the following major version upgrades to a Microsoft SQL Server DB instance.

You can upgrade your existing DB instance to SQL Server 2017 or 2019 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Supported upgrade versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL Server 2017</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td>SQL Server 2016</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td>SQL Server 2014</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td>SQL Server 2012</td>
<td>SQL Server 2019</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2017</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2014</td>
</tr>
<tr>
<td>SQL Server 2008 R2 (Deprecated)</td>
<td>SQL Server 2016</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2014</td>
</tr>
<tr>
<td></td>
<td>SQL Server 2012</td>
</tr>
</tbody>
</table>

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.
Example

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine sqlserver-se \
  --engine-version 14.00.3049.1.v1 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
  --output table
```

For Windows:

```bash
aws rds describe-db-engine-versions ^ \
  --engine sqlserver-se ^ \
  --engine-version 14.00.3049.1.v1 ^ \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^ \
  --output table
```

The output shows that you can upgrade version 14.00.3049.1 to the latest SQL Server 2017 or 2019 versions.

```
<table>
<thead>
<tr>
<th>DescribeDBEngineVersions</th>
<th>EngineVersion</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>14.00.3294.2.v1</td>
</tr>
<tr>
<td></td>
<td>14.00.3356.20.v1</td>
</tr>
<tr>
<td></td>
<td>14.00.3381.3.v1</td>
</tr>
<tr>
<td></td>
<td>15.00.4043.16.v1</td>
</tr>
<tr>
<td></td>
<td>15.00.4073.23.v1</td>
</tr>
</tbody>
</table>
```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see Compatibility level in the Microsoft documentation.

When you upgrade your DB instance, all existing databases remain at their original compatibility level. For example, if you upgrade from SQL Server 2012 to SQL Server 2014, all existing databases have a compatibility level of 110. Any new database created after the upgrade have compatibility level 120.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named customeracct to be compatible with SQL Server 2014, issue the following command:

```sql
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 120
```

Multi-AZ and in-memory optimization considerations

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).

If your DB instance is in a Multi-AZ deployment, both the primary and standby instances are upgraded. Amazon RDS does rolling upgrades. You have an outage only for the duration of a failover.

Option group considerations

If your DB instance uses a custom DB option group, in some cases Amazon RDS can't automatically assign your DB instance a new option group. For example, when you upgrade to a new major version, you must specify a new option group. We recommend that you create a new option group, and add the same options to it as your existing custom option group.

For more information, see Creating an option group (p. 264) or Copying an option group (p. 265).

Parameter group considerations

If your DB instance uses a custom DB parameter group:

- Amazon RDS automatically reboots the DB instance after an upgrade.
- In some cases, RDS can't automatically assign a new parameter group to your DB instance.

For example, when you upgrade to a new major version, you must specify a new parameter group. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group (p. 280) or Copying a DB parameter group (p. 287).

Testing an upgrade

Before you perform a major version upgrade on your DB instance, you should thoroughly test your database, and all applications that access the database, for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review Upgrade SQL Server in the Microsoft documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations (p. 960).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations (p. 960).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 428).
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 432).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console (p. 344)
   - AWS CLI (p. 345)
   - RDS API (p. 345)
7. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
8. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.

9. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you do not allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a SQL Server DB instance

For information about manually or automatically upgrading a SQL Server DB instance, see the following:

- Upgrading a DB instance engine version (p. 344)
- Best practices for upgrading SQL Server 2008 R2 to SQL Server 2016 on Amazon RDS for SQL Server

**Important**

If you have any snapshots that are encrypted using AWS KMS, we recommend that you initiate an upgrade before support ends.

Upgrading deprecated DB instances before support ends

After a major version is deprecated, you can't install it on new DB instances. RDS will try to automatically upgrade all existing DB instances.

If you need to restore a deprecated DB instance, you can do point-in-time recovery (PITR) or restore a snapshot. Doing this gives you temporary access a DB instance that uses the version that is being deprecated. However, after a major version is fully deprecated, these DB instances will also be automatically upgraded to a supported version.
Importing and exporting SQL Server databases

Amazon RDS supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). When you use RDS, you access files stored in Amazon S3 rather than using the local file system on the database server.

For example, you can create a full backup from your local server, store it on S3, and then restore it onto an existing Amazon RDS DB instance. You can also make backups from RDS, store them on S3, and then restore them wherever you want.

Native backup and restore is available in all AWS Regions for Single-AZ and Multi-AZ DB instances, including Multi-AZ DB instances with read replicas. Native backup and restore is available for all editions of Microsoft SQL Server supported on Amazon RDS.

The following diagram shows the supported scenarios.

![Diagram showing supported scenarios for importing and exporting SQL Server databases]

Using native .bak files to back up and restore databases is usually the fastest way to back up and restore databases. There are many additional advantages to using native backup and restore. For example, you can do the following:

- Migrate databases to or from Amazon RDS.
- Move databases between RDS for SQL Server DB instances.
- Migrate data, schemas, stored procedures, triggers, and other database code inside .bak files.
- Backup and restore single databases, instead of entire DB instances.
- Create copies of databases for development, testing, training, and demonstrations.
- Store and transfer backup files with Amazon S3, for an added layer of protection for disaster recovery.

Limitations and recommendations

The following are some limitations to using native backup and restore:

- You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance.
- You can't restore a database with the same name as an existing database. Database names are unique.
- We strongly recommend that you don't restore backups from one time zone to a different time zone. If you restore backups from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change.
• Amazon S3 has a size limit of 5 TB per file. For native backups of larger databases, you can use multfile backup.

• The maximum database size that can be backed up to S3 depends on the available memory, CPU, I/O, and network resources on the DB instance. The larger the database, the more memory the backup agent consumes. Our testing shows that you can make a compressed backup of a 16-TB database on our newest-generation instance types from 2xlarge instance sizes and larger, given sufficient system resources.

• You can't back up to or restore from more than 10 backup files at the same time.

• A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a manual or automated snapshot exists, then do another full backup before proceeding with the differential backup.

• Differential and log restores aren't supported for databases with files that have their file_guid (unique identifier) set to NULL.

• You can run up to two backup or restore tasks at the same time.

• You can't perform native log backups from SQL Server on Amazon RDS.

• RDS supports native restores of databases up to 16 TB. Native restores of databases on SQL Server Express Edition are limited to 10 GB.

• You can't do a native backup during the maintenance window, or any time Amazon RDS is in the process of taking a snapshot of the database. If a native backup task overlaps with the RDS daily backup window, the native backup task is canceled.

• On Multi-AZ DB instances, you can only natively restore databases that are backed up in the full recovery model.

• Restoring from differential backups on Multi-AZ instances isn't supported.

• Calling the RDS procedures for native backup and restore within a transaction isn't supported.

• Use a symmetric AWS KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Using symmetric and asymmetric keys in the AWS Key Management Service Developer Guide.

• Native backup files are encrypted with the specified KMS key using the "Encryption-Only" crypto mode. When you are restoring encrypted backup files, be aware that they were encrypted with the "Encryption-Only" crypto mode.

• You can't restore a database that contains a FILESTREAM file group.

• You can create native backups of Transparent Data Encryption (TDE)-enabled databases, but you can't restore those backups to on-premises databases. You can't restore native backups of TDE-enabled, on-premises databases.

If your database can be offline while the backup file is created, copied, and restored, we recommend that you use native backup and restore to migrate it to RDS. If your on-premises database can't be offline, we recommend that you use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Native backup and restore isn't intended to replace the data recovery capabilities of the cross-region snapshot copy feature. We recommend that you use snapshot copy to copy your database snapshot to another AWS Region for cross-region disaster recovery in Amazon RDS. For more information, see Copying a snapshot (p. 438).

Setting up for native backup and restore

To set up for native backup and restore, you need three components:

1. An Amazon S3 bucket to store your backup files.
You must have an S3 bucket to use for your backup files and then upload backups you want to migrate to RDS. If you already have an Amazon S3 bucket, you can use that. If you don't, you can create a bucket. Alternatively, you can choose to have a new bucket created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console.

For information on using S3, see the Amazon Simple Storage Service User Guide for a simple introduction. For more depth, see the Amazon Simple Storage Service User Guide.

2. An AWS Identity and Access Management (IAM) role to access the bucket.

If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually.

If you want to create a new IAM role manually, take the approach discussed in the next section. Do the same if you want to attach trust relationships and permissions policies to an existing IAM role.

3. The SQLSERVER_BACKUP_RESTORE option added to an option group on your DB instance.

To enable native backup and restore on your DB instance, you add the SQLSERVER_BACKUP_RESTORE option to an option group on your DB instance. For more information and instructions, see Support for native backup and restore in SQL Server (p. 1046).

Manually creating an IAM role for native backup and restore

If you want to manually create a new IAM role to use with native backup and restore, you can do so. In this case, you create a role to delegate permissions from the Amazon RDS service to your Amazon S3 bucket. When you create an IAM role, you attach a trust relationship and a permissions policy. The trust relationship allows RDS to assume this role. The permissions policy defines the actions this role can perform. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

For the native backup and restore feature, use trust relationships and permissions policies similar to the examples in this section. In the following example, we use the service principal name rds.amazonaws.com as an alias for all service accounts. In the other examples, we specify an Amazon Resource Name (ARN) to identify another account, user, or role that we're granting access to in the trust policy.

Example trust relationship for native backup and restore

```
{
  "Version": "2012-10-17",
  "Statement":
  [{
    "Effect": "Allow",
    "Principal": {"Service": "rds.amazonaws.com"},
    "Action": "sts:AssumeRole"
  }]
}
```

We recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the aws:SourceArn value contain the account ID. In this case, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same statement.

- Use aws:SourceArn if you want cross-service access for a single resource.
• Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full ARN of the resources accessing the role. For native backup and restore, make sure to include both the DB option group and the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for native backup and restore**

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
         },
         "Action": "sts:AssumeRole",
         "Condition": {
            "StringEquals": {
               "aws:SourceArn": [
                  "arn:aws:rds:Region:my_account_ID:og:option_group_name"
               ]
            }
         }
      }
   ]
}
```

The following example uses an ARN to specify a resource. For more information on using ARNs, see Amazon resource names (ARNs).

**Example permissions policy for native backup and restore without encryption support**

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket",
            "s3:GetBucketLocation"
         ],
         "Resource": "arn:aws:s3:::bucket_name"
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetObject",
            "s3:PutObject",
            "s3:ListMultipartUploadParts",
            "s3:AbortMultipartUpload"
         ],
         "Resource": "arn:aws:s3:::bucket_name/*"
      }
   ]
}
```
Example permissions policy for native backup and restore with encryption support

If you want to encrypt your backup files, include an encryption key in your permissions policy. For more information about encryption keys, see Getting started in the AWS Key Management Service Developer Guide.

**Note**
You must use a symmetric KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Using symmetric and asymmetric keys in the AWS Key Management Service Developer Guide.
The IAM role must also be a key user and key administrator for the KMS key, that is, it must be specified in the key policy. For more information, see Creating symmetric KMS keys in the AWS Key Management Service Developer Guide.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:DescribeKey",
        "kms:GenerateDataKey",
        "kms:Encrypt",
        "kms:Decrypt"
      ],
      "Resource": "arn:aws:kms:region:account-id:key/key-id"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucket_name"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": "arn:aws:s3:::bucket_name/*"
    }
  ]
}
```

Using native backup and restore

After you have enabled and configured native backup and restore, you can start using it. First, you connect to your Microsoft SQL Server database, and then you call an Amazon RDS stored procedure to do the work. For instructions on connecting to your database, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 947).

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your Amazon S3 bucket and file. The format for your ARN is
Using native backup and restore

Amazon S3 doesn't require an account number or AWS Region in ARNs.

If you also provide an optional KMS key, the format for the ARN of the key is
arn:aws:kms:region:account-id:key/key-id. For more information, see Amazon resource names (ARNs) and AWS service namespaces. You must use a symmetric KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Using symmetric and asymmetric keys in the AWS Key Management Service Developer Guide.

Note
Whether or not you use a KMS key, the native backup and restore tasks enable server-side Advanced Encryption Standard (AES) 256-bit encryption by default for files uploaded to S3.

For instructions on how to call each stored procedure, see the following topics:

- Backing up a database (p. 967)
- Restoring a database (p. 969)
- Restoring a log (p. 972)
- Finishing a database restore (p. 973)
- Working with partially restored databases (p. 974)
- Canceling a task (p. 974)
- Tracking the status of tasks (p. 974)

Backing up a database

To back up your database, use the rds_backup_database stored procedure.

Note
You can't back up a database during the maintenance window, or while Amazon RDS is taking a snapshot.

Usage

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='database_name',
@s3_arn_to_backup_to='arn:aws:s3:::bucket_name/file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@overwrite_s3_backup_file=0|1],
[@type='DIFFERENTIAL|FULL'],
[@number_of_files=n];
```

The following parameters are required:

- @source_db_name – The name of the database to back up.
- @s3_arn_to_backup_to – The ARN indicating the Amazon S3 bucket to use for the backup, plus the name of the backup file.

The file can have any extension, but .bak is usually used.

The following parameters are optional:

- @kms_master_key_arn – The ARN for the symmetric KMS key to use to encrypt the item.
  - You can't use the default encryption key. If you use the default key, the database won't be backed up.
• If you don't specify a KMS key identifier, the backup file won't be encrypted. For more information, see Encrypting Amazon RDS resources.
• When you specify a KMS key, client-side encryption is used.
• Amazon RDS doesn't support asymmetric KMS keys. For more information, see Using symmetric and asymmetric keys in the AWS Key Management Service Developer Guide.
• @overwrite_s3_backup_file – A value that indicates whether to overwrite an existing backup file.
  0 – Doesn't overwrite an existing file. This value is the default.
  Setting @overwrite_s3_backup_file to 0 returns an error if the file already exists.
  1 – Overwrites an existing file that has the specified name, even if it isn't a backup file.
• @type – The type of backup.
  DIFFERENTIAL – Makes a differential backup.
  FULL – Makes a full backup. This value is the default.

A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a snapshot exists, then do another full backup before proceeding with the differential backup.

You can look for the last full backup or snapshot using the following example SQL query:

```sql
select top 1
database_name,
    backup_start_date,
    backup_finish_date
from    msdb.dbo.backupset
where   database_name='mydatabase'
    and     type = 'D'
order by backup_start_date desc;
```

• @number_of_files – The number of files into which the backup will be divided (chunked). The maximum number is 10.
• Multifile backup is supported for both full and differential backups.
• If you enter a value of 1 or omit the parameter, a single backup file is created.

Provide the prefix that the files have in common, then suffix that with an asterisk (*). The asterisk can be anywhere in the file name part of the S3 ARN. The asterisk is replaced by a series of alphanumeric strings in the generated files, starting with 1-of-number_of_files.

For example, if the file names in the S3 ARN are backup*.bak and you set @number_of_files=4, the backup files generated are backup1-of-4.bak, backup2-of-4.bak, backup3-of-4.bak, and backup4-of-4.bak.
• If any of the file names already exists, and @overwrite_s3_backup_file is 0, an error is returned.
• Multifile backups can only have one asterisk in the file name part of the S3 ARN.
• Single-file backups can have any number of asterisks in the file name part of the S3 ARN. Asterisks aren't removed from the generated file name.

Examples

Example of differential backup

```sql
exec msdb.dbo.rds_backup_database
    @source_db_name='mydatabase',
    @s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
    @overwrite_s3_backup_file=1;
```
Example of full backup with encryption

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/ AKIAIOSFODNN7EXAMPLE',
overwrite_s3_backup_file=1,
@type='FULL';
```

Example of multifile backup

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=4;
```

Example of multifile differential backup

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@type='DIFFERENTIAL',
@number_of_files=4;
```

Example of multifile backup with encryption

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/ AKIAIOSFODNN7EXAMPLE',
@number_of_files=4;
```

Example of multifile backup with S3 overwrite

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@overwrite_s3_backup_file=1,
@number_of_files=4;
```

Example of single-file backup with the @number_of_files parameter

This example generates a backup file named backup*.bak.

```sql
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=1;
```

Restoring a database

To restore your database, call the rds_restore_database stored procedure. Amazon RDS creates an initial snapshot of the database after the restore task is complete and the database is open.
**Usage**

exec msdb.dbo.rds_restore_database
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/file_name.extension',
@with_norecovery=0|1,
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@type='DIFFERENTIAL|FULL'];

The following parameters are required:

- **@restore_db_name** – The name of the database to restore. Database names are unique. You can't restore a database with the same name as an existing database.
- **@s3_arn_to_restore_from** – The ARN indicating the Amazon S3 prefix and names of the backup files used to restore the database.
  - For a single-file backup, provide the entire file name.
  - For a multifile backup, provide the prefix that the files have in common, then suffix that with an asterisk (*).
  - If @s3_arn_to_restore_from is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameter is required for differential restores, but optional for full restores:

- **@with_norecovery** – The recovery clause to use for the restore operation.
  - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later differential restores.
  - For DIFFERENTIAL restores, specify 0 or 1.
  - For FULL restores, this value defaults to 0.

The following parameters are optional:

- **@kms_master_key_arn** – If you encrypted the backup file, the KMS key to use to decrypt the file.
  - When you specify a KMS key, client-side encryption is used.
- **@type** – The type of restore. Valid types are DIFFERENTIAL and FULL. The default value is FULL.

**Note**

For differential restores, either the database must be in the RESTORING state or a task must already exist that restores with NORECOVERY.

You can't restore later differential backups while the database is online.

You can't submit a restore task for a database that already has a pending restore task with RECOVERY.

Full restores with NORECOVERY and differential restores aren't supported on Multi-AZ instances.

Restoring a database on a Multi-AZ instance with read replicas is similar to restoring a database on a Multi-AZ instance. You don't have to take any additional actions to restore a database on a replica.

**Examples**

**Example of single-file restore**

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';

Example of multfile restore

To avoid errors when restoring multiple files, make sure that all the backup files have the same prefix, and that no other files use that prefix.

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*';

Example of full database restore with RECOVERY

The following three examples perform the same task, full restore with RECOVERY.

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
[@type='DIFFERENTIAL|FULL'];

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=0;

Example of full database restore with encryption

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';

Example of full database restore with NORECOVERY

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=1;

Example of differential restore with NORECOVERY

exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=1;

Example of differential restore with RECOVERY

exec msdb.dbo.rds_restore_database
### Restoring a log

To restore your log, call the `rds_restore_log` stored procedure.

#### Usage

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/log_file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@with_norecovery=0/1],
[@stopat='datetime'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database whose log to restore.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and name of the log file used to restore the log. The file can have any extension, but `.trn` is usually used.

   If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the log, the KMS key to use to decrypt the log.
- `@with_norecovery` – The recovery clause to use for the restore operation. This value defaults to 1.
  - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore. You can't restore further log backups while the database is online.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later log restores.
- `@stopat` – A value that specifies that the database is restored to its state at the date and time specified (in datetime format). Only transaction log records written before the specified date and time are applied to the database.

If this parameter isn't specified (it is NULL), the complete log is restored.

**Note**

For log restores, either the database must be in a state of restoring or a task must already exist that restores with NORECOVERY.

You can't restore log backups while the database is online.

You can't submit a log restore task on a database that already has a pending restore task with RECOVERY.

Log restores aren't supported on Multi-AZ instances.

#### Examples

**Example of log restore**

```sql
exec msdb.dbo.rds_restore_log
```
Example of log restore with encryption

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/ARIAIOSFODNN7EXAMPLE';
```

Example of log restore with NORECOVERY

The following two examples perform the same task, log restore with NORECOVERY.

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=1;
```

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of log restore with RECOVERY

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0;
```

Example of log restore with STOPAT clause

```sql
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0,
@stopat='2019-12-01 03:57:09';
```

Finishing a database restore

If the last restore task on the database was performed using @with_norecovery=1, the database is now in the RESTORING state. Open this database for normal operation by using the rds_finish_restore stored procedure.

Usage

```sql
exec msdb.dbo.rds_finish_restore @db_name='database_name';
```

Note

To use this approach, the database must be in the RESTORING state without any pending restore tasks. The rds_finish_restore procedure isn't supported on Multi-AZ instances.
To finish restoring the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

**Working with partially restored databases**

**Dropping a partially restored database**

To drop a partially restored database (left in the RESTORING state), use the `rds_drop_database` stored procedure.

```sql
exec msdb.dbo.rds_drop_database @db_name='database_name';
```

**Note**

You can't submit a DROP database request for a database that already has a pending restore or finish restore task.

To drop the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

**Snapshot restore and point-in-time recovery behavior for partially restored databases**

Partially restored databases in the source instance (left in the RESTORING state) are dropped from the target instance during snapshot restore and point-in-time recovery.

**Canceling a task**

To cancel a backup or restore task, call the `rds_cancel_task` stored procedure.

**Note**

You can't cancel a FINISH_RESTORE task.

**Usage**

```sql
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can get the task ID by calling `rds_task_status`.

**Tracking the status of tasks**

To track the status of your backup and restore tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks. The status for tasks is updated approximately every two minutes. Task history is retained for 36 days.

**Usage**

```sql
exec msdb.dbo.rds_task_status
[@db_name='database_name'],
[@task_id=ID_number];
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
• @task_id – The ID of the task to show the task status for.

Examples

Example of listing the status for a specific task

```sql
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task

```sql
exec msdb.dbo.rds_task_status @db_name='my_database',
@task_id=5;
```

Example of listing all tasks and their statuses on a specific database

```sql
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their statuses on the current instance

```sql
exec msdb.dbo.rds_task_status;
```

Response

The `rds_task_status` stored procedure returns the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>Task type depending on the input parameters, as follows:</td>
</tr>
<tr>
<td></td>
<td>• For backup tasks:</td>
</tr>
<tr>
<td></td>
<td>• BACKUP_DB – Full database backup</td>
</tr>
<tr>
<td></td>
<td>• BACKUP_DB_DIFFERENTIAL – Differential database backup</td>
</tr>
<tr>
<td></td>
<td>• For restore tasks:</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB – Full database restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_NORECOVERY – Full database restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_DIFFERENTIAL – Differential database restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_DIFFERENTIAL_NORECOVERY – Differential database restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_LOG – Log restore with RECOVERY</td>
</tr>
<tr>
<td></td>
<td>• RESTORE_DB_LOG_NORECOVERY – Log restore with NORECOVERY</td>
</tr>
<tr>
<td></td>
<td>• For tasks that finish a restore:</td>
</tr>
<tr>
<td></td>
<td>• FINISH_RESTORE – Finish restore and open database</td>
</tr>
</tbody>
</table>

Amazon RDS creates an initial snapshot of the database after it is open on completion of the following restore tasks:

• RESTORE_DB
Compressing backup files

To save space in your Amazon S3 bucket, you can compress your backup files. For more information about compressing backup files, see Backup compression in the Microsoft documentation.
Compressing your backup files is supported for the following database editions:

- Microsoft SQL Server Enterprise Edition
- Microsoft SQL Server Standard Edition

To turn on compression for your backup files, run the following code:

```
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'true';
```

To turn off compression for your backup files, run the following code:

```
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'false';
```

**Troubleshooting**

The following are issues you might encounter when you use native backup and restore.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database backup/restore option is not enabled yet or is in the process of being enabled. Please try again later.</td>
<td>Make sure that you have added the SQLSERVER_BACKUP_RESTORE option to the DB option group associated with your DB instance. For more information, see Adding the native backup and restore option (p. 1046).</td>
</tr>
<tr>
<td>Access Denied</td>
<td>The backup or restore process can't access the backup file. This is usually caused by issues like the following:</td>
</tr>
<tr>
<td></td>
<td>- Referencing the incorrect bucket. Referencing the bucket using an incorrect format. Referencing a file name without using the ARN.</td>
</tr>
<tr>
<td></td>
<td>- Incorrect permissions on the bucket file. For example, if it is created by a different account that is trying to access it now, add the correct permissions.</td>
</tr>
<tr>
<td></td>
<td>- An IAM policy that is incorrect or incomplete. Your IAM role must include all the necessary elements, including, for example, the correct version. These are highlighted in Importing and exporting SQL Server databases (p. 962).</td>
</tr>
<tr>
<td>BACKUP DATABASE WITH COMPRESSION isn't supported on &lt;edition_name&gt; Edition</td>
<td>Compressing your backup files is only supported for Microsoft SQL Server Enterprise Edition and Standard Edition. For more information, see Compressing backup files (p. 976).</td>
</tr>
<tr>
<td>Key &lt;ARN&gt; does not exist</td>
<td>You attempted to restore an encrypted backup, but didn't provide a valid encryption key. Check your encryption key and retry. For more information, see Restoring a database (p. 969).</td>
</tr>
<tr>
<td>Please reissue task with correct type and overwrite property</td>
<td>If you attempt to back up your database and provide the name of a file that already exists, but set the overwrite property to false, the save operation fails. To fix this error, either provide the name of a file that doesn't already exist, or set the overwrite property to true. For more information, see Backing up a database (p. 967).</td>
</tr>
<tr>
<td>Issue</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>-------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>It's also possible that you intended to restore your database, but called the <code>rds_backup_database</code> stored procedure accidentally. In that case, call the <code>rds_restore_database</code> stored procedure instead.</td>
<td>For more information, see Restoring a database (p. 969).</td>
</tr>
<tr>
<td>If you intended to restore your database and called the <code>rds_restore_database</code> stored procedure, make sure that you provided the name of a valid backup file.</td>
<td>For more information, see Using native backup and restore (p. 966).</td>
</tr>
<tr>
<td>Please specify a bucket that is in the same region as RDS instance</td>
<td>You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance. You can use Amazon S3 replication to copy the backup file to the correct AWS Region.</td>
</tr>
<tr>
<td>The specified bucket does not exist</td>

</table>
Importing and exporting SQL Server data using other methods

Following, you can find information about using snapshots to import your Microsoft SQL Server data to Amazon RDS. You can also find information about using snapshots to export your data from an RDS DB instance running SQL Server.

If your scenario supports it, it's easier to move data in and out of Amazon RDS by using the native backup and restore functionality. For more information, see Importing and exporting SQL Server databases (p. 962).

Note

Amazon RDS for Microsoft SQL Server does not support importing data into the msdb database.

Importing data into SQL Server on Amazon RDS by using a snapshot

To import data into a SQL Server DB instance by using a snapshot

1. Create a DB instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
2. Stop applications from accessing the destination DB instance.
   
   If you prevent access to your DB instance while you are importing data, data transfer is faster. Additionally, you don't need to worry about conflicts while data is being loaded if other applications cannot write to the DB instance at the same time. If something goes wrong and you have to roll back to an earlier database snapshot, the only changes that you lose are the imported data. You can import this data again after you resolve the issue.

   For information about controlling access to your DB instance, see Working with DB security groups (EC2-Classic platform) (p. 1827).
3. Create a snapshot of the target database.
   
   If the target database is already populated with data, we recommend that you take a snapshot of the database before you import the data. If something goes wrong with the data import or you want to discard the changes, you can restore the database to its previous state by using the snapshot. For information about database snapshots, see Creating a DB snapshot (p. 428).

   Note
   
   When you take a database snapshot, I/O operations to the database are suspended for a moment (milliseconds) while the backup is in progress.
4. Disable automated backups on the target database.
   
   Disabling automated backups on the target DB instance improves performance while you are importing your data because Amazon RDS doesn't log transactions when automatic backups are disabled. However, there are some things to consider. Automated backups are required to perform a point-in-time recovery. Thus, you can't restore the database to a specific point in time while you are importing data. Additionally, any automated backups that were created on the DB instance are erased unless you choose to retain them.

   Choosing to retain the automated backups can help protect you against accidental deletion of data. Amazon RDS also saves the database instance properties along with each automated backup to make it easy to recover. Using this option lets you can restore a deleted database instance to a specified point in time within the backup retention period even after deleting it. Automated backups are automatically deleted at the end of the specified backup window, just as they are for an active database instance.
You can also use previous snapshots to recover the database, and any snapshots that you have taken remain available. For information about automated backups, see Working with backups (p. 407).

5. Disable foreign key constraints, if applicable.

If you need to disable foreign key constraints, you can do so with the following script.

```
--Disable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;

WHILE @@FETCH_STATUS = 0 BEGIN
    SELECT @cmd = 'ALTER TABLE ' + QUOTENAME(@table_name) + ' NOCHECK CONSTRAINT ALL';
    EXEC (@cmd);
    FETCH NEXT FROM table_cursor INTO @table_name;
END
CLOSE table_cursor;
DEALLOCATE table_cursor;
GO
```

6. Drop indexes, if applicable.

7. Disable triggers, if applicable.

If you need to disable triggers, you can do so with the following script.

```
--Disable triggers on all tables
DECLARE @enable BIT = 0;
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';

OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

WHILE @@FETCH_STATUS = 0 BEGIN
    IF @enable = 1
        SET @cmd = 'ENABLE ';
    ELSE
        SET @cmd = 'DISABLE ';
    SET @cmd = @cmd + ' TRIGGER dbo.' + QUOTENAME(@trigger) + ' ON dbo.' + QUOTENAME(@table) + ' ';
    EXEC (@cmd);
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END
CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;
GO
```
8. Query the source SQL Server instance for any logins that you want to import to the destination DB instance.

SQL Server stores logins and passwords in the master database. Because Amazon RDS doesn't grant access to the master database, you cannot directly import logins and passwords into your destination DB instance. Instead, you must query the master database on the source SQL Server instance to generate a data definition language (DDL) file. This file should include all logins and passwords that you want to add to the destination DB instance. This file also should include role memberships and permissions that you want to transfer.

For information about querying the master database, see How to transfer the logins and the passwords between instances of SQL Server 2005 and SQL Server 2008 in the Microsoft Knowledge Base.

The output of the script is another script that you can run on the destination DB instance. The script in the Knowledge Base article has the following code:

```sql
p.type in
```

Every place `p.type` appears, use the following code instead:

```sql
p.type = 'S'
```

9. Import the data using the method in Import the data (p. 982).

10. Grant applications access to the target DB instance.

   When your data import is complete, you can grant access to the DB instance to those applications that you blocked during the import. For information about controlling access to your DB instance, see Working with DB security groups (EC2-Classic platform) (p. 1827).

11. Enable automated backups on the target DB instance.

    For information about enabling backups, see Working with backups (p. 407).

12. Enable foreign key constraints.

    If you disabled foreign key constraints earlier, you can now enable them with the following script.

    ```sql
    --Enable foreign keys on all tables
    DECLARE @table_name SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;
    OPEN table_cursor;
    FETCH NEXT FROM table_cursor INTO @table_name;
    WHILE @@FETCH_STATUS = 0 BEGIN
      SELECT @cmd = 'ALTER TABLE ' + QUOTENAME(@table_name) + ' CHECK CONSTRAINT ALL';
      EXEC (@cmd);
      FETCH NEXT FROM table_cursor INTO @table_name;
    END
    CLOSE table_cursor;
    DEALLOCATE table_cursor;
    ```

13. Enable indexes, if applicable.

14. Enable triggers, if applicable.

    If you disabled triggers earlier, you can now enable them with the following script.
--Enable triggers on all tables
DECLARE @enable BIT = 1;
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';
OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
WHILE @@FETCH_STATUS = 0 BEGIN
  IF @enable = 1
    SET @cmd = 'ENABLE ';
  ELSE
    SET @cmd = 'DISABLE ';
  SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
dbo.'+QUOTENAME(@table)+' ';
  EXEC (@cmd);
  FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END
CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;

Import the data

Microsoft SQL Server Management Studio is a graphical SQL Server client that is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

Note
SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio includes the following tools, which are useful in importing data to a SQL Server DB instance:

- Generate and Publish Scripts Wizard
- Import and Export Wizard
- Bulk copy

Generate and Publish Scripts Wizard

The Generate and Publish Scripts Wizard creates a script that contains the schema of a database, the data itself, or both. You can generate a script for a database in your local SQL Server deployment. You can then run the script to transfer the information that it contains to an Amazon RDS DB instance.

Note
For databases of 1 GiB or larger, it's more efficient to script only the database schema. You then use the Import and Export Wizard or the bulk copy feature of SQL Server to transfer the data.

For detailed information about the Generate and Publish Scripts Wizard, see the Microsoft SQL Server documentation.
In the wizard, pay particular attention to the advanced options on the **Set Scripting Options** page to ensure that everything you want your script to include is selected. For example, by default, database triggers are not included in the script.

When the script is generated and saved, you can use SQL Server Management Studio to connect to your DB instance and then run the script.

**Import and Export Wizard**

The Import and Export Wizard creates a special Integration Services package, which you can use to copy data from your local SQL Server database to the destination DB instance. The wizard can filter which tables and even which tuples within a table are copied to the destination DB instance.

**Note**
The Import and Export Wizard works well for large datasets, but it might not be the fastest way to remotely export data from your local deployment. For an even faster way, consider the SQL Server bulk copy feature.

For detailed information about the Import and Export Wizard, see the [Microsoft SQL Server documentation](#).

In the wizard, on the **Choose a Destination** page, do the following:

- For **Server Name**, type the name of the endpoint for your DB instance.
- For the server authentication mode, choose **Use SQL Server Authentication**.
- For **User name** and **Password**, type the credentials for the master user that you created for the DB instance.

**Bulk copy**

The SQL Server bulk copy feature is an efficient means of copying data from a source database to your DB instance. Bulk copy writes the data that you specify to a data file, such as an ASCII file. You can then run bulk copy again to write the contents of the file to the destination DB instance.

This section uses the **bcp** utility, which is included with all editions of SQL Server. For detailed information about bulk import and export operations, see the [Microsoft SQL Server documentation](#).

**Note**
Before you use bulk copy, you must first import your database schema to the destination DB instance. The Generate and Publish Scripts Wizard, described earlier in this topic, is an excellent tool for this purpose.

The following command connects to the local SQL Server instance. It generates a tab-delimited file of a specified table in the C:\ root directory of your existing SQL Server deployment. The table is specified by its fully qualified name, and the text file has the same name as the table that is being copied.

```
bcp dbname.schema_name.table_name out C:\table_name.txt -n -S localhost -U username -P password -b 10000
```

The preceding code includes the following options:

- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server instance that the **bcp** utility connects to.
- `-U` specifies the user name of the account to log in to the SQL Server instance.
- `-P` specifies the password for the user specified by `-U`.
• \texttt{-b} specifies the number of rows per batch of imported data.

\textbf{Note}
There might be other parameters that are important to your import situation. For example, you might need the \texttt{-E} parameter that pertains to identity values. For more information; see the full description of the command line syntax for the \texttt{bcp} utility in the Microsoft SQL Server documentation.

For example, suppose that a database named \texttt{store} that uses the default schema, \texttt{dbo}, contains a table named \texttt{customers}. The user account \texttt{admin}, with the password \texttt{insecure}, copies 10,000 rows of the \texttt{customers} table to a file named \texttt{customers.txt}.

\begin{verbatim}
bcp store.dbo.customers out C:\customers.txt -n -S localhost -U admin -P insecure -b 10000
\end{verbatim}

After you generate the data file, you can upload the data to your DB instance by using a similar command. Beforehand, create the database and schema on the target DB instance. Then use the \texttt{in} argument to specify an input file instead of \texttt{out} to specify an output file. Instead of using localhost to specify the local SQL Server instance, specify the endpoint of your DB instance. If you use a port other than 1433, specify that too. The user name and password are the master user and password for your DB instance. The syntax is as follows.

\begin{verbatim}
bcp dbname.schema_name.table_name in C:\table_name.txt -n -S endpoint,port -U master_user_name -P master_user_password -b 10000
\end{verbatim}

To continue the previous example, suppose that the master user name is \texttt{admin}, and the password is \texttt{insecure}. The endpoint for the DB instance is \texttt{rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com}, and you use port 4080. The command is as follows.

\begin{verbatim}
bcp store.dbo.customers in C:\customers.txt -n -S rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com,4080 -U admin -P insecure -b 10000
\end{verbatim}

\section*{Exporting data from SQL Server on Amazon RDS}
You can choose one of the following options to export data from an RDS for SQL Server DB instance:

\begin{itemize}
\item \textbf{Native database backup using a full backup file (.bak)} – Using .bak files to backup databases is heavily optimized, and is usually the fastest way to export data. For more information, see Importing and exporting SQL Server databases (p. 962).
\item \textbf{SQL Server Import and Export Wizard} – For more information, see SQL Server Import and Export Wizard (p. 984).
\item \textbf{SQL Server Generate and Publish Scripts Wizard and bcp utility} – For more information, see SQL Server Generate and Publish Scripts Wizard and bcp utility (p. 986).
\end{itemize}

\section*{SQL Server Import and Export Wizard}
You can use the SQL Server Import and Export Wizard to copy one or more tables, views, or queries from your RDS for SQL Server DB instance to another data store. This choice is best if the target data store is not SQL Server. For more information, see SQL Server Import and Export Wizard in the SQL Server documentation.

The SQL Server Import and Export Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application.
SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

To use the SQL Server Import and Export Wizard to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 947).
2. In Object Explorer, expand Databases, open the context (right-click) menu for the source database, choose Tasks, and then choose Export Data. The wizard appears.
3. On the Choose a Data Source page, do the following:
   a. For Data source, choose SQL Server Native Client 11.0.
   b. Verify that the Server name box shows the endpoint of your RDS for SQL Server DB instance.
   c. Select Use SQL Server Authentication. For User name and Password, type the master user name and password of your DB instance.
   d. Verify that the Database box shows the database from which you want to export data.
   e. Choose Next.
4. On the Choose a Destination page, do the following:
   a. For Destination, choose SQL Server Native Client 11.0.
      
      Note
      Other target data sources are available. These include .NET Framework data providers, OLE DB providers, SQL Server Native Client providers, ADO.NET providers, Microsoft Office Excel, Microsoft Office Access, and the Flat File source. If you choose to target one of these data sources, skip the remainder of step 4. For details on the connection information to provide next, see Choose a destination in the SQL Server documentation.
   b. For Server name, type the server name of the target SQL Server DB instance.
   c. Choose the appropriate authentication type. Type a user name and password if necessary.
   d. For Database, choose the name of the target database, or choose New to create a new database to contain the exported data.
      If you choose New, see Create database in the SQL Server documentation for details on the database information to provide.
   e. Choose Next.
5. On the Table Copy or Query page, choose Copy data from one or more tables or views or Write a query to specify the data to transfer. Choose Next.
6. If you chose Write a query to specify the data to transfer, you see the Provide a Source Query page. Type or paste in a SQL query, and then choose Parse to verify it. Once the query validates, choose Next.
7. On the Select Source Tables and Views page, do the following:
   a. Select the tables and views that you want to export, or verify that the query you provided is selected.
   b. Choose Edit Mappings and specify database and column mapping information. For more information, see Column mappings in the SQL Server documentation.
   c. (Optional) To see a preview of data to be exported, select the table, view, or query, and then choose Preview.
   d. Choose Next.
8. On the Run Package page, verify that Run immediately is selected. Choose Next.
9. On the Complete the Wizard page, verify that the data export details are as you expect. Choose Finish.
10. On the **The execution was successful** page, choose **Close**.

### SQL Server Generate and Publish Scripts Wizard and bcp utility

You can use the SQL Server Generate and Publish Scripts Wizard to create scripts for an entire database or just selected objects. You can run these scripts on a target SQL Server DB instance to recreate the scripted objects. You can then use the bcp utility to bulk export the data for the selected objects to the target DB instance. This choice is best if you want to move a whole database (including objects other than tables) or large quantities of data between two SQL Server DB instances. For a full description of the bcp command-line syntax, see **bcp utility** in the Microsoft SQL Server documentation.

The SQL Server Generate and Publish Scripts Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download.

#### To use the SQL Server Generate and Publish Scripts Wizard and the bcp utility to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see **Connecting to a DB instance running the Microsoft SQL Server database engine (p. 947)**.
2. In **Object Explorer**, expand the **Databases** node and select the database you want to script.
3. Follow the instructions in **Generate and publish scripts Wizard** in the SQL Server documentation to create a script file.
4. In SQL Server Management Studio, connect to your target SQL Server DB instance.
5. With the target SQL Server DB instance selected in **Object Explorer**, choose **Open** on the **File** menu, choose **File**, and then open the script file.
6. If you have scripted the entire database, review the CREATE DATABASE statement in the script. Make sure that the database is being created in the location and with the parameters that you want. For more information, see **CREATE DATABASE** in the SQL Server documentation.
7. If you are creating database users in the script, check to see if server logins exist on the target DB instance for those users. If not, create logins for those users; the scripted commands to create the database users fail otherwise. For more information, see **Create a login** in the SQL Server documentation.
8. Choose **Execute** on the SQL Editor menu to run the script file and create the database objects. When the script finishes, verify that all database objects exist as expected.
9. Use the bcp utility to export data from the RDS for SQL Server DB instance into files. Open a command prompt and type the following command.

   ```
   bcp database_name.schema_name.table_name out data_file -n -S aws_rds_sql_endpoint -U username -P password
   ```

   The preceding code includes the following options:

   - **table_name** is the name of one of the tables that you’ve recreated in the target database and now want to populate with data.
   - **data_file** is the full path and name of the data file to be created.
   - `-n` specifies that the bulk copy uses the native data types of the data to be copied.
   - `-S` specifies the SQL Server DB instance to export from.
   - `-U` specifies the user name to use when connecting to the SQL Server DB instance.
   - `-P` specifies the password for the user specified by `-U`.

   The following shows an example command.
Repeat this step until you have data files for all of the tables you want to export.

10. Prepare your target DB instance for bulk import of data by following the instructions at Basic guidelines for bulk importing data in the SQL Server documentation.

11. Decide on a bulk import method to use after considering performance and other concerns discussed in About bulk import and bulk export operations in the SQL Server documentation.

12. Bulk import the data from the data files that you created using the bcp utility. To do so, follow the instructions at either Import and export bulk data by using the bcp utility or Import bulk data by using BULK INSERT or OPENROWSET(BULK...) in the SQL Server documentation, depending on what you decided in step 11.
Working with read replicas for Microsoft SQL Server in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 354).

In this section, you can find specific information about working with read replicas on Amazon RDS for SQL Server.

Topics
- Configuring read replicas for SQL Server (p. 988)
- Read replica limitations with SQL Server (p. 988)
- Troubleshooting a SQL Server read replica problem (p. 989)

Configuring read replicas for SQL Server

Before a DB instance can serve as a source instance for replication, you must enable automatic backups on the source DB instance. To do so, you set the backup retention period to a value other than 0. The source DB instance must be a Multi-AZ deployment with Always On Availability Groups (AGs). Setting this type of deployment also enforces that automatic backups are enabled.

Creating a SQL Server read replica doesn't require an outage for the primary DB instance. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without any service interruption. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to five read replicas from one source DB instance. For replication to operate effectively, we recommend that you configure each read replica with the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

The SQL Server DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS upgrades the primary immediately after upgrading the read replicas, regardless of the maintenance window. For more information about upgrading the DB engine version, see Upgrading the Microsoft SQL Server DB engine (p. 957).

For a read replica to receive and apply changes from the source, it should have sufficient compute and storage resources. If a read replica reaches compute, network, or storage resource capacity, the read replica stops receiving or applying changes from its source. You can modify the storage and CPU resources of a read replica independently from its source and other read replicas.

Read replica limitations with SQL Server

The following limitations apply to SQL Server read replicas on Amazon RDS:

- Read replicas are only available on the SQL Server Enterprise Edition (EE) engine.
- Read replicas are available for SQL Server versions 2016–2019.
- The source DB instance to be replicated must be a Multi-AZ deployment with Always On AGs.
- Read replicas are only available for DB instances on the EC2-VPC platform.
- Read replicas are only available for DB instances running on DB instance classes with four or more vCPUs.
- The following aren’t supported on Amazon RDS for SQL Server:
  - Creating a read replica in a different AWS Region (a cross-Region read replica)
### Troubleshooting a SQL Server read replica problem

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. For information about replication lag time, see Monitoring read replication (p. 364).

If replication lag is too long, you can use the following query to get information about the lag.

```sql
SELECT AR.replica_server_name,
    DB_NAME(ARS.database_id) 'database_name',
    AR.availability_mode_desc,
    ARS.synchronization_health_desc,
    ARS:last_hardened_lsn,
    ARS:last_redone_lsn,
    ARS.secondary_lag_seconds
FROM sys.dm_hadr_database_replica_states ARS
INNER JOIN sys.availability_replicas AR
    ON ARS.replica_id = AR.replica_id
--WHERE DB_NAME(ARS.database_id) = 'database_name'
ORDER BY AR.replica_server_name;
```
Multi-AZ deployments for Amazon RDS for Microsoft SQL Server

Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS supports Multi-AZ deployments for Microsoft SQL Server by using either SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Amazon RDS monitors and maintains the health of your Multi-AZ deployment. If problems occur, RDS automatically repairs unhealthy DB instances, reestablishes synchronization, and initiates failovers. Failover only occurs if the standby and primary are fully in sync. You don't have to manage anything.

When you set up SQL Server Multi-AZ, RDS automatically configures all databases on the instance to use DBM or AGs. Amazon RDS handles the primary, the witness, and the secondary DB instance for you. Because configuration is automatic, RDS selects DBM or Always On AGs based on the version of SQL Server that you deploy.

Amazon RDS supports Multi-AZ with Always On AGs for the following SQL Server versions and editions:

- SQL Server 2019:
  - Standard Edition 15.00.4073.23 and higher
  - Enterprise Edition
- SQL Server 2017:
  - Standard Edition 14.00.3401.7 and higher
  - Enterprise Edition 14.00.3049.1 and higher
- SQL Server 2016: Enterprise Edition 13.00.5216.0 and higher

Amazon RDS supports Multi-AZ with DBM for the following SQL Server versions and editions, except for the versions noted previously:

- SQL Server 2019: Standard Edition 15.00.4043.16
- SQL Server 2017: Standard and Enterprise Editions
- SQL Server 2016: Standard and Enterprise Editions
- SQL Server 2014: Standard and Enterprise Editions
- SQL Server 2012: Standard and Enterprise Editions

You can use the following SQL query to determine whether your SQL Server DB instance is Single-AZ, Multi-AZ with DBM, or Multi-AZ with Always On AGs:

```sql
SELECT CASE WHEN dm.mirroring_state_desc IS NOT NULL THEN 'Multi-AZ (Mirroring)'
    WHEN dhdrs.group_database_id IS NOT NULL THEN 'Multi-AZ (AlwaysOn)'
    ELSE 'Single-AZ'
END 'high_availability'
FROM sys.databases sd
LEFT JOIN sys.database_mirroring dm ON sd.database_id = dm.database_id
LEFT JOIN sys.dm_hadr_database_replica_states dhdrs ON sd.database_id = dhdrs.database_id
AND dhdrs.is_local = 1
WHERE DB_NAME(sd.database_id) = 'rdsadmin';
```
Adding Multi-AZ to a Microsoft SQL Server DB instance

When you create a new SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with Database Mirroring (DBM) or Always On AGs. You do so by choosing Yes (Mirroring / Always On) from Multi-AZ deployment. For more information, see Creating an Amazon RDS DB instance (p. 175).

When you modify an existing SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with DBM or AGs by choosing Yes (Mirroring / Always On) from Multi-AZ deployment on the Modify DB instance page. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Note
If your DB instance is running Database Mirroring (DBM)—not Always On Availability Groups (AGs)—you might need to disable in-memory optimization before you add Multi-AZ. Disable in-memory optimization with DBM before you add Multi-AZ if your DB instance runs SQL Server 2014, 2016, or 2017 Enterprise Edition and has in-memory optimization enabled. If your DB instance is running AGs, it doesn't require this step.

Microsoft SQL Server Multi-AZ deployment
limitations, notes, and recommendations

The following are some limitations when working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

- Cross-Region Multi-AZ isn't supported.
- You can't configure the secondary DB instance to accept database read activity.
- Multi-AZ with Always On Availability Groups (AGs) supports in-memory optimization.
- Multi-AZ with Always On Availability Groups (AGs) doesn't support Kerberos authentication for the availability group listener. This is because the listener has no Service Principal Name (SPN).
- You can't rename a database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment. If you need to rename a database on such an instance, first turn off Multi-AZ for the DB instance, then rename the database. Finally, turn Multi-AZ back on for the DB instance.
- You can only restore Multi-AZ DB instances that are backed up using the full recovery model.
- Multi-AZ deployments have a limit of 100 SQL Server Agent jobs.

If you need a higher limit, request an increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.

The following are some notes about working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

- Amazon RDS exposes the Always On AGs availability group listener endpoint. The endpoint is visible in the console, and is returned by the DescribeDBInstances API as an entry in the endpoints field.
- Amazon RDS supports availability group multisubnet failovers.
- To use SQL Server Multi-AZ with a SQL Server DB instance in a VPC, first create a DB subnet group that has subnets in at least two distinct Availability Zones. Then assign the DB subnet group to the primary replica of the SQL Server DB instance.
When a DB instance is modified to be a Multi-AZ deployment, during the modification it has a status of modifying. Amazon RDS creates the standby, and makes a backup of the primary DB instance. After the process is complete, the status of the primary DB instance becomes available.

Multi-AZ deployments maintain all databases on the same node. If a database on the primary host fails over, all your SQL Server databases fail over as one atomic unit to your standby host. Amazon RDS provisions a new healthy host, and replaces the unhealthy host.

Multi-AZ with DBM or AGs supports a single standby replica.

Users, logins, and permissions are automatically replicated for you on the secondary. You don't need to recreate them. User-defined server roles (a SQL Server 2012 feature) are only replicated in Multi-AZ instances for AGs instances.

If you have SQL Server Agent jobs, recreate them on the secondary. You do so because these jobs are stored in the msdb database, and you can't replicate this database by using Database Mirroring (DBM) or Always On Availability Groups (AGs). Create the jobs first in the original primary, then fail over, and create the same jobs in the new primary.

You might observe elevated latencies compared to a standard DB instance deployment (in a single Availability Zone) because of the synchronous data replication.

Failover times are affected by the time it takes to complete the recovery process. Large transactions increase the failover time.

In SQL Server Multi-AZ deployments, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

The following are some recommendations for working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

For databases used in production or preproduction, we recommend the following options:

- Multi-AZ deployments for high availability
- " Provisioned IOPS" for fast, consistent performance
- "Memory optimized" rather than "General purpose"

You can't select the Availability Zone (AZ) for the secondary instance, so when you deploy application hosts, take this into account. Your database might fail over to another AZ, and the application hosts might not be in the same AZ as the database. For this reason, we recommend that you balance your application hosts across all AZs in the given AWS Region.

For best performance, don't enable Database Mirroring or Always On AGs during a large data load operation. If you want your data load to be as fast as possible, finish loading data before you convert your DB instance to a Multi-AZ deployment.

Applications that access the SQL Server databases should have exception handling that catches connection errors. The following code sample shows a try/catch block that catches a communication error. In this example, the break statement exits the while loop if the connection is successful, but retries up to 10 times if an exception is thrown.

```csharp
int RetryMaxAttempts = 10;
int RetryIntervalPeriodInSeconds = 1;
int iRetryCount = 0;
while (iRetryCount < RetryMaxAttempts)
{
    using (SqlConnection connection = new SqlConnection(DatabaseConnString))
    {
        using (SqlCommand command = connection.CreateCommand())
        {
            command.CommandText = "INSERT INTO SOME_TABLE VALUES ('SomeValue');";
            try
```
{  
    connection.Open();  
    command.ExecuteNonQuery();  
    break;  
}  
  
catch (Exception ex)  
  {  
    Logger(ex.Message);  
    iRetryCount++;  
  }  
  
finally {  
    connection.Close();  
  }  
  
}  
  
Thread.Sleep(RetryIntervalPeriodInSeconds * 1000);  
}  

• Don't use the Set Partner Off command when working with Multi-AZ instances. For example, don't do the following.

```--Don't do this
ALTER DATABASE db1 SET PARTNER off```

• Don't set the recovery mode to simple. For example, don't do the following.

```--Don't do this
ALTER DATABASE db1 SET RECOVERY simple```

• Don't use the DEFAULT_DATABASE parameter when creating new logins on Multi-AZ DB instances, because these settings can't be applied to the standby mirror. For example, don't do the following.

```--Don't do this
CREATE LOGIN [test_dba] WITH PASSWORD=foo, DEFAULT_DATABASE=[db2]```

Also, don't do the following.

```--Don't do this
ALTER LOGIN [test_dba] SET DEFAULT_DATABASE=[db3]```

## Determining the location of the secondary

You can determine the location of the secondary replica by using the AWS Management Console. You need to know the location of the secondary if you are setting up your primary DB instance in a VPC.
Migrating to Always On AGs

You can also view the Availability Zone of the secondary using the AWS CLI command `describe-db-instances` or RDS API operation `DescribeDBInstances`. The output shows the secondary AZ where the standby mirror is located.

Migrating from Database Mirroring to Always On Availability Groups

In version 14.00.3049.1 of Microsoft SQL Server Enterprise Edition, Always On Availability Groups (AGs) are enabled by default.

To migrate from Database Mirroring (DBM) to AGs, first check your version. If you are using a DB instance with a version prior to Enterprise Edition 13.00.5216.0, modify the instance to patch it to 13.00.5216.0 or later. If you are using a DB instance with a version prior to Enterprise Edition 14.00.3049.1, modify the instance to patch it to 14.00.3049.1 or later.

If you want to upgrade a mirrored DB instance to use AGs, run the upgrade first, modify the instance to remove Multi-AZ, and then modify it again to add Multi-AZ. This converts your instance to use Always On AGs.
Additional features for Microsoft SQL Server on Amazon RDS

In the following sections, you can find information about augmenting Amazon RDS instances running the Microsoft SQL Server DB engine.

**Topics**
- Using SSL with a Microsoft SQL Server DB instance (p. 996)
- Configuring security protocols and ciphers (p. 999)
- Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004)
- Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1014)
- Using Database Mail on Amazon RDS for SQL Server (p. 1028)
- Instance store support for the tempdb database on Amazon RDS for SQL Server (p. 1039)
- Using extended events with Amazon RDS for Microsoft SQL Server (p. 1041)
Using SSL with a Microsoft SQL Server DB instance

You can use Secure Sockets Layer (SSL) to encrypt connections between your client applications and your Amazon RDS DB instances running Microsoft SQL Server. SSL support is available in all AWS regions for all supported SQL Server editions.

When you create a SQL Server DB instance, Amazon RDS creates an SSL certificate for it. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

There are 2 ways to use SSL to connect to your SQL Server DB instance:

- **Force SSL for all connections** — this happens transparently to the client, and the client doesn't have to do any work to use SSL.
- **Encrypt specific connections** — this sets up an SSL connection from a specific client computer, and you must do work on the client to encrypt connections.

For information about Transport Layer Security (TLS) support for SQL Server, see [TLS 1.2 support for Microsoft SQL Server](#).

Forcing connections to your DB instance to use SSL

You can force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

If you want to force SSL, use the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). Set the `rds.force_ssl` parameter to 1 (on) to force connections to use SSL. The `rds.force_ssl` parameter is static, so after you change the value, you must reboot your DB instance for the change to take effect.

**To force all connections to your DB instance to use SSL**

1. Determine the parameter group that is attached to your DB instance:
   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the top right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
   c. In the navigation pane, choose Databases, and then choose the name of your DB instance to show its details.
   d. Choose the Configuration tab. Find the Parameter group in the section.
2. If necessary, create a new parameter group. If your DB instance uses the default parameter group, you must create a new parameter group. If your DB instance uses a nondefault parameter group, you can choose to edit the existing parameter group or to create a new parameter group. If you edit an existing parameter group, the change affects all DB instances that use that parameter group.
   To create a new parameter group, follow the instructions in [Creating a DB parameter group](#).
3. Edit your new or existing parameter group to set the `rds.force_ssl` parameter to true. To edit the parameter group, follow the instructions in [Modifying parameters in a DB parameter group](#).
4. If you created a new parameter group, modify your DB instance to attach the new parameter group. Modify the DB Parameter Group setting of the DB instance. For more information, see [Modifying an Amazon RDS DB instance](#).
5. Reboot your DB instance. For more information, see [Rebooting a DB instance](#).
Encrypting specific connections

You can force all connections to your DB instance to use SSL, or you can encrypting connections from specific client computers only. To use SSL from a specific client, you must obtain certificates for the client computer, import certificates on the client computer, and then encrypt the connections from the client computer.

**Note**

All SQL Server instances created after August 5, 2014, use the DB instance endpoint in the Common Name (CN) field of the SSL certificate. Prior to August 5, 2014, SSL certificate verification was not available for VPC-based SQL Server instances. If you have a VPC-based SQL Server DB instance that was created before August 5, 2014, and you want to use SSL certificate verification and ensure that the instance endpoint is included as the CN for the SSL certificate for that DB instance, then rename the instance. When you rename a DB instance, a new certificate is deployed and the instance is rebooted to enable the new certificate.

Obtaining certificates for client computers

To encrypt connections from a client computer to an Amazon RDS DB instance running Microsoft SQL Server, you need a certificate on your client computer.

To obtain that certificate, download the certificate to your client computer. You can download a root certificate that works for all regions. You can also download a certificate bundle that contains both the old and new root certificate. In addition, you can download region-specific intermediate certificates. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

After you have downloaded the appropriate certificate, import the certificate into your Microsoft Windows operating system by following the procedure in the section following.

Importing certificates on client computers

You can use the following procedure to import your certificate into the Microsoft Windows operating system on your client computer.

**To import the certificate into your Windows operating system:**

1. On the **Start** menu, type **Run** in the search box and press **Enter**.
2. In the **Open** box, type **MMC** and then choose **OK**.
3. In the MMC console, on the **File** menu, choose **Add/Remove Snap-in**.
4. In the **Add or Remove Snap-ins** dialog box, for **Available snap-ins**, select **Certificates**, and then choose **Add**.
5. In the **Certificates snap-in** dialog box, choose **Computer account**, and then choose **Next**.
6. In the **Select computer** dialog box, choose **Computer account**, and then choose **Next**.
7. In the **Add or Remove Snap-ins** dialog box, choose **OK**.
8. In the MMC console, expand **Certificates**, open the context (right-click) menu for **Trusted Root Certification Authorities**, choose **All Tasks**, and then choose **Import**.
9. On the first page of the Certificate Import Wizard, choose **Next**.
10. On the second page of the Certificate Import Wizard, choose **Browse**. In the browse window, change the file type to **All files (*.*)** because .pem is not a standard certificate extension. Locate the .pem file that you downloaded previously.
11. Choose **Open** to select the certificate file, and then choose **Next**.
12. On the third page of the Certificate Import Wizard, choose **Next**.
13. On the fourth page of the Certificate Import Wizard, choose **Finish**. A dialog box appears indicating that the import was successful.
14. In the MMC console, expand **Certificates**, expand **Trusted Root Certification Authorities**, and then choose **Certificates**. Locate the certificate to confirm it exists, as shown here.

15. Restart your computer.

**Encrypting connections to an Amazon RDS DB instance running Microsoft SQL Server**

After you have imported a certificate into your client computer, you can encrypt connections from the client computer to an Amazon RDS DB instance running Microsoft SQL Server.

For SQL Server Management Studio, use the following procedure. For more information about SQL Server Management Studio, see Use SQL Server management studio.

**To encrypt connections from SQL Server Management Studio**

1. Launch SQL Server Management Studio.
2. For **Connect to server**, type the server information, login user name, and password.
3. Choose **Options**.
4. Select **Encrypt connection**.
5. Choose **Connect**.
6. Confirm that your connection is encrypted by running the following query. Verify that the query returns true for encrypt_option.

```sql
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

For any other SQL client, use the following procedure.

**To encrypt connections from other SQL clients**

1. Append `encrypt=true` to your connection string. This string might be available as an option, or as a property on the connection page in GUI tools.

   **Note**
   To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS SQL certificate to the Java CA certificate (cacerts) store. You can do this by using the `keytool` utility.

2. Confirm that your connection is encrypted by running the following query. Verify that the query returns true for encrypt_option.

```sql
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```
## Configuring security protocols and ciphers

You can turn certain security protocols and ciphers on and off using DB parameters. The security parameters that you can configure (except for TLS version 1.2) are shown in the following table.

For parameters other than `rds.fips`, the value of `default` means that the operating system default value is used, whether it is enabled or disabled.

**Note**
You can't disable TLS 1.2, because Amazon RDS uses it internally.

<table>
<thead>
<tr>
<th>DB parameter</th>
<th>Allowed values (default in bold)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds.tls10</td>
<td>default, enabled, disabled</td>
<td>TLS 1.0.</td>
</tr>
<tr>
<td>rds.tls11</td>
<td>default, enabled, disabled</td>
<td>TLS 1.1.</td>
</tr>
<tr>
<td>rds.tls12</td>
<td>default</td>
<td>TLS 1.2. You can't modify this value.</td>
</tr>
<tr>
<td>rds.fips</td>
<td>0, 1</td>
<td>When you set the parameter to 1, RDS forces the use of modules that are compliant with the Federal Information Processing Standard (FIPS) 140-2 standard. For more information, see Use SQL Server 2016 in FIPS 140-2-compliant mode in the Microsoft documentation. <strong>Note</strong> You must reboot the DB instance after the modification to make it effective.</td>
</tr>
<tr>
<td>rds.rc4</td>
<td>default, enabled, disabled</td>
<td>RC4 stream cipher.</td>
</tr>
<tr>
<td>rds.diffie-hellman</td>
<td>default, enabled, disabled</td>
<td>Diffie-Hellman key-exchange encryption.</td>
</tr>
<tr>
<td>rds.diffie-hellman-min-key-bit-length</td>
<td>default, 1024, 2048, 4096</td>
<td>Minimum bit length for Diffie-Hellman keys.</td>
</tr>
<tr>
<td>rds.curve25519</td>
<td>default, enabled, disabled</td>
<td>Curve25519 elliptic-curve encryption cipher. This parameter isn't supported for all engine versions.</td>
</tr>
<tr>
<td>rds.3des168</td>
<td>default, enabled, disabled</td>
<td>Triple Data Encryption Standard (DES) encryption cipher with a 168-bit key length.</td>
</tr>
</tbody>
</table>
Note
For more information on the default values for SQL Server security protocols and ciphers, see Protocols in TLS/SSL (Schannel SSP) and Cipher Suites in TLS/SSL (Schannel SSP) in the Microsoft documentation.
For more information on viewing and setting these values in the Windows Registry, see Transport Layer Security (TLS) best practices with the .NET Framework in the Microsoft documentation.

Use the following process to configure the security protocols and ciphers:

1. Create a custom DB parameter group.
2. Modify the parameters in the parameter group.
3. Associate the DB parameter group with your DB instance.

For more information on DB parameter groups, see Working with parameter groups (p. 278).

Creating the security-related parameter group

Create a parameter group for your security-related parameters that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as sqlserver-ciphers-se-13.
   c. For Description, enter Parameter group for security protocols and ciphers.
5. Choose Create.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group
  --db-parameter-group-name sqlserver-ciphers-se-13
  --db-parameter-group-family "sqlserver-se-13.0"
```
Modifying security-related parameters

Modify the security-related parameters in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

**Console**

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as sqlserver-ciphers-se-13.
4. Under Parameters, filter the parameter list for rds.
5. Choose Edit parameters.
7. For Values, choose disabled.
8. Choose Save changes.

**CLI**

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

**To modify the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name sqlserver-ciphers-se-13 \
  --parameters "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
```
## Configuring security protocols and ciphers

```
--db-parameter-group-name sqlserver-ciphers-se-13
--parameters
"ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

### Associating the security-related parameter group with your DB instance

To associate the parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

**Console**

You can associate the parameter group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 175).
- For an existing DB instance, associate it by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance](p. 309).

**CLI**

You can associate the parameter group with a new or existing DB instance.

**To create a DB instance with the parameter group**

- Specify the same DB engine type and major version as you used when creating the parameter group.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance
  --db-instance-identifier mydbinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 13.00.5426.0.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --db-parameter-group-name sqlserver-ciphers-se-13
```

For Windows:

```
aws rds create-db-instance
  --db-instance-identifier mydbinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 13.00.5426.0.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --db-parameter-group-name sqlserver-ciphers-se-13
```
To modify a DB instance and associate the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --db-parameter-group-name sqlserver-ciphers-se-13 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --db-parameter-group-name sqlserver-ciphers-se-13 ^
  --apply-immediately
```
Using Windows Authentication with an Amazon RDS for SQL Server DB instance

You can use Microsoft Windows Authentication to authenticate users when they connect to your Amazon RDS for Microsoft SQL Server DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to enable Windows Authentication. When users authenticate with a SQL Server DB instance joined to the trusting domain, authentication requests are forwarded to the domain directory that you create with AWS Directory Service.

Amazon RDS supports Windows Authentication for SQL Server in all AWS Regions. RDS supports using only AWS Managed Microsoft AD for Windows Authentication. RDS doesn't support using AD Connector. For more information, see the following:

- Application compatibility policy for AWS Managed Microsoft AD
- Application compatibility policy for AD Connector
