DevOps Guru for RDS collects data about your RDS for PostgreSQL databases from Amazon RDS Performance Insights. The most important metric is `DBLoad`. DevOps Guru for RDS consumes the Performance Insights metrics, analyzes them with machine learning, and publishes insights to the dashboard.

An *insight* is a collection of related anomalies that were detected by DevOps Guru.

In DevOps Guru for RDS, an *anomaly* is a pattern that deviates from what is considered normal performance for your RDS for PostgreSQL database.

Proactive insights

A *proactive insight* lets you know about problematic behavior before it occurs. It contains anomalies with recommendations and related metrics to help you address issues in your RDS for PostgreSQL databases before become bigger problems. These insights are published in the DevOps Guru dashboard.

For example, DevOps Guru might detect that your RDS for PostgreSQL database is creating many on-disk temporary tables. If not addressed, this trend might lead to performance issues. Each proactive insight includes recommendations for corrective behavior and links to relevant topics in Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights. For more information, see Working with insights in DevOps Guru in the *Amazon DevOps Guru User Guide*.

Reactive insights

A *reactive insight* identifies anomalous behavior as it occurs. If DevOps Guru for RDS finds performance issues in your RDS for PostgreSQL DB instances, it publishes a reactive insight in the DevOps Guru dashboard. For more information, see Working with insights in DevOps Guru in the *Amazon DevOps Guru User Guide*.

Causal anomalies

A *causal anomaly* is a top-level anomaly within a reactive insight. **Database load (DB load)** is the causal anomaly for DevOps Guru for RDS.

An anomaly measures performance impact by assigning a severity level of **High**, **Medium**, or **Low**. To learn more, see Key concepts for DevOps Guru for RDS in the *Amazon DevOps Guru User Guide*.

If DevOps Guru detects a current anomaly on your DB instance, you're alerted in the **Databases** page of the RDS console. The console also alerts you to anomalies that occurred in the past 24 hours. To go to the anomaly page from the RDS console, choose the link in the alert message. The RDS console also alerts you in the page for your RDS for PostgreSQL DB instance.

Contextual anomalies

A *contextual anomaly* is a finding within **Database load (DB load)** that is related to a reactive insight. Each contextual anomaly describes a specific RDS for PostgreSQL performance issue that

requires investigation. For example, DevOps Guru for RDS might recommend that you consider increasing CPU capacity or investigate wait events that are contributing to DB load.

> **Important**
>
> We recommend that you test any changes on a test instance before modifying a production instance. In this way, you understand the impact of the change.

To learn more, see Analyzing anomalies in Amazon RDS in the *Amazon DevOps Guru User Guide*.

Setting up DevOps Guru for RDS

To allow DevOps Guru for Amazon RDS to publish insights for a RDS for PostgreSQL database, complete the following tasks.

Topics

- Configuring IAM access policies for DevOps Guru for RDS
- Turning on Performance Insights for your RDS for PostgreSQL DB instances
- Turning on DevOps Guru and specifying resource coverage

Configuring IAM access policies for DevOps Guru for RDS

To view alerts from DevOps Guru in the RDS console, your AWS Identity and Access Management (IAM) user or role must have either of the following policies:

- The AWS managed policy `AmazonDevOpsGuruConsoleFullAccess`
- The AWS managed policy `AmazonDevOpsGuruConsoleReadOnlyAccess` and either of the following policies:
  - The AWS managed policy `AmazonRDSFullAccess`
  - A customer managed policy that includes `pi:GetResourceMetrics` and `pi:DescribeDimensionKeys`

For more information, see Configuring access policies for Performance Insights.

Turning on Performance Insights for your RDS for PostgreSQL DB instances

DevOps Guru for RDS relies on Performance Insights for its data. Without Performance Insights, DevOps Guru publishes anomalies, but doesn't include the detailed analysis and recommendations.

When you create or modify a RDS for PostgreSQL DB instance, you can turn on Performance Insights. For more information, see Turning Performance Insights on and off for Amazon RDS.

Turning on DevOps Guru and specifying resource coverage

You can turn on DevOps Guru to have it monitor your RDS for PostgreSQL databases in either of the following ways.

Topics

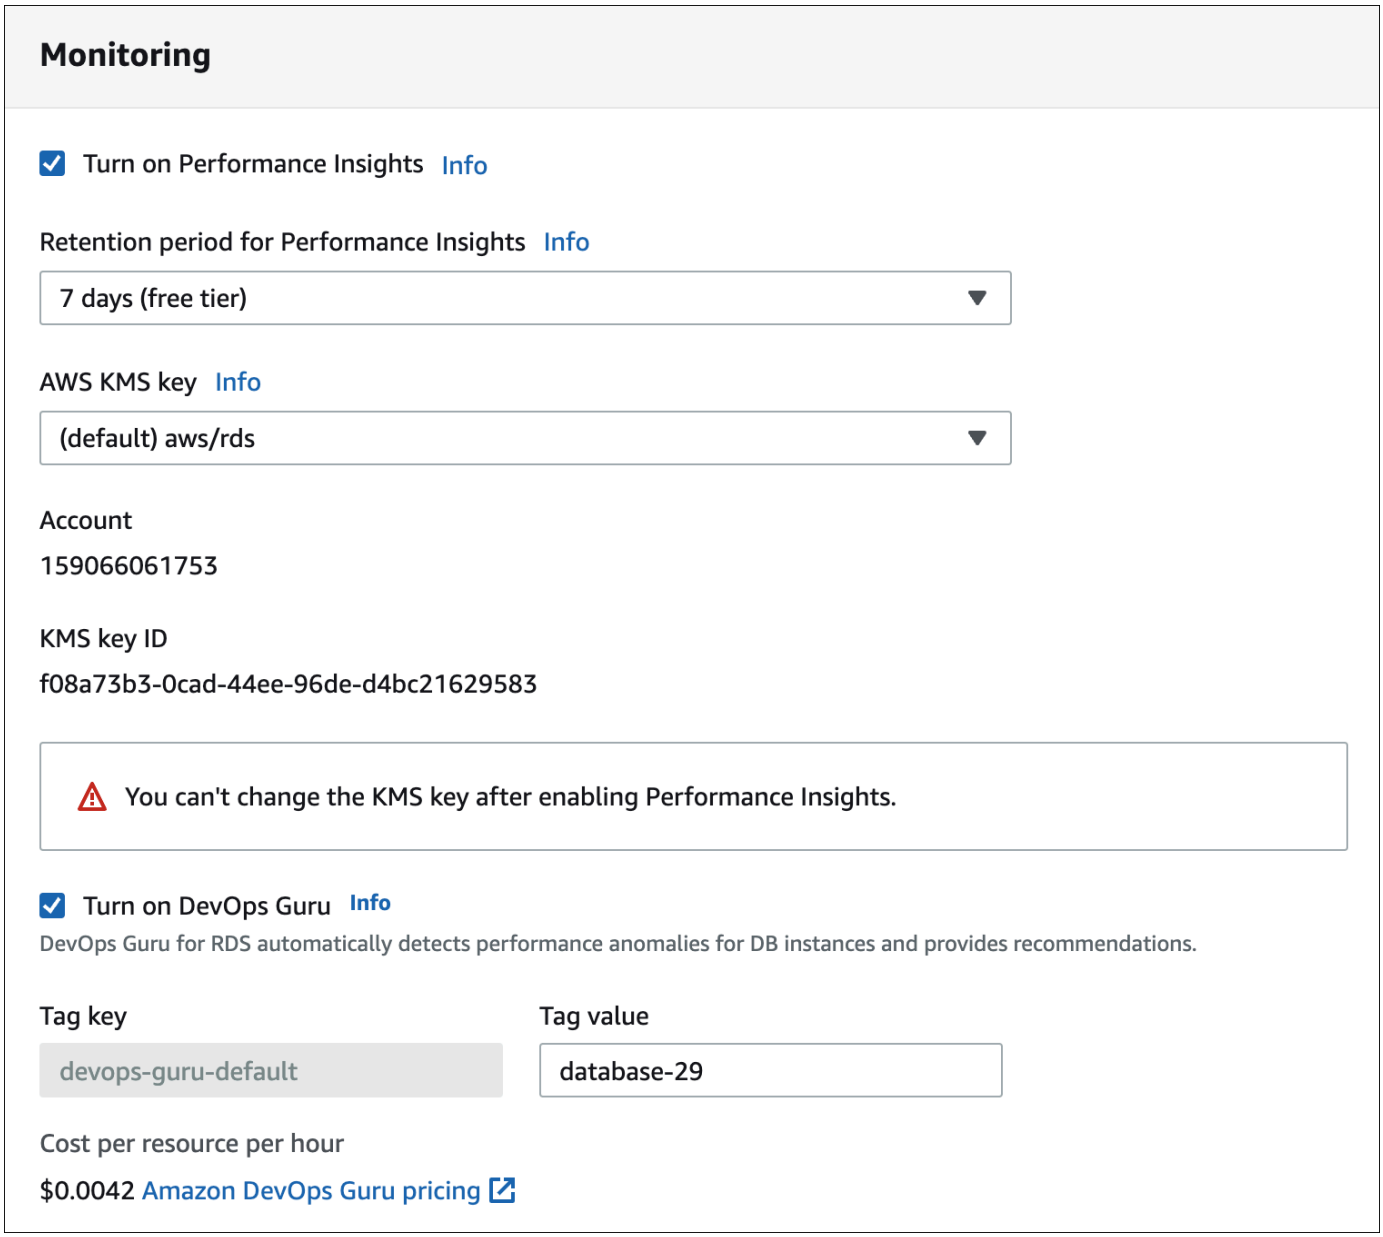
- Turning on DevOps Guru in the RDS console
- Adding RDS for PostgreSQL resources in the DevOps Guru console
- Adding RDS for PostgreSQL resources using CloudFormation

Turning on DevOps Guru in the RDS console

You can take multiple paths in the Amazon RDS console to turn on DevOps Guru.

Topics

- Turning on DevOps Guru when you create an RDS for PostgreSQL database
- Turning on DevOps Guru from the notification banner
- Responding to a permissions error when you turn on DevOps Guru



Turning on DevOps Guru when you create an RDS for PostgreSQL database

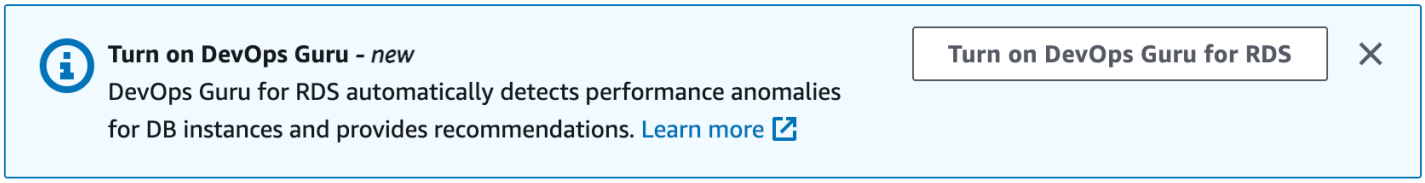
The creation workflow includes a setting that turns on DevOps Guru coverage for your database. This setting is turned on by default when you choose the **Production** template.

To turn on DevOps Guru when you create an RDS for PostgreSQL database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Follow the steps in Creating a DB instance, up to but not including the step where you choose monitoring settings.

3. In **Monitoring**, choose **Turn on Performance Insights**. For DevOps Guru for RDS to provide detailed analysis of performance anomalies, Performance Insights must be turned on.
4. Choose **Turn on DevOps Guru**.

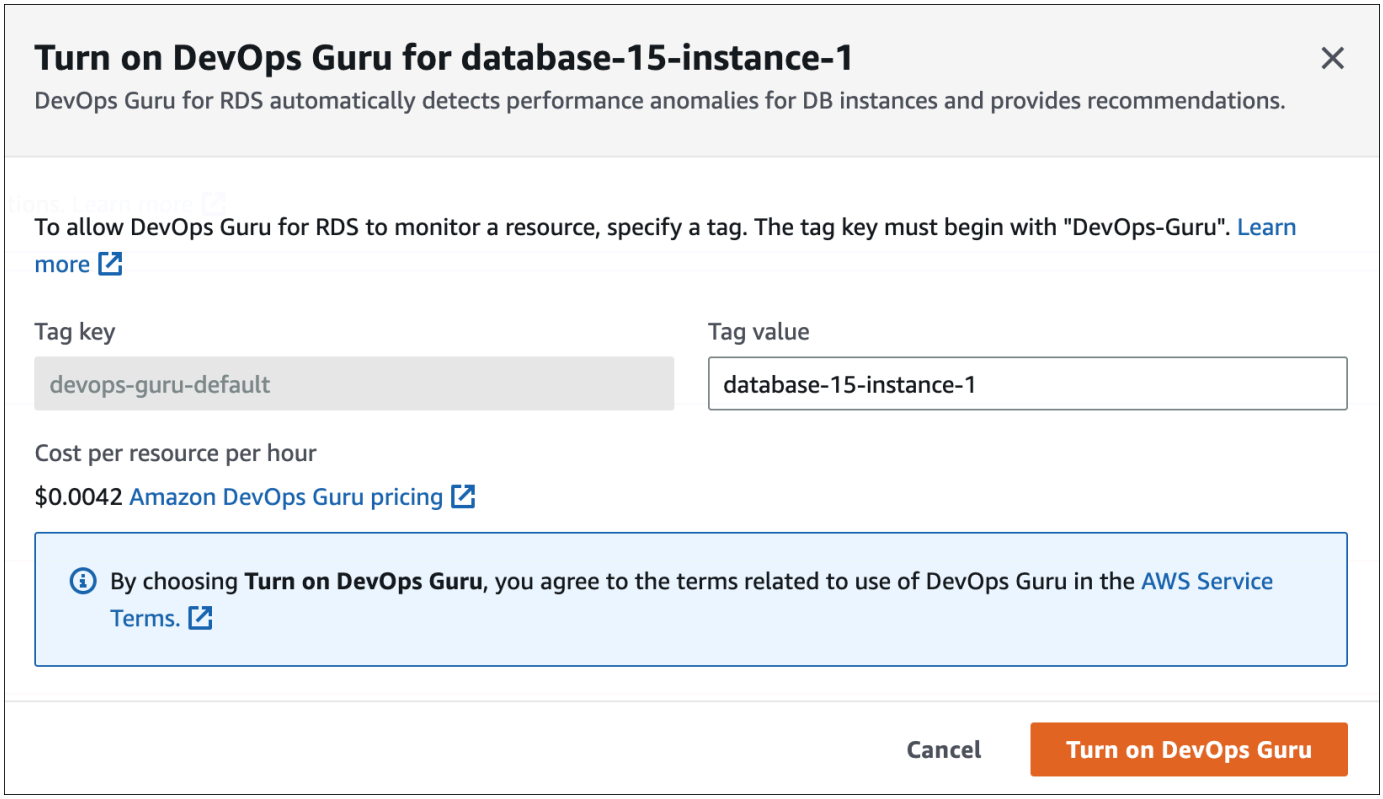
5. Create a tag for your database so that DevOps Guru can monitor it. Do the following:
   - In the text field for **Tag key**, enter a name that begins with **`Devops-Guru-`**.
   - In the text field for **Tag value**, enter any value. For example, if you enter **`rds-database-1`** for the name of your RDS for PostgreSQL database, you can also enter **`rds-database-1`** as the tag value.



For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.

6. Complete the remaining steps in Creating a DB instance.

Turning on DevOps Guru from the notification banner



If your resources aren't covered by DevOps Guru, Amazon RDS notifies you with a banner in the following locations:

- The **Monitoring** tab of a DB cluster instance
- The Performance Insights dashboard

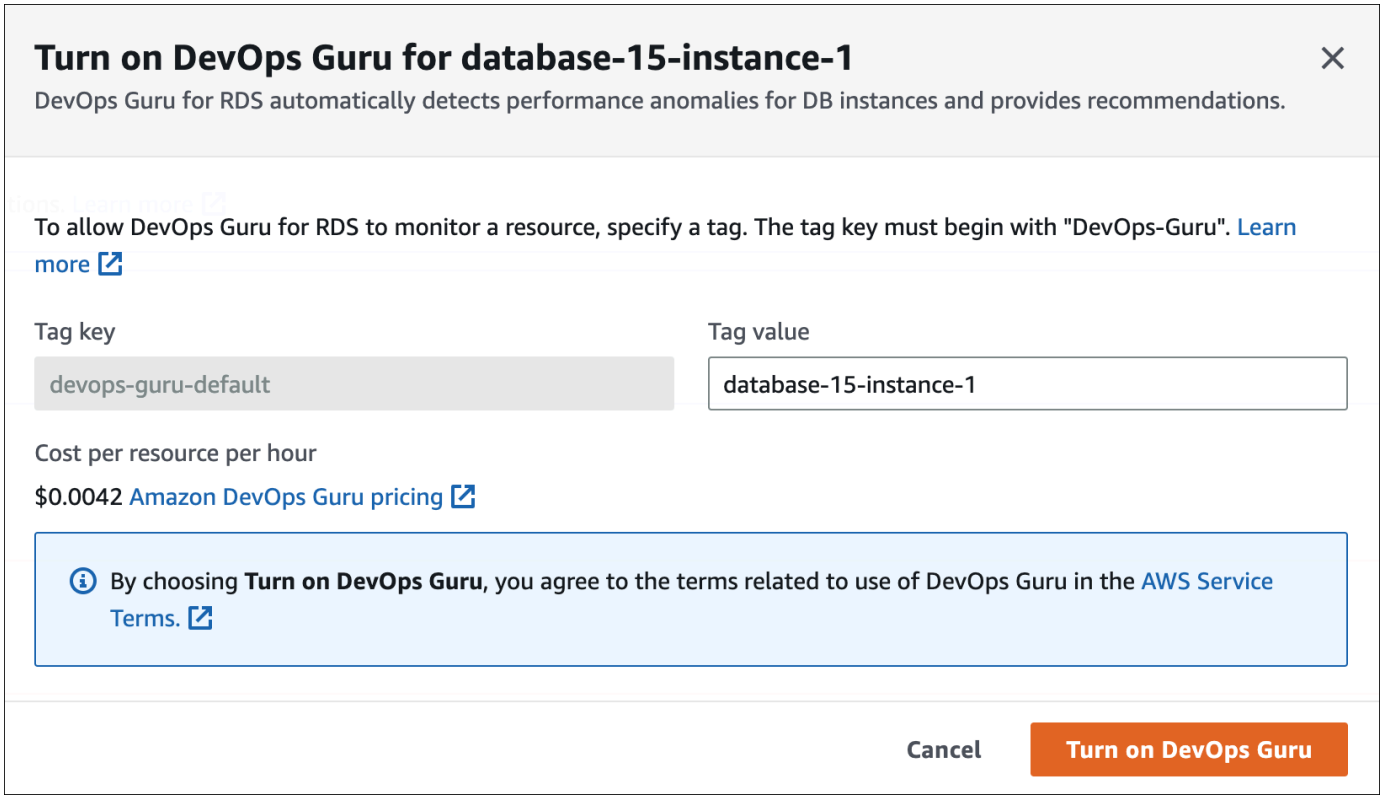
To turn on DevOps Guru for your RDS for PostgreSQL database

1. In the banner, choose **Turn on DevOps Guru for RDS**.
2. Enter a tag key name and value. For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.

3. Choose **Turn on DevOps Guru**.

Responding to a permissions error when you turn on DevOps Guru

If you turn on DevOps Guru from the RDS console when you create a database, RDS might display the following banner about missing permissions.



To respond to a permissions error

1. Grant your IAM user or role the user managed role `AmazonDevOpsGuruConsoleFullAccess`. For more information, see Configuring IAM access policies for DevOps Guru for RDS.
2. Open the RDS console.
3. In the navigation pane, choose **Performance Insights**.
4. Choose a DB instance in the cluster that you just created.
5. Choose the switch to turn on **DevOps Guru for RDS**.

DevOps Guru for RDS

6. Choose a tag value. For more information, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.

7. Choose **Turn on DevOps Guru**.

Adding RDS for PostgreSQL resources in the DevOps Guru console

You can specify your DevOps Guru resource coverage on the DevOps Guru console. Follow the step described in Specify your DevOps Guru resource coverage in the *Amazon DevOps Guru User Guide*. When you edit your analyzed resources, choose one of the following options:

- Choose **All account resources** to analyze all supported resources, including the RDS for PostgreSQL databases, in your AWS account and Region.
- Choose **CloudFormation stacks** to analyze the RDS for PostgreSQL databases that are in stacks you choose. For more information, see Use AWS CloudFormation stacks to identify resources in your DevOps Guru applications in the *Amazon DevOps Guru User Guide*.
- Choose **Tags** to analyze the RDS for PostgreSQL databases that you have tagged. For more information, see Use tags to identify resources in your DevOps Guru applications in the *Amazon DevOps Guru User Guide*.

For more information, see Enable DevOps Guru in the *Amazon DevOps Guru User Guide*.

Adding RDS for PostgreSQL resources using CloudFormation

You can use tags to add coverage for your RDS for PostgreSQL resources to your CloudFormation templates. The following procedure assumes that you have a CloudFormation template both for your RDS for PostgreSQL DB instance and DevOps Guru stack.

To specify an RDS for PostgreSQL DB instance using a CloudFormation tag

1. In the CloudFormation template for your DB instance, define a tag using a key/value pair.

   The following example assigns the value `my-db-instance1` to `Devops-guru-cfn-default` for an RDS for PostgreSQL DB instance.

   ```
   MyDBInstance1:
     Type: "AWS::RDS::DBInstance"
     Properties:
       DBInstanceIdentifier: my-db-instance1
       Tags:
         - Key: Devops-guru-cfn-default
           Value: devopsguru-my-db-instance1
   ```

2. In the CloudFormation template for your DevOps Guru stack, specify the same tag in your resource collection filter.

   The following example configures DevOps Guru to provide coverage for the resource with the tag value `my-db-instance1`.

   ```
   DevOpsGuruResourceCollection:
     Type: AWS::DevOpsGuru::ResourceCollection
     Properties:
       ResourceCollectionFilter:
         Tags:
           - AppBoundaryKey: "Devops-guru-cfn-default"
             TagValues:
             - "devopsguru-my-db-instance1"
   ```

   The following example provides coverage for all resources within the application boundary `Devops-guru-cfn-default`.

   ```
   DevOpsGuruResourceCollection:
   ```

```
Type: AWS::DevOpsGuru::ResourceCollection
Properties:
  ResourceCollectionFilter:
    Tags:
      - AppBoundaryKey: "Devops-guru-cfn-default"
        TagValues:
        - "*"
```

For more information, see AWS::DevOpsGuru::ResourceCollection and AWS::RDS::DBInstance in the *CloudFormation User Guide*.

Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics

- Overview of Enhanced Monitoring
- Setting up and enabling Enhanced Monitoring
- Viewing OS metrics in the RDS console
- Viewing OS metrics using CloudWatch Logs

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring.

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see Enhanced Monitoring in the Amazon RDS FAQs.

Topics

- Enhanced Monitoring availability
- Differences between CloudWatch and Enhanced Monitoring metrics
- Retention of Enhanced Monitoring metrics
- Cost of Enhanced Monitoring

Enhanced Monitoring availability

Enhanced Monitoring is available for the following database engines:

- Db2
- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Differences between CloudWatch and Enhanced Monitoring metrics

A *hypervisor* creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring. For more information about CloudWatch metrics, see the *Amazon CloudWatch User Guide*.

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.

To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the `RDSOSMetrics` log group in the CloudWatch console. For more information, see Change log data retention in CloudWatch logs in the *Amazon CloudWatch Logs User Guide*.

Cost of Enhanced Monitoring

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the amount of data transfer and storage provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.

- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see Amazon CloudWatch pricing.

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Topics

- Creating an IAM role for Enhanced Monitoring
- Turning Enhanced Monitoring on and off
- Protecting against the confused deputy problem

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

Topics

- Creating the IAM role when you enable Enhanced Monitoring
- Creating the IAM role before you enable Enhanced Monitoring

Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named `rds-monitoring-role`. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in Turning Enhanced Monitoring on and off.
2. Set **Monitoring Role** to **Default** in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the `PassRole` permission. For more information, see Example 2 in Granting a user permissions to pass a role to an AWS service in the *IAM User Guide*.

To create an IAM role for Amazon RDS enhanced monitoring

1. Open the IAM console at https://console.aws.amazon.com.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose the **AWS service** tab, and then choose **RDS** from the list of services.
5. Choose **RDS - Enhanced Monitoring**, and then choose **Next**.
6. Ensure that the **Permissions policies** shows **AmazonRDSEnhancedMonitoringRole**, and then choose **Next**.
7. For **Role name**, enter a name for your role. For example, enter **`emaccess`**.

   The trusted entity for your role is the AWS service **monitoring.rds.amazonaws.com**.
8. Choose **Create role**.

Turning Enhanced Monitoring on and off

You can manage Enhanced Monitoring using the AWS Management Console, AWS CLI, or RDS API. You can set different granularities for metric collection on each DB instance.

Console

You can turn on Enhanced Monitoring when you create a DB instance, Multi-AZ DB cluster, or read replica, or when you modify a DB instance or Multi-AZ DB cluster. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the **Databases** page:

- **Create a DB instance or Multi-AZ DB cluster** – Choose **Create database**.
- **Create a read replica** – Choose **Actions**, then **Create read replica**.
- **Modify a DB instance or Multi-AZ DB cluster** – Choose **Modify**.

To turn Enhanced Monitoring on or off in the RDS console

1. Scroll to **Additional configuration**.
2. In **Monitoring**, choose **Enable Enhanced Monitoring** for your DB instance or read replica. Deselect the option to disable Enhanced Monitoring.
3. Set the **Monitoring Role** property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose **Default** to have RDS create a role for you named `rds-monitoring-role`.
4. Set the **Granularity** property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The **Granularity** property can be set to one of the following values: `1`, `5`, `10`, `15`, `30`, or `60`.

   The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

AWS CLI

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than `0` and set the `--monitoring-role-arn` option to the role you created in Creating an IAM role for Enhanced Monitoring.

- create-db-instance
- create-db-instance-read-replica
- modify-db-instance
- create-db-cluster (Multi-AZ DB cluster)
- modify-db-cluster (Multi-AZ DB cluster)

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are `0`, `1`, `5`, `10`, `15`, `30`, and `60`.

To turn off Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to `0` in these commands.

Example

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --monitoring-interval 30 \
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --monitoring-interval 30 ^
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

Example

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --monitoring-interval 30 \
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --monitoring-interval 30 ^
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To turn on Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than `0` and set the `MonitoringRoleArn` parameter to the role you created in Creating an IAM role for Enhanced Monitoring. Set these parameters in the following actions:

- CreateDBInstance
- CreateDBInstanceReadReplica
- ModifyDBInstance
- CreateDBCluster (Multi-AZ DB cluster)
- ModifyDBCluster (Multi-AZ DB cluster)

The `MonitoringInterval` parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are `0`, `1`, `5`, `10`, `15`, `30`, and `60`.

To turn off Enhanced Monitoring using the RDS API, set `MonitoringInterval` to `0`.

Protecting against the confused deputy problem

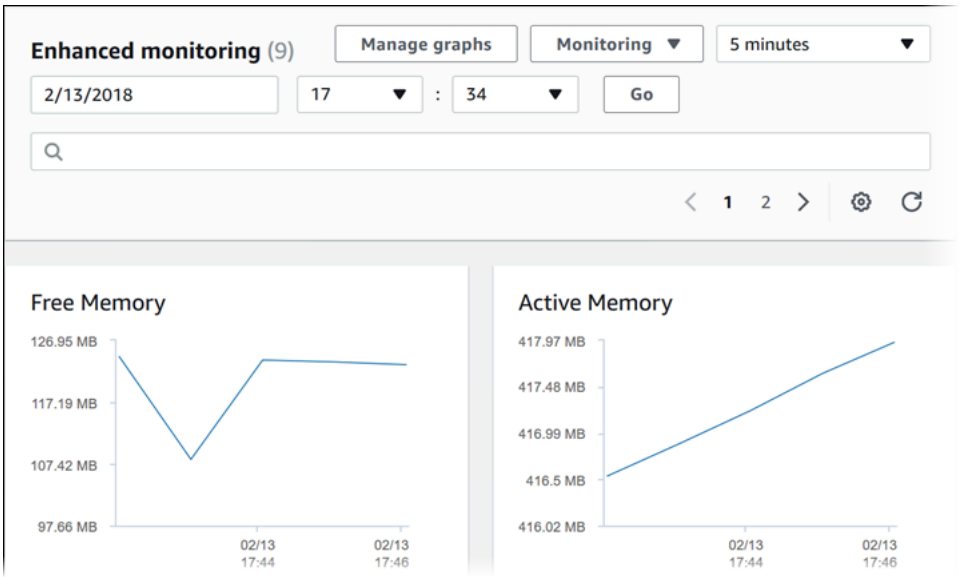
The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service

can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem.

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.

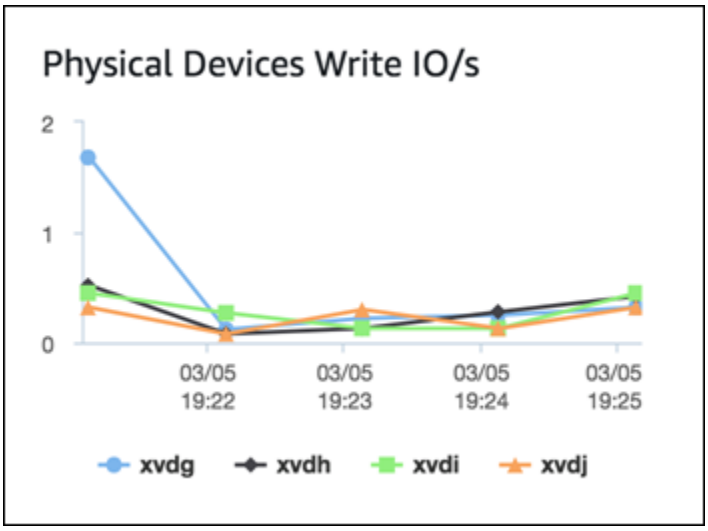
The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. For Amazon RDS, set `aws:SourceArn` to `arn:aws:rds:`*`Region`*`:`*`my-account-id`*`:db:`*`dbname`*.

The following example uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy to prevent the confused deputy problem.



JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "monitoring.rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringLike": {
          "aws:SourceArn": "arn:aws:rds:Region:my-123456789012:db:dbname"
        },
        "StringEquals": {
          "aws:SourceAccount": "my-123456789012"
        }
      }
    }
  ]
}
```

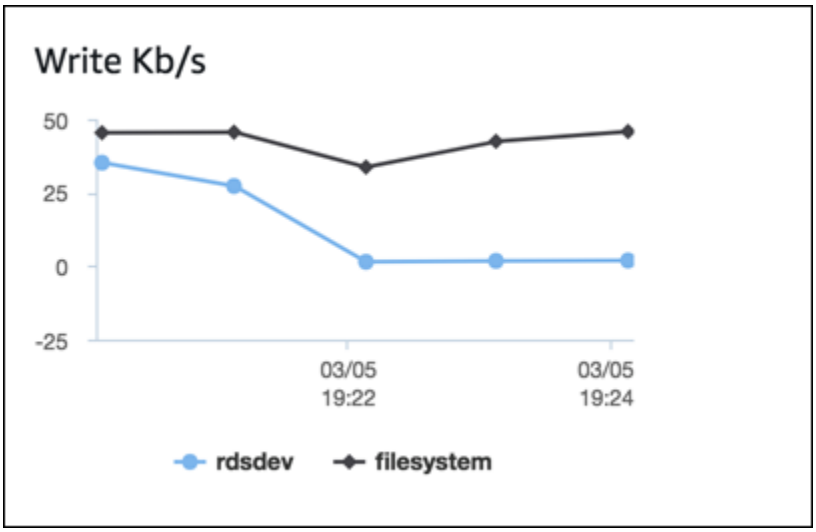


Viewing OS metrics in the RDS console

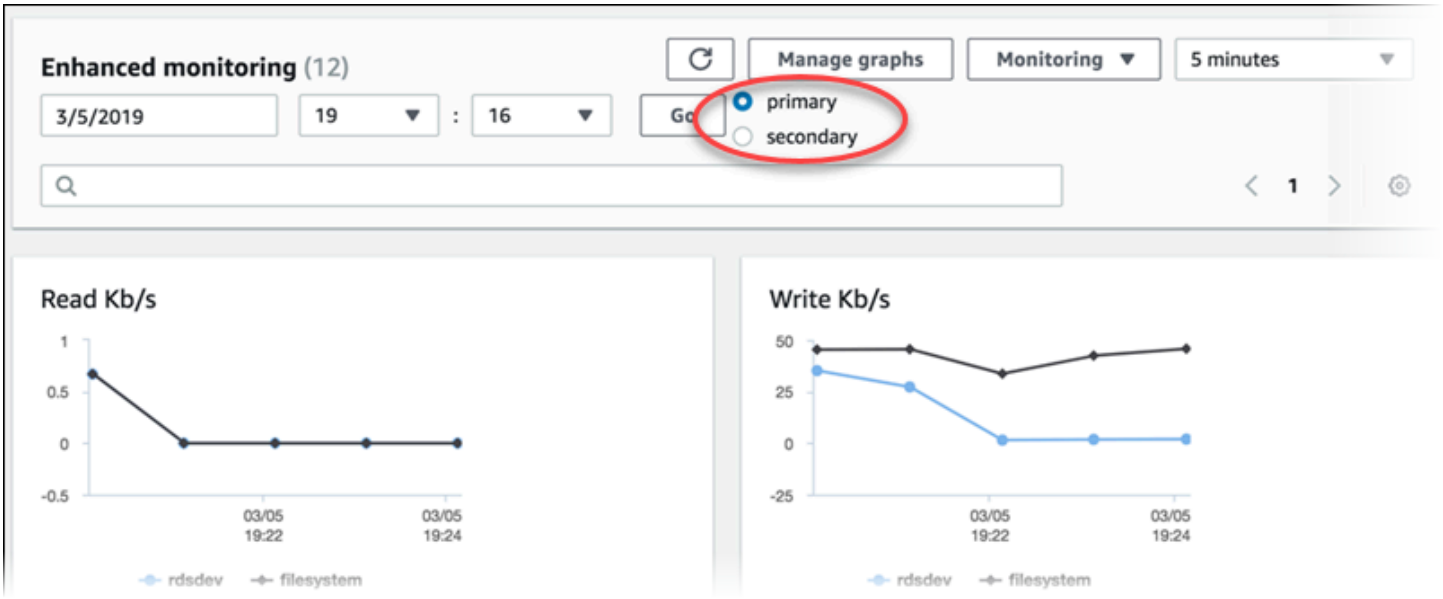
You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring** for **Monitoring**.

The following example shows the Enhanced Monitoring page. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring.

Some DB instances use more than one disk for the DB instance's data storage volume. On those DB instances, the **Physical Devices** graphs show metrics for each one of the disks. For example, the following graph shows metrics for four disks.



> **Note**
>
> Currently, **Physical Devices** graphs are not available for Microsoft SQL Server DB instances.

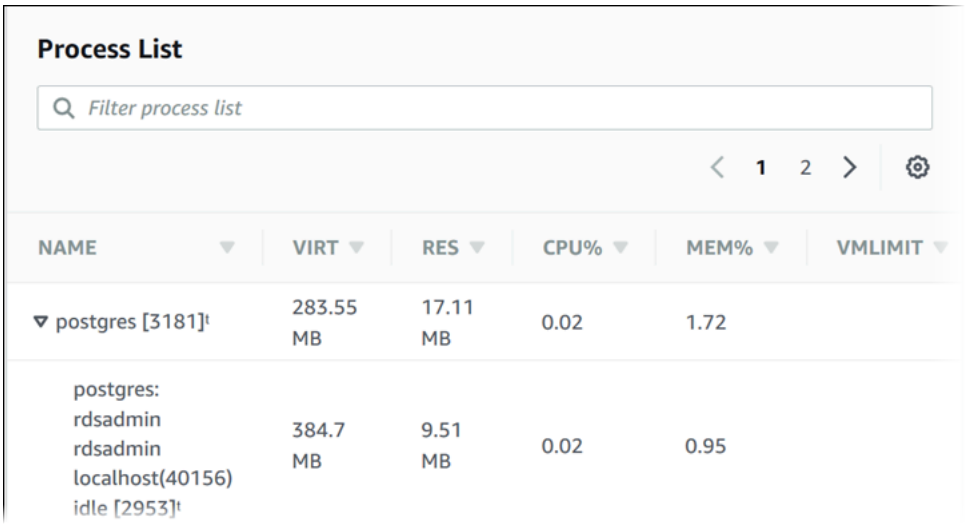


When you are viewing aggregated **File system** graphs, the **rdsdbdata*** device relates to the `rdsfilesys/rdsdbdata*` file system, where all database files and logs are stored. The **rootfilesys** device relates to the `/` file system (also known as root), where files related to the operating system are stored. When using additional storage volumes, view the `rdsdbdata2`, `rdsdbdata3`, and `rdsdbdata4` volume metrics for volume specific information.

When you are viewing aggregated **Disk I/O** graphs, the **rdsdbdata** device relates to the primary `/rdsdbdata` storage volume. When using additional storage volumes, view the `rdsdbdata2`, `rdsdbdata3`, and `rdsdbdata4` volume metrics for volume specific information. The filesystem device relates to the /file system (also known as root), where files related to the operating system are stored.

The **rdsdev** device name is deprecated. The **rdsdev** device only relates to the primary `/rdsdbdata` storage volume and does not include metrics from additional storage volumes.

If the DB instance is a Multi-AZ deployment, you can view the OS metrics for the primary DB instance and its Multi-AZ standby replica. In the **Enhanced monitoring** view, choose **primary** to view the OS metrics for the primary DB instance, or choose **secondary** to view the OS metrics for the standby replica.



For more information about Multi-AZ deployments, see [Configuring and managing a Multi-AZ deployment for Amazon RDS](#).

> **Note**
>
> Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB DB instances.

If you want to see details for the processes running on your DB instance, choose **OS process list** for **Monitoring**.

The **Process List** view is shown following.

The Enhanced Monitoring metrics shown in the **Process list** view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example `mysqld` for MySQL DB instances. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.
- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.
- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.

The items listed for each process are:

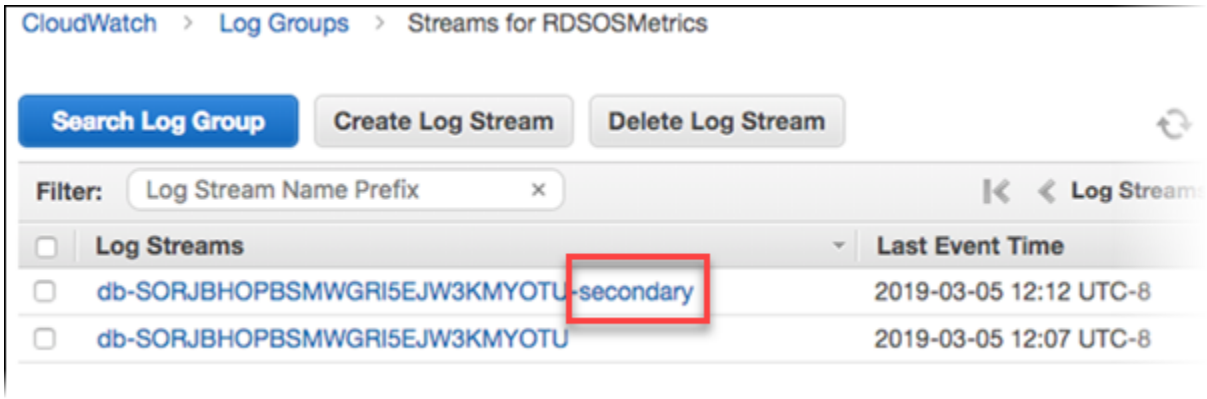
- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see Viewing OS metrics using CloudWatch Logs.

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.



Viewing OS metrics using CloudWatch Logs

After you have enabled Enhanced Monitoring for your DB instance or Multi-AZ DB cluster, you can view the metrics for it using CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored. The log stream identifier is the resource identifier (`DbiResourceId`) for the DB instance or DB cluster.

To view Enhanced Monitoring log data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, choose the AWS Region that your DB instance or Multi-AZ DB cluster is in. For more information, see Regions and endpoints in the *Amazon Web Services General Reference*.
3. Choose **Logs** in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.

   In a Multi-AZ DB instance deployment, log files with `-secondary` appended to the name are for the Multi-AZ standby replica.

5. Choose the log stream that you want to view from the list of log streams.

Metrics reference for Amazon RDS

In this reference, you can find descriptions of Amazon RDS metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Topics

- Amazon CloudWatch metrics for Amazon RDS
- Amazon CloudWatch dimensions for Amazon RDS
- Amazon CloudWatch metrics for Amazon RDS Performance Insights
- Performance Insights counter metrics
- SQL statistics for Performance Insights
- OS metrics in Enhanced Monitoring

Amazon CloudWatch metrics for Amazon RDS

Amazon CloudWatch metrics provide insights into the performance and health of Amazon RDS instances and clusters, allowing you to monitor system behavior and make data-driven decisions. These metrics help track resource utilization, database activity, and operational efficiency, offering visibility into how your instances are performing.

This reference outlines the specific metrics available for Amazon RDS and explains how to interpret and use them to optimize database performance, troubleshoot issues, and ensure high availability.

Amazon RDS publishes metrics to Amazon CloudWatch in the `AWS/RDS` and `AWS/Usage` namespaces.

Topics

- Amazon CloudWatch instance-level metrics for Amazon RDS
- Amazon CloudWatch usage metrics for Amazon RDS

Amazon CloudWatch instance-level metrics for Amazon RDS

The `AWS/RDS` namespace in Amazon CloudWatch includes the following instance-level metrics.

Note

The Amazon RDS console might display metrics in units that are different from the units sent to Amazon CloudWatch. For example, the Amazon RDS console might display a metric in megabytes (MB), while the metric is sent to Amazon CloudWatch in bytes.

Metric	Description	Applies to	Units
`BinLogDiskUsage`	The amount of disk space occupied by binary logs. If automatic backups are enabled for MySQL and MariaDB instances, including read replicas, binary logs are created.	MariaDB MySQL	Bytes
`BurstBalance`	The percent of General Purpose SSD (gp2) burst-bucket I/O credits available.	All	Percent
`CheckpointLag`	The amount of time since the most recent checkpoint.		Seconds
`ConnectionAttempts`	The number of attempts to connect to an instance, whether successful or not.	MySQL	Count
`CPUUtilization`	The percentage of CPU utilization.	All	Percent
`CPUCreditUsage`	The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100 percent utilization for one minute or an equivalent combination of vCPUs, utilization, and time. For example, you might have one vCPU running at 50 percent utilization for two minutes or two vCPUs running at 25 percent utilization for two minutes.		Credits (vCPU-minutes)

Metric	Description	Applies to	Units
	This metric applies only to `db.t2`, `db.t3`, and `db.t4g` instances. **Note** We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the `Sum` statistic instead of the `Average` statistic.		

Metric	Description	Applies to	Units
`CPUCreditBalance`	The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the `CPUCreditBalance` also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits don't count towards the limit. The credits in the `CPUCreditBalance` are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the `CPUCreditBalance` don't expire. When the instance stops, the `CPUCreditBalance` does not persist, and all accrued credits are lost. CPU credit metrics are available at a five-minute frequency only. This metric applies only to `db.t2`, `db.t3`, and `db.t4g` instances.		Credits (vCPU-minutes)

Metric	Description	Applies to	Units
	Note We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types Launch credits work the same way in Amazon RDS as they do in Amazon EC2. For more information, see Launch credits in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.		
`CPUSurplusCreditBalance`	The number of surplus credits that have been spent by an unlimited instance when its `CPUCreditBalance` value is zero. The `CPUSurplusCreditBalance` value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. CPU credit metrics are available at a 5-minute frequency only.	All	Credits (vCPU-minutes)

Metric	Description	Applies to	Units
`CPUSurplusCreditsCharged`	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when any of the following occurs: • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from `unlimited` to `standard`. CPU credit metrics are available at a 5-minute frequency only.	All	Credits (vCPU-minutes)

Metric	Description	Applies to	Units
`DatabaseConnections`	The number of client network connections to the database instance. The number of database sessions can be higher than the metric value because the metric value doesn't include the following: • Sessions that no longer have a network connection but which the database hasn't cleaned up • Sessions created by the database engine for its own purposes • Sessions created by the database engine's parallel execution capabilities • Sessions created by the database engine job scheduler • Amazon RDS connections	All	Count
`DiskQueueDepth`	The number of outstanding I/Os (read/write requests) waiting to access the disk.	All	Count
`DiskQueueDepthLogVolume`	The number of outstanding I/Os (read/write requests) waiting to access the log volume disk.	DB instances with dedicated log volume enabled	Count

Metric	Description	Applies to	Units
EBSByteBalance%	The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only. The metric value is based on the throughput of all volumes, including the root volume, rather than on only those volumes containing database files. To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in *Amazon EC2 User Guide*. The Sum statistic is not applicable to this metric.	All	Percent

Metric	Description	Applies to	Units
`EBSIOBalance%`	The percentage of I/O credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only. The metric value is based on the IOPS of all volumes, including the root volume, rather than on only those volumes containing database files. To find the instance sizes that support this metric, see Amazon EBS–optimized instance types in *Amazon EC2 User Guide*. The `Sum` statistic isn't applicable to this metric. This metric is different from `BurstBalance` . To learn how to use this metric, see Improving application performance and reducing costs with Amazon EBS-Optimized Instance burst capability.	All	Percent
`FailedSQLServerAgentJobsCount`	The number of failed Microsoft SQL Server Agent jobs during the last minute.	Microsoft SQL Server	Count per minute
`FreeableMemory`	The amount of available random access memory. For MariaDB, MySQL, Oracle, and PostgreSQL DB instances, this metric reports the value of the `MemAvailable` field of `/proc/meminfo` .	All	Bytes

Metric	Description	Applies to	Units
FreeLocalStorage	The amount of available local storage space. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Bytes
FreeLocalStoragePercent	The percentage of available local storage space. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Percent
FreeStorageSpace	The amount of available storage space.	All	Bytes

Metric	Description	Applies to	Units
FreeStorageSpaceLogVolume	The amount of available storage space on the log volume.	DB instances with dedicated log volume enabled	Bytes
IamDbAuthConnectionRequests	The number of connection requests using IAM authentication to the DB instance.	All	Count
MaximumUsedTransactionIDs	The maximum transaction IDs that have been used.	PostgreSQL	Count
NetworkReceiveThroughput	The incoming (receive) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	All	Bytes per second
NetworkTransmitThroughput	The outgoing (transmit) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	All	Bytes per second
OldestLogicalReplicationSlotLag	The lagging size of the Amazon RDS commits a transaction on the source database and the time when RDS applies the transaction on the replica database.	PostgreSQL	Bytes
OldestReplicationSlotLag	The lagging size of the replica lagging the most in terms of write-ahead log (WAL) data received.	PostgreSQL	Bytes

Metric	Description	Applies to	Units
ReadIOPS	The average number of disk read I/O operations per second.	All	Count per second
ReadIOPSLocalStorage	The average number of disk read I/O operations to local storage per second. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Count per second
ReadIOPSLogVolume	The average number of disk read I/O operations per second for the log volume.	DB instances with dedicated log volume enabled	Count per second
ReadLatency	The average amount of time taken per disk I/O operation.	All	Seconds

Metric	Description	Applies to	Units
`ReadLatencyLocalStorage`	The average amount of time taken per disk I/O operation for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Seconds
`ReadLatencyLogVolume`	The average amount of time taken per disk I/O operation for the log volume.	DB instances with dedicated log volume enabled	Seconds
`ReadThroughput`	The average number of bytes read from disk per second.	All	Bytes per second

Metric	Description	Applies to	Units
ReadThroughputLocalStorage	The average number of bytes read from disk per second for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Bytes per second
ReadThroughputLogVolume	The average number of bytes read from disk per second for the log volume.	DB instances with dedicated log volume enabled	Bytes per second
ReplicaLag	For read replica configurations, the amount of time a read replica DB instance lags behind the source DB instance. Applies to MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL read replicas. For Multi-AZ DB clusters, the difference in time between the latest transaction on the writer DB instance and the latest applied transaction on a reader DB instance.		Seconds

Metric	Description	Applies to	Units
`ReplicationChannelLag`	For multi-source replica configurations, the amount of time a particular channel on the multi-source replica lags behind the source DB instance. For more information, see the section called "Monitoring multi-source replication channels".	MySQL	Seconds
`ReplicationSlotDiskUsage`	The disk space used by replication slot files.	PostgreSQL	Bytes
`SwapUsage`	The amount of swap space used on the DB instance.	MariaDB MySQL Oracle PostgreSQL	Bytes
`TempDbAvailableDataSpace`	The amount of available data space on the tempdb and the volume where tempdb is located. Use this metric to monitor tempdb data space availability and plan capacity accordingly. Low values may indicate the need to increase storage or optimize queries that heavily use tempdb.	SQL Server	Bytes

Metric	Description	Applies to	Units
TempDbAvailableLogSpace	The amount of available log space on the tempdb and the volume where tempdb is located. Use this metric to monitor tempdb log space availability and prevent transaction log full conditions. Critical for workloads with large transactions or high concurrency that generate significant log activity.	SQL Server	Bytes
TempDbDataFileUsage	The percentage of data files used on the tempdb. This metric doesn't account for potential file growth. Use this metric to monitor tempdb data file utilization and identify potential performance bottlenecks. High values may indicate the need to optimize queries that create large temporary objects or increase tempdb size.	SQL Server	Percent
TempDbLogFileUsage	The percentage of log files used on the tempdb. This metric doesn't account for potential file growth. Use this metric to monitor tempdb log file utilization and prevent performance issues. High values may indicate long-running transactions or excessive logging activity that could impact overall database performance.	SQL Server	Percent

Metric	Description	Applies to	Units
TransactionLogsDiskUsage	The disk space used by transaction logs.	PostgreSQL	Bytes
TransactionLogsGeneration	The size of transaction logs generated per second.	PostgreSQL	Bytes per second
WriteIOPS	The average number of disk write I/O operations per second.	All	Count per second
WriteIOPSLocalStorage	The average number of disk write I/O operations per second on local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Count per second
WriteIOPSLogVolume	The average number of disk write I/O operations per second for the log volume.	DB instances with dedicated log volume enabled	Count per second
WriteLatency	The average amount of time taken per disk I/O operation.	All	Seconds

Metric	Description	Applies to	Units
`WriteLatencyLocalStorage`	The average amount of time taken per disk I/O operation on local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Seconds
`WriteLatencyLogVolume`	The average amount of time taken per disk I/O operation for the log volume.	DB instances with dedicated log volume enabled	Seconds
`WriteThroughput`	The average number of bytes written to disk per second.	All	Bytes per second
`WriteThroughputLogVolume`	The average number of bytes written to disk per second for the log volume.	DB instances with dedicated log volume enabled	Bytes per second

Metric	Description	Applies to	Units
`WriteThroughputLocalStorage`	The average number of bytes written to disk per second for local storage. This metric only applies to DB instance classes with NVMe SSD instance store volumes. For information about Amazon EC2 instances with NVMe SSD instance store volumes, see Instance store volumes. The equivalent RDS DB instance classes have the same instance store volumes. For example, the db.m6gd and db.r6gd DB instance classes have NVMe SSD instance store volumes.		Bytes per second

Amazon CloudWatch usage metrics for Amazon RDS

The `AWS/Usage` namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. CloudWatch collects usage metrics automatically for all AWS Regions.

For more information, see CloudWatch usage metrics in the *Amazon CloudWatch User Guide*. For more information about quotas, see Quotas and constraints for Amazon RDS and Requesting a quota increase in the *Service Quotas User Guide*.

Metric	Description	Units*
`AllocatedStorage`	The total storage for all DB instances. The sum excludes temporary migration instances.	Gigabytes
`AuthorizationsPerDBSecurityGroup`	The number of ingress rules per DB security group in your AWS account. The used value is the highest number of ingress rules in a DB security group in the account. Other DB security groups in the account might have a lower number of ingress rules.	Count

Metric	Description	Units*
CustomEndpointsPerDBCluster	The number of custom endpoints per DB cluster in your AWS account. The used value is the highest number of custom endpoints in a DB cluster in the account. Other DB clusters in the account might have a lower number of custom endpoints.	Count
CustomEngineVersions	The number of custom engine versions (CEVs) for Amazon RDS Custom in your AWS account.	Count
DBClusterParameterGroups	The number of DB cluster parameter groups in your AWS account. The count excludes default parameter groups.	Count
DBClusterRoles	The number of associated AWS Identity and Access Management (IAM) roles per DB cluster in your AWS account. The used value is the highest number of associated IAM roles for a DB cluster in the account. Other DB clusters in the account might have a lower number of associated IAM roles.	Count
DBClusters	The number of Amazon Aurora DB clusters in your AWS account.	Count
DBInstanceRoles	The number of associated AWS Identity and Access Management (IAM) roles per DB instance in your AWS account. The used value is the highest number of associated IAM roles for a DB instance in the account. Other DB instances in the account might have a lower number of associated IAM roles.	Count
DBInstances	The number of DB instances in your AWS account.	Count
DBParameterGroups	The number of DB parameter groups in your AWS account. The count excludes the default DB parameter groups.	Count

Metric	Description	Units*
DBSecurityGroups	The number of security groups in your AWS account. The count excludes the default security group and the default VPC security group.	Count
DBSubnetGroups	The number of DB subnet groups in your AWS account. The count excludes the default subnet group.	Count
EventSubscriptions	The number of event notification subscriptions in your AWS account.	Count
Integrations	The number of zero-ETL integrations with Amazon Redshift in your AWS account.	Count
ManualClusterSnapshots	The number of manually created DB cluster snapshots in your AWS account. The count excludes invalid snapshots.	Count
ManualSnapshots	The number of manually created DB snapshots in your AWS account. The count excludes invalid snapshots.	Count
OptionGroups	The number of option groups in your AWS account. The count excludes the default option groups.	Count
Proxies	The number of RDS proxies in your AWS account.	Count
ReadReplicasPerMaster	The number of read replicas per DB instance in your account. The used value is the highest number of read replicas for a DB instance in the account. Other DB instances in the account might have a lower number of read replicas.	Count
ReservedDBInstances	The number of reserved DB instances in your AWS account. The count excludes retired or declined instances.	Count
SubnetsPerDBSubnetGroup	The number of subnets per DB subnet group in your AWS account. The highest number of subnets for a DB subnet group in the account. Other DB subnet groups in the account might have a lower number of subnets.	Count

Note

Amazon RDS doesn't publish units for usage metrics to CloudWatch. The units only appear in the documentation.

Amazon CloudWatch dimensions for Amazon RDS

You can filter Amazon RDS metrics data by using any dimension in the following table.

Dimension	Filters the requested data for . . .
`DBInstanceIdentifier`	A specific DB instance.
`DatabaseClass`	All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class `db.r5.large` .
`EngineName`	The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name `postgres`.
`SourceRegion`	The specified Region only. For example, you can aggregate metrics for all DB instances in the `us-east-1` Region.
`DbInstanceIdentifier, VolumeName`	The metrics per-volume for a single instance. RDS captures metrics for multiple storage volumes.

Note

If you are using additional storage volumes, you can see aggregate storage metrics under the `DBInstanceIdentifier` dimension. To see per-volume storage metrics, use the `DbInstanceIdentifier, VolumeName` dimensions.

Amazon CloudWatch metrics for Amazon RDS Performance Insights

Performance Insights automatically publishes some metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

Metric	Description
DBLoad	The number of active sessions for the database. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as `db.load.avg` .
DBLoadCPU	The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as `db.load.avg` , filtered by the wait event type CPU.
DBLoadNonCPU	The number of active sessions where the wait event type is not CPU.
DBLoadRelativeToNumVCPUs	The ratio of the DB load to the number of virtual CPUs for the database.

Note

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API. You can also examine other Performance Insights counter metrics using a special metric math function. For more information, see Querying other Performance Insights counter metrics in CloudWatch.

For example, you can get the statistics for the `DBLoad` metric by running the get-metric-statistics command.

```
aws cloudwatch get-metric-statistics \
    --region us-west-2 \
    --namespace AWS/RDS \
    --metric-name DBLoad  \
    --period 60 \
    --statistics Average \
    --start-time 1532035185 \
    --end-time 1532036185 \
    --dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```
{
  "Datapoints": [
  {
  "Timestamp": "2021-07-19T21:30:00Z",
  "Unit": "None",
  "Average": 2.1
  },
  {
  "Timestamp": "2021-07-19T21:34:00Z",
  "Unit": "None",
  "Average": 1.7
  },
  {
  "Timestamp": "2021-07-19T21:35:00Z",
  "Unit": "None",
  "Average": 2.8
  },
  {
  "Timestamp": "2021-07-19T21:31:00Z",
  "Unit": "None",
  "Average": 1.5
  },
  {
  "Timestamp": "2021-07-19T21:32:00Z",
  "Unit": "None",
  "Average": 1.8
  },
  {
  "Timestamp": "2021-07-19T21:29:00Z",
  "Unit": "None",
  "Average": 3.0
```

```
},
{
"Timestamp": "2021-07-19T21:33:00Z",
"Unit": "None",
"Average": 2.4
}
],
"Label": "DBLoad"
}
```

For more information about CloudWatch, see What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*.

Querying other Performance Insights counter metrics in CloudWatch

> **Note**
>
> If you enable the Advanced mode of Database Insights, Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch. With Database Insights, you don't need to use the `DB_PERF_INSIGHTS` metric math function. You can use the CloudWatch Database Insights dashboard to search, query, and set alarms for Performance Insights counter metrics.

You can query, alarm, and graphs on RDS Performance Insights metrics from CloudWatch. You can access information about your DB instance by using the `DB_PERF_INSIGHTS` metric math function for CloudWatch. This function allows you to use the Performance Insights metrics that are not directly reported to CloudWatch to create a new time series.

You can use the new Metric Math function by clicking on the **Add Math** drop-down menu in the **Select metric** screen in the CloudWatch console. You can use it to create alarms and graphs on Performance Insights metrics or on combinations of CloudWatch and Performance Insights metrics, including high-resolution alarms for sub-minute metrics. You can also use the function programmatically by including the Metric Math expression in a `get-metric-data` request. For more information, see Metric math syntax and functions and Create an alarm on Performance Insights counter metrics from an AWS database.

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load. You must append a statistic function to the metric to get the metric values. For example, the supported functions for `os.memory.active` metric are `.avg`, `.min`, `.max`, `.sum`, and `.sample_count`.

The counter metrics are collected one time each minute. The OS metrics collection depends on whether Enhanced Monitoring is turned on or off. If Enhanced Monitoring is turned off, the OS metrics are collected one time each minute. If Enhanced Monitoring is turned on, the OS metrics are collected for the selected time period. For more information about turning Enhanced Monitoring on or off, see Turning Enhanced Monitoring on and off.

Performance Insights operating system counters

The following operating system counters, which are prefixed with `os`, are available with Performance Insights for all RDS engines except RDS for SQL Server .

You can use `ListAvailableResourceMetrics` API for the list of available counter metrics for your DB instance. For more information, see ListAvailableResourceMetrics in the Amazon RDS Performance Insights API Reference guide.

Counter	Type	Unit	Metric	Description
Active	Memory	Kilobytes	os.memory .active	The amount of assigned memory, in kilobytes.

Counter	Type	Unit	Metric	Description
Buffers	Memory	Kilobytes	os.memory .buffers	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.
Cached	Memory	Kilobytes	os.memory .cached	The amount of memory used for caching file system–based I/O, in kilobytes.
DB Cache	Memory	Bytes	os.memory .db.cache	The amount of memory used for page cache by database process in cluding tmpfs (shmem), in bytes.
DB Resident Set Size	Memory	Bytes	os.memory .db.resid entSetSize	The amount of memory used for anonymous and swap cache by database process not including tmpfs (shmem), in bytes.

Counter	Type	Unit	Metric	Description
DB Swap	Memory	Bytes	os.memory .db.swap	The amount of memory used for swap by database process, in bytes.
Dirty	Memory	Kilobytes	os.memory.dirty	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
Free	Memory	Kilobytes	os.memory.free	The amount of unassigne d memory, in kilobytes.
Huge Pages Free	Memory	Pages	os.memory .hugePagesFree	The number of free huge pages. Huge pages are a feature of the Linux kernel.
Huge Pages Rsvd	Memory	Pages	os.memory .hugePagesRsvd	The number of committed huge pages.
Huge Pages Size	Memory	Kilobytes	os.memory .hugePagesSize	The size for each huge pages unit, in kilobytes.

Counter	Type	Unit	Metric	Description
Huge Pages Surp	Memory	Pages	os.memory .hugePagesSurp	The number of available surplus huge pages over the total.
Huge Pages Total	Memory	Pages	os.memory .hugePagesTotal	The total number of huge pages.
Inactive	Memory	Kilobytes	os.memory .inactive	The amount of least-fre quently used memory pages, in kilobytes.
Mapped	Memory	Kilobytes	os.memory .mapped	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.
Out of Memory Kill Count	Memory	Kills	os.memory .outOfMem oryKillCount	The number of OOM kills that happened over the last collectio n interval.
Page Tables	Memory	Kilobytes	os.memory .pageTables	The amount of memory used by page tables, in kilobytes.

Counter	Type	Unit	Metric	Description
Slab	Memory	Kilobytes	os.memory.slab	The amount of reusable kernel data structures, in kilobytes.
Total	Memory	Kilobytes	os.memory.total	The total amount of memory, in kilobytes.
Writeback	Memory	Kilobytes	os.memory .writeback	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.
Guest	Cpu Utilization	Percentage	os.cpuUti lization.guest	The percentage of CPU in use by guest programs.
Idle	Cpu Utilization	Percentage	os.cpuUti lization.idle	The percentag e of CPU that is idle.
Irq	Cpu Utilization	Percentage	os.cpuUti lization.irq	The percentag e of CPU in use by software interrupts.
Nice	Cpu Utilization	Percentage	os.cpuUti lization.nice	The percentag e of CPU in use by programs running at lowest priority.

Counter	Type	Unit	Metric	Description
Steal	Cpu Utilization	Percentage	os.cpuUtilization.steal	The percentage of CPU in use by other virtual machines.
System	Cpu Utilization	Percentage	os.cpuUtilization.system	The percentage of CPU in use by the kernel.
Total	Cpu Utilization	Percentage	os.cpuUtilization.total	The total percentage of the CPU in use. This value includes the nice value.
User	Cpu Utilization	Percentage	os.cpuUtilization.user	The percentage of CPU in use by user programs.
Wait	Cpu Utilization	Percentage	os.cpuUtilization.wait	The percentage of CPU unused while waiting for I/O access.
Read IOs PS	Disk IO	Requests per second	os.diskIO.<devicename>.readIOsPS	The number of read operations per second.
Write IOs PS	Disk IO	Requests per second	os.diskIO.<devicename>.writeIOsPS	The number of write operations per second.

Counter	Type	Unit	Metric	Description
Avg Queue Len	Disk IO	Requests	os.diskIO.<devicename>.avgQueueLen	The number of requests waiting in the I/O device's queue.
Avg Req Sz	Disk IO	Requests	os.diskIO.<devicename>.avgReqSz	The number of requests waiting in the I/O device's queue.
Await	Disk IO	Milliseconds	os.diskIO.<devicename>.await	The number of milliseconds required to respond to requests, including queue time and service time.
Read IOs PS	Disk IO	Requests	os.diskIO.<devicename>.readIOsPS	The number of read operations per second.
Read KB	Disk IO	Kilobytes	os.diskIO.<devicename>.readKb	The total number of kilobytes read.
Read KB PS	Disk IO	Kilobytes per second	os.diskIO.<devicename>.readKbPS	The number of kilobytes read per second.

Counter	Type	Unit	Metric	Description
Rrqm PS	Disk IO	Requests per second	os.diskIO.<devicename>.rrqmPS	The number of merged read requests queued per second.
TPS	Disk IO	Transactions per second	os.diskIO.<devicename>.tps	The number of I/O transactions per second.
Util	Disk IO	Percentage	os.diskIO.<devicename>.util	The percentage of CPU time during which requests were issued.
Write KB	Disk IO	Kilobytes	os.diskIO.<devicename>.writeKb	The total number of kilobytes written.
Write KB PS	Disk IO	Kilobytes per second	os.diskIO.<devicename>.writeKbPS	The number of kilobytes written per second.
Wrqm PS	Disk IO	Requests per second	os.diskIO.<devicename>.wrqmPS	The number of merged write requests queued per second.
Blocked	Tasks	Tasks	os.tasks.blocked	The number of tasks that are blocked.

Counter	Type	Unit	Metric	Description
Running	Tasks	Tasks	os.tasks.running	The number of tasks that are running.
Sleeping	Tasks	Tasks	os.tasks.sleeping	The number of tasks that are sleeping.
Stopped	Tasks	Tasks	os.tasks.stopped	The number of tasks that are stopped.
Total	Tasks	Tasks	os.tasks.total	The total number of tasks.
Zombie	Tasks	Tasks	os.tasks.zombie	The number of child tasks that are inactive with an active parent task.
One	Load Average Minute	Processes	os.loadAverageMinute.one	The number of processes requesting CPU time over the last minute.
Fifteen	Load Average Minute	Processes	os.loadAverageMinute.fifteen	The number of processes requesting CPU time over the last 15 minutes.

Counter	Type	Unit	Metric	Description
Five	Load Average Minute	Processes	os.loadAverageMinute.five	The number of processes requesting CPU time over the last 5 minutes.
Cached	Swap	Kilobytes	os.swap.cached	The amount of swap memory, in kilobytes, used as cache memory.
Free	Swap	Kilobytes	os.swap.free	The amount of swap memory free, in kilobytes.
In	Swap	Kilobytes	os.swap.in	The amount of memory, in kilobytes, swapped in from disk.
Out	Swap	Kilobytes	os.swap.out	The amount of memory, in kilobytes, swapped out to disk.
Total	Swap	Kilobytes	os.swap.total	The total amount of swap memory available in kilobytes.

Counter	Type	Unit	Metric	Description
Max Files	File Sys	Files	os.fileSys.maxFiles	The maximum number of files that can be created for the file system across all storage volumes.
Used Files	File Sys	Files	os.fileSys.usedFiles	The number of files in the file system across all storage volumes.
Used File Percent	File Sys	Files	os.fileSys.usedFilePercent	The percentage of available files in use across all storage volumes.
Used Percent	File Sys	Percentage	os.fileSys.usedPercent	The percentage of the file-system disk space in use across all storage volumes.
Used	File Sys	Kilobytes	os.fileSys.used	The amount of disk space used by files in the file system across all storage volumes, in kilobytes.

Counter	Type	Unit	Metric	Description
Total	File Sys	Kilobytes	os.fileSys.total	The total disk space available for the file system across all storage volumes, in kilobytes.
Max Files	File Sys	Files	os.fileSys.<volume Name>.maxFiles	The maximum number of files that can be created for the storage volume.
Used Files	File Sys	Files	os.fileSys.<volume Name>.usedFiles	The number of files in the storage volume.
Used File Percent	File Sys	Files	os.fileSys.<volume Name>.usedFilePercent	The percentage of available files in use in the storage volume.
Used Percent	File Sys	Percentage	os.fileSys.<volume Name>.usedPercent	The percentage of the storage volume disk space in use.
Used	File Sys	Kilobytes	os.fileSys.<volume Name>.used	The amount of disk space used by files in the storage volume, in kilobytes.

Counter	Type	Unit	Metric	Description
Total	File Sys	Kilobytes	os.fileSys.<volume Name>.total	The total disk space available in the storage volume, in kilobytes.
Rx	Network	Bytes per second	os.network.rx	The number of bytes received per second.
Tx	Network	Bytes per second	os.network.tx	The number of bytes uploaded per second.
Acu Utilization	General	Percentage	os.general.acuUtilization	The percentage of current capacity out of the maximum configured capacity.
Max Configured Acu	General	ACUs	os.general.maxConfiguredAcu	The maximum capacity configured by the user, in Aurora capacity units (ACUs).
Min Configured Acu	General	ACUs	os.general.minConfiguredAcu	The minimum capacity configured by the user, in ACUs.

Counter	Type	Unit	Metric	Description
Num VCPUs	General	vCPUs	os.general.numVCPUs	The number of virtual CPUs (vCPUs) for the DB instance.
Serverless Database Capacity	General	ACUs	os.general.serverlessDatabaseCapacity	The current capacity of the instance, in ACUs.

Performance Insights counters for Amazon RDS for MariaDB and MySQL

The following database counters are available with Performance Insights for Amazon RDS for MariaDB and MySQL.

Topics

- Native counters for RDS for MariaDB and RDS for MySQL
- Non-native counters for Amazon RDS for MariaDB and MySQL

Native counters for RDS for MariaDB and RDS for MySQL

Native metrics are defined by the database engine and not by Amazon RDS. For definitions of these native metrics, see Server Status Variables (for 8.0) and Server Status Variables (for 8.4) in the MySQL documentation.

Counter	Type	Unit	Metric
Com_analyze	SQL	Queries per second	db.SQL.Com_analyze
Com_optimize	SQL	Queries per second	db.SQL.Com_optimize
Com_select	SQL	Queries per second	db.SQL.Com_select

Counter	Type	Unit	Metric
Connections	SQL	The number of connection attempts per minute (successful or not) to the MySQL server	db.Users.Connections
Innodb_rows_deleted	SQL	Rows per second	db.SQL.Innodb_rows_deleted
Innodb_rows_inserted	SQL	Rows per second	db.SQL.Innodb_rows_inserted
Innodb_rows_read	SQL	Rows per second	db.SQL.Innodb_rows_read
Innodb_rows_updated	SQL	Rows per second	db.SQL.Innodb_rows_updated
Select_full_join	SQL	Queries per second	db.SQL.Select_full_join
Select_full_range_join	SQL	Queries per second	db.SQL.Select_full_range_join
Select_range	SQL	Queries per second	db.SQL.Select_range
Select_range_check	SQL	Queries per second	db.SQL.Select_range_check
Select_scan	SQL	Queries per second	db.SQL.Select_scan

Counter	Type	Unit	Metric
Slow_queries	SQL	Queries per second	db.SQL.Slow_queries
Sort_merge_passes	SQL	Queries per second	db.SQL.Sort_merge_passes
Sort_range	SQL	Queries per second	db.SQL.Sort_range
Sort_rows	SQL	Queries per second	db.SQL.Sort_rows
Sort_scan	SQL	Queries per second	db.SQL.Sort_scan
Questions	SQL	Queries per second	db.SQL.Questions
Innodb_row_lock_time	Locks	Milliseconds (average)	db.Locks.Innodb_row_lock_time
Table_locks_immediate	Locks	Requests per second	db.Locks.Table_locks_immediate
Table_locks_waited	Locks	Requests per second	db.Locks.Table_locks_waited
Aborted_clients	Users	Connections	db.Users.Aborted_clients
Aborted_connects	Users	Connections	db.Users.Aborted_connects
max_connections	Users	Connections	db.User.max_connections
Threads_created	Users	Connections	db.Users.Threads_created
Threads_running	Users	Connections	db.Users.Threads_running

Counter	Type	Unit	Metric
Innodb_data_writes	I/O	Operations per second	db.IO.Innodb_data_writes
Innodb_dblwr_writes	I/O	Operations per second	db.IO.Innodb_dblwr_writes
Innodb_log_write_requests	I/O	Operations per second	db.IO.Innodb_log_write_requests
Innodb_log_writes	I/O	Operations per second	db.IO.Innodb_log_writes
Innodb_pages_written	I/O	Pages per second	db.IO.Innodb_pages_written
Created_tmp_disk_tables	Temp	Tables per second	db.Temp.Created_tmp_disk_tables
Created_tmp_tables	Temp	Tables per second	db.Temp.Created_tmp_tables
Innodb_buffer_pool_pages_data	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_data
Innodb_buffer_pool_pages_total	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_total
Innodb_buffer_pool_read_requests	Cache	Pages per second	db.Cache.Innodb_buffer_pool_read_requests
Innodb_buffer_pool_reads	Cache	Pages per second	db.Cache.Innodb_buffer_pool_reads
Opened_tables	Cache	Tables	db.Cache.Opened_tables
Opened_table_definitions	Cache	Tables	db.Cache.Opened_table_definitions

Counter	Type	Unit	Metric
Qcache_hits	Cache	Queries	db.Cache.Qcache_hits

Non-native counters for Amazon RDS for MariaDB and MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Unit	Metric	Description	Definition
innodb_buffer_pool_hits	Cache	Reads	db.Cache.innoDB_buffer_pool_hits	The number of reads that InnoDB could satisfy from the buffer pool.	`innodb_buffer_pool_read_requests - innodb_buffer_pool_reads`
innodb_buffer_pool_hit_rate	Cache	Percentage	db.Cache.innoDB_buffer_pool_hit_rate	The percentage of reads that InnoDB could satisfy from the buffer pool.	`100 * innodb_buffer_pool_read_requests / (innodb_buffer_pool_read_requests + innodb_buffer_pool_reads)`

Counter	Type	Unit	Metric	Description	Definition
innodb_buffer_pool_usage	Cache	Percentage	db.Cache.innoDB_buffer_pool_usage	The percentage of the InnoDB buffer pool that contains data (pages). **Note** When using compr d tables, this value can vary. For more inform on, see the info rmatio about Innod ffer_ _page	`Innodb_buffer_pool_pages_data / Innodb_buffer_pool_pages_total * 100.0`

Counter	Type	Unit	Metric	Description	Definition
				ta and Innodffer_pagetal in Server Status Variab (for 8.0) and Server Status Variab (for 8.4) in the MySQl do cumen on.	
query_cache_hit_rate	Cache	Percentage	db.Cache.query_cache_hit_rate	MySQL result set cache (query cache) hit ratio.	`Qcache_hits / (QCache_hits + Com_select) * 100`

Counter	Type	Unit	Metric	Description	Definition
innodb_datafile_writes_to_disk	I/O	Writes	db.IO.innoDB_datafile_writes_to_disk	The number of InnoDB data file writes to disk, excluding double write and redo logging write operations.	`Innodb_data_writes - Innodb_log_writes - Innodb_dblwr_writes`
innodb_rows_changed	SQL	Rows	db.SQL.innodb_rows_changed	The total InnoDB row operations.	`db.SQL.Innodb_rows_inserted + db.SQL.Innodb_rows_deleted + db.SQL.Innodb_rows_updated`
active_transactions	Transactions	Transactions	db.Transactions.active_transactions	The total active transactions.	`SELECT COUNT(1) AS active_transactions FROM INFORMATION_SCHEMA.INNODB_TRX`

Counter	Type	Unit	Metric	Description	Definition
trx_rseg_history_len	Transactions	None	db.Transactions.trx_rseg_history_len	A list of the undo log pages for committed transactions that is maintained by the InnoDB transaction system to implement multi-version concurrency control. For more information about undo log records details, see InnoDB Multi-Versioning (for 8.0) and InnoDB Multi-Versioning	`SELECT COUNT AS trx_rseg_history_len FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='trx_rseg_history_len'`

Counter	Type	Unit	Metric	Description	Definition
				(for 8.4) in the MySQL documentation.	
innodb_deadlocks	Locks	Locks	db.Locks.innodb_deadlocks	The total number of deadlocks.	`SELECT COUNT AS innodb_deadlocks FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_deadlocks'`
innodb_lock_timeouts	Locks	Locks	db.Locks.innodb_lock_timeouts	The total number of locks that timed out.	`SELECT COUNT AS innodb_lock_timeouts FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_timeouts'`

Counter	Type	Unit	Metric	Description	Definition
innodb_row_lock_waits	Locks	Locks	db.Locks.innodb_row_lock_waits	The total number of row locks that resulted in a wait.	`SELECT COUNT AS innodb_row_lock_waits FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_row_lock_waits'`

Performance Insights counters for Amazon RDS for Microsoft SQL Server

The following database counters are available with Performance Insights for RDS for Microsoft SQL Server.

Native counters for RDS for Microsoft SQL Server

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in Use SQL Server Objects in the Microsoft SQL Server documentation.

Counter	Type	Unit	Metric
Forwarded Records	Access Methods	Records per second	db.Access Methods.Forwarded Records
Page Splits	Access Methods	Splits per second	db.Access Methods.Page Splits
Buffer cache hit ratio	Buffer Manager	Ratio	db.Buffer Manager.Buffer cache hit ratio
Page life expectancy	Buffer Manager	Expectancy in seconds	db.Buffer Manager.Page life expectancy

Counter	Type	Unit	Metric
Page lookups	Buffer Manager	Lookups per second	db.Buffer Manager.Page lookups
Page reads	Buffer Manager	Reads per second	db.Buffer Manager.Page reads
Page writes	Buffer Manager	Writes per second	db.Buffer Manager.Page writes
Active Transactions	Databases	Transactions	db.Databases.Active Transactions (_Total)
Log Bytes Flushed	Databases	Bytes flushed per second	db.Databases.Log Bytes Flushed (_Total)
Log Flush Waits	Databases	Waits per second	db.Databases.Log Flush Waits (_Total)
Log Flushes	Databases	Flushes per second	db.Databases.Log Flushes (_Total)
Write Transactions	Databases	Transactions per second	db.Databases.Write Transactions (_Total)
Processes blocked	General Statistics	Processes blocked	db.General Statistics.Processes blocked
User Connections	General Statistics	Connections	db.General Statistics.User Connections
Latch Waits	Latches	Waits per second	db.Latches.Latch Waits
Number of Deadlocks	Locks	Deadlocks per second	db.Locks.Number of Deadlocks (_Total)

Counter	Type	Unit	Metric
Memory Grants Pending	Memory Manager	Memory grants	db.Memory Manager.Memory Grants Pending
Batch Requests	SQL Statistics	Requests per second	db.SQL Statistic s.Batch Requests
SQL Compilations	SQL Statistics	Compilations per second	db.SQL Statistics.SQL Compilations
SQL Re-Compilations	SQL Statistics	Re-compilations per second	db.SQL Statistics.SQL Re-Compilations

Performance Insights counters for Amazon RDS for Oracle

The following database counters are available with Performance Insights for RDS for Oracle.

Native counters for RDS for Oracle

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in Statistics Descriptions in the Oracle documentation.

> **Note**
>
> For the `CPU used by this session` counter metric, the unit has been transformed from the native centiseconds to active sessions to make the value easier to use. For example, CPU send in the DB Load chart represents the demand for CPU. The counter metric `CPU used by this session` represents the amount of CPU used by Oracle sessions. You can compare CPU send to the `CPU used by this session` counter metric. When demand for CPU is higher than CPU used, sessions are waiting for CPU time.

Counter	Type	Unit	Metric
CPU used by this session	User	Active sessions	db.User.CPU used by this session

Counter	Type	Unit	Metric
SQL*Net roundtrips to/from client	User	Roundtrips per second	db.User.SQL*Net roundtrips to/from client
Bytes received via SQL*Net from client	User	Bytes per second	db.User.bytes received via SQL*Net from client
User commits	User	Commits per second	db.User.user commits
Logons cumulative	User	Logons per second	db.User.logons cumulative
User calls	User	Calls per second	db.User.user calls
Bytes sent via SQL*Net to client	User	Bytes per second	db.User.bytes sent via SQL*Net to client
User rollbacks	User	Rollbacks per second	db.User.user rollbacks
Redo size	Redo	Bytes per second	db.Redo.redo size
Parse count (total)	SQL	Parses per second	db.SQL.parse count (total)
Parse count (hard)	SQL	Parses per second	db.SQL.parse count (hard)
Table scan rows gotten	SQL	Rows per second	db.SQL.table scan rows gotten
Sorts (memory)	SQL	Sorts per second	db.SQL.sorts (memory)
Sorts (disk)	SQL	Sorts per second	db.SQL.sorts (disk)
Sorts (rows)	SQL	Sorts per second	db.SQL.sorts (rows)

Counter	Type	Unit	Metric
Physical read bytes	Cache	Bytes per second	db.Cache.physical read bytes
DB block gets	Cache	Blocks per second	db.Cache.db block gets
DBWR checkpoints	Cache	Checkpoints per minute	db.Cache.DBWR checkpoints
Physical reads	Cache	Reads per second	db.Cache.physical reads
Consistent gets from cache	Cache	Gets per second	db.Cache.consistent gets from cache
DB block gets from cache	Cache	Gets per second	db.Cache.db block gets from cache
Consistent gets	Cache	Gets per second	db.Cache.consistent gets

Performance Insights counters for Amazon RDS for PostgreSQL

The following database counters are available with Performance Insights for Amazon RDS for PostgreSQL.

Topics

- Native counters for Amazon RDS for PostgreSQL
- Non-native counters for Amazon RDS for PostgreSQL

Native counters for Amazon RDS for PostgreSQL

Native metrics are defined by the database engine and not by Amazon RDS. You can find definitions for these native metrics in Viewing Statistics in the PostgreSQL documentation.

Counter	Type	Unit	Metric
blks_hit	Cache	Blocks per second	db.Cache.blks_hit
buffers_alloc	Cache	Blocks per second	db.Cache.buffers_alloc
buffers_checkpoint	Checkpoint	Blocks per second	db.Checkpoint.buffers_checkpoint
checkpoint_sync_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_sync_time
checkpoint_write_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_write_time
checkpoints_req	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_req
checkpoints_timed	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_timed
maxwritten_clean	Checkpoint	Bgwriter clean stops per minute	db.Checkpoint.maxwritten_clean
deadlocks	Concurrency	Deadlocks per minute	db.Concurrency.deadlocks
blk_read_time	I/O	Milliseconds	db.IO.blk_read_time
blks_read	I/O	Blocks per second	db.IO.blks_read
buffers_backend	I/O	Blocks per second	db.IO.buffers_backend
buffers_backend_fsync	I/O	Blocks per second	db.IO.buffers_backend_fsync
buffers_clean	I/O	Blocks per second	db.IO.buffers_clean
tup_deleted	SQL	Tuples per second	db.SQL.tup_deleted
tup_fetched	SQL	Tuples per second	db.SQL.tup_fetched

Counter	Type	Unit	Metric
tup_inserted	SQL	Tuples per second	db.SQL.tup_inserted
tup_returned	SQL	Tuples per second	db.SQL.tup_returned
tup_updated	SQL	Tuples per second	db.SQL.tup_updated
temp_bytes	Temp	Bytes per second	db.Temp.temp_bytes
temp_files	Temp	Files per minute	db.Temp.temp_files
xact_commit	Transactions	Commits per second	db.Transactions.xact_commit
xact_rollback	Transactions	Rollbacks per second	db.Transactions.xact_rollback
numbackends	User	Connections	db.User.numbackends
archived_count	Write-ahead log (WAL)	Files per minute	db.WAL.archived_count

Non-native counters for Amazon RDS for PostgreSQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Unit	Metric	Description	Definition
checkpoint_sync_latency	Checkpoint	db.Checkpoint.checkpoint_sync_latency		The total amount of time that has been spent in the portion of checkpoint processing where	`checkpoint_sync_time / (checkpoints_timed + checkpoints_req)`

Counter	Type	Unit	Metric	Description	Definition
				files are synchronized to disk.	
checkpoint_write_latency	Checkpoint	db.Checkpoint.checkpoint_write_latency	The total amount of time that has been spent in the portion of checkpoint processing where files are written to disk.	`checkpoint_write_time / (checkpoints_timed + checkpoints_req)`	
read_latency	I/O	db.IO.rd_late	The time spent reading data file blocks by backends in this instance.	`blk_read_time / blks_read`	
idle_in_transaction_aborted_count	State	Sessio	db.state.idle_in_transaction_aborted_count	The number of sessions in the `idle in transaction (aborted)` state.	Not applicable
idle_in_transaction_count	State	Sessio	db.state.idle_in_transaction_count	The number of sessions in the `idle in transaction` state.	Not applicable
idle_in_transaction_max_time	State	Secon	db.state.idle_in_transaction_max_time	The duration of the longest running transaction in the `idle in transaction` state, in seconds.	Not applicable

Counter	Type	Unit	Metric	Description	Definition
active_transactions	Transactions	Transactions	db.Transactions.active_transactions	The number of active transactions.	Not applicable
blocked_transactions	Transactions	Transactions	db.Transactions.blocked_transactions	The number of blocked transactions.	Not applicable
oldest_active_logical_replication_slot_xid_age	Transactions	db.Transactions.oldest_active_logical_replication_slot_xid_age	The age of the oldest transaction in an active logical replication slot. For more information, see Logical replication slot.	–	
oldest_inactive_logical_replication_slot_xid_age	Transactions	db.Transactions.oldest_inactive_logical_replication_slot_xid_age	The age of the oldest transaction in an inactive logical replication slot. For more information, see Logical replication slot.	–	
oldest_prepared_transaction_xid_age	Transactions	db.Transactions.oldest_prepared_transaction_xid_age	The age of the oldest prepared transaction. For more information, see Prepared transaction.	–	

Counter	Type	Unit	Metric	Description	Definition
oldest_running_transaction_xid_age	Transactions	db.Transactions.oldest_running_transaction_age	The age of the oldest running transaction. For more information, see Active statement for the oldest running active transaction and Idle in transaction for the oldest running idle-in-transaction.	–	
oldest_hot_standby_feedback_xid_age	Transactions	db.Transactions.oldest_hot_standby_feedback_age	The age of the oldest running transaction on a read replica with `hot_standby_feedback` enabled. For more information, see Read replicas.	–	
max_used_xact_ids	Transactions	Transactions	db.Transactions.max_used_xact_ids	The number of transactions that haven't been vacuumed.	Not applicable
max_connections	Users	Connections	db.User.max_connections	The maximum number of connections allowed for a DB instance as configured in `max_connections` parameter.	Not applicable

Counter	Type	Unit	Metric	Description	Definition
archive_failed_count	WAL	Files per minute	db.WAL.archive_failed_count	The number of failed attempts for archiving WAL files, in files per minute.	Not applicable

SQL statistics for Performance Insights

SQL statistics are performance-related metrics about SQL queries that are collected by Performance Insights. Performance Insights gathers statistics for each second that a query is running and for each SQL call. The SQL statistics are an average for the selected time range.

A SQL digest is a composite of all queries having a given pattern but not necessarily having the same literal values. The digest replaces literal values with a question mark. For example, `SELECT * FROM emp WHERE lname= ?`. This digest might consist of the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

All engines support SQL statistics for digest queries.

For the region, DB engine, and instance class support information for this feature, see Amazon RDS DB engine, Region, and instance class support for Performance Insights features

SQL statistics for MariaDB and MySQL

MariaDB and MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics

- Digest statistics for MariaDB and MySQL
- Per-second statistics for MariaDB and MySQL
- Per-call statistics for MariaDB and MySQL
- Primary statistics for MariaDB and MySQL

Digest statistics for MariaDB and MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

```
Performance Insights is unable to collect SQL Digest statistics on new queries because
 the table events_statements_summary_by_digest is full.
Please truncate events_statements_summary_by_digest table to clear the issue. Check the
 User Guide for more details.
```

In this situation, MariaDB and MySQL don't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically.

  For automatic management, the `performance_schema` parameter must be set to `0` and the **Source** must not be set to `user`. If Performance Insights isn't managing the Performance Schema automatically, see Overview of the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL.

In the AWS CLI, check the source of a parameter value by running the describe-db-parameters command.

Per-second statistics for MariaDB and MySQL

The following SQL statistics are available for MariaDB and MySQL DB instances.

Metric	Unit
db.sql_tokenized.stats.count_star_per_sec	Calls per second
db.sql_tokenized.stats.sum_timer_wait_per_sec	Average latency per second (in ms)
db.sql_tokenized.stats.sum_select_full_join_per_sec	Select full join per second
db.sql_tokenized.stats.sum_select_range_check_per_sec	Select range check per second
db.sql_tokenized.stats.sum_select_scan_per_sec	Select scan per second
db.sql_tokenized.stats.sum_sort_merge_passes_per_sec	Sort merge passes per second
db.sql_tokenized.stats.sum_sort_scan_per_sec	Sort scans per second
db.sql_tokenized.stats.sum_sort_range_per_sec	Sort ranges per second
db.sql_tokenized.stats.sum_sort_rows_per_sec	Sort rows per second
db.sql_tokenized.stats.sum_rows_affected_per_sec	Rows affected per second
db.sql_tokenized.stats.sum_rows_examined_per_sec	Rows examined per second
db.sql_tokenized.stats.sum_rows_sent_per_sec	Rows sent per second
db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_sec	Created temporary disk tables per second
db.sql_tokenized.stats.sum_created_tmp_tables_per_sec	Created temporary tables per second

Metric	Unit
db.sql_tokenized.stats.sum_lock_time_per_sec	Lock time per second (in ms)

Per-call statistics for MariaDB and MySQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.sum_timer_wait_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.sum_select_full_join_per_call	Select full joins per call
db.sql_tokenized.stats.sum_select_range_check_per_call	Select range check per call
db.sql_tokenized.stats.sum_select_scan_per_call	Select scans per call
db.sql_tokenized.stats.sum_sort_merge_passes_per_call	Sort merge passes per call
db.sql_tokenized.stats.sum_sort_scan_per_call	Sort scans per call
db.sql_tokenized.stats.sum_sort_range_per_call	Sort ranges per call
db.sql_tokenized.stats.sum_sort_rows_per_call	Sort rows per call
db.sql_tokenized.stats.sum_rows_affected_per_call	Rows affected per call
db.sql_tokenized.stats.sum_rows_examined_per_call	Rows examined per call

Metric	Unit
db.sql_tokenized.stats.sum_rows_sent_per_call	Rows sent per call
db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_call	Created temporary disk tables per call
db.sql_tokenized.stats.sum_created_tmp_tables_per_call	Created temporary tables per call
db.sql_tokenized.stats.sum_lock_time_per_call	Lock time per call (in ms)

Primary statistics for MariaDB and MySQL

The following SQL statistics are available for MariaDB and MySQL DB instances.

Metric	Unit
db.sql_tokenized.stats.count_star	Calls
db.sql_tokenized.stats.sum_timer_wait	Wait time (in ms)
db.sql_tokenized.stats.sum_select_full_join	Select full join
db.sql_tokenized.stats.sum_select_range_check	Select range checks
db.sql_tokenized.stats.sum_select_scan	Select scans
db.sql_tokenized.stats.sum_sort_merge_passes	Sort merge passes
db.sql_tokenized.stats.sum_sort_scan	Sort scans
db.sql_tokenized.stats.sum_sort_range	Sort ranges
db.sql_tokenized.stats.sum_sort_rows	Sort rows
db.sql_tokenized.stats.sum_rows_affected	Rows affected

Metric	Unit
db.sql_tokenized.stats.sum_rows_examined	Rows examined
db.sql_tokenized.stats.sum_rows_sent	Rows sent
db.sql_tokenized.stats.sum_created_tmp_disk_tables	Created temporary disk tables
db.sql_tokenized.stats.sum_created_tmp_tables	Created temporary tables
db.sql_tokenized.stats.sum_lock_time	Lock time (in ms)

SQL statistics for Amazon RDS for Oracle

Amazon RDS for Oracle collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of `V$SQL.SQL_ID`. At the digest level, the ID column shows the value of `V$SQL.FORCE_MATCHING_SIGNATURE`.

If the ID is `0` at the digest level, Oracle Database has determined that this statement is not suitable for reuse. In this case, the child SQL statements could belong to different digests. However, the statements are grouped together under the `digest_text` for the first SQL statement collected.

Topics

- Per-second statistics for Oracle
- Per-call statistics for Oracle
- Primary statistics for Oracle

Per-second statistics for Oracle

The following metrics provide per-second statistics for an Oracle SQL query.

Metric	Unit
db.sql.stats.executions_per_sec	Number of executions per second
db.sql.stats.elapsed_time_per_sec	Average active executions (AAE)

Metric	Unit
db.sql.stats.rows_processed_per_sec	Rows processed per second
db.sql.stats.buffer_gets_per_sec	Buffer gets per second
db.sql.stats.physical_read_requests_per_sec	Physical reads per second
db.sql.stats.physical_write_requests_per_sec	Physical writes per second
db.sql.stats.total_sharable_mem_per_sec	Total shareable memory per second (in bytes)
db.sql.stats.cpu_time_per_sec	CPU time per second (in ms)

The following metrics provide per-second statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.executions_per_sec	Number of executions per second
db.sql_tokenized.stats.elapsed_time_per_sec	Average active executions (AAE)
db.sql_tokenized.stats.rows_processe d_per_sec	Rows processed per second
db.sql_tokenized.stats.buffer_gets_per_sec	Buffer gets per second
db.sql_tokenized.stats.physical_read_requests _per_sec	Physical reads per second
db.sql_tokenized.stats.physical_write_request s_per_sec	Physical writes per second
db.sql_tokenized.stats.total_sharabl e_mem_per_sec	Total shareable memory per second (in bytes)
db.sql_tokenized.stats.cpu_time_per_sec	CPU time per second (in ms)

Per-call statistics for Oracle

The following metrics provide per-call statistics for an Oracle SQL statement.

Metric	Unit
db.sql.stats.elapsed_time_per_exec	Elapsed time per executions (in ms)
db.sql.stats.rows_processed_per_exec	Rows processed per execution
db.sql.stats.buffer_gets_per_exec	Buffer gets per execution
db.sql.stats.physical_read_requests_per_exec	Physical reads per execution
db.sql.stats.physical_write_requests_per_exec	Physical writes per execution
db.sql.stats.total_sharable_mem_per_exec	Total shareable memory per execution (in bytes)
db.sql.stats.cpu_time_per_exec	CPU time per execution (in ms)

The following metrics provide per-call statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.elapsed_time_per_exec	Elapsed time per executions (in ms)
db.sql_tokenized.stats.rows_processed_per_exec	Rows processed per execution
db.sql_tokenized.stats.buffer_gets_per_exec	Buffer gets per execution
db.sql_tokenized.stats.physical_read_requests_per_exec	Physical reads per execution
db.sql_tokenized.stats.physical_write_requests_per_exec	Physical writes per execution
db.sql_tokenized.stats.total_sharable_mem_per_exec	Total shareable memory per execution (in bytes)

Metric	Unit
db.sql_tokenized.stats.cpu_time_per_exec	CPU time per execution (in ms)

Primary statistics for Oracle

The following metrics provide primary statistics for an Oracle SQL query.

Metric	Unit
db.sql.stats.executions	Number of executions
db.sql.stats.elapsed_time	Elapsed time (in ms)
db.sql.stats.rows_processed	Rows processed
db.sql.stats.buffer_gets	Buffer gets
db.sql.stats.physical_read_requests	Physical reads
db.sql.stats.physical_write_requests	Physical writes
db.sql.stats.total_sharable_mem	Total shareable memory (in bytes)
db.sql.stats.cpu_time	CPU time (in ms)

The following metrics provide primary statistics for an Oracle SQL digest query.

Metric	Unit
db.sql_tokenized.stats.executions	Number of executions
db.sql_tokenized.stats.elapsed_time	Elapsed time (in ms)
db.sql_tokenized.stats.rows_processed	Rows processed
db.sql_tokenized.stats.buffer_gets	Buffer gets
db.sql_tokenized.stats.physical_read_requests	Physical reads

Metric	Unit
db.sql_tokenized.stats.physical_write_requests	Physical writes
db.sql_tokenized.stats.total_sharable_mem	Total shareable memory (in bytes)
db.sql_tokenized.stats.cpu_time	CPU time (in ms)

SQL statistics for Amazon RDS for SQL Server

Amazon RDS for SQL Server collects SQL statistics both at the statement and digest level. At the statement level, the ID column represents the value of `sql_handle`. At the digest level, the ID column shows the value of `query_hash`.

SQL Server returns NULL values for `query_hash` for a few statements. For example, ALTER INDEX, CHECKPOINT, UPDATE STATISTICS, COMMIT TRANSACTION, FETCH NEXT FROM Cursor, and a few INSERT statements, SELECT @<variable>, conditional statements, and executable stored procedures. In this case, the `sql_handle` value is displayed as the ID at the digest level for that statement.

Per-second statistics for SQL Server

The following metrics provide per-second statistics for a SQL Server SQL query.

Metric	Unit
db.sql.stats.execution_count_per_sec	Number of executions per second
db.sql.stats.total_elapsed_time_per_sec	Total elapsed time per second
db.sql.stats.total_rows_per_sec	Total rows processed per second
db.sql.stats.total_logical_reads_per_sec	Total logical reads per second

Metric	Unit
db.sql.stats.total_logical_writes_per_sec	Total logical writes per second
db.sql.stats.total_physical_reads_per_sec	Total physical reads per second
db.sql.stats.total_worker_time_per_sec	Total CPU time (in ms)

The following metrics provide per-second statistics for a SQL Server SQL digest query.

Metric	Unit
db.sql_tokenized.stats.execution_count_per_sec	Number of execution per second
db.sql_tokenized.stats.total_elapsed_time_per_sec	Total elapsed time per second
db.sql_tokenized.stats.total_rows_per_sec	Total rows processed per second
db.sql_tokenized.stats.total_logical_reads_per_sec	Total logical reads per second
db.sql_tokenized.stats.total_logical_writes_per_sec	Total logical writes per second
db.sql_tokenized.stats.total_physical_reads_per_sec	Total physical reads per second
db.sql_tokenized.stats.total_worker_time_per_sec	Total CPU time (in ms)

Per-call statistics for SQL Server

The following metrics provide per-call statistics for a SQL Server SQL statement.

Metric	Unit
db.sql.stats.total_elapsed_time_per_call	Total elapsed time per execution (in ms)
db.sql.stats.total_rows_per_call	Total rows processed per execution
db.sql.stats.total_logical_reads_per_call	Total logical reads per execution
db.sql.stats.total_logical_writes_per_call	Total logical writes per execution
db.sql.stats.total_physical_reads_per_call	Total physical reads per execution
db.sql.stats.total_worker_time_per_call	Total CPU time per execution (in ms)

The following metrics provide per-call statistics for a SQL Server SQL digest query.

Metric	Unit
db.sql_tokenized.stats.total_elapsed_time_per_call	Total elapsed time per execution
db.sql_tokenized.stats.total_rows_per_call	Total rows processed per execution
db.sql_tokenized.stats.total_logical_reads_per_call	Total logical reads per execution
db.sql_tokenized.stats.total_logical_writes_per_call	Total logical writes per execution
db.sql_tokenized.stats.total_physical_reads_per_call	Total physical reads per execution
db.sql_tokenized.stats.total_worker_time_per_call	Total CPU time per execution (in ms)

Primary statistics for SQL Server

The following metrics provide primary statistics for a SQL Server SQL query.

Metric	Unit
db.sql.stats.execution_count	Number of executions
db.sql.stats.total_elapsed_time	Total elapsed time (in ms)
db.sql.stats.total_rows	Total rows processed
db.sql.stats.total_logical_reads	Total logical reads
db.sql.stats.total_logical_writes	Total logical writes
db.sql.stats.total_physical_reads	Total physical reads
db.sql.stats.total_worker_time	Total CPU time (in ms)

The following metrics provide primary statistics for a SQL Server SQL digest query.

Metric	Unit
db.sql_tokenized.stats.execution_count	Number of execution
db.sql_tokenized.stats.total_elapsed_time	Total elapsed time (in ms)
db.sql_tokenized.stats.total_rows	Total rows processed
db.sql_tokenized.stats.total_logical_reads	Total logical reads
db.sql_tokenized.stats.total_logical_writes	Total logical writes
db.sql_tokenized.stats.total_physical_reads	Total physical reads
db.sql_tokenized.stats.total_worker_time	Total CPU time (in ms)

SQL statistics for RDS PostgreSQL

For each SQL call and for each second that a query runs, Performance Insights collects SQL statistics. RDS for PostgreSQL collect SQL statistics only at the digest–level. No statistics are shown at the statement-level.

Following, you can find information about digest-level statistics for RDS for PostgreSQL.

Topics

- Digest statistics for RDS PostgreSQL
- Per-second digest statistics for RDS PostgreSQL
- Per-call digest statistics for RDS PostgreSQL
- Primary statistics for RDS PostgreSQL

Digest statistics for RDS PostgreSQL

To view SQL digest statistics, RDS PostgreSQL must load the `pg_stat_statements` library. For PostgreSQL DB instances that are compatible with PostgreSQL 11 or later, the database loads this library by default. For PostgreSQL DB instances that are compatible with PostgreSQL 10 or earlier, enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see Parameter groups for Amazon RDS.

> **Note**
>
> Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

Per-second digest statistics for RDS PostgreSQL

The following SQL digest statistics are available for PostgreSQL DB instances.

Metric	Unit
db.sql_tokenized.stats.calls_per_sec	Calls per second
db.sql_tokenized.stats.rows_per_sec	Rows per second
db.sql_tokenized.stats.total_time_per_sec	Average active executions per second (AAE)

Metric	Unit
db.sql_tokenized.stats.shared_blks_hit_per_sec	Block hits per second
db.sql_tokenized.stats.shared_blks_read_per_sec	Block reads per second
db.sql_tokenized.stats.shared_blks_dirtied_per_sec	Blocks dirtied per second
db.sql_tokenized.stats.shared_blks_written_per_sec	Block writes per second
db.sql_tokenized.stats.local_blks_hit_per_sec	Local block hits per second
db.sql_tokenized.stats.local_blks_read_per_sec	Local block reads per second
db.sql_tokenized.stats.local_blks_dirtied_per_sec	Local block dirtied per second
db.sql_tokenized.stats.local_blks_written_per_sec	Local block writes per second
db.sql_tokenized.stats.temp_blks_written_per_sec	Temporary writes per second
db.sql_tokenized.stats.temp_blks_read_per_sec	Temporary reads per second
db.sql_tokenized.stats.blk_read_time_per_sec	Average concurrent reads per second
db.sql_tokenized.stats.blk_write_time_per_sec	Average concurrent writes per second

Per-call digest statistics for RDS PostgreSQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.rows_per_call	Rows per call
db.sql_tokenized.stats.avg_latency_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.shared_blks_hit_per_call	Block hits per call
db.sql_tokenized.stats.shared_blks_read_per_call	Block reads per call
db.sql_tokenized.stats.shared_blks_written_per_call	Block writes per call
db.sql_tokenized.stats.shared_blks_dirtied_per_call	Blocks dirtied per call
db.sql_tokenized.stats.local_blks_hit_per_call	Local block hits per call
db.sql_tokenized.stats.local_blks_read_per_call	Local block reads per call
db.sql_tokenized.stats.local_blks_dirtied_per_call	Local block dirtied per call
db.sql_tokenized.stats.local_blks_written_per_call	Local block writes per call
db.sql_tokenized.stats.temp_blks_written_per_call	Temporary block writes per call
db.sql_tokenized.stats.temp_blks_read_per_call	Temporary block reads per call
db.sql_tokenized.stats.blk_read_time_per_call	Read time per call (in ms)
db.sql_tokenized.stats.blk_write_time_per_call	Write time per call (in ms)

Primary statistics for RDS PostgreSQL

The following SQL statistics are available for PostgreSQL DB instances.

Metric	Unit
db.sql_tokenized.stats.calls	Calls
db.sql_tokenized.stats.rows	Rows
db.sql_tokenized.stats.total_time	Total time (in ms)
db.sql_tokenized.stats.shared_blks_hit	Block hits
db.sql_tokenized.stats.shared_blks_read	Block reads
db.sql_tokenized.stats.shared_blks_dirtied	Blocks dirtied
db.sql_tokenized.stats.shared_blks_written	Block writes
db.sql_tokenized.stats.local_blks_hit	Local block hits
db.sql_tokenized.stats.local_blks_read	Local block reads
db.sql_tokenized.stats.local_blks_dirtied	Local blocks dirtied
db.sql_tokenized.stats.local_blks_written	Local block writes
db.sql_tokenized.stats.temp_blks_written	Temporary writes
db.sql_tokenized.stats.temp_blks_read	Temporary reads
db.sql_tokenized.stats.blk_read_time	Average concurrent reads (in ms)
db.sql_tokenized.stats.blk_write_time	Average concurrent writes (in ms)

For more information about these metrics, see pg_stat_statements in the PostgreSQL documentation.

OS metrics in Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. The following tables list the OS metrics available using Amazon CloudWatch Logs.

Topics

- OS metrics for Db2, MariaDB, MySQL, Oracle, and PostgreSQL
- OS metrics for Microsoft SQL Server

OS metrics for Db2, MariaDB, MySQL, Oracle, and PostgreSQL

RDS collects disk metrics for `rdsdbdata` as well as additional storage volumes present in the OS. To view OS metrics in CloudWatch Logs, see Viewing OS metrics using CloudWatch Logs.

Group	Metric	Console name	Description
`General`	`engine`	Not applicable	The database engine for the DB instance.
	`instanceID`	Not applicable	The DB instance identifier.
	`instanceResourceID`	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	`numVCPUs`	Not applicable	The number of virtual CPUs for the DB instance.
	`timestamp`	Not applicable	The time at which the metrics were taken.
	`uptime`	Not applicable	The amount of time that the DB instance has been active.

Group	Metric	Console name	Description
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	guest	**CPU Guest**	The percentage of CPU in use by guest programs.
	idle	**CPU Idle**	The percentage of CPU that is idle.
	irq	**CPU IRQ**	The percentage of CPU in use by software interrupts.
	nice	**CPU Nice**	The percentage of CPU in use by programs running at lowest priority.
	steal	**CPU Steal**	The percentage of CPU in use by other virtual machines.
	system	**CPU System**	The percentage of CPU in use by the kernel.
	total	**CPU Total**	The total percentage of the CPU in use. This value includes the nice value.
	user	**CPU User**	The percentage of CPU in use by user programs.
	wait	**CPU Wait**	The percentage of CPU unused while waiting for I/O access.
diskIO	avgQueueLen	**Avg Queue Size**	The number of requests waiting in the I/O device's queue.
	avgReqSz	**Ave Request Size**	The average request size, in kilobytes.
	await	**Disk I/O Await**	The number of milliseconds required to respond to requests, including queue time and service time.

Group	Metric	Console name	Description
	device	Not applicable	The identifier of the disk device in use.
	readIOsPS	**Read IO/s**	The number of read operations per second.
	readKb	**Read Total**	The total number of kilobytes read.
	readKbPS	**Read Kb/s**	The number of kilobytes read per second.
	readLatency	**Read Latency**	The elapsed time between the submission of a read I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	readThroughput	**Read Throughput**	The amount of network throughput used by requests to the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	rrqmPS	**Rrqms**	The number of merged read requests queued per second.
	tps	**TPS**	The number of I/O transactions per second.
	util	**Disk I/O Util**	The percentage of CPU time during which requests were issued.
	writeIOsPS	**Write IO/s**	The number of write operations per second.
	writeKb	**Write Total**	The total number of kilobytes written.
	writeKbPS	**Write Kb/s**	The number of kilobytes written per second.

Group	Metric	Console name	Description
	writeLatency	**Write Latency**	The average elapsed time between the submission of a write I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	writeThroughput	**Write Throughput**	The amount of network throughput used by responses from the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	wrqmPS	**Wrqms**	The number of merged write requests queued per second.
physicalDeviceIO	avgQueueLen	**Physical Devices Avg Queue Size**	The number of requests waiting in the I/O device's queue.
	avgReqSz	**Physical Devices Ave Request Size**	The average request size, in kilobytes.
	await	**Physical Devices Disk I/O Await**	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	mountPoint	Not applicable	The path to the file system.

Group	Metric	Console name	Description
	readIOsPS	**Physical Devices Read IO/s**	The number of read operations per second.
	readKb	**Physical Devices Read Total**	The total number of kilobytes read.
	readKbPS	**Physical Devices Read Kb/s**	The number of kilobytes read per second.
	rrqmPS	**Physical Devices Rrqms**	The number of merged read requests queued per second.
	tps	**Physical Devices TPS**	The number of I/O transactions per second.
	util	**Physical Devices Disk I/O Util**	The percentage of CPU time during which requests were issued.
	writeIOsPS	**Physical Devices Write IO/s**	The number of write operations per second.
	writeKb	**Physical Devices Write Total**	The total number of kilobytes written.

Group	Metric	Console name	Description
	writeKbPS	**Physical Devices Write Kb/s**	The number of kilobytes written per second.
	wrqmPS	**Physical Devices Wrqms**	The number of merged write requests queued per second.
fileSys	maxFiles	**Max Inodes**	The maximum number of files that can be created for the file system.
	mountPoint	Not applicable	The path to the file system. When this is /rdsdbdata* , it represents the aggregate of all storage volumes.
	name	Not applicable	The name of the file system.
	total	**Total Filesystem**	The total number of disk space available for the file system, in kilobytes.
	used	**Used Filesystem**	The amount of disk space used by files in the file system, in kilobytes.
	usedFilePercent	**Used Inodes**	The percentage of available files in use.
	usedFiles	**Used%**	The number of files in the file system.
	usedPercent	**Used Filesystem**	The percentage of the file-system disk space in use.
loadAverageMinute	fifteen	**Load Avg 15 min**	The number of processes requesting CPU time over the last 15 minutes.

Group	Metric	Console name	Description
	five	**Load Avg 5 min**	The number of processes requesting CPU time over the last 5 minutes.
	one	**Load Avg 1 min**	The number of processes requesting CPU time over the last minute.
memory	active	**Active Memory**	The amount of assigned memory, in kilobytes.
	buffers	**Buffered Memory**	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.
	cached	**Cached Memory**	The amount of memory used for caching file system–based I/O.
	dirty	**Dirty Memory**	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
	free	**Free Memory**	The amount of unassigned memory, in kilobytes.
	hugePagesFree	**Huge Pages Free**	The number of free huge pages. Huge pages are a feature of the Linux kernel.
	hugePagesRsvd	**Huge Pages Rsvd**	The number of committed huge pages.
	hugePagesSize	**Huge Pages Size**	The size for each huge pages unit, in kilobytes.
	hugePagesSurp	**Huge Pages Surp**	The number of available surplus huge pages over the total.

Group	Metric	Console name	Description
	hugePagesTotal	**Huge Pages Total**	The total number of huge pages.
	inactive	**Inactive Memory**	The amount of least-frequently used memory pages, in kilobytes.
	mapped	**Mapped Memory**	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.
	pageTables	**Page Tables**	The amount of memory used by page tables, in kilobytes.
	slab	**Slab Memory**	The amount of reusable kernel data structures, in kilobytes.
	total	**Total Memory**	The total amount of memory, in kilobytes.
	writeback	**Writeback Memory**	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rx	**RX**	The number of bytes received per second.
	tx	**TX**	The number of bytes uploaded per second.
processList	cpuUsedPc	**CPU %**	The percentage of CPU used by the process.
	id	Not applicable	The identifier of the process.

Group	Metric	Console name	Description
	memoryUsedPc	**MEM%**	The percentage of memory used by the process.
	name	Not applicable	The name of the process.
	parentID	Not applicable	The process identifier for the parent process of the process.
	rss	**RES**	The amount of RAM allocated to the process, in kilobytes.
	tgid	Not applicable	The thread group identifier, which is a number representing the process ID to which a thread belongs. This identifier is used to group threads from the same process.
	vss	**VIRT**	The amount of virtual memory allocated to the process, in kilobytes.
swap	total	**Swap**	The amount of swap memory available, in kilobytes.
	in	**Swaps in**	The amount of memory, in kilobytes, swapped in from disk.
	out	**Swaps out**	The amount of memory, in kilobytes, swapped out to disk.
	free	**Free Swap**	The amount of swap memory free, in kilobytes.
	cached	**Committed Swap**	The amount of swap memory, in kilobytes, used as cache memory.
tasks	blocked	**Tasks Blocked**	The number of tasks that are blocked.

Group	Metric	Console name	Description
	running	**Tasks Running**	The number of tasks that are running.
	sleeping	**Tasks Sleeping**	The number of tasks that are sleeping.
	stopped	**Tasks Stopped**	The number of tasks that are stopped.
	total	**Tasks Total**	The total number of tasks.
	zombie	**Tasks Zombie**	The number of child tasks that are inactive with an active parent task.

OS metrics for Microsoft SQL Server

RDS collects disk metrics for `rdsdbdata` as well as additional storage volumes present in the OS. To view OS metrics in CloudWatch Logs, see Viewing OS metrics using CloudWatch Logs.

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResourceID	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCPUs	Not applicable	The number of virtual CPUs for the DB instance.

Group	Metric	Console name	Description
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	idle	**CPU Idle**	The percentage of CPU that is idle.
	kern	**CPU Kernel**	The percentage of CPU in use by the kernel.
	user	**CPU User**	The percentage of CPU in use by user programs.
disks	name	Not applicable	The identifier for the disk.
	totalKb	**Total Disk Space**	The total space of the disk, in kilobytes.
	usedKb	**Used Disk Space**	The amount of space used on the disk, in kilobytes.
	usedPc	**Used Disk Space %**	The percentage of space used on the disk.
	availKb	**Available Disk Space**	The space available on the disk, in kilobytes.
	availPc	**Available Disk Space %**	The percentage of space available on the disk.
	rdCountPS	**Reads/s**	The number of read operations per second

Group	Metric	Console name	Description
	rdBytesPS	**Read Kb/s**	The number of bytes read per second.
	wrCountPS	**Write IO/s**	The number of write operations per second.
	wrBytesPS	**Write Kb/s**	The amount of bytes written per second.
memory	commitTotKb	**Commit Total**	The amount of pagefile-backed virtual address space in use, that is, the current commit charge. This value is composed of main memory (RAM) and disk (pagefiles).
	commitLimitKb	**Maximum Commit**	The maximum possible value for the commitTotKb metric. This value is the sum of the current pagefile size plus the physical memory available for pageable contents, excluding RAM that is assigned to nonpageable areas.
	commitPeakKb	**Commit Peak**	The largest value of the commitTotKb metric since the operating system was last started.
	kernTotKb	**Total Kernel Memory**	The sum of the memory in the paged and nonpaged kernel pools, in kilobytes.
	kernPagedKb	**Paged Kernel Memory**	The amount of memory in the paged kernel pool, in kilobytes.
	kernNonpagedKb	**Nonpaged Kerenel Memory**	The amount of memory in the nonpaged kernel pool, in kilobytes.
	pageSize	**Page Size**	The size of a page, in bytes.

Group	Metric	Console name	Description
	physTotKb	**Total Memory**	The amount of physical memory, in kilobytes.
	physAvailKb	**Available Memory**	The amount of available physical memory, in kilobytes.
	sqlServerTotKb	**SQL Server Total Memory**	The amount of memory committed to SQL Server, in kilobytes.
	sysCacheKb	**System Cache**	The amount of system cache memory, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rdBytesPS	**Network Read Kb/s**	The number of bytes received per second.
	wrBytesPS	**Network Write Kb/s**	The number of bytes sent per second.
processList	cpuUsedPc	**Used %**	The percentage of CPU used by the process.
	memUsedPc	**MEM%**	The percentage of total memory used by the process.
	name	Not applicable	The name of the process.
	pid	Not applicable	The identifier of the process. This value is not present for processes that are owned by Amazon RDS.

Group	Metric	Console name	Description
	ppid	Not applicable	The process identifier for the parent of this process. This value is only present for child processes.
	tid	Not applicable	The thread identifier. This value is only present for threads. The owning process can be identified by using the pid value.
	workingSetKb	Not applicable	The amount of memory in the private working set plus the amount of memory that is in use by the process and can be shared with other processes, in kilobytes.
	workingSetPrivKb	Not applicable	The amount of memory that is in use by a process, but can't be shared with other processes, in kilobytes.
	workingSetShareableKb	Not applicable	The amount of memory that is in use by a process and can be shared with other processes, in kilobytes.
	virtKb	Not applicable	The amount of virtual address space the process is using, in kilobytes. Use of virtual address space doesn't necessarily imply corresponding use of either disk or main memory pages.
system	handles	**Handles**	The number of handles that the system is using.
	processes	**Processes**	The number of processes running on the system.
	threads	**Threads**	The number of threads running on the system.

Monitoring events, logs, and streams in an Amazon RDS DB instance

When you monitor your Amazon RDS databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance
- Security

Monitoring metrics in an Amazon RDS instance explains how to monitor your instance using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services. EventBridge routes that data to targets such as AWS Lambda. This way, you can monitor events that happen in services and build event-driven architectures. For more information, see the Amazon EventBridge User Guide.
- *Amazon CloudWatch Logs* provides a way to monitor, store, and access your log files from Amazon RDS instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account. CloudTrail delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.
- *Database Activity Streams* is an Amazon RDS feature that provides a near real-time stream of the activity in your DB instance. Amazon RDS pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Data Firehose and AWS Lambda to consume the stream and store the data.

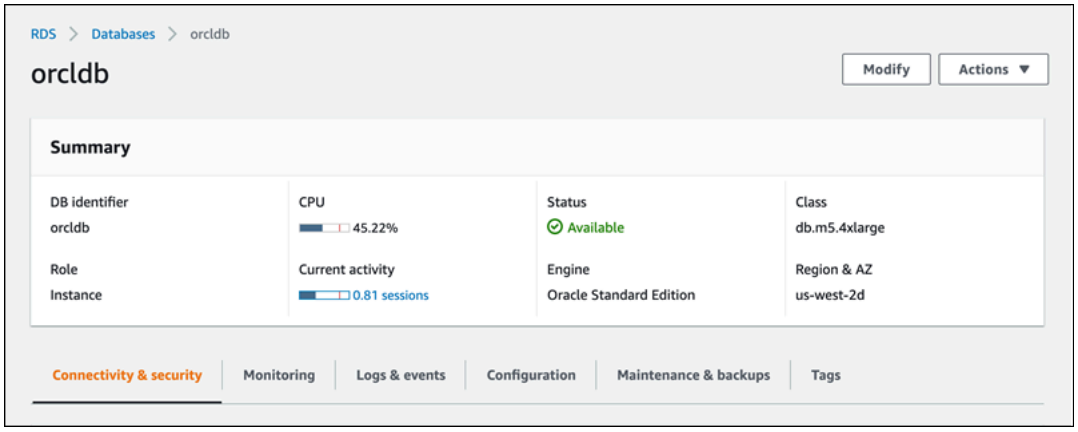
Topics

- Viewing logs, events, and streams in the Amazon RDS console
- Monitoring Amazon RDS events
- Monitoring Amazon RDS log files
- Monitoring Amazon RDS API calls in AWS CloudTrail
- Monitoring Amazon RDS with Database Activity Streams
- Monitoring threats with Amazon GuardDuty RDS Protection

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.

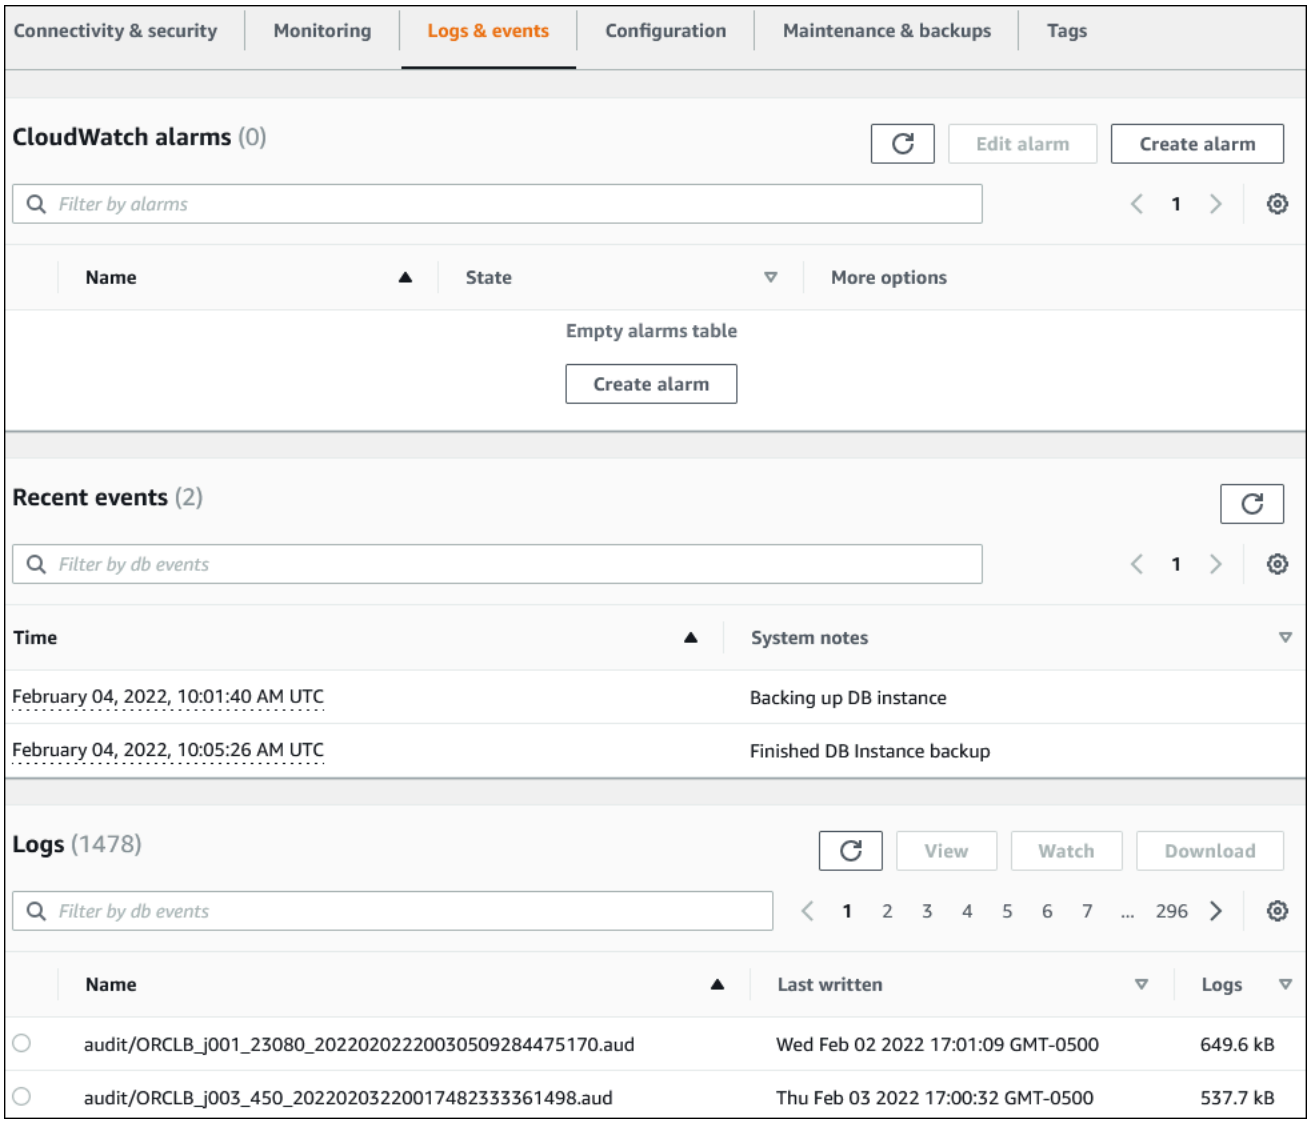
The **Logs & events** tab for your RDS DB instance shows the following information:



- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance. If you haven't configured alarms, you can create them in the RDS console. For more information, see Monitoring Amazon RDS metrics with Amazon CloudWatch.
- **Recent events** – Shows a summary of events (environment changes) for your RDS DB instance . For more information, see Viewing Amazon RDS events.
- **Logs** – Shows database log files generated by a DB instance. For more information, see Monitoring Amazon RDS log files.

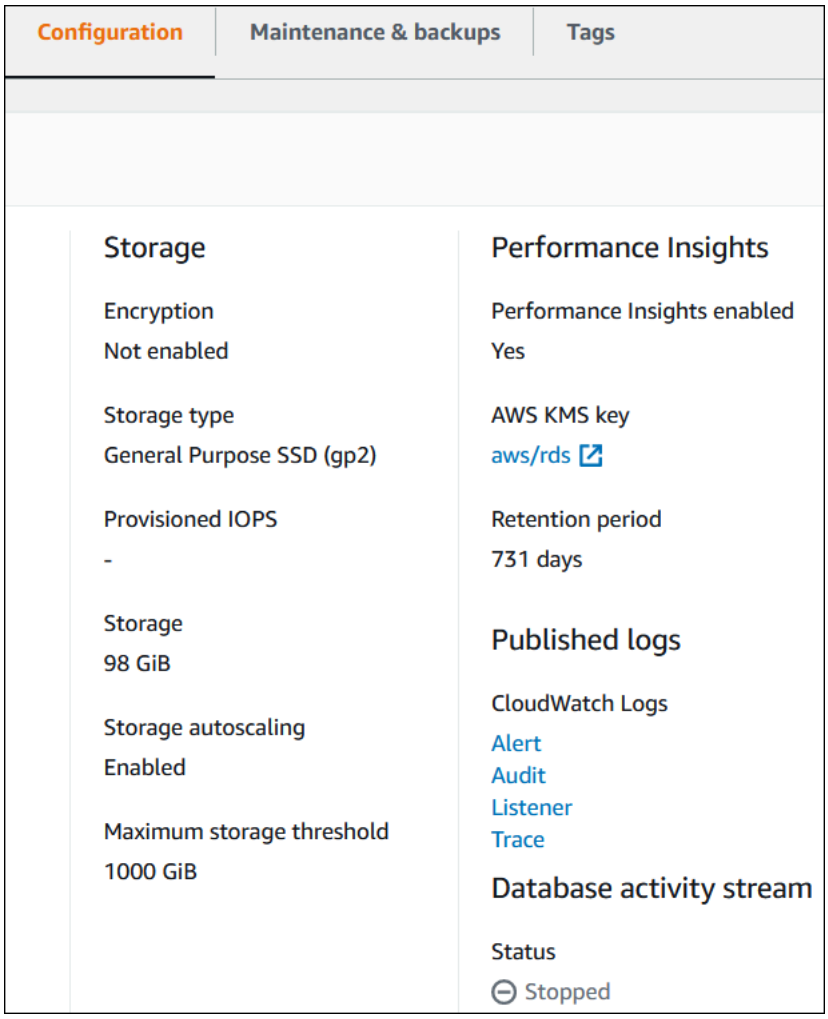
The **Configuration** tab displays information about database activity streams.

To view logs, events, and streams for your DB instance in the RDS console



1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to monitor.

   The database page appears. The following example shows an Oracle database named `orclb`.



4. Choose **Logs & events**.

   The Logs & events section appears.

5. Choose **Configuration**.

   The following example shows the status of the database activity streams for your DB instance.

Monitoring Amazon RDS events

An *event* indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service. For descriptions of the RDS events, see Amazon RDS event categories and event messages.

Topics

- Overview of events for Amazon RDS
- Viewing Amazon RDS events
- Working with Amazon RDS event notification
- Creating a rule that triggers on an Amazon RDS event
- Amazon RDS event categories and event messages

Overview of events for Amazon RDS

An *RDS event* indicates a change in the Amazon RDS environment. For example, Amazon RDS generates an event when the state of a DB instance changes from pending to running. Amazon RDS delivers events to EventBridge in near-real time.

> **Note**
>
> Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to the following resources:

- DB instances

  For a list of DB instance events, see DB instance events.
- DB parameter groups

  For a list of DB parameter group events, see DB parameter group events.
- DB security groups

  For a list of DB security group events, see DB security group events.

- DB snapshots

  For a list of DB snapshot events, see DB snapshot events.
- RDS Proxy events

  For a list of RDS Proxy events, see RDS Proxy events.
- Blue/green deployment events

  For a list of blue/green deployment events, see Blue/green deployment events.

This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event
- Event notifications include tags from when the message was sent and may not reflect tags at the time when the event occurred

Viewing Amazon RDS events

You can retrieve the following event information for your Amazon RDS resources:

- Resource name
- Resource type
- Time of the event
- Message summary of the event

You can access events in the following parts of the AWS Management Console:

- The **Events** tab, which shows events from the past 24 hours.
- The **Recent events** table in the **Logs & events** section in the **Databases** tab, which can show events for up to the past 2 weeks.

You can also retrieve events by using the describe-events AWS CLI command, or the DescribeEvents RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

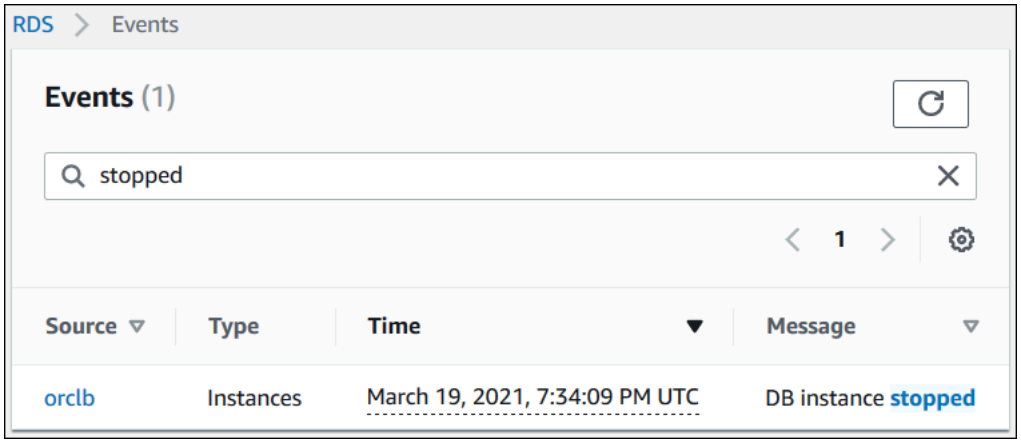
> **Note**
>
> If you need to store events for longer periods of time, you can send Amazon RDS events to EventBridge. For more information, see Creating a rule that triggers on an Amazon RDS event

For descriptions of the Amazon RDS events, see Amazon RDS event categories and event messages.

To access detailed information about events using AWS CloudTrail, including request parameters, see CloudTrail events.

Console

To view all Amazon RDS events for the past 24 hours



1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Events**.

   The available events appear in a list.

3. (Optional) Enter a search term to filter your results.

   The following example shows a list of events filtered by the characters **`stopped`**.

AWS CLI

To view all events generated in the last hour, call describe-events with no parameters.

```
aws rds describe-events
```

The following sample output shows that a DB instance has been stopped.

```
{
    "Events": [
        {
            "EventCategories": [
                "notification"
            ],
            "SourceType": "db-instance",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:testinst",
            "Date": "2022-04-22T21:31:00.681Z",
            "Message": "DB instance stopped",
            "SourceIdentifier": "testinst"
        }
    ]
}
```

To view all Amazon RDS events for the past 10080 minutes (7 days), call the describe-events AWS CLI command and set the `--duration` parameter to `10080`.

```
aws rds describe-events --duration 10080
```

The following example shows the events in the specified time range for DB instance *test-instance*.

```
aws rds describe-events \
    --source-identifier test-instance \
    --source-type db-instance \
    --start-time 2022-03-13T22:00Z \
    --end-time 2022-03-13T23:59Z
```

The following sample output shows the status of a backup.

```
{
    "Events": [
        {
            "SourceType": "db-instance",
            "SourceIdentifier": "test-instance",
            "EventCategories": [
                "backup"
            ],
            "Message": "Backing up DB instance",
            "Date": "2022-03-13T23:09:23.983Z",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
        },
        {
            "SourceType": "db-instance",
            "SourceIdentifier": "test-instance",
            "EventCategories": [
                "backup"
            ],
            "Message": "Finished DB Instance backup",
            "Date": "2022-03-13T23:15:13.049Z",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
        }
    ]
}
```

API

You can view all Amazon RDS instance events for the past 14 days by calling the DescribeEvents RDS API operation and setting the `Duration` parameter to `20160`.

Working with Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics

- Overview of Amazon RDS event notification
- Granting permissions to publish notifications to an Amazon SNS topic
- Subscribing to Amazon RDS event notification
- Amazon RDS event notification tags and attributes
- Listing Amazon RDS event notification subscriptions
- Modifying an Amazon RDS event notification subscription
- Adding a source identifier to an Amazon RDS event notification subscription
- Removing a source identifier from an Amazon RDS event notification subscription
- Listing the Amazon RDS event notification categories
- Deleting an Amazon RDS event notification subscription

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs.

Topics

- RDS resources eligible for event subscription
- Basic process for subscribing to Amazon RDS event notifications
- Delivery of RDS event notifications
- Billing for Amazon RDS event notifications
- Examples of Amazon RDS events using Amazon EventBridge

RDS resources eligible for event subscription

You can subscribe to an event category for the following resources:

- DB instance
- DB snapshot
- DB parameter group
- DB security group
- RDS Proxy
- Custom engine version

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB instance, you're notified when the DB instance is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription that receives all event notifications for all DB instances and another subscription that includes only critical events for a subset of the DB instances. For the second subscription, specify one or more DB instances in the filter.

Basic process for subscribing to Amazon RDS event notifications

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

   Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.
2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription.
3. You confirm your subscription by choosing the link in the notification you received.
4. The Amazon RDS console updates the **My Event Subscriptions** section with the status of your subscription.
5. Amazon RDS begins sending the notifications to the addresses that you provided when you created the subscription.

To learn about identity and access management when using Amazon SNS, see Identity and access management in Amazon SNS in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see Using AWS Lambda with Amazon RDS in the *AWS Lambda Developer Guide*.

Delivery of RDS event notifications

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. The notification can include message attributes which provide structured metadata about the message. For more information about message attributes, see Amazon RDS event categories and event messages.

Event notifications might take up to five minutes to be delivered.

> **Important**
>
> Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see Amazon SNS message and JSON formats in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see Mobile text messaging (SMS) in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the `Enabled` parameter to `false` using the AWS CLI or Amazon RDS API.

Billing for Amazon RDS event notifications

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see Amazon Simple Notification Service pricing.

Examples of Amazon RDS events using Amazon EventBridge

The following examples illustrate different types of Amazon RDS events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see Tutorial: Log DB instance state changes using Amazon EventBridge.

Topics

- Example of a DB instance event
- Example of a DB parameter group event
- Example of a DB snapshot event

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named `my-db-instance`. The event ID is RDS-EVENT-0049.

```
{
  "version": "0",
  "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ffd4e",
  "detail-type": "RDS DB Instance Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-09-27T22:36:43Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"
  ],
  "detail": {
    "EventCategories": [
      "failover"
    ],
    "SourceType": "DB_INSTANCE",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:my-db-instance",
    "Date": "2018-09-27T22:36:43.292Z",
    "Message": "A Multi-AZ failover has completed.",
    "SourceIdentifier": "my-db-instance",
    "EventID": "RDS-EVENT-0049"
  }
}
```

Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is RDS-EVENT-0037.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Parameter Group Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
  ],
  "detail": {
    "EventCategories": [
      "configuration change"
    ],
    "SourceType": "DB_PARAM",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "my-db-param-group",
    "EventID": "RDS-EVENT-0037"
  }
}
```

Example of a DB snapshot event

The following is an example of a DB snapshot event in JSON format. The event shows the deletion of the snapshot named `my-db-snapshot`. The event ID is RDS-EVENT-0041.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Snapshot Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
```

```
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot"
  ],
  "detail": {
    "EventCategories": [
      "deletion"
    ],
    "SourceType": "SNAPSHOT",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Deleted manual snapshot",
    "SourceIdentifier": "my-db-snapshot",
    "EventID": "RDS-EVENT-0041"
  }
}
```

Granting permissions to publish notifications to an Amazon SNS topic

To grant Amazon RDS permissions to publish notifications to an Amazon Simple Notification Service (Amazon SNS) topic, attach an AWS Identity and Access Management (IAM) policy to the destination topic. For more information about permissions, see Example cases for Amazon Simple Notification Service access control in the *Amazon Simple Notification Service Developer Guide*.

By default, an Amazon SNS topic has a policy allowing all Amazon RDS resources within the same account to publish notifications to it. You can attach a custom policy to allow cross-account notifications, or to restrict access to certain resources.

The following is an example of an IAM policy that you attach to the destination Amazon SNS topic. It restricts the topic to DB instances with names that match the specified prefix. To use this policy, specify the following values:

- `Resource` – The Amazon Resource Name (ARN) for your Amazon SNS topic
- `SourceARN` – Your RDS resource ARN
- `SourceAccount` – Your AWS account ID

To see a list of resource types and their ARNs, see Resources Defined by Amazon RDS in the *Service Authorization Reference*.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "events.rds.amazonaws.com"
      },
      "Action": [
        "sns:Publish"
      ],
      "Resource": "arn:aws:sns:us-east-1:123456789012:topic_name",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:prefix-*"
        },
```

```
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event:

Source type

The type of source. For example, **Source type** might be **Instances**. You must choose a source type.

Resources **to include**

The Amazon RDS resources that are generating the events. For example, you might choose **Select specific instances** and then **myDBInstance1**.

The following table explains the result when you specify or don't specify ***Resources*** **to include**.

Resources to include	Description	Example
Specified	RDS notifies you about all events for the specified resource only.	If your **Source type** is **Instances** and your resource is **myDBInstance1**, RDS notifies you about all events for myDBInstance1 only.
Not specified	RDS notifies you about the events for the specified source type for all your Amazon RDS resources.	If your **Source type** is **Instances**, RDS notifies you about all instance-related events in your account.

An Amazon SNS topic subscriber receives every message published to the topic by default. To receive only a subset of the messages, the subscriber must assign a filter policy to the topic subscription. For more information about SNS message filtering, see Amazon SNS message filtering in the *Amazon Simple Notification Service Developer Guide*

Console

To subscribe to RDS event notification

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. Enter your subscription details as follows:

   a. For **Name**, enter a name for the event notification subscription.

   b. For **Send notifications to**, do one of the following:

   - Choose **New email topic**. Enter a name for your email topic and a list of recipients. We recommend that you configure the events subscriptions to the same email address as your primary account contact. The recommendations, service events, and personal health messages are sent using different channels. The subscriptions to the same email address ensures that all the messages are consolidated in one location.
   - Choose **Amazon Resource Name (ARN)**. Then choose existing Amazon SNS ARN for an Amazon SNS topic.

     If you want to use a topic that has been enabled for server-side encryption (SSE), grant Amazon RDS the necessary permissions to access the AWS KMS key. For more information, see Enable compatibility between event sources from AWS services and encrypted topics in the *Amazon Simple Notification Service Developer Guide*.

   c. For **Source type**, choose a source type. For example, choose **Instances** or **Parameter groups**.

   d. Choose the event categories and resources that you want to receive event notifications for.

   The following example configures event notifications for the DB instance named `testinst`.

e. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

AWS CLI

To subscribe to RDS event notification, use the AWS CLI `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

Example

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
```

```
    --subscription-name myeventsubscription \
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS \
    --enabled
```

For Windows:

```
aws rds create-event-subscription ^
    --subscription-name myeventsubscription ^
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS ^
    --enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function `CreateEventSubscription`. Include the following required parameters:

- `SubscriptionName`
- `SnsTopicArn`

Amazon RDS event notification tags and attributes

When Amazon RDS sends an event notification to Amazon Simple Notification Service (SNS) or Amazon EventBridge, the notification contains message attributes and event tags. RDS sends the message attributes separately along with the message, while the event tags are in the body of the message. Use the message attributes and the Amazon RDS tags to add metadata to your resources. You can modify these tags with your own notations about the DB instances. For more information about tagging Amazon RDS resources, see Tagging Amazon RDS resources.

By default, the Amazon SNS and Amazon EventBridge receives every message sent to them. SNS and EventBridge can filter the message and send the notifications to the preferred communication mode, such as an email, a text message, or a call to an HTTP endpoint.

> **Note**
>
> The notification sent in an email or a text message will not have event tags.

The following table shows the message attributes for RDS events sent to the topic subscriber.

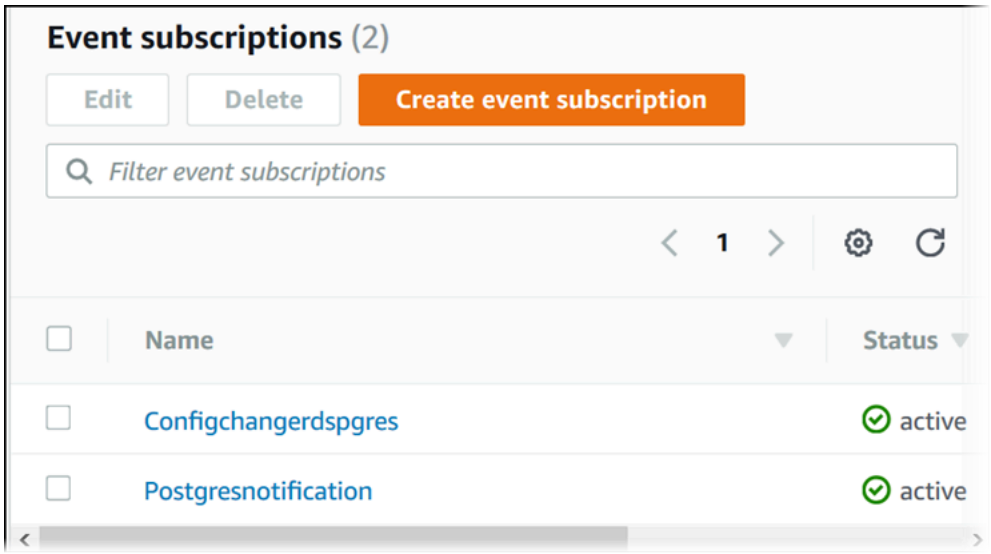
Amazon RDS event attribute	Description
EventID	Identifier for the RDS event message, for example, RDS-EVENT-0006.
Resource	The ARN identifier for the resource emitting the event, for example, `arn:aws:rds:ap-southeast-2:123456789012:db:database-1` .

The RDS tags provide data about the resource that was affected by the service event. RDS adds the current state of the tags in the message body when the notification is sent to SNS or EventBridge.

For more information about filtering message attributes for SNS, see Amazon SNS message filtering in the *Amazon Simple Notification Service Developer Guide*.

For more information about filtering event tags for EventBridge, see Comparison operators for use in event patterns in Amazon EventBridge in the *Amazon EventBridge User Guide*.

For more information about filtering payload-based tags for SNS, see Introducing payload-based message filtering for Amazon SNS



Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.

AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI `describe-event-subscriptions` command.

Example

The following example describes all event subscriptions.

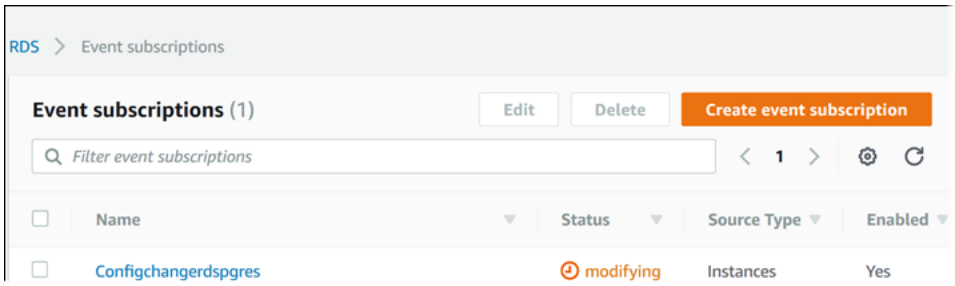
```
aws rds describe-event-subscriptions
```

The following example describes the `myfirsteventsubscription`.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API `DescribeEventSubscriptions` action.



Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose the subscription that you want to modify and choose **Edit**.
4. Make your changes to the subscription in either the **Target** or **Source** section.
5. Choose **Edit**. The Amazon RDS console indicates that the subscription is being modified.

AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI `modify-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following code enables `myeventsubscription`.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
```

```
    --subscription-name myeventsubscription \
    --enabled
```

For Windows:

```
aws rds modify-event-subscription ^
    --subscription-name myeventsubscription ^
    --enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation `ModifyEventSubscription`. Include the following required parameter:

- `SubscriptionName`

Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription.

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI `add-source-identifier-to-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example adds the source identifier `mysqldb` to the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds add-source-identifier-to-subscription \
    --subscription-name myrdseventsubscription \
    --source-identifier mysqldb
```

For Windows:

```
aws rds add-source-identifier-to-subscription ^
    --subscription-name myrdseventsubscription ^
    --source-identifier mysqldb
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API `AddSourceIdentifierToSubscription`. Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`

Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription.

AWS CLI

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example removes the source identifier `mysqldb` from the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

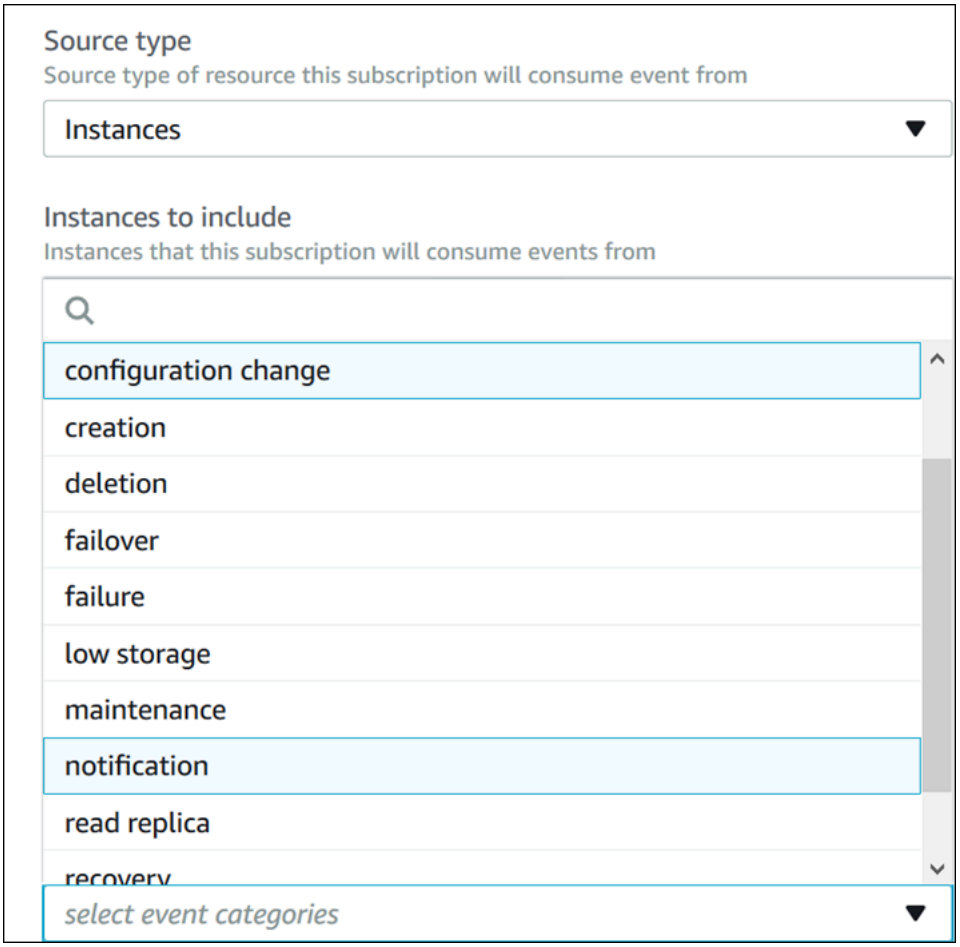
```
aws rds remove-source-identifier-from-subscription \
    --subscription-name myrdseventsubscription \
    --source-identifier mysqldb
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
    --subscription-name myrdseventsubscription ^
    --source-identifier mysqldb
```

API

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:



- `SubscriptionName`
- `SourceIdentifier`

Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

Console

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see Modifying an Amazon RDS event notification subscription.

AWS CLI

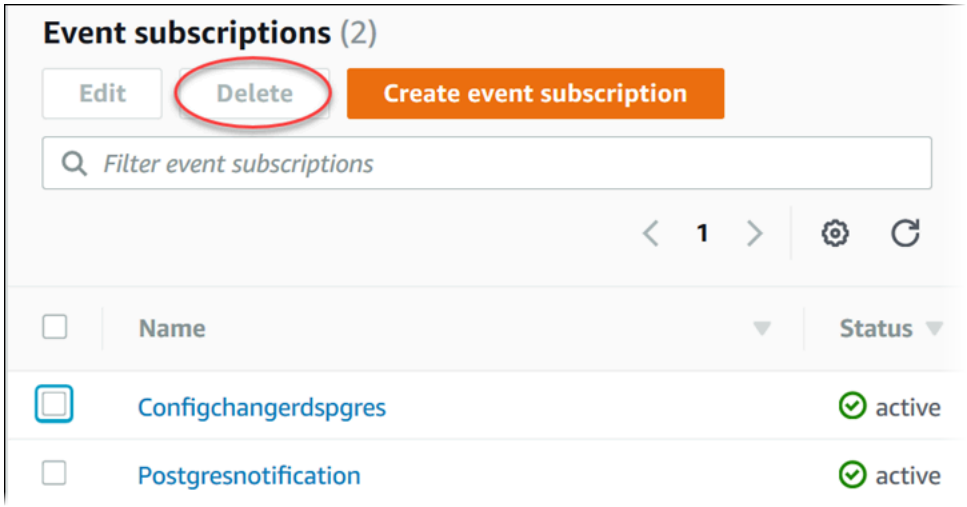
To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

Example

```
aws rds describe-event-categories
```

API

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.



Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI `delete-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following example deletes the subscription `myrdssubscription`.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API `DeleteEventSubscription` command. Include the following required parameter:

- `SubscriptionName`

Creating a rule that triggers on an Amazon RDS event

Using Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics

- Creating rules to send Amazon RDS events to Amazon EventBridge
- Tutorial: Log DB instance state changes using Amazon EventBridge

Creating rules to send Amazon RDS events to Amazon EventBridge

You can write simple rules to indicate which Amazon RDS events interest you and which automated actions to take when an event matches a rule. You can set a variety of targets, such as an AWS Lambda function or an Amazon SNS topic, which receive events in JSON format. For example, you can configure Amazon RDS to send events to Amazon EventBridge whenever a DB instance is created or deleted. For more information, see the Amazon CloudWatch Events User Guide and the Amazon EventBridge User Guide.

To create a rule that triggers on an RDS event:

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Under **Events** in the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. For **Event Source**, do the following:
    a. Choose **Event Pattern**.
    b. For **Service Name**, choose **Relational Database Service (RDS)**.
    c. For **Event Type**, choose the type of Amazon RDS resource that triggers the event. For example, if a DB instance triggers the event, choose **RDS DB Instance Event**.
5. For **Targets**, choose **Add Target** and choose the AWS service that is to act when an event of the selected type is detected.
6. In the other fields in this section, enter information specific to this target type, if any is needed.
7. For many target types, EventBridge needs permissions to send events to the target. In these cases, EventBridge can create the IAM role needed for your event to run:

- To create an IAM role automatically, choose **Create a new role for this specific resource**.
- To use an IAM role that you created before, choose **Use existing role**.

8. Optionally, repeat steps 5-7 to add another target for this rule.
9. Choose **Configure details**. For **Rule definition**, type a name and description for the rule.

   The rule name must be unique within this Region.
10. Choose **Create rule**.

For more information, see Creating an EventBridge Rule That Triggers on an Event in the *Amazon CloudWatch User Guide*.

Tutorial: Log DB instance state changes using Amazon EventBridge

In this tutorial, you create an AWS Lambda function that logs the state changes for an Amazon RDS instance. You then create a rule that runs the function whenever there is a state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

> **Important**
>
> Don't perform this tutorial on a running production DB instance.

Topics

- Step 1: Create an AWS Lambda function
- Step 2: Create a rule
- Step 3: Test the rule

Step 1: Create an AWS Lambda function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.

2. If you're new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the **Create function** page, do the following:

   a. Enter a name and description for the Lambda function. For example, name the function **`RDSInstanceStateChange`**.

   b. In **Runtime**, select **Node.js 16x**.

   c. For **Architecture**, choose **x86_64**.

   d. For **Execution role**, do either of the following:

      - Choose **Create a new role with basic Lambda permissions**.
      - For **Existing role**, choose **Use an existing role**. Choose the role that you want to use.

   e. Choose **Create function**.
5. On the **RDSInstanceStateChange** page, do the following:

   a. In **Code source**, select **index.js**.

   b. In the **index.js** pane, delete the existing code.

   c. Enter the following code:

```
console.log('Loading function');

exports.handler = async (event, context) => {
    console.log('Received event:', JSON.stringify(event));
};
```

   d. Choose **Deploy**.

Step 2: Create a rule

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

To create the EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.

4. Enter a name and description for the rule. For example, enter **`RDSInstanceStateChangeRule`**.
5. Choose **Rule with an event pattern**, and then choose **Next**.
6. For **Event source**, choose **AWS events or EventBridge partner events**.
7. Scroll down to the **Event pattern** section.
8. For **Event source**, choose **AWS services**.
9. For **AWS service**, choose **Relational Database Service (RDS)**.
10. For **Event type**, choose **RDS DB Instance Event**.
11. Leave the default event pattern. Then choose **Next**.
12. For **Target types**, choose **AWS service**.
13. For **Select a target**, choose **Lambda function**.
14. For **Function**, choose the Lambda function that you created. Then choose **Next**.
15. In **Configure tags**, choose **Next**.
16. Review the steps in your rule. Then choose **Create rule**.

Step 3: Test the rule

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

To test your rule by stopping a DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Monitoring**.

   You are redirected to the Amazon CloudWatch console. If you are not redirected, click **View the metrics in CloudWatch**.
6. In **All metrics**, choose the name of the rule that you created.

   The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.

8. Choose the name of the log group for your Lambda function (**/aws/lambda/*function-name***).
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```
{
    "version": "0",
    "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "111111111111",
    "time": "2021-03-19T19:34:09Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:111111111111:db:testdb"
    ],
    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "DB_INSTANCE",
        "SourceArn": "arn:aws:rds:us-east-1:111111111111:db:testdb",
        "Date": "2021-03-19T19:34:09.293Z",
        "Message": "DB instance stopped",
        "SourceIdentifier": "testdb",
        "EventID": "RDS-EVENT-0087"
    }
}
```

   For more examples of RDS events in JSON format, see Overview of events for Amazon RDS.
10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.

Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API.

Topics

- DB cluster events
- DB cluster snapshot events
- DB instance events
- DB parameter group events
- DB security group events
- DB snapshot events
- RDS Proxy events
- Blue/green deployment events
- Custom engine version events

DB cluster events

The following table shows the event category and a list of events when a DB cluster is the source type.

For more information about Multi-AZ DB cluster deployments, see Multi-AZ DB cluster deployments for Amazon RDS.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0016	Reset master credentials.	None
creation	RDS-EVENT-0170	DB cluster created.	None
failover	RDS-EVENT-0069	Cluster failover failed, check the health of your cluster instances and try again.	None

Category	RDS event ID	Message	Notes
failover	RDS-EVENT-0070	Promoting previous primary again: *name*.	None
failover	RDS-EVENT-0071	Completed failover to DB instance: *name*.	None
failover	RDS-EVENT-0072	Started same AZ failover to DB instance: *name*.	None
failover	RDS-EVENT-0073	Started cross AZ failover to DB instance: *name*.	None
failure	RDS-EVENT-0354	You can't create the DB cluster because of incompatible resources. *message*.	The *message* includes details about the failure.
failure	RDS-EVENT-0355	The DB cluster can't be created because of insufficient resource limits. *message*.	The *message* includes details about the failure.
maintenance	RDS-EVENT-0156	The DB cluster has a DB engine minor version upgrade available.	None
maintenance	RDS-EVENT-0173	Database cluster engine version has been upgraded.	Patching of the DB cluster has completed.
maintenance	RDS-EVENT-0174	Database cluster is in a state that cannot be upgraded.	None
maintenance	RDS-EVENT-0176	Database cluster engine major version has been upgraded.	None

Category	RDS event ID	Message	Notes
maintenance	RDS-EVENT-0177	Database cluster upgrade is in progress.	None
maintenance	RDS-EVENT-0286	Database cluster engine *version_number* version upgrade started. Cluster remains online.	None
maintenance	RDS-EVENT-0287	Operating system upgrade requirement detected.	None
maintenance	RDS-EVENT-0288	Cluster operating system upgrade starting.	None
maintenance	RDS-EVENT-0289	Cluster operating system upgrade completed.	None
maintenance	RDS-EVENT-0290	Database cluster has been patched: source version *version_number* => *new_version_number* .	None
maintenance	RDS-EVENT-0410	The pre-check started for the database cluster engine version upgrade.	None
maintenance	RDS-EVENT-0412	The pre-check for the database cluster engine version upgrade failed or timed out.	None
maintenance	RDS-EVENT-0413	The DB cluster pre-upgrade tasks are in progress.	None
maintenance	RDS-EVENT-0414	The DB cluster post-upgrade tasks are in progress.	None

Category	RDS event ID	Message	Notes
maintenance	RDS-EVENT-0417	Database cluster engine version upgrade started.	None
notification	RDS-EVENT-0172	Renamed cluster from *name* to *name*.	None
read replica	RDS-EVENT-0411	The pre-check finished for the database cluster engine version upgrade.	None

DB cluster snapshot events

The following table shows the event category and a list of events when a DB cluster snapshot is the source type.

Category	RDS event ID	Message	Notes
backup	RDS-EVENT-0074	Creating manual cluster snapshot.	None
backup	RDS-EVENT-0075	Manual cluster snapshot created.	None
notification	RDS-EVENT-0162	The cluster snapshot export task failed.	None
notification	RDS-EVENT-0163	The cluster snapshot export task was canceled.	None
notification	RDS-EVENT-0164	The cluster snapshot export task completed.	None
backup	RDS-EVENT-0168	Creating automated cluster snapshot.	None

Category	RDS event ID	Message	Notes
backup	RDS-EVENT-0169	Automated cluster snapshot created.	None
failure	RDS-EVENT-0489	Export task *name*: Table extraction failed for table *name* due to *message*.	This event is not supported by faster export.
notification	RDS-EVENT-0491	Export task *name*: Table *name* will be exported in a slower single-threaded mode. Please expect a delay in export completio n.	This event is not supported by faster export.
notification	RDS-EVENT-0492	Export task *name*: Table *name* is in progress, and the exported size is *number* GB.	This event will only be sent for tables taking more than 1 hour to complete. This event is not supported by faster export.
notification	RDS-EVENT-0493	Export task *name* is at *name* stage.	None
		Export task *name*: Export progress is at *number*% with *number* table(s) in-progress and *number* table(s) finished. The total size of finished tables is *number* GB.	This event is not supported by faster export.

DB instance events

The following table shows the event category and a list of events when a DB instance is the source type.

Category	RDS event ID	Message	Notes
availability	RDS-EVENT-0004	DB instance shutdown.	None
availability	RDS-EVENT-0006	DB instance restarted.	None
availability	RDS-EVENT-0022	Error restarting mysql: *message*.	An error has occurred while restarting MySQL.
availability	RDS-EVENT-0221	DB instance has reached the storage-full threshold , and the database has been shut down. You can increase the allocated storage to address this issue.	None
availability	RDS-EVENT-0222	Free storage capacity for DB instance *name* is low at *percentage* of the allocated storage [Allocated storage: *amount*, Free storage: *amount*]. The database will be shut down to prevent corruption if free storage is lower than *amount*. You can increase the allocated storage to address this issue.	Applies only to RDS for MySQL when a DB instance consumes more than 90% of the allocated storage. Monitor the storage space for a DB instance using the Free Storage Space metric. For more information, see Amazon RDS DB instance storage.
availability	RDS-EVENT-0330	The free storage capacity of the dedicated transaction log volume is too low for DB instance *name*. The log volume free storage is *percentage* of the allocated storage.	For more information, see Dedicated log volume (DLV).

Category	RDS event ID	Message	Notes
		[Allocated storage: *amount*, Free storage: *amount*] The database will be shut down to prevent corruption if the free storage is lower than *amount*. You can disable the dedicated transaction log volume to resolve this issue.	
availability	RDS-EVENT-0331	The free storage capacity of the dedicated transacti on log volume is too low for DB instance *name*. The log volume free storage is *percentage* of the provisioned storage. [Provisioned Storage: *amount*, Free Storage: *amount*] You can disable the dedicated transaction log volume to resolve this issue.	For more information, see Dedicated log volume (DLV).
availability	RDS-EVENT-0396	Amazon RDS has scheduled a reboot for this read replica in this instance's next maintenan ce window after internal user password rotation.	None

Category	RDS event ID	Message	Notes
availability	RDS-EVENT-0419	Amazon RDS has been unable to access the KMS encryption key for database instance *name*. This database will be placed into an inaccessi ble state. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	None
backup	RDS-EVENT-0001	Backing up DB instance.	None
backup	RDS-EVENT-0002	Finished DB instance backup.	None
backup	RDS-EVENT-0086	We are unable to associate the option group *name* with the database instance *name*. Confirm that option group *name* is supported on your DB instance class and configuration. If so, verify all option group settings and retry.	For more information see Working with option groups.
configuration change	RDS-EVENT-0011	Updated to use DBParamet erGroup *name*.	None
configuration change	RDS-EVENT-0012	Applying modification to database instance class.	None
configuration change	RDS-EVENT-0014	Finished applying modification to DB instance class.	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0016	Reset master credentials.	None
configuration change	RDS-EVENT-0017	Finished applying modification to allocated storage.	None
configuration change	RDS-EVENT-0018	Applying modification to allocated storage.	None
configuration change	RDS-EVENT-0024	Applying modification to convert to a Multi-AZ DB instance.	None
configuration change	RDS-EVENT-0025	Finished applying modification to convert to a Multi-AZ DB instance.	None
configuration change	RDS-EVENT-0028	Disabled automated backups.	None
configuration change	RDS-EVENT-0029	Finished applying modification to convert to a standard (Single-AZ) DB instance.	None
configuration change	RDS-EVENT-0030	Applying modification to convert to a standard (Single-AZ) DB instance.	None
configuration change	RDS-EVENT-0032	Enabled automated backups.	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0033	There are *number* users matching the master username; only resetting the one not tied to a specific host.	None
configuration change	RDS-EVENT-0067	Unable to reset your password. Error informati on: *message*.	None
configuration change	RDS-EVENT-0078	Monitoring Interval changed to *number*.	The Enhanced Monitorin g configuration has been changed.
configuration change	RDS-EVENT-0092	Finished updating DB parameter group.	None
configuration change	RDS-EVENT-0217	Applying autoscaling-initiated modification to allocated storage.	None
configuration change	RDS-EVENT-0218	Finished applying autoscali ng-initiated modification to allocated storage.	None
configuration change	RDS-EVENT-0295	Storage configuration upgrade started.	None
configuration change	RDS-EVENT-0296	Storage configuration upgrade completed.	None
configuration change	RDS-EVENT-0332	The dedicated log volume is disabled.	For more information, see Dedicated log volume (DLV).

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0333	Disabling the dedicated log volume has started.	For more information, see Dedicated log volume (DLV).
configuration change	RDS-EVENT-0334	Enabling the dedicated log volume has started.	For more information, see Dedicated log volume (DLV).
configuration change	RDS-EVENT-0335	The dedicated log volume is enabled.	For more information, see Dedicated log volume (DLV).
configuration change	RDS-EVENT-0383	*engine version* doesn't support the memcached plugin. RDS will continue upgrading your DB instance and remove this plugin.	Starting with MySQL 8.3.0, the memcached plugin isn't supported. For more information, see Changes in MySQL 8.3.0 (2024-01-16, Innovation Release).
creation	RDS-EVENT-0005	DB instance created.	None
deletion	RDS-EVENT-0003	DB instance deleted.	None
failover	RDS-EVENT-0013	Multi-AZ instance failover started.	A Multi-AZ failover that resulted in the promotion of a standby DB instance has started.
failover	RDS-EVENT-0015	Multi-AZ failover to standby complete - DNS propagation may take a few minutes.	A Multi-AZ failover that resulted in the promotion of a standby DB instance is complete. It may take several minutes for the DNS to transfer to the new primary DB instance.

Category	RDS event ID	Message	Notes
failover	RDS-EVENT-0034	Abandoning user requested failover since a failover recently occurred on the database instance.	Amazon RDS isn't attempting a requested failover because a failover recently occurred on the DB instance.
failover	RDS-EVENT-0049	Multi-AZ instance failover completed.	None
failover	RDS-EVENT-0050	Multi-AZ instance activation started.	A Multi-AZ activation has started after a successful DB instance recovery. This event occurs if Amazon RDS promotes the primary DB instance to the same AZ as the previous primary DB instance.
failover	RDS-EVENT-0051	Multi-AZ instance activation completed.	A Multi-AZ activation is complete. Your database should be accessible now.
failover	RDS-EVENT-0065	Recovered from partial failover.	None
failure	RDS-EVENT-0031	DB instance put into *name* state. RDS recommends that you initiate a point-in-time-restore.	The DB instance has failed due to an incompatible configuration or an underlying storage issue. Begin a point-in-time-restore for the DB instance.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0035	Database instance put into *state*. *message*.	The DB instance has invalid parameters. For example, if the DB instance could not start because a memory-related parameter is set too high for this instance class, your action would be to modify the memory parameter and reboot the DB instance.
failure	RDS-EVENT-0036	Database instance in *state*. *message*.	The DB instance is in an incompatible network. Some of the specified subnet IDs are invalid or do not exist.
failure	RDS-EVENT-0058	The Statspack installation failed. *message*.	Error while creating Oracle Statspack user account PERFSTAT. Drop the account before you add the STATSPACK option.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0079	Amazon RDS has been unable to create credentials for enhanced monitoring and this feature has been disabled. This is likely due to the rds-monitoring-role not being present and configured correctly in your account. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	Enhanced Monitoring can't be enabled without the Enhanced Monitoring IAM role. For information about creating the IAM role, see To create an IAM role for Amazon RDS enhanced monitoring.
failure	RDS-EVENT-0080	Amazon RDS has been unable to configure enhanced monitoring on your instance: *name* and this feature has been disabled. This is likely due to the rds-monitoring-role not being present and configured correctly in your account. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	Enhanced Monitoring was disabled because an error occurred during the configuration change. It is likely that the Enhanced Monitoring IAM role is configured incorrectly. For information about creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0081	Amazon RDS has been unable to create credentials for *name* option. This is due to the *name* IAM role not being configured correctly in your account. Please refer to the troubleshooting section in the Amazon RDS documentation for further details.	The IAM role that you use to access your Amazon S3 bucket for SQL Server native backup and restore is configured incorrectly. For more information, see Setting up for native backup and restore.
failure	RDS-EVENT-0165	The RDS Custom DB instance is outside the support perimeter.	It's your responsibility to fix configuration issues that put your RDS Custom DB instance into the `unsupported-configuration` state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it. For more information, see RDS Custom support perimeter.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0188	The DB instance is in a state that can't be upgraded. *message*	Amazon RDS was unable to upgrade a MySQL DB instance because of incompatibilities related to the data dictionary. The DB instance was rolled back to MySQL version 5.7 because an attempted upgrade to version 8.0 failed, or rolled back to MySQL version 8.0 because an attempted upgrade to version 8.4 failed. For more informati on, see Rollback after failure to upgrade.
failure	RDS-EVENT-0219	DB instance is in an invalid state. No actions are necessary. Autoscaling will retry later.	None
failure	RDS-EVENT-0220	DB instance is in the cooling-off period for a previous scale storage operation. We're optimizin g your DB instance. This takes at least 6 hours. No actions are necessary. Autoscaling will retry after the cooling-off period.	None
failure	RDS-EVENT-0223	Storage autoscaling is unable to scale the storage for the reason: *reason*.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0224	Storage autoscaling has triggered a pending scale storage task that will reach or exceed the maximum storage threshold. Increase the maximum storage threshold.	None
failure	RDS-EVENT-0237	DB instance has a storage type that's currently unavailable in the Availabil ity Zone. Autoscaling will retry later.	None
failure	RDS-EVENT-0254	Underlying storage quota for this customer account has exceeded the limit. Please increase the allowed storage quota to let the scaling go through on the instance.	None
failure	RDS-EVENT-0278	The DB instance creation failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0279	The promotion of the RDS Custom read replica failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0280	RDS Custom couldn't upgrade the DB instance because the pre-check failed. *message*	The *message* includes details about the failure.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0281	RDS Custom couldn't modify the DB instance because the pre-check failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0282	RDS Custom couldn't modify the DB instance because the Elastic IP permissions aren't correct. Please confirm the Elastic IP address is tagged with `AWSRDSCustom` .	None
failure	RDS-EVENT-0283	RDS Custom couldn't modify the DB instance because the Elastic IP limit has been reached in your account. Release unused Elastic IPs or request a quota increase for your Elastic IP address limit.	None
failure	RDS-EVENT-0284	RDS Custom couldn't convert the instance to high availability because the pre-check failed. *message*	The *message* includes details about the failure.
failure	RDS-EVENT-0285	RDS Custom couldn't create a final snapshot for the DB instance because *message*.	The *message* includes details about the failure.

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0421	RDS Custom couldn't convert the DB instance to a Multi-AZ deployment: *message*. The instance will remain a Single-AZ deployment. See the RDS User Guide for information about Multi-AZ deployments for RDS Custom for Oracle.	The *message* includes details about the failure.
failure	RDS-EVENT-0306	Storage configuration upgrade failed. Please retry the upgrade.	None
failure	RDS-EVENT-0315	Unable to move incompatible-network database, *name*, to the available status: *message*	The database networking configuration is invalid. The database could not be moved from incompatible-network to available.
failure	RDS-EVENT-0328	Failed to join a host to a domain. Domain membership status for instance *instancename* has been set to Failed.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0329	Failed to join a host to your domain. During the domain join process, Microsoft Windows returned the error code *message*. Verify your network and permission configurations and issue a `modify-db-instance` request to re-attempt the domain join.	When using a self-managed Active Directory, see Troubleshooting self-managed Active Directory.
failure	RDS-EVENT-0353	The DB instance can't be created because of insufficient resource limits. *message*.	The *message* includes details about the failure.
failure	RDS-EVENT-0356	RDS was unable to configure the Kerberos endpoint in your domain. This might prevent Kerberos authentication for your DB instance. Verify the network configuration between your DB instance and domain controllers.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0418	Amazon RDS is unable to access the KMS encryption key for database instance *name*. This is likely due to the key being disabled or Amazon RDS being unable to access it. If this continues the database will be placed into an inaccessible state. Please refer to the troublesh ooting section in the Amazon RDS documenta tion for further details.	None
failure	RDS-EVENT-0420	Amazon RDS can now successfully access the KMS encryption key for database instance *name*.	None
low storage	RDS-EVENT-0007	Allocated storage has been exhausted. Allocate additional storage to resolve.	The allocated storage for the DB instance has been consumed. To resolve this issue, allocate additional storage for the DB instance. For more information, see the RDS FAQ. You can monitor the storage space for a DB instance using the **Free Storage Space** metric.

Category	RDS event ID	Message	Notes
low storage	RDS-EVENT-0089	The free storage capacity for DB instance: *name* is low at *percentage* of the provisioned storage [Provisioned Storage: *size*, Free Storage: *size*]. You may want to increase the provisioned storage to address this issue.	The DB instance has consumed more than 90% of its allocated storage. You can monitor the storage space for a DB instance using the **Free Storage Space** metric.
low storage	RDS-EVENT-0227	Your Aurora cluster's storage is dangerously low with only *amount* terabytes remaining. Please take measures to reduce the storage load on your cluster.	The Aurora storage subsystem is running low on space.
maintenance	RDS-EVENT-0026	Applying off-line patches to DB instance.	Offline maintenance of the DB instance is taking place. The DB instance is currently unavailable.
maintenance	RDS-EVENT-0027	Finished applying off-line patches to DB instance.	Offline maintenance of the DB instance is complete. The DB instance is now available.
maintenance	RDS-EVENT-0047	Database instance patched.	None
maintenance	RDS-EVENT-0155	The DB instance has a DB engine minor version upgrade available.	None

Category	RDS event ID	Message	Notes
maintenance	RDS-EVENT-0178	Database instance upgrade is in progress.	None
maintenance	RDS-EVENT-0264	The pre-check started for the DB engine version upgrade.	None
maintenance	RDS-EVENT-0265	The pre-check finished for the DB engine version upgrade.	None
maintenance	RDS-EVENT-0266	The downtime started for the DB instance.	None
maintenance	RDS-EVENT-0267	The engine version upgrade started.	None
maintenance	RDS-EVENT-0268	The engine version upgrade finished.	None
maintenance	RDS-EVENT-0269	The post-upgrade tasks are in progress.	None
maintenance	RDS-EVENT-0270	The DB engine version upgrade failed. The engine version upgrade rollback succeeded.	None
maintenance	RDS-EVENT-0398	Waiting for the DB engine version upgrade to finish on the primary DB instance.	Emitted on a read replica during a major engine version upgrade.
maintenance	RDS-EVENT-0399	Waiting for the DB engine version upgrade to finish on the read replicas.	Emitted on source DB engine during a major engine version upgrade.

Category	RDS event ID	Message	Notes
maintenance	RDS-EVENT-0422	RDS will replace the host of DB instance *name* due to a pending maintenance action.	None
maintenance, failure	RDS-EVENT-0195	*message*	The update of the Oracle time zone file failed. For more information, see Oracle time zone file autoupgrade.
maintenance, notification	RDS-EVENT-0191	A new version of the time zone file is available for update.	If you update your RDS for Oracle DB engine, Amazon RDS generates this event if you haven't chosen a time zone file upgrade and the database doesn’t use the latest DST time zone file available on the instance. For more information, see Oracle time zone file autoupgrade.
maintenance, notification	RDS-EVENT-0192	The update of your time zone file has started.	The upgrade of your Oracle time zone file has begun. For more informati on, see Oracle time zone file autoupgrade.

Category	RDS event ID	Message	Notes
maintenance, notification	RDS-EVENT-0193	No update is available for the current time zone file version.	Your Oracle DB instance is using latest time zone file version, and either of the following statements is true: • You recently added the `TIMEZONE_FILE_AUTOUPGRADE` option. • Your Oracle DB engine is being upgraded. For more information, see Oracle time zone file autoupgrade.
maintenance, notification	RDS-EVENT-0194	The update of your time zone file has finished.	The update of your Oracle time zone file has completed. For more information, see Oracle time zone file autoupgrade.
notification	RDS-EVENT-0044	*message*	This is an operator-issued notification. For more information, see the event message.
notification	RDS-EVENT-0048	Delaying database engine upgrade since this instance has read replicas that need to be upgraded first.	Patching of the DB instance has been delayed.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0054	*message*	The MySQL storage engine you are using is not InnoDB, which is the recommended MySQL storage engine for Amazon RDS. For information about MySQL storage engines, see Supported storage engines for RDS for MySQL.
notification	RDS-EVENT-0055	*message*	The number of tables you have for your DB instance exceeds the recommended best practices for Amazon RDS. Reduce the number of tables on your DB instance. For information about recommended best practices, see Amazon RDS basic operational guidelines.
notification	RDS-EVENT-0056	*message*	The number of databases you have for your DB instance exceeds the recommended best practices for Amazon RDS. Reduce the number of databases on your DB instance. For information about recommended best practices, see Amazon RDS basic operational guidelines.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0064	The TDE encryption key was rotated successfully.	For information about recommended best practices, see Amazon RDS basic operational guidelines.
notification	RDS-EVENT-0084	Unable to convert the DB instance to Multi-AZ: *message*.	You attempted to convert a DB instance to Multi-AZ, but it contains in-memory file groups that are not supported for Multi-AZ. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.
notification	RDS-EVENT-0087	DB instance stopped.	None
notification	RDS-EVENT-0088	DB instance started.	None
notification	RDS-EVENT-0154	DB instance is being started due to it exceeding the maximum allowed time being stopped.	None

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0157	Unable to modify the DB instance class. *message*.	RDS can't modify the DB instance class because the target instance class can't support the number of databases that exist on the source DB instance. The error message appears as: "The instance has *N* databases, but after conversion it would only support *N*". For more information, see Limitations for Microsoft SQL Server DB instances.
notification	RDS-EVENT-0158	Database instance is in a state that cannot be upgraded: *message*.	None
notification	RDS-EVENT-0167	*message*	The RDS Custom support perimeter configuration has changed.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0189	The gp2 burst balance credits for the RDS database instance are low. To resolve this issue, reduce IOPS usage or modify your storage settings to enable higher performance.	The gp2 burst balance credits for the RDS database instance are low. To resolve this issue, reduce IOPS usage or modify your storage settings to enable higher performance. For more information, see I/O credits and burst performance in the *Amazon Elastic Compute Cloud User Guide*.
notification	RDS-EVENT-0225	Allocated storage size *amount* GB is approaching the maximum storage threshold *amount* GB. Increase the maximum storage threshold.	This event is invoked when the allocated storage reaches 80% of the maximum storage threshold. To avoid the event, increase the maximum storage threshold.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0231	Your DB instance's storage modification encounter ed an internal error. The modification request is pending and will be retried later.	An error has occurred in the read replicati on process. For more information, see the event message. In addition, see the troubleshooting section for read replicas for your DB engine. • Troubleshooting a MariaDB read replica problem • Troubleshooting a SQL Server read replica problem • Troubleshooting a MySQL read replica problem • Troubleshooting RDS for Oracle replicas

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0253	The database is using the doublewrite buffer. *message*. For more information see the RDS Optimized Writes for *name* documentation.	RDS Optimized Writes is incompatible with the instance storage configuration. For more information, see Improving write performance with RDS Optimized Writes for MySQL and Improving write performance with Amazon RDS Optimized Writes for MariaDB. You can perform storage configuration upgrade to enable Optimized Writes by Creating a blue/green deployment.
notification	RDS-EVENT-0297	The storage configuration for DB instance *name* supports a maximum size of 16384 GiB. Perform a storage configuration upgrade to support storage sizes greater than 16384 GiB.	You cannot increase the allocated storage size of the DB instance beyond 16384 GiB. To overcome this limitation, perform a storage configuration upgrade. For more information, see Upgrading the storage file system for a DB instance.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0298	The storage configuration for DB instance *name* supports a maximum table size of 2048 GiB. Perform a storage configuration upgrade to support table sizes greater than 2048 GiB.	RDS MySQL and MariaDB instances with this limitation cannot have a table size exceeding 2048 GiB. To overcome this limitation, perform a storage configuration upgrade. For more information, see Upgrading the storage file system for a DB instance.
notification	RDS-EVENT-0327	Amazon RDS could not find the secret *SECRET ARN*. *message.*	None
notification	RDS-EVENT-0365	Timezone files were updated. Restart your RDS instance for the changes to take effect.	None
notification	RDS-EVENT-0385	Cluster topology is updated.	There are DNS changes to the DB cluster for the DB instance. This includes when new DB instances are added or deleted, or there's a failover.
notification	RDS-EVENT-0403	A database workload is causing the system to run critically low on memory. To help mitigate the issue, RDS automatically set the value of innodb_buffer_pool_size to *amount*.	Applies only to RDS for MySQL and RDS for MariaDB DB instances.

Category	RDS event ID	Message	Notes
notification	RDS-EVENT-0404	A database workload is causing the system to run critically low on memory. To help mitigate the issue, RDS automatically set the value of shared_buffers to *amount*.	Applies only to RDS for PostgreSQL DB instances.
read replica	RDS-EVENT-0045	Replication has stopped.	This message appears when there is an error during replication. To determine the type of error, see Troubleshooting a MySQL read replica problem.
read replica	RDS-EVENT-0046	Replication for the Read Replica resumed.	This message appears when you first create a read replica, or as a monitoring message confirming that replication is functioning properly. If this message follows an RDS-EVENT-0045 notification, then replication has resumed following an error or after replication was stopped.
read replica	RDS-EVENT-0057	Replication streaming has been terminated.	None
read replica	RDS-EVENT-0062	Replication for the Read Replica has been manually stopped.	None

Category	RDS event ID	Message	Notes

Category	RDS event ID	Message	Notes
		the target group of the DB proxy *name*.	
configuration change	RDS-EVENT-0214	RDS detected deletion of DB instance *name* and automatically removed it from target group *name* of DB proxy *name*.	None
configuration change	RDS-EVENT-0215	RDS detected deletion of DB cluster *name* and automatically removed it from target group *name* of DB proxy *name*.	None
creation	RDS-EVENT-0203	RDS created DB proxy *name*.	None
creation	RDS-EVENT-0206	RDS created endpoint *name* for DB proxy *name*.	None
deletion	RDS-EVENT-0205	RDS deleted DB proxy *name*.	None
deletion	RDS-EVENT-0208	RDS deleted endpoint *name* for DB proxy *name*.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0243	RDS failed to provision capacity for proxy *name* because there aren't enough IP addresses available in your subnets: *name*. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses as recommend ed in the RDS Proxy documentation.	To determine the recommended number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.	None

Blue/green deployment events

The following table shows the event category and a list of events when a blue/green deployment is the source type.

For more information about blue/green deployments, see Using Amazon RDS Blue/Green Deployments for database updates.

Category	Amazon RDS event ID	Message	Notes
creation	RDS-EVENT-0244	Blue/green deployment tasks completed. You can make more modifications	None

Category	Amazon RDS event ID	Message	Notes
		to the green environment databases or switch over the deployment.	
failure	RDS-EVENT-0245	Creation of blue/green deployment failed because *reason*.	None
deletion	RDS-EVENT-0246	Blue/green deployment deleted.	None
notification	RDS-EVENT-0247	Switchover from *blue* to *green* started.	None
notification	RDS-EVENT-0248	Switchover completed on blue/green deployment.	None
failure	RDS-EVENT-0249	Switchover canceled on blue/green deployment.	None
notification	RDS-EVENT-0250	Switchover from primary/read replica *blue* to *green* started.	None
notification	RDS-EVENT-0251	Switchover from primary/read replica *blue* to *green* completed. Renamed *blue* to *blue-old* and *green* to *blue*.	None
failure	RDS-EVENT-0252	Switchover from primary/read replica *blue* to *green* was canceled due to *reason*.	None

Category	Amazon RDS event ID	Message	Notes
notification	RDS-EVENT-0307	Sequence sync for switchover of *blue* to *green* has initiated. Switchover when using sequences may lead to extended downtime.	None
notification	RDS-EVENT-0308	Sequence sync for switchover of *blue* to *green* has completed.	None
failure	RDS-EVENT-0310	Sequence sync for switchover of *blue* to *green* was cancelled because sequences failed to sync.	None
notification	RDS-EVENT-0405	Your storage volumes are being initialized.	None
notification	RDS-EVENT-0406	Your storage volumes have been initialized.	None
notification	RDS-EVENT-0409	*message*	None

Custom engine version events

The following table shows the event category and a list of events when a custom engine version is the source type.

Category	Amazon RDS event ID	Message	Notes
creation	RDS-EVENT-0316	Preparing to create custom engine version *name*. The	None

Category	Amazon RDS event ID	Message	Notes
		entire creation process may take up to four hours to complete.	
creation	RDS-EVENT-0317	Creating custom engine version *name*.	None
creation	RDS-EVENT-0318	Validating custom engine version *name*.	None
creation	RDS-EVENT-0319	Custom engine version *name* has been created successfully.	None
creation	RDS-EVENT-0320	RDS can't create custom engine version *name* because of an internal issue. We are addressin g the problem and will contact you if necessary . For further assistance, contact AWS Premium Support/.	None
failure	RDS-EVENT-0198	Creation failed for custom engine version *name*. *message*	The *message* includes details about the failure, such as missing files.
failure	RDS-EVENT-0277	Failure during deletion of custom engine version *name*. *message*	The *message* includes details about the failure.

Category	Amazon RDS event ID	Message	Notes
restoring	RDS-EVENT-0352	The maximum database count supported for point-in-time restore has changed.	The *message* includes details about the event.

Monitoring Amazon RDS log files

Every RDS database engine generates logs that you can access for auditing and troubleshooting. The type of logs depends on your database engine.

You can access database logs for DB instances using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can't view, watch, or download transaction logs.

Topics

- Viewing and listing database log files
- Downloading a database log file
- Watching a database log file
- Publishing database logs to Amazon CloudWatch Logs
- Reading log file contents using REST
- Amazon RDS for Db2 database log files
- MariaDB database log files
- Amazon RDS for Microsoft SQL Server database log files
- MySQL database log files
- Amazon RDS for Oracle database log files
- RDS for PostgreSQL database log files

Viewing and listing database log files

You can view database log files for your Amazon RDS DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

> **Note**
>
> If you can't view the list of log files for an existing RDS for Oracle DB instance, reboot the instance to view the list.

Console

To view a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. (Optional) Enter a search term to filter your results.
7. Choose the log that you want to view, and then choose **View**.

AWS CLI

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

Example

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

RDS API

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFiles` action.

Downloading a database log file

You can use the AWS Management Console, AWS CLI, or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.

4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the button next to the log that you want to download, and then choose **Download**.
7. Open the context (right-click) menu for the link provided, and then choose **Save Link As**. Enter the location where you want the log file to be saved, and then choose **Save**.

AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called *log/ERROR.4* and store it in a local file called *errorlog.txt*.

Example

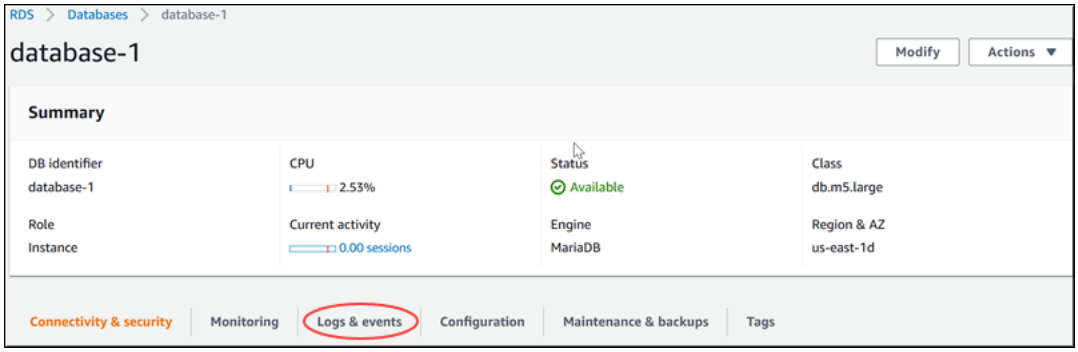
For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
    --db-instance-identifier myexampledb \
    --starting-token 0 --output text \
    --log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

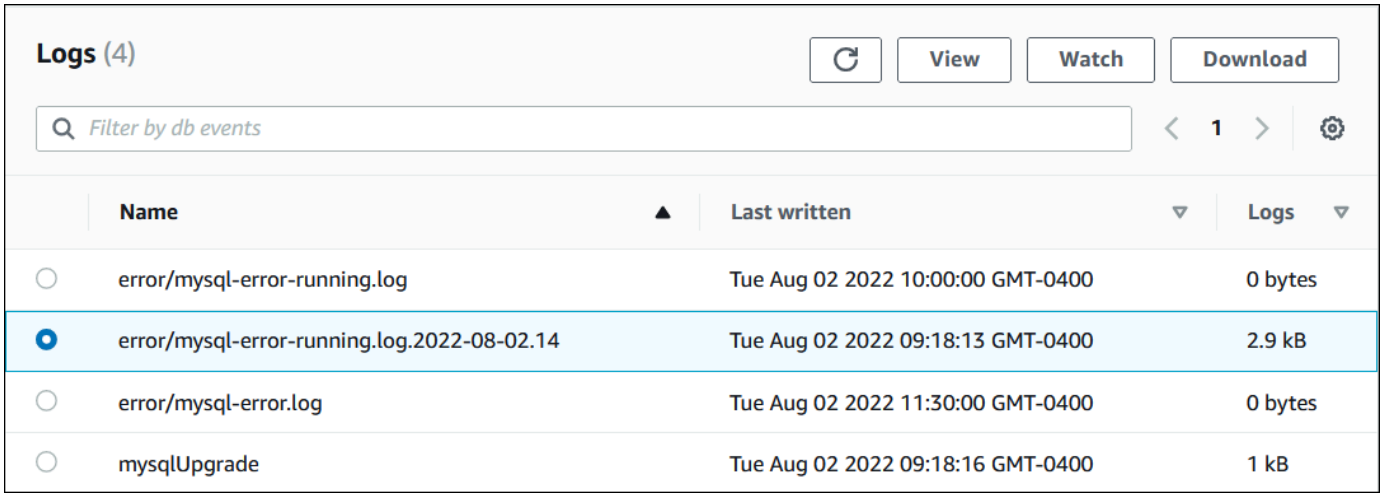
```
aws rds download-db-log-file-portion ^
    --db-instance-identifier myexampledb ^
    --starting-token 0 --output text ^
    --log-file-name log/ERROR.4 > errorlog.txt
```

RDS API



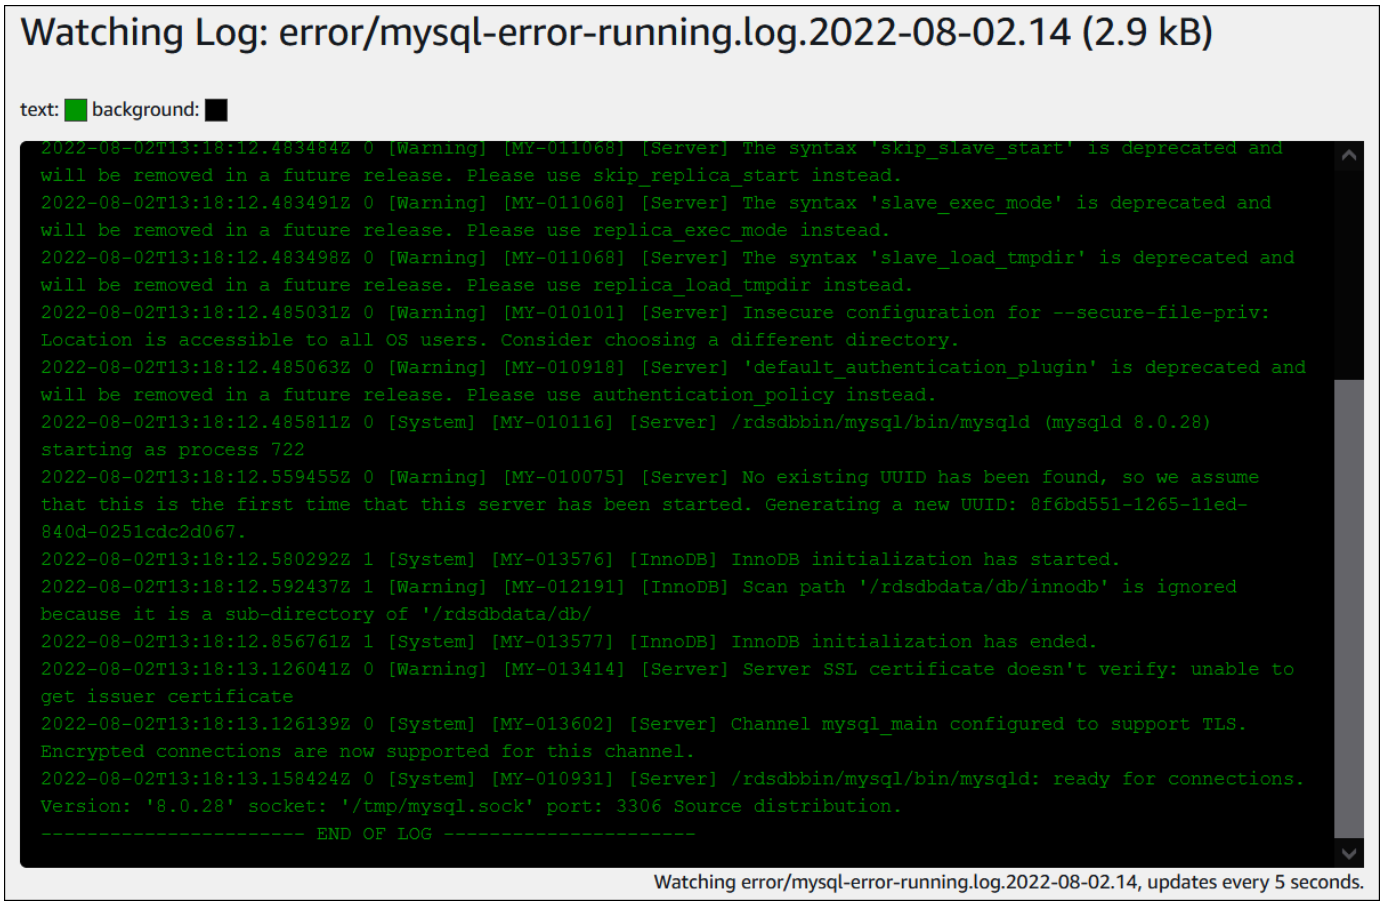
To download a database log file, use the Amazon RDS API `DownloadDBLogFilePortion` action.

Watching a database log file



Watching a database log file is equivalent to tailing the file on a UNIX or Linux system. You can watch a log file by using the AWS Management Console. RDS refreshes the tail of the log every 5 seconds.

To watch a database log file



1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.

5. In the **Logs** section, choose a log file, and then choose **Watch**.

RDS shows the tail of the log, as in the following MySQL example.

Publishing database logs to Amazon CloudWatch Logs

In an on-premises database, the database logs reside on the file system. Amazon RDS doesn't provide host access to the database logs on the file system of your DB instance. For this reason,

Amazon RDS lets you export database logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data. You can also store the data in highly durable storage and manage the data with the CloudWatch Logs Agent.

Topics

- Overview of RDS integration with CloudWatch Logs
- Deciding which logs to publish to CloudWatch Logs
- Specifying the logs to publish to CloudWatch Logs
- Searching and filtering your logs in CloudWatch Logs

Overview of RDS integration with CloudWatch Logs

In CloudWatch Logs, a *log stream* is a sequence of log events that share the same source. Each separate source of logs in CloudWatch Logs makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

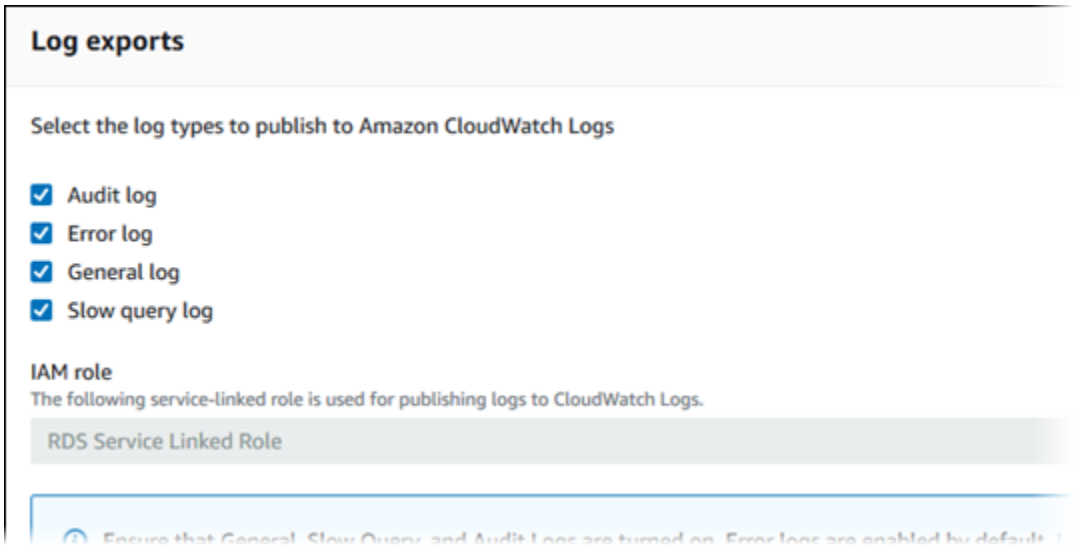
Amazon RDS continuously streams your DB instance log records to a log group. For example, you have a log group `/aws/rds/instance/`*`instance_name`*`/`*`log_type`* for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see Change log data retention in CloudWatch Logs.

Deciding which logs to publish to CloudWatch Logs

Each RDS database engine supports its own set of logs. To learn about the options for your database engine, review the following topics:

- the section called “Publishing Db2 logs to Amazon CloudWatch Logs”
- the section called “Publishing MariaDB logs to Amazon CloudWatch Logs”
- the section called “Publishing MySQL logs to Amazon CloudWatch Logs”
- the section called “Publishing Oracle logs to Amazon CloudWatch Logs”
- the section called “Publishing PostgreSQL logs to Amazon CloudWatch Logs”
- the section called “Publishing SQL Server logs to Amazon CloudWatch Logs”



Specifying the logs to publish to CloudWatch Logs

You specify which logs to publish in the console. Make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see Using service-linked roles for Amazon RDS.

To specify the logs to publish

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Do either of the following:
   - Choose **Create database**.
   - Choose a database from the list, and then choose **Modify**.
4. In **Logs exports**, choose which logs to publish.

   The following example specifies the audit log, error logs, general log, and slow query log for an RDS for MySQL DB instance.

Searching and filtering your logs in CloudWatch Logs

You can search for log entries that meet a specified criteria using the CloudWatch Logs console. You can access the logs either through the RDS console, which leads you to the CloudWatch Logs console, or from the CloudWatch Logs console directly.

To search your RDS logs using the RDS console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose a DB instance.
4. Choose **Configuration**.
5. Under **Published logs**, choose the database log that you want to view.

To search your RDS logs using the CloudWatch Logs console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Log groups**.
3. In the filter box, enter **`/aws/rds`**.
4. For **Log Groups**, choose the name of the log group containing the log stream to search.
5. For **Log Streams**, choose the name of the log stream to search.
6. Under **Log events**, enter the filter syntax to use.

For more information, see Searching and filtering log data in the *Amazon CloudWatch Logs User Guide*. For a blog tutorial explaining how to monitor RDS logs, see Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS.

Reading log file contents using REST

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- *`DBInstanceIdentifier`*—the name of the DB instance that contains the log file you want to download.

- *LogFileName*—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named *log/ERROR.6* for the DB instance named *sample-sql* in the *us-west-2* region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH//////////
wEa0AIXLhngC5zp9CyB1R6abwKrXHVR5efnAVN3XvR7IwqKYalFSn6UyJuEFTft9nObglx4QJ+GXV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d46ce7d4ec091d0cdabbcf8b40c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

- DBInstanceNotFound—*DBInstanceIdentifier* does not refer to an existing DB instance. (HTTP status code: 404)

Amazon RDS for Db2 database log files

You can access RDS for Db2 diagnostic logs and notify logs by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Topics

- Retention schedule
- Publishing Db2 logs to Amazon CloudWatch Logs

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for RDS for Db2 logs on Amazon RDS.

Log type	Retention schedule
Diagnostic logs	Db2 deletes logs outside of the retention settings in the instance-level configuration. Amazon RDS sets the `diagsize` parameter to 1000.
Notify logs	Db2 deletes logs outside of the retention settings in the instance-level configuration. Amazon RDS sets the `diagsize` parameter to 1000.

Publishing Db2 logs to Amazon CloudWatch Logs

With RDS for Db2, you can publish diagnostic and notify log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

- Store logs in highly durable storage space with a retention period that you define.
- Search and filter log data.
- Share log data between accounts.
- Export logs to Amazon S3.
- Stream data to Amazon OpenSearch Service.

- Process log data in real time with Amazon Kinesis Data Streams. For more information, see Working with Amazon CloudWatch Logs in the *Amazon Managed Service for Apache Flink for SQL Applications Developer Guide*.

Amazon RDS publishes each RDS for Db2 database log as a separate database stream in the log group. For example, if you publish the diagnostic logs and notify logs, diagnostic data is stored in a diagnostic log stream in the `/aws/rds/instance/my_instance/diagnostic` log group, and notify log data is stored in the `/aws/rds/instance/my_instance/notify` log group.

> **Note**
>
> Publishing RDS for Db2 logs to CloudWatch Logs isn't enabled by default. Publishing self-tuning memory manager (STMM) and optimizer statistics logs isn't supported. Publishing RDS for Db2 logs to CloudWatch Logs is supported in all Regions, except for Asia Pacific (Hong Kong).

Console

To publish RDS for Db2 logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

   You can choose **diag.log**, **notify.log**, or both.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish RDS for Db2 logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`

- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish RDS for Db2 logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an RDS for Db2 DB instance with CloudWatch Logs publishing enabled. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings that can include `diag.log`, `notify.log`, or both.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["diag.log","notify.log"]' \
    --db-instance-class db.m4.large \
    --engine db2-se
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports "[\"diag.log\",\"notify.log\"]" ^
    --db-instance-class db.m4.large ^
    --engine db2-se
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing RDS for Db2 DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings that can include `diag.log`, `notify.log`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["diag.log","notify.log"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"EnableLogTypes\":[\"diag.log\",
\"notify.log\"]}"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing RDS for Db2 DB instance to disable publishing diagnostic log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings that can include `diag.log`, `notify.log`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["diag.log"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"DisableLogTypes\":[\"diag.log\"]}"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

MariaDB database log files

You can monitor the MariaDB error log, slow query log, the IAM database authentication error log, and the general log. The MariaDB error log is generated by default; you can generate the slow query and general logs by setting parameters in your DB parameter group. Amazon RDS rotates all of the MariaDB log files; the intervals for each type are given following.

You can monitor the MariaDB logs directly through the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs. You can also access MariaDB logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Topics

- Accessing MariaDB error logs
- Accessing the MariaDB slow query and general logs
- Publishing MariaDB logs to Amazon CloudWatch Logs
- Log rotation and retention for MariaDB
- Managing table-based MariaDB logs
- Configuring MariaDB binary logging
- Accessing MariaDB binary logs
- Enabling MariaDB binary log annotation

Accessing MariaDB error logs

The MariaDB error log is written to the `<host-name>.err` file. You can view this file by using the Amazon RDS console, You can also retrieve the log using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs. The `<host-name>.err` file is flushed every 5 minutes, and its contents are appended to `mysql-error-running.log`. The `mysql-error-running.log` file is then rotated every hour and the hourly files generated during the last 24 hours are retained. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MariaDB writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that resulted in a log entry.

Accessing the MariaDB slow query and general logs

You can write the MariaDB slow query log and general log to a file or database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Parameter groups for Amazon RDS. You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, AWS CLI, or AWS SDKs.

You can control MariaDB logging by using the parameters in this list:

- `slow_query_log` or `log_slow_query`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time` or `log_slow_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` or `log_slow_query_time` value are logged. For example, setting `long_query_time` or `log_slow_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set this parameter to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the `long_query_time` parameter.
- `log_output` *`option`*: You can specify one of the following options for the `log_output` parameter:
  - **TABLE** (default)– Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
  - **FILE**– Write both general and slow query logs to the file system. Log files are rotated hourly.
  - **NONE**– Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. FILE and TABLE logging approach rotation and deletion as follows:

- When FILE logging is enabled, log files are examined every hour and log files older than 24 hours are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.
- When TABLE logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB.

  When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

  You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

  Table logs are rotated during a database version upgrade.

Amazon RDS records both TABLE and FILE log rotation in an Amazon RDS event and sends you a notification.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to FILE. Like the MariaDB error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained.

For more information about the slow query and general logs, go to the following topics in the MariaDB documentation:

- Slow query log
- General query log

Publishing MariaDB logs to Amazon CloudWatch Logs

You can configure your MariaDB DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MariaDB database log as a separate database stream in the log group. For example, suppose that you configure the export function to include the slow query log. Then slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MariaDB logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option.
General log	The DB instance must use a custom parameter group with the parameter setting `general_log = 1` to enable the general log.
Slow query log	The DB instance must use a custom parameter group with the parameter setting `slow_query_log = 1` or `log_slow_query = 1` to enable the slow query log.
IAM database authentication error log	You must enable the log type `iam-db-auth-error` for a DB instance by creating or modifying a DB instance.

Log	Requirement
Log output	The DB instance must use a custom parameter group with the parameter setting `log_output = FILE` to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MariaDB logs to CloudWatch Logs from the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish a MariaDB logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MariaDB logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MariaDB DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

Example

The following command creates a MariaDB DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' \
    --db-instance-class db.m4.large \
    --engine mariadb
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' ^
    --db-instance-class db.m4.large ^
    --engine mariadb
```

RDS API

You can publish MariaDB logs with the RDS API. You can call the `ModifyDBInstance` operation with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MariaDB logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

Log rotation and retention for MariaDB

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance.

The MariaDB slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour and log files older than 24 hours are removed. If the combined log file size exceeds the threshold after removing old log files, then the largest log files are deleted until the log file size no longer exceeds the threshold.

Amazon RDS rotates IAM database authentication error log files larger than 10 MB. Amazon RDS removes IAM database authentication error log files that are older than five days or larger than 100 MB.

Managing table-based MariaDB logs

You can direct the general and slow query logs to tables on the DB instance. To do so, create a DB parameter group and set the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. To enable logging to tables, you must also set the following server parameters to 1:

- `general_log`
- `slow_query_log` or `log_slow_query`

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to `0`. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Configuring MariaDB binary logging

The *binary log* is a set of log files that contain information about data modifications made to a MariaDB server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn't

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see Binary Log in the MariaDB documentation.

The automated backups feature determines whether binary logging is turned on or off for MariaDB. You have the following options:

Turn binary logging on

Set the backup retention period to a positive nonzero value.

Turn binary logging off

Set the backup retention period to zero.

For more information, see Enabling automated backups.

MariaDB on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. The default binary logging format is *mixed*. For details on the different MariaDB binary log formats, see Binary Log Formats in the MariaDB documentation.

If you plan to use replication, the binary logging format is important. This is because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and Disadvantages of Statement-Based and Row-Based Replication in the MySQL documentation.

Important

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance. They also can increase the amount of time to perform a restore operation of a DB instance.
Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see Unsafe Statements for Statement-based Replication in the MariaDB documentation.
Enabling binary logging increases the number of write disk I/O operations to the DB instance. You can monitor IOPS usage with the `WriteIOPS` CloudWatch metric.

To set the MariaDB binary logging format

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group that is used by the DB instance that you want to modify.

   You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

   For more information on DB parameter groups, see Parameter groups for Amazon RDS.

4. For **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**).

   You can turn off binary logging by setting the backup retention period of a DB instance to zero, but this disables daily automated backups. Disabling automated backups turns off or disables the `log_bin` session variable. This disables binary logging on the RDS for MariaDB DB instance, which in turn resets the `binlog_format` session variable to the default value of `ROW` in the database. We recommend that you don't disable backups. For more information about the **Backup retention period** setting, see Settings for DB instances.
6. Choose **Save changes** to save the updates to the DB parameter group.

Because the `binlog_format` parameter is dynamic in RDS for MariaDB, you don't need to reboot the DB instance for the changes to apply.

> **Important**
>
> Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MariaDB DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB parameter group to the each DB instance.

Accessing MariaDB binary logs

You can use the mysqlbinlog utility to download binary logs in text format from MariaDB DB instances. The binary log is downloaded to your local computer. For more information about using the mysqlbinlog utility, go to Using mysqlbinlog in the MariaDB documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MariaDB user that has been granted the replication slave permission.

- `--password`: Specify the password for the user, or omit a password value so the utility prompts you for a password.
- `--result-file`: Specify the local file that receives the output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command SHOW BINARY LOGS.

For more information about mysqlbinlog options, go to mysqlbinlog options in the MariaDB documentation.

The following is an example:

For Linux, macOS, or Unix:

```
mysqlbinlog \
    --read-from-remote-server \
    --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com \
    --port=3306  \
    --user ReplUser \
    --password <password> \
    --result-file=/tmp/binlog.txt
```

For Windows:

```
mysqlbinlog ^
    --read-from-remote-server ^
    --host=mariadbinstance1.1234abcd.region.rds.amazonaws.com ^
    --port=3306  ^
    --user ReplUser ^
    --password <password> ^
    --result-file=/tmp/binlog.txt
```

Amazon RDS normally purges a binary log as soon as possible. However, the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure. Specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```
call mysql.rds_show_configuration;
```

Enabling MariaDB binary log annotation

In a MariaDB DB instance, you can use the `Annotate_rows` event to annotate a row event with a copy of the SQL query that caused the row event. This approach provides similar functionality to enabling the `binlog_rows_query_log_events` parameter on an RDS for MySQL DB instance.

You can enable binary log annotations globally by creating a custom parameter group and setting the `binlog_annotate_row_events` parameter to **1**. You can also enable annotations at the session level, by calling `SET SESSION binlog_annotate_row_events = 1`. Use the `replicate_annotate_row_events` to replicate binary log annotations to the replica instance if binary logging is enabled on it. No special privileges are required to use these settings.

The following is an example of a row-based transaction in MariaDB. The use of row-based logging is triggered by setting the transaction isolation level to read-committed.

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
BEGIN
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
```

Without annotations, the binary log entries for the transaction look like the following:

```
BEGIN
/*!*/;
# at 1163
# at 1209
#150922  7:55:57 server id 1855786460  end_log_pos 1209         Table_map:
 `test`.`square` mapped to number 76
#150922  7:55:57 server id 1855786460  end_log_pos 1247         Write_rows: table id 76
 flags: STMT_END_F
### INSERT INTO `test`.`square`
```

```
### SET
###   @1=5
###   @2=25
# at 1247
#150922  7:56:01 server id 1855786460  end_log_pos 1274         Xid = 62
COMMIT/*!*/;
```

The following statement enables session-level annotations for this same transaction, and disables them after committing the transaction:

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
SET SESSION binlog_annotate_row_events = 1;
BEGIN;
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
SET SESSION binlog_annotate_row_events = 0;
```

With annotations, the binary log entries for the transaction look like the following:

```
BEGIN
/*!*/;
# at 423
# at 483
# at 529
#150922  8:04:24 server id 1855786460  end_log_pos 483  Annotate_rows:
#Q> INSERT INTO square(x, y) VALUES(5, 5 * 5)
#150922  8:04:24 server id 1855786460  end_log_pos 529  Table_map: `test`.`square`
 mapped to number 76
#150922  8:04:24 server id 1855786460  end_log_pos 567  Write_rows: table id 76 flags:
 STMT_END_F
### INSERT INTO `test`.`square`
### SET
###   @1=5
###   @2=25
# at 567
#150922  8:04:26 server id 1855786460  end_log_pos 594  Xid = 88
COMMIT/*!*/;
```

Amazon RDS for Microsoft SQL Server database log files

You can access Microsoft SQL Server error logs, agent logs, trace files, and dump files by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for Microsoft SQL Server logs on Amazon RDS.

Log type	Retention schedule
Error logs	A maximum of 30 error logs are retained. Amazon RDS might delete error logs older than 7 days.
Agent logs	A maximum of 10 agent logs are retained. Amazon RDS might delete agent logs older than 7 days.
Trace files	Trace files are retained according to the trace file retention period of your DB instance. The default trace file retention period is 7 days. To modify the trace file retention period for your DB instance, see Setting the retention period for trace and dump files.
Dump files	Dump files are retained according to the dump file retention period of your DB instance. The default dump file retention period is 7 days. To modify the dump file retention period for your DB instance, see Setting the retention period for trace and dump files.

Viewing the SQL Server error log by using the rds_read_error_log procedure

You can use the Amazon RDS stored procedure `rds_read_error_log` to view error logs and agent logs. For more information, see Viewing error and agent logs.

Publishing SQL Server logs to Amazon CloudWatch Logs

With Amazon RDS for SQL Server, you can publish error and agent log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

- Store logs in highly durable storage space with a retention period that you define.
- Search and filter log data.
- Share log data between accounts.
- Export logs to Amazon S3.
- Stream data to Amazon OpenSearch Service.
- Process log data in real time with Amazon Kinesis Data Streams. For more information, see Working with Amazon CloudWatch Logs in the *Amazon Managed Service for Apache Flink for SQL Applications Developer Guide*.

Amazon RDS publishes each SQL Server database log as a separate database stream in the log group. For example, if you publish the agent logs and error logs, error data is stored in an error log stream in the `/aws/rds/instance/my_instance.node1/error` log group, and agent log data is stored in the `/aws/rds/instance/my_instance.node1/agent` log group.

For Multi-AZ DB instances, Amazon RDS publishes the database log as two separate streams in the log group. For example, if you publish the error logs, the error data is stored in the error log streams `/aws/rds/instance/my_instance.node1/error` and `/aws/rds/instance/my_instance.node2/error` respectively. The log streams don't change during a failover and the error log stream of each node can contain error logs from primary or secondary instance. With Multi-AZ, a log stream is automatically created for `/aws/rds/instance/my_instance/rds-events` to store event data such as DB instance failovers.

> **Note**
>
> Publishing SQL Server logs to CloudWatch Logs isn't enabled by default. Publishing trace and dump files isn't supported. Publishing SQL Server logs to CloudWatch Logs is supported in all regions.

Console

To publish SQL Server DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

   You can choose **Agent log**, **Error log**, or both.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish SQL Server logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish SQL Server logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an SQL Server DB instance with CloudWatch Logs publishing enabled. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["error","agent"]' \
    --db-instance-class db.m4.large \
    --engine sqlserver-se
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports "[\"error\",\"agent\"]" ^
    --db-instance-class db.m4.large ^
    --engine sqlserver-se
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":["error","agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"EnableLogTypes\":[\"error\",\"agent\"]}"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to disable publishing agent log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration "{\"DisableLogTypes\":[\"agent\"]}"
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

MySQL database log files

You can monitor the MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

Overview of RDS for MySQL database logs

You can monitor the following types of RDS for MySQL log files:

- Error log
- Slow query log
- General log
- Audit log
- Instance log
- IAM database authentication error log

The RDS for MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics

- RDS for MySQL error logs

- RDS for MySQL slow query and general logs
- MySQL audit log
- Log rotation and retention for RDS for MySQL
- Size limits on redo logs

RDS for MySQL error logs

RDS for MySQL writes errors in the `mysql-error.log` file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

RDS for MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry.

By design, the error logs are filtered so that only unexpected events such as errors are shown. However, the error logs also contain some additional database information, for example query progress, which isn't shown. Therefore, even without any actual errors the size of the error logs might increase because of ongoing database activities. And while you might see a certain size in bytes or kilobytes for the error logs in the AWS Management Console, they might have 0 bytes when you download them.

RDS for MySQL writes `mysql-error.log` to disk every 5 minutes. It appends the contents of the log to `mysql-error-running.log`.

RDS for MySQL rotates the `mysql-error-running.log` file every hour. It retains the logs generated during the last two weeks.

> **Note**
>
> The log retention period is different between Amazon RDS and Aurora.

RDS for MySQL slow query and general logs

You can write the RDS for MySQL slow query log and the general log to a file or a database table. To do so, set parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Parameter groups for Amazon RDS. You must set these

parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control RDS for MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query runtime to be logged, in seconds. The default is 10 seconds; the minimum is 0. If log_output = FILE, you can specify a floating point value that goes to microsecond resolution. If log_output = TABLE, you must specify an integer value with second resolution. Only queries whose runtime exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. Queries that don't use an index are logged even if their runtime is less than the value of the `long_query_time` parameter. The default is 0.
- `log_output` *`option`*: You can specify one of the following options for the `log_output` parameter.
  - **TABLE** (default) – Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
  - **FILE** – Write both general and slow query logs to the file system.
  - **NONE** – Disable logging.

For slow query data to appear in Amazon CloudWatch Logs, the following conditions must be met:

- CloudWatch Logs must be configured to include slow query logs.
- `slow_query_log` must be enabled.
- `log_output` must be set to `FILE`.
- The query must take longer than the time configured for `long_query_time`.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- The slow query log

- The general query log

MySQL audit log

To access the audit log, the DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option. For more information, see MariaDB Audit Plugin support for MySQL.

Log rotation and retention for RDS for MySQL

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. RDS for MySQL handles rotation and deletion as follows:

- The MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. MySQL removes log files more than two weeks old. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When `FILE` logging is enabled, log files are examined every hour and log files more than two weeks old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When `TABLE` logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space. It also occurs if the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space. They're also rotated if the size of all logs combined is greater than 5 GB. You can subscribe to the `low storage` event category to be notified when log tables are rotated to free up space. For more information, see Working with Amazon RDS event notification.

  When log tables are rotated, the current log table is first copied to a backup log table. Then the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named

`mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to FILE. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous two weeks are retained. Note that the retention period is different between Amazon RDS and Aurora.

Size limits on redo logs

For RDS for MySQL version 8.0.32 and lower, the default value of this parameter is 256 MB. This amount is derived by multiplying the default value of the `innodb_log_file_size` parameter (128 MB) by the default value of the `innodb_log_files_in_group` parameter (2). For more information, see Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance.

For RDS for MySQL version 8.0.33 and higher minor versions, Amazon RDS uses the `innodb_redo_log_capacity` parameter instead of the `innodb_log_file_size` parameter. The Amazon RDS default value of the `innodb_redo_log_capacity` parameter is 2 GB. For more information, see Changes in MySQL 8.0.30 in the MySQL documentation.

Starting with MySQL 8.4, Amazon RDS enables the `innodb_dedicated_server` parameter by default. With the `innodb_dedicated_server` parameter, the database engine calculates the `innodb_buffer_pool_size` and `innodb_redo_log_capacity` parameters. For more information, see Configuring buffer pool size and redo log capacity in MySQL 8.4.

Publishing MySQL logs to Amazon CloudWatch Logs

You can configure your MySQL DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MySQL database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MySQL logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option.
General log	The DB instance must use a custom parameter group with the parameter setting `general_log = 1` to enable the general log.
Slow query log	The DB instance must use a custom parameter group with the parameter setting `slow_query_log = 1` to enable the slow query log.
IAM database authentication error log	You must enable the log type `iam-db-auth-error` for a DB instance by creating or modifying a DB instance.
Log output	The DB instance must use a custom parameter group with the parameter setting `log_output = FILE` to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MySQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.

3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish MySQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MySQL logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["audit","error","general","slowquery"]}'
```

Example

The following example creates a MySQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' \
    --db-instance-class db.m4.large \
    --engine MySQL
```

For Windows:

```
aws rds create-db-instance ^
```

```
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["audit","error","general","slowquery"]' ^
    --db-instance-class db.m4.large ^
    --engine MySQL
```

RDS API

You can publish MySQL logs with the RDS API. You can call the ModifyDBInstance action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MySQL logs by calling the following RDS API operations:

- CreateDBInstance
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

Sending MySQL log output to tables

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to `1`.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to `0`. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Configuring RDS for MySQL binary logging for Single-AZ databases

The *binary log* is a set of log files that contain information about data modifications made to an MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn't

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see The Binary Log in the MySQL documentation.

The automated backups feature determines whether binary logging is turned on or off for MySQL. You have the following options:

Turn binary logging on

Set the backup retention period to a positive nonzero value.

Turn binary logging off

Set the backup retention period to zero.

For more information, see Enabling automated backups.

MySQL on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. We recommend mixed unless you need a specific binlog format. For details on the different MySQL binary log formats, see Binary Logging Formats in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and Disadvantages of Statement-Based and Row-Based Replication in the MySQL documentation.

Important

With MySQL 8.0.34, MySQL deprecated the `binlog_format` parameter. In later MySQL versions, MySQL plans to remove the parameter and only support row-based replication. As a result, we recommend using row-based logging for new MySQL replication setups. For more information, see binlog_format in the MySQL documentation.
MySQL versions 8.0 and 8.4 accept the parameter `binlog_format`. When using this parameter, MySQL issues a deprecation warning. In a future major release, MySQL will remove the parameter `binlog_format`.
Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see Determination of Safe and Unsafe Statements in Binary Logging in the MySQL documentation.
Enabling binary logging increases the number of write disk I/O operations to the DB instance. You can monitor IOPS usage with the `WriteIOPS` CloudWatch metric.

To set the MySQL binary logging format

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Parameter groups**.
3. Choose the DB parameter group, associated with the DB instance, that you want to modify.

   You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

   For more information on parameter groups, see Parameter groups for Amazon RDS.
4. From **Actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (`ROW`, `STATEMENT`, or `MIXED`).

   You can turn off binary logging by setting the backup retention period of a DB instance to zero, but this disables daily automated backups. Disabling automated backups turns off or disables the `log_bin` session variable. This disables binary logging on the RDS for MySQL DB instance, which in turn resets the `binlog_format` session variable to the default value of `ROW` in the database. We recommend that you don't disable backups. For more information about the **Backup retention period** setting, see Settings for DB instances.
6. Choose **Save changes** to save the updates to the DB parameter group.

Because the `binlog_format` parameter is dynamic in RDS for MySQL, you don't need to reboot the DB instance for the changes to apply. (Note that in Aurora MySQL, this parameter is static. For more information, see Configuring Aurora MySQL binary logging.)

> **Important**
>
> Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MySQL DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB parameter group to the each DB instance.

Configuring MySQL binary logging for Multi-AZ DB clusters

Binary logging in Amazon RDS for MySQL Multi-AZ DB clusters records all database changes to support replication, point-in-time recovery, and auditing. In Multi-AZ DB clusters, binary logs

synchronize secondary nodes with the primary node, ensuring data consistency across Availability Zones and enabling seamless failovers.

To optimize binary logging, Amazon RDS supports binary log transaction compression, which reduces the storage requirements for binary logs and improves replication efficiency.

Topics

- Binary log transaction compression for Multi-AZ DB clusters
- Configuring binary log transaction compression for Multi-AZ DB clusters

Binary log transaction compression for Multi-AZ DB clusters

Binary log transaction compression uses the zstd algorithm to reduce the size of transaction data stored in binary logs. When enabled, the MySQL database engine compresses transaction payloads into a single event, minimizing I/O and storage overhead. This feature improves database performance, reduces binary log size, and optimizes resource use for managing and replicating logs in Multi-AZ DB clusters.

Amazon RDS provides binary log transaction compression for RDS for MySQL Multi-AZ DB clusters through the following parameters:

- `binlog_transaction_compression` – When enabled (1), the database engine compresses transaction payloads and writes them to the binary log as a single event. This reduces storage usage and I/O overhead. The parameter is disabled by default.
- `binlog_transaction_compression_level_zstd` – Configures the zstd compression level for binary log transactions. Higher values increase the compression ratio, reducing storage requirements further but increasing CPU and memory usage for compression. The default value is 3, with a range of 1-22.

These parameters let you fine-tune binary log compression based on workload characteristics and resource availability. For more information, see Binary Log Transaction Compression in the MySQL documentation.

Binary log transaction compression has the following main benefits:

- Compression decreases the size of binary logs, particularly for workloads with large transactions or high write volumes.
- Smaller binary logs reduce network and I/O overhead, enhancing replication performance.

- The `binlog_transaction_compression_level_zstd` parameter provides control over the trade-off between compression ratio and resource consumption.

Configuring binary log transaction compression for Multi-AZ DB clusters

To configure binary log transaction compression for an RDS for MySQL Multi-AZ DB cluster, modify the relevant cluster parameter settings to match your workload requirements.

Console

To enable binary log transaction compression

1. Modify the DB cluster parameter group to set the `binlog_transaction_compression` parameter to 1.
2. (Optional) Adjust the value of the `binlog_transaction_compression_level_zstd` parameter based on your workload requirements and resource availability.

For more information, see the section called “Modifying parameters in a DB cluster parameter group”.

AWS CLI

To configure binary log transaction compression using the AWS CLI, use the modify-db-cluster-parameter-group command.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name your-cluster-parameter-group \
  --parameters
 "ParameterName=binlog_transaction_compression,ParameterValue=1,ApplyMethod=pending-
reboot"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name your-cluster-parameter-group ^
```

```
  --parameters
 "ParameterName=binlog_transaction_compression,ParameterValue=1,ApplyMethod=pending-
reboot"
```

RDS API

To configure binary log transaction compression using the Amazon RDS API, use the `ModifyDBClusterParameterGroup` operation.

Accessing MySQL binary logs

You can use the mysqlbinlog utility to download or stream binary logs from RDS for MySQL DB instances. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the mysql utility. For more information about using the mysqlbinlog utility, see Using mysqlbinlog to back up binary log files in the MySQL documentation.

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- `--read-from-remote-server` – Required.
- `--host` – The DNS name from the endpoint of the instance.
- `--port` – The port used by the instance.
- `--user` – A MySQL user that has been granted the `REPLICATION SLAVE` permission.
- `--password` – The password for the MySQL user, or omit a password value so that the utility prompts you for a password.
- `--raw` – Download the file in binary format.
- `--result-file` – The local file to receive the raw output.
- `--stop-never` – Stream the binary log files.
- `--verbose` – When you use the `ROW` binlog format, include this option to see the row events as pseudo-SQL statements. For more information on the `--verbose` option, see mysqlbinlog row event display in the MySQL documentation.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.

For more information about mysqlbinlog options, see mysqlbinlog — Utility for processing binary log files in the MySQL documentation.

The following examples show how to use the mysqlbinlog utility.

For Linux, macOS, or Unix:

```
mysqlbinlog \
    --read-from-remote-server \
    --host=MySQLInstance1.cg034hpkmmjt.region.rds.amazonaws.com \
    --port=3306  \
    --user ReplUser \
    --password \
    --raw \
    --verbose \
    --result-file=/tmp/ \
    binlog.00098
```

For Windows:

```
mysqlbinlog ^
    --read-from-remote-server ^
    --host=MySQLInstance1.cg034hpkmmjt.region.rds.amazonaws.com ^
    --port=3306  ^
    --user ReplUser ^
    --password ^
    --raw ^
    --verbose ^
    --result-file=/tmp/ ^
    binlog.00098
```

Binary logs must remain available on the DB instance for the mysqlbinlog utility to access them. To ensure their availability, use the mysql.rds_set_configuration stored procedure and specify a period with enough time for you to download the logs. If this configuration isn't set, Amazon RDS purges the binary logs as soon as possible, leading to gaps in the binary logs that the mysqlbinlog utility retrieves.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the mysql.rds_show_configuration stored procedure.

```
call mysql.rds_show_configuration;
```

Amazon RDS for Oracle database log files

You can access Oracle alert logs, audit files, and trace files by using the Amazon RDS console or API. For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon RDS log files.

The Oracle audit files provided are the standard Oracle auditing files. Amazon RDS supports the Oracle fine-grained auditing (FGA) feature. However, log access doesn't provide access to FGA events that are stored in the `SYS.FGA_LOG$` table and that are accessible through the `DBA_FGA_AUDIT_TRAIL` view.

The `DescribeDBLogFiles` API operation that lists the Oracle log files that are available for a DB instance ignores the `MaxRecords` parameter and returns up to 1,000 records. The call returns `LastWritten` as a POSIX date in milliseconds.

Topics

- Retention schedule
- Working with Oracle trace files
- Publishing Oracle logs to Amazon CloudWatch Logs
- Accessing alert logs and listener logs

Retention schedule

The Oracle database engine might rotate log files if they get very large. To retain audit or trace files, download them. If you store the files locally, you reduce your Amazon RDS storage costs and make more space available for your data.

The following table shows the retention schedule for Oracle alert logs, audit files, and trace files on Amazon RDS.

Log type	Retention schedule
Alert logs	The text alert log is rotated daily with 30-day retention managed by Amazon RDS. The XML alert log is retained for at least seven days. You can access this log by using the `ALERTLOG` view.
Audit files	The default retention period for audit files is seven days. Amazon RDS might delete audit files older than seven days.

Log type	Retention schedule
Trace files	The default retention period for trace files is seven days. Amazon RDS might delete trace files older than seven days.
Listener logs	The default retention period for the listener logs is seven days. Amazon RDS might delete listener logs older than seven days.

> **Note**
>
> Audit files and trace files share the same retention configuration.

Working with Oracle trace files

Following, you can find descriptions of Amazon RDS procedures to create, refresh, access, and delete trace files.

Topics

- Listing files
- Generating trace files and tracing a session
- Retrieving trace files
- Purging trace files

Listing files

You can use either of two procedures to allow access to any file in the `background_dump_dest` path. The first procedure refreshes a view containing a listing of all files currently in `background_dump_dest`.

```
EXEC rdsadmin.manage_tracefiles.refresh_tracefile_listing;
```

After the view is refreshed, query the following view to access the results.

```
SELECT * FROM rdsadmin.tracefile_listing;
```

An alternative to the previous process is to use `FROM table` to stream nonrelational data in a table-like format to list database directory contents.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('BDUMP'));
```

The following query shows the text of a log file.

```
SELECT text FROM
 TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','alert_dbname.log.date'));
```

On a read replica, get the name of the BDUMP directory by querying `V$DATABASE.DB_UNIQUE_NAME`. If the unique name is `DATABASE_B`, then the BDUMP directory is `BDUMP_B`. The following example queries the BDUMP name on a replica and then uses this name to query the contents of `alert_DATABASE.log.2020-06-23`.

```
SELECT 'BDUMP' || (SELECT regexp_replace(DB_UNIQUE_NAME,'.*(_[A-Z])', '\1') FROM V
$DATABASE) AS BDUMP_VARIABLE FROM DUAL;

BDUMP_VARIABLE
--------------
BDUMP_B

SELECT TEXT FROM
 table(rdsadmin.rds_file_util.read_text_file('BDUMP_B','alert_DATABASE.log.2020-06-23'));
```

Generating trace files and tracing a session

Because there are no restrictions on `ALTER SESSION`, many standard methods to generate trace files in Oracle remain available to an Amazon RDS DB instance. The following procedures are provided for trace files that require greater access.

Oracle method	Amazon RDS method
`oradebug hanganalyze 3`	`EXEC rdsadmin.manage_tracefiles.hanganalyze;`
`oradebug dump systemstate 266`	`EXEC rdsadmin.manage_tracefiles.dump_systemstate;`

You can use many standard methods to trace individual sessions connected to an Oracle DB instance in Amazon RDS. To enable tracing for a session, you can run subprograms in PL/SQL packages supplied by Oracle, such as `DBMS_SESSION` and `DBMS_MONITOR`. For more information, see Enabling tracing for a session in the Oracle documentation.

Retrieving trace files

You can retrieve any trace file in `background_dump_dest` using a standard SQL query on an Amazon RDS–managed external table. To use this method, you must execute the procedure to set the location for this table to the specific trace file.

For example, you can use the `rdsadmin.tracefile_listing` view mentioned preceding to list all of the trace files on the system. You can then set the `tracefile_table` view to point to the intended trace file using the following procedure.

```
EXEC
 rdsadmin.manage_tracefiles.set_tracefile_table_location('CUST01_ora_3260_SYSTEMSTATE.trc');
```

The following example creates an external table in the current schema with the location set to the file provided. You can retrieve the contents into a local file using a SQL query.

```
SPOOL /tmp/tracefile.txt
SELECT * FROM tracefile_table;
SPOOL OFF;
```

Purging trace files

Trace files can accumulate and consume disk space. Amazon RDS purges trace files by default and log files that are older than seven days. You can view and set the trace file retention period using the `show_configuration` procedure. You should run the command `SET SERVEROUTPUT ON` so that you can view the configuration results.

The following example shows the current trace file retention period, and then sets a new trace file retention period.

```
# Show the current tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:10080
```

```
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
 bdump are automatically deleted.

# Set the tracefile retention to 24 hours:
SQL> EXEC rdsadmin.rdsadmin_util.set_configuration('tracefile retention',1440);
SQL> commit;

#show the new tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:1440
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
 bdump are automatically deleted.
```

In addition to the periodic purge process, you can manually remove files from the `background_dump_dest`. The following example shows how to purge all files older than five minutes.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles(5);
```

You can also purge all files that match a specific pattern (if you do, don't include the file extension, such as .trc). The following example shows how to purge all files that start with `SCHPOC1_ora_5935`.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles('SCHPOC1_ora_5935');
```

Publishing Oracle logs to Amazon CloudWatch Logs

You can configure your RDS for Oracle DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can analyze the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each Oracle database log as a separate database stream in the log group. For example, if you configure the export function to include the audit log, audit data is stored in an audit log stream in the `/aws/rds/instance/my_instance/audit` log group. The following table summarizes the requirements for RDS for Oracle to publish logs to Amazon CloudWatch Logs.

Log name	Requirement	Default
Alert log	None. You can't disable this log.	Enabled
Trace log	Set the `trace_enabled` parameter to TRUE or leave it set at the default.	TRUE
Audit log	Set the `audit_trail` parameter to any of the following allowed values: `{ none | os | db [, extended] | xml [, extended] }`	none
Listener log	None. You can't disable this log.	Enabled
Oracle Management Agent log	None. You can't disable this log.	Enabled

This Oracle Management Agent log consists of the log groups shown in the following table.

Log name	CloudWatch log group
emctl.log	oemagent-emctl
emdctlj.log	oemagent-emdctlj
gcagent.log	oemagent-gcagent
gcagent_errors.log	oemagent-gcagent-errors
emagent.nohup	oemagent-emagent-nohup
secure.log	oemagent-secure

For more information, see Locating Management Agent Log and Trace Files in the Oracle documentation.

Console

To publish Oracle DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish Oracle logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish Oracle logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an Oracle DB instance with CloudWatch Logs publishing enabled. The `--cloudwatch-logs-export-configuration` value is a JSON array of strings. The strings can be any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration
 '["trace","audit","alert","listener","oemagent"]' \
    --db-instance-class db.m5.large \
    --allocated-storage 20 \
    --engine oracle-ee \
    --engine-version 19.0.0.0.ru-2024-04.rur-2024-04.r1 \
    --license-model bring-your-own-license \
    --master-username myadmin \
    --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration trace alert audit listener oemagent ^
    --db-instance-class db.m5.large ^
    --allocated-storage 20 ^
    --engine oracle-ee ^
    --engine-version 19.0.0.0.ru-2024-04.rur-2024-04.r1 ^
    --license-model bring-your-own-license ^
    --master-username myadmin ^
    --manage-master-user-password
```

Example

The following example modifies an existing Oracle DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["trace","alert","audit","listener","oemagent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration EnableLogTypes=\"trace\",\"alert\",\"audit
\",\"listener\",\"oemagent\"
```

Example

The following example modifies an existing Oracle DB instance to disable publishing audit and listener log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings with any combination of `alert`, `audit`, `listener`, and `trace`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["audit","listener"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration DisableLogTypes=\"audit\",\"listener\"
```

RDS API

You can publish Oracle DB logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish Oracle logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the RDS operation that you run.

Accessing alert logs and listener logs

You can view the alert log using the Amazon RDS console. You can also use the following SQL statement.

```
SELECT message_text FROM alertlog;
```

Access the listener log using Amazon CloudWatch Logs.

> **Note**
>
> Oracle rotates the alert and listener logs when they exceed 10 MB, at which point they are unavailable from Amazon RDS views.

RDS for PostgreSQL database log files

You can monitor the following types of log files:

- PostgreSQL log
- Upgrade log
- IAM database authentication error log

> **Note**
>
> To enable IAM database authentication error logs, you must first enable IAM database authentication for your RDS for PostgreSQL DB instance. For more information about enabling IAM database authentication, see Enabling and disabling IAM database authentication.

RDS for PostgreSQL logs database activities to the default PostgreSQL log file. For an on-premises PostgreSQL DB instance, these messages are stored locally in `log/postgresql.log`. For an RDS for PostgreSQL DB instance, the log file is available on the Amazon RDS instance. These logs are also accessible via the AWS Management Console, where you can view or download them. The default logging level captures login failures, fatal server errors, deadlocks, and query failures.

For more information about how you can view, download, and watch file-based database logs, see Monitoring Amazon RDS log files. To learn more about PostgreSQL logs, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1 and Working with Amazon RDS and Aurora PostgreSQL logs: Part 2.

In addition to the standard PostgreSQL logs discussed in this topic, RDS for PostgreSQL also supports the PostgreSQL Audit extension (`pgAudit`). Most regulated industries and government agencies need to maintain an audit log or audit trail of changes made to data to comply with legal requirements. For information about installing and using pgAudit, see Using pgAudit to log database activity.

Topics

- Parameters for logging in RDS for PostgreSQL
- Turning on query logging for your RDS for PostgreSQL DB instance
- Publishing PostgreSQL logs to Amazon CloudWatch Logs

Parameters for logging in RDS for PostgreSQL

You can customize the logging behavior for your RDS for PostgreSQL DB instance by modifying various parameters. In the following table you can find the parameters that affect how long the logs are stored, when to rotate the log, and whether to output the log as a CSV (comma-separated value) format. You can also find the text output sent to STDERR, among other settings. To change settings for the parameters that are modifiable, use a custom DB parameter group for your RDS for PostgreSQL instance. For more information, see DB parameter groups for Amazon RDS DB instances.

Parameter	Default	Description
log_destination	stderr	Sets the output format for the log. The default is `stderr` but you can also specify comma-separated value (CSV) by adding `csvlog` to the setting. For more information, see Setting the log destination (`stderr`, `csvlog`).
log_filename	postgresql.log.%Y-%m-%d-%H	Specifies the pattern for the log file name. In addition to the default, this parameter supports `postgresql.log.%Y-%m-%d` and `postgresql.log.%Y-%m-%d-%H%M` for the filename pattern.
log_line_prefix	%t:%r:%u@%d:[%p]:	Defines the prefix for each log line that gets written to `stderr`, to note the time (%t), remote host (%r), user (%u), database (%d), and process ID (%p).
log_rotation_age	60	Minutes after which log file is automatically rotated. You can change this value within the range of 1 and 1440 minutes. For more infor mation, see Setting log file rotation.
log_rotation_size	–	The size (kB) at which the log is automatic ally rotated. By default, this parameter isn't used because logs are rotated based on the

Parameter	Default	Description
		`log_rotation_age` parameter. To learn more, see Setting log file rotation.
rds.log_retention_period	4320	PostgreSQL logs that are older than the specified number of minutes are deleted. The default value of 4320 minutes deletes log files after 3 days. For more information, see Setting the log retention period.

To identify application issues, you can look for query failures, login failures, deadlocks, and fatal server errors in the log. For example, suppose that you converted a legacy application from Oracle to Amazon RDS PostgreSQL, but not all queries converted correctly. These incorrectly formatted queries generate error messages that you can find in the logs to help identify problems. For more information about logging queries, see Turning on query logging for your RDS for PostgreSQL DB instance.

In the following topics, you can find information about how to set various parameters that control the basic details for your PostgreSQL logs.

Topics

- Setting the log retention period
- Setting log file rotation
- Setting the log destination (stderr, csvlog)
- Understanding the log_line_prefix parameter

Setting the log retention period

The `rds.log_retention_period` parameter specifies how long your RDS for PostgreSQL DB instance keeps its log files. The default setting is 3 days (4,320 minutes), but you can set this value to anywhere from 1 day (1,440 minutes) to 7 days (10,080 minutes). Be sure that your RDS for PostgreSQL DB instance has sufficient storage to hold the log files for the period of time.

We recommend that you have your logs routinely published to Amazon CloudWatch Logs so that you can view and analyze system data long after the logs have been removed from your RDS

for PostgreSQL DB instance. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs.

Setting log file rotation

Amazon RDS creates new log files every hour by default. The timing is controlled by the `log_rotation_age` parameter. This parameter has a default value of 60 (minutes), but you can set it to anywhere from 1 minute to 24 hours (1,440 minutes). When it's time for rotation, a new distinct log file is created. The file is named according to the pattern specified by the `log_filename` parameter.

Log files can also be rotated according to their size, as specified in the `log_rotation_size` parameter. This parameter specifies that the log should be rotated when it reaches the specified size (in kilobytes). For an RDS for PostgreSQL DB instance, `log_rotation_size` is unset, that is, there is no value specified. However, you can set the parameter from 0-2097151 kB (kilobytes).

The log file names are based on the file name pattern specified in the `log_filename` parameter. The available settings for this parameter are as follows:

- `postgresql.log.%Y-%m-%d` – Default format for the log file name. Includes the year, month, and date in the name of the log file.
- `postgresql.log.%Y-%m-%d-%H` – Includes the hour in the log file name format.

For more information, see `log_rotation_age` and `log_rotation_size` in the PostgreSQL documentation.

Setting the log destination (`stderr`, `csvlog`)

By default, Amazon RDS PostgreSQL generates logs in standard error (stderr) format. This format is the default setting for the `log_destination` parameter. Each message is prefixed using the pattern specified in the `log_line_prefix` parameter. For more information, see Understanding the log_line_prefix parameter.

RDS for PostgreSQL can also generate the logs in `csvlog` format. The `csvlog` is useful for analyzing the log data as comma-separated values (CSV) data. For example, suppose that you use the `log_fdw` extension to work with your logs as foreign tables. The foreign table created on `stderr` log files contains a single column with log event data. By adding `csvlog` to the `log_destination` parameter, you get the log file in the CSV format with demarcations for the multiple columns of the foreign table. You can now sort and analyze your logs more easily. To learn

how to use the `log_fdw` with `csvlog`, see Using the log_fdw extension to access the DB log using SQL.

If you specify `csvlog` for this parameter, be aware that both `stderr` and `csvlog` files are generated. Be sure to monitor the storage consumed by the logs, taking into account the `rds.log_retention_period` and other settings that affect log storage and turnover. Using `stderr` and `csvlog` more than doubles the storage consumed by the logs.

If you add `csvlog` to `log_destination` and you want to revert to the `stderr` alone, you need to reset the parameter. To do so, open the Amazon RDS Console and then open the custom DB parameter group for your instance. Choose the `log_destination` parameter, choose **Edit parameter**, and then choose **Reset**.

For more information about configuring logging, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1.

Understanding the log_line_prefix parameter

The `stderr` log format prefixes each log message with the details specified by the `log_line_prefix` parameter. The default value is:

```
%t:%r:%u@%d:[%p]:t
```

Starting from Aurora PostgreSQL version 16, you can also choose:

```
%m:%r:%u@%d:[%p]:%l:%e:%s:%v:%x:%c:%q%a
```

Each log entry sent to stderr includes the following information based on the selected value:

- `%t` – Time of log entry without milliseconds
- `%m` – Time of log entry with milliseconds
- `%r` – Remote host address
- `%u@%d` – User name @ database name
- `[%p]` – Process ID if available
- `%l` – Log line number per session
- `%e` – SQL error code
- `%s` – Process start timestamp

- %v – Virtual transaction id
- %x – Transaction ID
- %c – Session ID
- %q – Non-session terminator
- %a – Application name

Turning on query logging for your RDS for PostgreSQL DB instance

You can collect more detailed information about your database activities, including queries, queries waiting for locks, checkpoints, and many other details by setting some of the parameters listed in the following table. This topic focuses on logging queries.

Parameter	Default	Description
log_connections	–	Logs each successful connection.
log_disconnections	–	Logs the end of each session and its duration.
log_checkpoints	1	Logs each checkpoint.
log_lock_waits	–	Logs long lock waits. By default, this parameter isn't set.
log_min_duration_sample	–	(ms) Sets the minimum execution time above which a sample of statements is logged. Sample size is set using the `log_statement_sample_rate` parameter.
log_min_duration_statement	–	Any SQL statement that runs atleast for the specified amount of time or longer gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.
log_statement	–	Sets the type of statements logged. By default, this parameter isn't set, but you can change it to `all`, `ddl`, or mod to specify

Parameter	Default	Description
		the types of SQL statements that you want logged. If you specify anything other than none for this parameter, you should also take additional steps to prevent the exposure of passwords in the log files. For more informati on, see Mitigating risk of password exposure when using query logging.
log_statement_samp le_rate	–	The percentage of statements exceeding the time specified in `log_min_duration_s ample` to be logged, expressed as a floating point value between 0.0 and 1.0.
log_statement_stats	–	Writes cumulative performance statistics to the server log.

Using logging to find slow performing queries

You can log SQL statements and queries to help find slow performing queries. You turn on this capability by modifying the settings in the `log_statement` and `log_min_duration` parameters as outlined in this section. Before turning on query logging for your RDS for PostgreSQL DB instance, you should be aware of possible password exposure in the logs and how to mitigate the risks. For more information, see Mitigating risk of password exposure when using query logging.

Following, you can find reference information about the `log_statement` and `log_min_duration` parameters.

log_statement

This parameter specifies the type of SQL statements that should get sent to the log. The default value is none. If you change this parameter to `all`, `ddl`, or `mod`, be sure to apply recommended actions to mitigate the risk of exposing passwords in the logs. For more information, see Mitigating risk of password exposure when using query logging.

all

Logs all statements. This setting is recommended for debugging purposes.

ddl

Logs all data definition language (DDL) statements, such as CREATE, ALTER, DROP, and so on.

mod

Logs all DDL statements and data manipulation language (DML) statements, such as INSERT, UPDATE, and DELETE, which modify the data.

none

No SQL statements get logged. We recommend this setting to avoid the risk of exposing passwords in the logs.

log_min_duration_statement

Any SQL statement that runs atleast for the specified amount of time or longer gets logged. By default, this parameter isn't set. Turning on this parameter can help you find unoptimized queries.

–1–2147483647

The number of milliseconds (ms) of runtime over which a statement gets logged.

To set up query logging

These steps assume that your RDS for PostgreSQL DB instance uses a custom DB parameter group.

1. Set the `log_statement` parameter to `all`. The following example shows the information that is written to the `postgresql.log` file with this parameter setting.

```
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: statement:
 SELECT feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:LOG: QUERY
 STATISTICS
2022-10-05 22:05:52 UTC:52.95.4.1(11335):postgres@labdb:[3639]:DETAIL: ! system
 usage stats:
! 0.017355 s user, 0.000000 s system, 0.168593 s elapsed
! [0.025146 s user, 0.000000 s system total]
! 36644 kB max resident size
! 0/8 [0/8] filesystem blocks in/out

2022-10-05 22:05:56 UTC:52.95.4.1(11335):postgres@labdb:[3639]:STATEMENT: ORDER BY
 s.confidence DESC;
----------------------- END OF LOG ----------------------
```

2. Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgresql.log` file when the parameter is set to 1.

   Queries that exceed the duration specified in the `log_min_duration_statement` parameter are logged. The following shows an example. You can view the log file for your RDS for PostgreSQL DB instance in the Amazon RDS Console.

```
2022-10-05 19:05:19 UTC:52.95.4.1(6461):postgres@labdb:[6144]:LOG: statement: DROP

 estimate=131028 kB
----------------------- END OF LOG ----------------------
```

Mitigating risk of password exposure when using query logging

We recommend that you keep `log_statement` set to none to avoid exposing passwords. If you set `log_statement` to `all`, `ddl`, or `mod`, we recommend that you take one or more of the following steps.

- For the client, encrypt sensitive information. For more information, see Encryption Options in the PostgreSQL documentation. Use the ENCRYPTED (and UNENCRYPTED) options of the CREATE and ALTER statements. For more information, see CREATE USER in the PostgreSQL documentation.

- For your RDS for PostgreSQL DB instance, set up and use the PostgreSQL Auditing (pgAudit) extension. This extension redacts sensitive information in CREATE and ALTER statements sent to the log. For more information, see Using pgAudit to log database activity.
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

Publishing PostgreSQL logs to Amazon CloudWatch Logs

To store your PostgreSQL log records in highly durable storage, you can use Amazon CloudWatch Logs. With CloudWatch Logs, you can also perform real-time analysis of log data and use CloudWatch to view metrics and create alarms. For example, if you set `log_statement` to `ddl`, you can set up an alarm to alert you whenever a DDL statement is executed. You can choose to have your PostgreSQL logs uploaded to CloudWatch Logs during the process of creating your RDS for PostgreSQL DB instance. If you chose not to upload logs at that time, you can later modify your instance to start uploading logs from that point forward. In other words, existing logs aren't uploaded. Only new logs are uploaded as they're created on your modified RDS for PostgreSQL DB instance.

All currently available RDS for PostgreSQL versions support publishing log files to CloudWatch Logs. For more information, see Amazon RDS for PostgreSQL updates in the *Amazon RDS for PostgreSQL Release Notes.*.

To work with CloudWatch Logs, configure your RDS for PostgreSQL DB instance to publish log data to a log group.

You can publish the following log types to CloudWatch Logs for RDS for PostgreSQL:

- PostgreSQL log
- Upgrade log
- IAM database authentication error log

After you complete the configuration, Amazon RDS publishes the log events to log streams within a CloudWatch log group. For example, the PostgreSQL log data is stored within the log group `/aws/rds/instance/my_instance/postgresql`. To view your logs, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

Console

To publish PostgreSQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and then choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

   The **Log exports** section is available only for PostgreSQL versions that support publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish PostgreSQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters.

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

> **Note**
>
> A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish PostgreSQL logs by calling the following CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Run one of these CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the CLI command you run.

Example Modify an instance to publish logs to CloudWatch Logs

The following example modifies an existing PostgreSQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql",
 "upgrade"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":
["postgresql","upgrade"]}'
```

Example Create an instance to publish logs to CloudWatch Logs

The following example creates a PostgreSQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
```

```
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '["postgresql","upgrade"]' \
    --db-instance-class db.m4.large \
    --engine postgres
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '["postgresql","upgrade"]' ^
    --db-instance-class db.m4.large ^
    --engine postgres
```

RDS API

You can publish PostgreSQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

> **Note**
>
> A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish PostgreSQL logs by calling the following RDS API operations:

- `CreateDBInstance`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`

- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the operation that you run.

Monitoring Amazon RDS API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the AWS CloudTrail User Guide.

Topics

- CloudTrail integration with Amazon RDS
- Amazon RDS log file entries

CloudTrail integration with Amazon RDS

All Amazon RDS actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS.

CloudTrail events

CloudTrail captures API calls for Amazon RDS as events. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon RDS activity is recorded in a CloudTrail event in **Event history**. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon RDS, create a *trail*. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

> **Note**
>
> If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon RDS log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```
{
    "eventVersion": "1.04",

        "dbiResourceId": "db-ETDZIIXHEWY5N7GXVC4SH7H5IA",
        "dBSecurityGroups": [],
        "pendingModifiedValues": {
            "masterUserPassword": "****",
            "pendingCloudwatchLogsExports": {
                "logTypesToEnable": [
                    "audit",
                    "error",
```

```
                    "general",
                    "slowquery"
                ]
            }
        },
        "dBInstanceStatus": "creating",
        "publiclyAccessible": true,
        "domainMemberships": [],
        "copyTagsToSnapshot": false,
        "dBInstanceIdentifier": "test-instance",
        "licenseModel": "general-public-license",
        "iAMDatabaseAuthenticationEnabled": false,
        "performanceInsightsEnabled": false,
        "vpcSecurityGroups": [
            {
                "status": "active",
                "vpcSecurityGroupId": "sg-f839b688"
            }
        ]
    },
    "requestID": "daf2e3f5-96a3-4df7-a026-863f96db793e",
    "eventID": "797163d3-5726-441d-80a7-6eeb7464acd4",
    "eventType": "AwsApiCall",
    "recipientAccountId": "123456789012"
}
```

As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the CloudTrail userIdentity element. For more information about `CreateDBInstance` and other Amazon RDS actions, see the Amazon RDS API Reference.

Monitoring Amazon RDS with Database Activity Streams

By using Database Activity Streams, you can monitor near real-time streams of database activity.

Topics

- Overview of Database Activity Streams
- Configuring unified auditing for Oracle Database
- Configuring auditing policy for Amazon RDS for Microsoft SQL Server
- Starting a database activity stream
- Modifying a database activity stream for Amazon RDS
- Getting the status of a database activity stream
- Stopping a database activity stream
- Monitoring database activity streams
- IAM policy examples for database activity streams

Overview of Database Activity Streams

As an Amazon RDS database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your database.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. Amazon RDS DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Contents

- How database activity streams work

- Region and version availability
- Supported DB instance classes for database activity streams

How database activity streams work

Amazon RDS pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Data Firehose and AWS Lambda to consume the stream and store the data.

> **Important**
>
> Use of the database activity streams feature in Amazon RDS is free, but Amazon Kinesis charges for a data stream. For more information, see Amazon Kinesis Data Streams pricing.

You can configure applications for compliance management to consume database activity streams. These applications can use the stream to generate alerts and audit activity on your database.

Amazon RDS supports database activity streams in Multi-AZ deployments. In this case, database activity streams audit both the primary and standby instances.

Auditing in Oracle Database and Microsoft SQL Server Database

Auditing is the monitoring and recording of configured database actions. Amazon RDS doesn't capture database activity by default. You create and manage audit policies in your database yourself.

Topics

- Unified auditing in Oracle Database
- Auditing in Microsoft SQL Server
- Non-native audit fields for Oracle Database and SQL Server
- DB parameter group override

Unified auditing in Oracle Database

In an Oracle database, a *unified audit policy* is a named group of audit settings that you can use to audit an aspect of user behavior. A policy can be as simple as auditing the activities of a single user. You can also create complex audit policies that use conditions.

An Oracle database writes audit records, including SYS audit records, to the *unified audit trail*. For example, if an error occurs during an `INSERT` statement, standard auditing indicates the error number and the SQL that was run. The audit trail resides in a read-only table in the `AUDSYS` schema. To access these records, query the `UNIFIED_AUDIT_TRAIL` data dictionary view.

Typically, you configure database activity streams as follows:

1. Create an Oracle Database audit policy by using the `CREATE AUDIT POLICY` command.

   The Oracle Database generates audit records.
2. Activate the audit policy by using the `AUDIT POLICY` command.
3. Configure database activity streams.

   Only activities that match the Oracle Database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled, an Oracle database administrator can't alter the audit policy or remove audit logs.

To learn more about unified audit policies, see About Auditing Activities with Unified Audit Policies and AUDIT in the *Oracle Database Security Guide*.

Auditing in Microsoft SQL Server

Database Activity Stream uses SQLAudit feature to audit the SQL Server database.

RDS for SQL Server instance contains the following:

- Server audit – The SQL server audit collects a single instance of server or database-level actions, and a group of actions to monitor. The server-level audits `RDS_DAS_AUDIT` and `RDS_DAS_AUDIT_CHANGES` are managed by RDS.
- Server audit specification – The server audit specification records the server-level events. You can modify the `RDS_DAS_SERVER_AUDIT_SPEC` specification. This specification is linked to the server audit `RDS_DAS_AUDIT`. The `RDS_DAS_CHANGES_AUDIT_SPEC` specification is managed by RDS.

- Database audit specification – The database audit specification records the database-level events. You can create a database audit specification RDS_DAS_DB_<name> and link it to RDS_DAS_AUDIT server audit.

You can configure database activity streams by using the console or CLI. Typically, you configure database activity streams as follows:

1. (Optional) Create a database audit specification with the CREATE DATABASE AUDIT SPECIFICATION command and link it to RDS_DAS_AUDIT server audit.
2. (Optional) Modify the server audit specification with the ALTER SERVER AUDIT SPECIFICATION command and define the policies.
3. Activate the database and server audit policies. For example:

   ```
   ALTER DATABASE AUDIT SPECIFICATION [<Your database specification>] WITH (STATE=ON)

   ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC] WITH (STATE=ON)
   ```
4. Configure database activity streams.

   Only activities that match the server and database audit policies are captured and sent to the Amazon Kinesis data stream. When database activity streams are enabled and the policies are locked, a database administrator can't alter the audit policy or remove audit logs.

   > **Important**
   >
   > If the database audit specification for a specific database is enabled and the policy is in a locked state, then the database can't be dropped.

For more information about SQL Server auditing, see SQL Server Audit Components in the *Microsoft SQL Server documentation*.

Non-native audit fields for Oracle Database and SQL Server

When you start a database activity stream, every database event generates a corresponding activity stream event. For example, a database user might run `SELECT` and `INSERT` statements. The database audits these events and sends them to an Amazon Kinesis data stream.

The events are represented in the stream as JSON objects. A JSON object contains a `DatabaseActivityMonitoringRecord`, which contains a `databaseActivityEventList` array. Predefined fields in the array include `class`, `clientApplication`, and `command`.

By default, an activity stream doesn't include engine-native audit fields. You can configure Amazon RDS for Oracle and SQL Server so that it includes these extra fields in the `engineNativeAuditFields` JSON object.

In Oracle Database, most events in the unified audit trail map to fields in the RDS data activity stream. For example, the `UNIFIED_AUDIT_TRAIL.SQL_TEXT` field in unified auditing maps to the `commandText` field in a database activity stream. However, Oracle Database audit fields such as `OS_USERNAME` don't map to predefined fields in a database activity stream.

In SQL Server, most of the event's fields that are recorded by the SQLAudit map to the fields in RDS database activity stream. For example, the `code` field from `sys.fn_get_audit_file` in the audit maps to the `commandText` field in a database activity stream. However, SQL Server database audit fields, such as `permission_bitmask`, don't map to predefined fields in a database activity stream.

For more information about databaseActivityEventList, see databaseActivityEventList JSON array for database activity streams.

DB parameter group override

Typically, you turn on unified auditing in RDS for Oracle by attaching a parameter group. However, Database Activity Streams require additional configuration. To improve your customer experience, Amazon RDS performs the following:

- If you activate an activity stream, RDS for Oracle ignores the auditing parameters in the parameter group.
- If you deactivate an activity stream, RDS for Oracle stops ignoring the auditing parameters.

The database activity stream for SQL Server is independent of any parameters you set in the SQL Audit option.

Asynchronous mode for database activity streams

Activity streams in Amazon RDS are always asynchronous. When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, Amazon RDS makes the activity stream event into a durable record.

If an error occurs in the background task, Amazon RDS generates an event. This event indicates the beginning and end of any time windows where activity stream event records might have been lost. Asynchronous mode favors database performance over the accuracy of the activity stream.

Requirements and limitations for database activity streams

In RDS, database activity streams have the following requirements and limitations:

- Amazon Kinesis is required for database activity streams.
- AWS Key Management Service (AWS KMS) is required for database activity streams because they are always encrypted.
- Applying additional encryption to your Amazon Kinesis data stream is incompatible with database activity streams, which are already encrypted with your AWS KMS key.
- You create and manage audit policies yourself. Unlike Amazon Aurora, RDS for Oracle doesn't capture database activities by default.
- You create and manage audit policies or specifications yourself. Unlike Amazon Aurora, Amazon RDS doesn't capture database activities by default.
- In a Multi-AZ deployment, start the database activity stream only on the primary DB instance. The activity stream audits both the primary and standby DB instances automatically. No additional steps are required during a failover.
- Renaming a DB instance doesn't create a new Kinesis stream.
- CDBs aren't supported for RDS for Oracle.
- Read replicas aren't supported.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with database activity streams, see Supported Regions and DB engines for database activity streams in Amazon RDS.

Supported DB instance classes for database activity streams

For RDS for Oracle you can use database activity streams with the following DB instance classes:

- db.m4.*large
- db.m5.*large
- db.m5d.*large
- db.m6i.*large
- db.r4.*large
- db.r5.*large
- db.r5.*large.tpc*.mem*x
- db.r5b.*large
- db.r5b.*large.tpc*.mem*x
- db.r5d.*large
- db.r6i.*large
- db.r6i.*large.tpc*.mem*x
- db.x2idn.*large
- db.x2iedn.*large
- db.x2iezn.*large
- db.z1d.*large

For RDS for SQL Server you can use database activity streams with the following DB instance classes:

- db.m4.*large
- db.m5.*large
- db.m5d.*large
- db.m6i.*large
- db.r4.*large
- db.r5.*large
- db.r5b.*large
- db.r5d.*large

- db.r6i.*large
- db.x1e.*large
- db.x2iedn.*large
- db.z1d.*large

For more information about instance class types, see DB instance classes.

Configuring unified auditing for Oracle Database

When you configure unified auditing for use with database activity streams, the following situations are possible:

- Unified auditing isn't configured for your Oracle database.

  In this case, create new policies with the `CREATE AUDIT POLICY` command, then activate them with the `AUDIT POLICY` command. The following example creates and activates a policy to monitor users with specific privileges and roles.

  ```
  CREATE AUDIT POLICY table_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ROLES emp_admin, sales_admin;

  AUDIT POLICY table_pol;
  ```

  For complete instructions, see Configuring Audit Policies in the Oracle Database documentation.
- Unified auditing is configured for your Oracle database.

  When you activate a database activity stream, RDS for Oracle automatically clears existing audit data. It also revokes audit trail privileges. RDS for Oracle can no longer do the following:
  - Purge unified audit trail records.
  - Add, delete, or modify the unified audit policy.
  - Update the last archived timestamp.

  Important

  We strongly recommend that you back up your audit data before activating a database activity stream.

For a description of the UNIFIED_AUDIT_TRAIL view, see UNIFIED_AUDIT_TRAIL. If you have an account with Oracle Support, see How To Purge The UNIFIED AUDIT TRAIL.

Configuring auditing policy for Amazon RDS for Microsoft SQL Server

A SQL Server database instance has the server audit RDS_DAS_AUDIT, which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification RDS_DAS_SERVER_AUDIT_SPEC. You can create a database audit specification, such as RDS_DAS_DB_<name>, and define the policies to record database events. For the list of server and database level audit action groups, see SQL Server Audit Action Groups and Actions in the *Microsoft SQL Server documentation*.

The default server policy monitors only failed logins and changes to any database or server audit specifications for database activity streams.

Limitations for the audit and audit specifications include the following:

- You can't modify the server or database audit specifications when the database activity stream is in a *locked* state.
- You can't modify the server audit RDS_DAS_AUDIT specification.
- You can't modify the SQL Server audit RDS_DAS_CHANGES or its related server audit specification RDS_DAS_CHANGES_AUDIT_SPEC.
- When creating a database audit specification, you must use the format RDS_DAS_DB_<name> for example, RDS_DAS_DB_databaseActions.

Important

For smaller instance classes, we recommend that you don't audit all but only the data that is required. This helps to reduce the performance impact of Database Activity Streams on these instance classes.

The following sample code modifies the server audit specification RDS_DAS_SERVER_AUDIT_SPEC and audits any logout and successful login actions:

```
ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC]
```

```
      WITH (STATE=OFF);
ALTER SERVER AUDIT SPECIFICATION [RDS_DAS_SERVER_AUDIT_SPEC]
      ADD (LOGOUT_GROUP),
      ADD (SUCCESSFUL_LOGIN_GROUP)
      WITH (STATE = ON );
```

The following sample code creates a database audit specification `RDS_DAS_DB_database_spec` and attaches it to the server audit `RDS_DAS_AUDIT`:

```
USE testDB;
CREATE DATABASE AUDIT SPECIFICATION [RDS_DAS_DB_database_spec]
     FOR SERVER AUDIT [RDS_DAS_AUDIT]
     ADD ( INSERT, UPDATE, DELETE
          ON testTable BY testUser )
     WITH (STATE = ON);
```

After the audit specifications are configured, make sure that the specifications `RDS_DAS_SERVER_AUDIT_SPEC` and `RDS_DAS_DB_<name>` are set to a state of `ON`. Now they can send the audit data to your database activity stream.

Starting a database activity stream

When you start an activity stream for the DB instance, each database activity event that you configured in the audit policy generates an activity stream event. SQL commands such as `CONNECT` and `SELECT` generate access events. SQL commands such as `CREATE` and `INSERT` generate change events.

> **Important**
>
> Turning on an activity stream for an Oracle DB instance clears existing audit data. It also revokes audit trail privileges. When the stream is enabled, RDS for Oracle can no longer do the following:
>
> - Purge unified audit trail records.
> - Add, delete, or modify the unified audit policy.
> - Update the last archived time stamp.

Console

To start a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Amazon RDS database instance on which you want to start an activity stream. In a Multi-AZ deployment, start the stream on only the primary instance. The activity stream audits both the primary and the standby instances.
4. For **Actions**, choose **Start activity stream**.

   The **Start database activity stream:** *name* window appears, where *name* is your RDS instance.
5. Enter the following settings:

   - For **AWS KMS key**, choose a key from the list of AWS KMS keys.

     Amazon RDS uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see What is AWS Key Management Service? in the *AWS Key Management Service Developer Guide.*
   - For **Database activity events**, choose **Enable engine-native audit fields** to include the engine specific audit fields.
   - Choose **Immediately**.

     When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.
6. Choose **Start database activity stream**.

   The status for the the database shows that the activity stream is starting.

> **Note**
>
> If you get the error `You can't start a database activity stream in this configuration`, check Supported DB instance classes for database activity streams to see whether your RDS instance is using a supported instance class.

AWS CLI

To start database activity streams for a DB instance, configure the database using the start-activity-stream AWS CLI command.

- `--resource-arn` *arn* – Specifies the Amazon Resource Name (ARN) of the DB instance.
- `--kms-key-id` *key* – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.
- `--engine-native-audit-fields-included` – Includes engine-specific auditing fields in the data stream. To exclude these fields, specify `--no-engine-native-audit-fields-included` (default).

The following example starts a database activity stream for a DB instance in asynchronous mode.

For Linux, macOS, or Unix:

```
aws rds start-activity-stream \
    --mode async \
    --kms-key-id my-kms-key-arn \
    --resource-arn my-instance-arn \
    --engine-native-audit-fields-included \
    --apply-immediately
```

For Windows:

```
aws rds start-activity-stream ^
    --mode async ^
    --kms-key-id my-kms-key-arn ^
    --resource-arn my-instance-arn ^
    --engine-native-audit-fields-included ^
    --apply-immediately
```

Amazon RDS API

To start database activity streams for a DB instance, configure the instance using the StartActivityStream operation.

Call the action with the parameters below:

- `Region`
- `KmsKeyId`
- `ResourceArn`
- `Mode`
- `EngineNativeAuditFieldsIncluded`

Modifying a database activity stream for Amazon RDS

You might want to customize your Amazon RDS audit policy when your activity stream is started. If you don't want to lose time and data by stopping your activity stream, you can change the *audit policy state* to either of the following settings:

Locked (default)

The audit policies in your database are read-only.

Unlocked

The audit policies in your database are read/write.

The basic steps are as follows:

1. Modify the audit policy state to unlocked.
2. Customize your audit policy.
3. Modify the audit policy state to locked.

Console

To modify the audit policy state of your activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. For **Actions**, choose **Modify database activity stream**.

   The **Modify database activity stream: *name*** window appears, where *name* is your RDS instance.
4. Choose either of the following options:

Locked

When you lock your audit policy, it becomes read-only. You can't edit your audit policy unless you unlock the policy or stop the activity stream.

Unlocked

When you unlock your audit policy, it becomes read/write. You can edit your audit policy while the activity stream is started.

5. Choose **Modify DB activity stream**.

   The status for the Amazon RDS database shows **Configuring activity stream**.

6. (Optional) Choose the DB instance link. Then choose the **Configuration** tab.

   The **Audit policy status** field shows one of the following values:

   - **Locked**
   - **Unlocked**
   - **Locking policy**
   - **Unlocking policy**

AWS CLI

To modify the activity stream state for the database instance, use the modify-activity-stream AWS CLI command.

Option	Required?	Description
`--resource-arn` *my-instance-ARN*	Yes	The Amazon Resource Name (ARN) of your RDS database instance.
`--audit-policy-state`	No	The new state of the audit policy for the database activity stream on your instance: `locked` or `unlocked`.

The following example unlocks the audit policy for the activity stream started on *my-instance-ARN*.

For Linux, macOS, or Unix:

```
aws rds modify-activity-stream \
    --resource-arn my-instance-ARN \
    --audit-policy-state unlocked
```

For Windows:

```
aws rds modify-activity-stream ^
    --resource-arn my-instance-ARN ^
    --audit-policy-state unlocked
```

The following example describes the instance *my-instance*. The partial sample output shows that the audit policy is unlocked.

```
aws rds describe-db-instances --db-instance-identifier my-instance

{
    "DBInstances": [
        {
            ...
            "Engine": "oracle-ee",
            ...
            "ActivityStreamStatus": "started",
            "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
            "ActivityStreamKinesisStreamName": "aws-rds-das-db-
AB1CDEFG23GHIJK4LMNOPQRST",
            "ActivityStreamMode": "async",
            "ActivityStreamEngineNativeAuditFieldsIncluded": true,
            "ActivityStreamPolicyStatus": "unlocked",
            ...
        }
    ]
}
```

RDS API

To modify the policy state of your database activity stream, use the ModifyActivityStream operation.

Call the action with the parameters below:

- `AuditPolicyState`
- `ResourceArn`

Getting the status of a database activity stream

You can get the status of an activity stream for your Amazon RDS database instance using the console or AWS CLI.

Console

To get the status of a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance link.
3. Choose the **Configuration** tab, and check **Database activity stream** for status.

AWS CLI

You can get the activity stream configuration for a database instance as the response to a describe-db-instances CLI request.

The following example describes *my-instance*.

```
aws rds --region my-region describe-db-instances --db-instance-identifier my-db
```

The following example shows a JSON response. The following fields are shown:

- `ActivityStreamKinesisStreamName`
- `ActivityStreamKmsKeyId`
- `ActivityStreamStatus`
- `ActivityStreamMode`
- `ActivityStreamPolicyStatus`

```
{
    "DBInstances": [
        {
            ...
```

```
            "Engine": "oracle-ee",
            ...
            "ActivityStreamStatus": "starting",
            "ActivityStreamKmsKeyId": "ab12345e-1111-2bc3-12a3-ab1cd12345e",
            "ActivityStreamKinesisStreamName": "aws-rds-das-db-
AB1CDEFG23GHIJK4LMNOPQRST",
            "ActivityStreamMode": "async",
            "ActivityStreamEngineNativeAuditFieldsIncluded": true,
            "ActivityStreamPolicyStatus": locked",
            ...
        }
    ]
}
```

RDS API

You can get the activity stream configuration for a database as the response to a DescribeDBInstances operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your Amazon RDS database instance, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.

Console

To turn off an activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose a database that you want to stop the database activity stream for.
4. For **Actions**, choose **Stop activity stream**. The **Database Activity Stream** window appears.
    a. Choose **Immediately**.

        When you choose **Immediately**, the RDS instance restarts right away. If you choose **During the next maintenance window**, the RDS instance doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.
    b. Choose **Continue**.

AWS CLI

To stop database activity streams for your database, configure the DB instance using the AWS CLI command stop-activity-stream. Identify the AWS Region for the DB instance using the `--region` parameter. The `--apply-immediately` parameter is optional.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION \
    stop-activity-stream \
    --resource-arn MY_DB_ARN \
    --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
    stop-activity-stream ^
    --resource-arn MY_DB_ARN ^
    --apply-immediately
```

RDS API

To stop database activity streams for your database, configure the DB instance using the StopActivityStream operation. Identify the AWS Region for the DB instance using the `Region` parameter. The `ApplyImmediately` parameter is optional.

Monitoring database activity streams

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command `describe-db-instances` or the RDS API `DescribeDBInstances` operation.

Amazon RDS manages the Kinesis stream for you as follows:

- Amazon RDS creates the Kinesis stream automatically with a 24-hour retention period.
- Amazon RDS scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB instance, Amazon RDS deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.
- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. Database activity streams also monitor the bind variables and stored procedure parameters.

  > **Important**
  >
  > The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Oracle can determine them from the context, such as in the following SQL statement.
  >
  > ```
  > ALTER ROLE role-name WITH password
  > ```

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

In the following sections, you can access, audit, and process database activity streams.

Topics

- Accessing an activity stream from Amazon Kinesis
- Audit log contents and examples for database activity streams
- databaseActivityEventList JSON array for database activity streams
- Processing a database activity stream using the AWS SDK

Accessing an activity stream from Amazon Kinesis

When you enable an activity stream for a database, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to

compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

You can access your Kinesis stream either from the RDS console or the Kinesis console.

To access an activity stream from Kinesis using the RDS console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Amazon RDS database instance on which you started an activity stream.
4. Choose **Configuration**.
5. Under **Database activity stream**, choose the link under **Kinesis stream**.
6. In the Kinesis console, choose **Monitoring** to begin observing the database activity.

To access an activity stream from Kinesis using the Kinesis console

1. Open the Kinesis console at https://console.aws.amazon.com/kinesis.
2. Choose your activity stream from the list of Kinesis streams.

   An activity stream's name includes the prefix `aws-rds-das-db-` followed by the resource ID of the database. The following is an example.

   ```
   aws-rds-das-db-NHVOV4PCLWHGF52NP
   ```

   To use the Amazon RDS console to find the resource ID for the database, choose your DB instance from the list of databases, and then choose the **Configuration** tab.

   To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a describe-db-instances CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.
3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see What Is Amazon Kinesis Data Streams?.

Audit log contents and examples for database activity streams

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

> **Note**
>
> For database activity streams, the `paramList` JSON array doesn't include null values from Hibernate applications.

Topics

- Examples of an audit log for an activity stream
- DatabaseActivityMonitoringRecords JSON object
- databaseActivityEvents JSON Object

Examples of an audit log for an activity stream

Following are sample decrypted JSON audit logs of activity event records.

Example Activity event record of a CONNECT SQL statement

The following activity event record shows a login with the use of a `CONNECT` SQL statement (`command`) by a JDBC Thin Client (`clientApplication`) for your Oracle DB.

```
{
    "class": "Standard",
    "clientApplication": "JDBC Thin Client",

}
```

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

JSON Field	Data Type	Description
`type`	string	The type of JSON record. The value is `DatabaseActivityMonitoringRecords`.

JSON Field	Data Type	Description
`version`	string	The version of the database activity monitoring records. Oracle DB uses version 1.3 and SQL Server uses version 1.4. These engine versions introduce the `engineNativeAuditFields` JSON object.
databaseActivityEvents	string	A JSON object that contains the activity events.
key	string	An encryption key that you use to decrypt the databaseActivityEventList JSON array

databaseActivityEvents JSON Object

The `databaseActivityEvents` JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

type

This field always has the value `DatabaseActivityMonitoringRecords`.

version

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

databaseActivityEvents

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

key

The encrypted data key used to encrypt the `databaseActivityEvents` string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```
{
  "type":"DatabaseActivityMonitoringRecords",
  "version":"1.3",
  "databaseActivityEvents":"encrypted audit records",
  "key":"encrypted key"
}
```

```
          "type":"DatabaseActivityMonitoringRecords",
          "version":"1.4",
          "databaseActivityEvents":"encrypted audit records",
          "key":"encrypted key"
```

Take the following steps to decrypt the contents of the `databaseActivityEvents` field:

1. Decrypt the value in the `key` JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the `databaseActivityEvents` JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
   - The encrypted payload is in the `databaseActivityEvents` field.
   - The `databaseActivityEventList` field contains an array of audit records. The `type` fields in the array can be `record` or `heartbeat`.

The audit log activity event record is a JSON object that contains the following information.

JSON Field	Data Type	Description
`type`	string	The type of JSON record. The value is `DatabaseActivityMonitoringRecord` .
`instanceId`	string	The DB instance resource identifier. It corresponds to the DB instance attribute `DbiResourceId` .
databaseActivityEventList JSON array	string	An array of activity audit records or heartbeat messages.

databaseActivityEventList JSON array for database activity streams

The audit log payload is an encrypted `databaseActivityEventList` JSON array. The following table lists alphabetically the fields for each activity event in the decrypted `DatabaseActivityEventList` array of an audit log.

When unified auditing is enabled in Oracle Database, the audit records are populated in this new audit trail. The `UNIFIED_AUDIT_TRAIL` view displays audit records in tabular form by retrieving the audit records from the audit trail. When you start a database activity stream, a column in `UNIFIED_AUDIT_TRAIL` maps to a field in the `databaseActivityEventList` array.

Important

The event structure is subject to change. Amazon RDS might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

databaseActivityEventList fields for Amazon RDS for Oracle

The following are `databaseActivityEventList` fields for Amazon RDS for Oracle.

Field	Data Type	Source	Description
class	string	AUDIT_TYPE column in UNIFIED_AUDIT_TRAIL	The class of activity event. This corresponds to the AUDIT_TYPE column in the UNIFIED_AUDIT_TRAIL view. Valid values for Amazon RDS for Oracle are the following: • Standard • FineGrainedAudit • XS • Database Vault • Label Security • RMAN_AUDIT • Datapump • Direct path API For more information, see UNIFIED_AUDIT_TRAIL in the Oracle documentation.
clientApplication	string	CLIENT_PROGRAM_NAME in UNIFIED_AUDIT_TRAIL	The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null. A sample value is JDBC Thin Client.

Field	Data Type	Source	Description
command	string	ACTION_NAME column in UNIFIED_AUDIT_TRAIL	Name of the action executed by the user. To understand the complete action, read both the command name and the AUDIT_TYPE value. A sample value is ALTER DATABASE.
commandText	string	SQL_TEXT column in UNIFIED_AUDIT_TRAIL	The SQL statement associated with the event. A sample value is ALTER DATABASE BEGIN BACKUP.
databaseName	string	NAME column in V$DATABASE	The name of the database.
dbid	numb	DBID column in UNIFIED_AUDIT_TRAIL	Numerical identifier for the database. A sample value is 1559204751 .
dbProtocol	string	N/A	The database protocol. In this beta, the value is oracle.
dbUserName	string	DBUSERNAME column in UNIFIED_AUDIT_TRAIL	Name of the database user whose actions were audited. A sample value is RDSADMIN.
endTime	string	N/A	This field isn't used for RDS for Oracle and is always null.

Field	Data Type	Source	Description
engineNativeAuditFields	objec	UNIFIED_AUDIT_TRAIL	By default, this object is empty. When you start the activity stream with the --engine-native-audit-fields-included option, this object includes the following columns and their values: ADDITIONAL_INFO APPLICATION_CONTEXTS AUDIT_OPTION AUTHENTICATION_TYPE CLIENT_IDENTIFIER CURRENT_USER DBLINK_INFO DBPROXY_USERNAME DIRECT_PATH_NUM_COLUMNS_LOADED DP_BOOLEAN_PARAMETERS1 DP_TEXT_PARAMETERS1 DV_ACTION_CODE DV_ACTION_NAME DV_ACTION_OBJECT_NAME DV_COMMENT DV_EXTENDED_ACTION_CODE DV_FACTOR_CONTEXT DV_GRANTEE DV_OBJECT_STATUS DV_RETURN_CODE

Field	Data Type	Source	Description
			DV_RULE_SET_NAME ENTRY_ID EXCLUDED_OBJECT EXCLUDED_SCHEMA EXCLUDED_USER EXECUTION_ID EXTERNAL_USERID FGA_POLICY_NAME GLOBAL_USERID INSTANCE_ID KSACL_SER VICE_NAME KSACL_SOURCE_LOCA TION KSACL_USER_NAME NEW_NAME NEW_SCHEMA OBJECT_EDITION OBJECT_PRIVILEGES OLS_GRANTEE OLS_LABEL_COM PONENT_NAME OLS_LABEL_COMPO NENT_TYPE OLS_MAX_READ_LABEL OLS_MAX_WRITE_LA BEL OLS_MIN_WRITE_ LABEL OLS_NEW_VALUE OLS_OLD_VALUE OLS_PARENT_ GROUP_NAME OLS_POLICY_NAME OLS_PRIVILEGES_GRA NTED OLS_PRIVILEGE S_USED OLS_PROGRAM _UNIT_NAME OLS_STRING_LABEL

Field	Data Type	Source	Description
			OS_USERNAME PROTOCOL_ACTIO N_NAME PROTOCOL_MESSAGE PROTOCOL_RET URN_CODE PROTOCOL_SESSION_I D PROTOCOL_USERHOST PROXY_SESSIONID RLS_INFO RMAN_DEVICE_TYPE RMAN_OBJECT_TYPE RMAN_OPERATION RMAN_SESSION_RECID RMAN_SESSION_STAMP ROLE SCN SYSTEM_PRIVILEGE SYSTEM_PRIVIL EGE_USED TARGET_USER TERMINAL UNIFIED_AUDIT_P OLICIES USERHOST XS_CALLBAC K_EVENT_TYPE XS_COOKIE XS_DATASEC_PO LICY_NAME XS_ENABLED_ROLE XS_ENTITY_TYPE XS_INACTIVITY _TIMEOUT XS_NS_ATTRIBUTE XS_NS_ATTRI BUTE_NEW_VAL XS_NS_ATTRIBUT E_OLD_VAL XS_NS_NAME

Field	Data Type	Source	Description
			XS_PACKAGE_NAME XS_PROCEDURE_NAME XS_PROXY_USER_NAME XS_SCHEMA_NAME XS_SESSIONID XS_TARGET_PRINC IPAL_NAME XS_USER_NAME For more informati on, see UNIFIED_A UDIT_TRAIL in the Oracle Database documenta tion.
errorMessage	string	N/A	This field isn't used for RDS for Oracle and is always null.
exitCode	numb	RETURN_CODE column in UNIFIED_AUDIT_TRAIL	Oracle Database error code generated by the action. If the action succeeded, the value is 0.
logTime	string	EVENT_TIMESTAMP_UT C column in UNIFIED_A UDIT_TRAIL	Timestamp of the creation of the audit trail entry. A sample value is 2020-11-27 06:56:14.981404 .
netProtocol	string	AUTHENTICATION_TYP E column in UNIFIED_A UDIT_TRAIL	The network communica tion protocol. A sample value is TCP.

Field	Data Type	Source	Description
objectName	string	OBJECT_NAME column in UNIFIED_AUDIT_TRAIL	The name of the object affected by the action. A sample value is employees .
objectType	string	OBJECT_SCHEMA column in UNIFIED_AUDIT_TRAIL	The schema name of object affected by the action. A sample value is hr.
paramList	list	SQL_BINDS column in UNIFIED_AUDIT_TRAIL	The list of bind variables , if any, associated with SQL_TEXT. A sample value is parameter _1,parameter_2 .
pid	numb	OS_PROCESS column in UNIFIED_AUDIT_TRAIL	Operating system process identifier of the Oracle database process. A sample value is 22396.
remoteHost	string	AUTHENTICATION_TYP E column in UNIFIED_A UDIT_TRAIL	Either the client IP address or name of the host from which the session was spawned. A sample value is 123.456.789.123 .
remotePort	string	AUTHENTICATION_TYP E column in UNIFIED_A UDIT_TRAIL	The client port number. A typical value in Oracle Database environments is 1521.

Field	Data Type	Source	Description
rowCount	numb	N/A	This field isn't used for RDS for Oracle and is always null.
serverHost	string	Database host	The IP address of the database server host. A sample value is 123.456.789.123 .
serverType	string	N/A	The database server type. The value is always ORACLE.
serverVersion	string	Database host	The Amazon RDS for Oracle version, Release Update (RU), and Release Update Revision (RUR). A sample value is 19.0.0.0.ru-2020-01.rur-2020-01.r1.EE.3 .
serviceName	string	Database host	The name of the service. A sample value is oracle-ee .
sessionId	numb	SESSIONID column in UNIFIED_AUDIT_TRAIL	The session identifier of the audit. An example is 1894327130 .
startTime	string	N/A	This field isn't used for RDS for Oracle and is always null.

Field	Data Type	Source	Description
statementId	numb	STATEMENT_ID column in UNIFIED_AUDIT_TRAIL	Numeric ID for each statement run. A statement can cause many actions. A sample value is 142197.
substatementId	N/A	N/A	This field isn't used for RDS for Oracle and is always null.
transactionId	string	TRANSACTION_ID column in UNIFIED_AUDIT_TRAIL	The identifier of the transaction in which the object is modified. A sample value is 02000800D5030000 .

databaseActivityEventList fields for Amazon RDS for SQL Server

The following are databaseActivityEventList fields for Amazon RDS for SQL Server.

Field	Data Type	Source	Description
class	string	sys.fn_get_audit_file.class_type mapped to sys.dm_audit_class_type_map.class_type_desc	The class of activity event. For more information, see SQL Server Audit (Database Engine) in the Microsoft documentation.
clientApplication	string	sys.fn_get_audit_file.application_name	The application that the client connects as reported by the client (SQL Server version 14 and higher). This field is null in SQL Server version 13.

Field	Data Type	Source	Description
command	string	sys.fn_get_audit_file.action_id mapped to sys.dm_audit_actions.name	The general category of the SQL statement. The value for this field depends on the value of the class.
commandText	string	sys.fn_get_audit_file.statement	This field indicates the SQL statement.
databaseName	string	sys.fn_get_audit_file.database_name	Name of the database.
dbProtocol	string	N/A	The database protocol. This value is SQLSERVER .
dbUserName	string	sys.fn_get_audit_file.server_principal_name	The database user for the client authentication.
endTime	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
engineNativeAuditFields	object	Each field in sys.fn_get_audit_file that is not listed in this column.	By default, this object is empty. When you start the activity stream with the --engine-native-audit-fields-included option, this object includes other native engine audit fields, which are not returned by this JSON map.
errorMessage	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.

Field	Data Type	Source	Description
exitCode	integer	sys.fn_get_audit_file.succeeded	Indicates whether the action that started the event succeeded. This field can't be null. For all the events except login events, this field reports whether the permission check succeeded or failed, but not whether the operation succeeded or failed. Values include: • 0 – Fail • 1 – Success
logTime	string	sys.fn_get_audit_file.event_time	The event timestamp that is recorded by the SQL Server.
netProtocol	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
objectName	string	sys.fn_get_audit_file.object_name	The name of the database object if the SQL statement is operating on an object.
objectType	string	sys.fn_get_audit_file.class_type mapped to sys.dm_audit_class_type_map.class_type_desc	The database object type if the SQL statement is operating on an object type.
paramList	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.

Field	Data Type	Source	Description
pid	integer	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
remoteHost	string	sys.fn_get_audit_file.client_ip	The IP address or hostname of the client that issued the SQL statement (SQL Server version 14 and higher). This field is null in SQL Server version 13.
remotePort	integer	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
rowCount	integer	sys.fn_get_audit_file.affected_rows	The number of table rows affected by the SQL statement (SQL Server version 14 and higher). This field is in SQL Server version 13.
serverHost	string	Database Host	The IP address of the host database server.
serverType	string	N/A	The database server type. The value is SQLSERVER .
serverVersion	string	Database Host	The database server version, for example, 15.00.4073.23.v1.R1 for SQL Server 2017.
serviceName	string	Database Host	The name of the service. An example value is sqlserver-ee.

Field	Data Type	Source	Description
sessionId	integer	sys.fn_get_audit_file.session_id	Unique identifier of the session.
startTime	string	N/A	This field isn't used by Amazon RDS for SQL Server and the value is null.
statementId	string	sys.fn_get_audit_file.sequence_group_id	A unique identifier for the client's SQL statement. The identifier is different for each event that is generated. A sample value is 0x38eaf4156267184094bb82071aaab644 .
substatementId	integer	sys.fn_get_audit_file.sequence_number	An identifier to determine the sequence number for a statement. This identifier helps when large records are split into multiple records.
transactionId	integer	sys.fn_get_audit_file.transaction_id	An identifier of a transaction. If there aren't any active transactions, the value is zero.
type	string	Database activity stream generated	The type of event. The values are record or heartbeat .

Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK. The following are fully functioning Java and Python examples of using Database Activity Streams records for instance based enablement.

IAM policy examples for database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB instance. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don't provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about Amazon RDS authentication, see Identity and access management for Amazon RDS. For more information about creating IAM policies, see Creating and using an IAM policy for IAM database access.

Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys `rds:StartActivityStream` and `rds:StopActivityStream` in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ConfigureActivityStreams",
            "Effect": "Allow",
            "Action": [
                "rds:StartActivityStream",
                "rds:StopActivityStream"
            ],
            "Resource": "*"
        }
    ]
```

```
}
```

Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"AllowStartActivityStreams",
            "Effect":"Allow",
            "Action":"rds:StartActivityStream",
            "Resource":"*"
        }
    ]
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"AllowStopActivityStreams",
            "Effect":"Allow",
            "Action":"rds:StopActivityStream",
            "Resource":"*"
        }
     ]
}
```

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyStartActivityStreams",
            "Effect":"Deny",
            "Action":"rds:StartActivityStream",
            "Resource":"*"
        }
     ]
}
```

Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"DenyStopActivityStreams",
            "Effect":"Deny",
            "Action":"rds:StopActivityStream",
            "Resource":"*"
        }
    ]
}
```

Monitoring threats with Amazon GuardDuty RDS Protection

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

GuardDuty RDS Protection analyzes and profiles login events for potential access threats to your Amazon RDS databases. When you turn on RDS Protection, GuardDuty consumes RDS login events from your RDS databases. RDS Protection monitors these events and profiles them for potential insider threats or external actors.

For more information about enabling GuardDuty RDS Protection, see GuardDuty RDS Protection in the *Amazon GuardDuty User Guide*.

When RDS Protection detects a potential threat, such as an unusual pattern in successful or failed login attempts, GuardDuty generates a new finding with details about the potentially compromised database. You can view the finding details in the finding summary section in the Amazon GuardDuty console. The finding details vary based on the finding type. The primary details, resource type and resource role, determine the kind of information available for any finding. For more information about the commonly available details for findings and the finding types, see Finding details and GuardDuty RDS Protection finding types respectively in the *Amazon GuardDuty User Guide*.

You can turn the RDS Protection feature on or off for any AWS account in any AWS Region where this feature is available. When RDS Protection isn't enabled, GuardDuty doesn't detect potentially compromised RDS databases or provide details of the compromise.

An existing GuardDuty account can enable RDS Protection with a 30-day trial period. For a new GuardDuty account, RDS Protection is already enabled and included in the 30-day free trial period. For more information, see Estimating GuardDuty cost in the *Amazon GuardDuty User Guide*.

For information about the AWS Regions where GuardDuty doesn't yet support RDS Protection, see Region-specific feature availability in the *Amazon GuardDuty User Guide*.

For information about the RDS database versions that GuardDuty RDS Protection supports, see Supported Amazon Aurora, Amazon RDS, and Aurora Limitless databases in the *Amazon GuardDuty User Guide*.

Amazon RDS Custom

Amazon RDS Custom automates database administration tasks and operations. RDS Custom makes it possible for you as a database administrator to access and customize your database environment and operating system. With RDS Custom, you can customize to meet the requirements of legacy, custom, and packaged applications.

For the latest webinars and blogs about RDS Custom, see Amazon RDS Custom resources.

Topics

- Addressing the challenge of database customization
- Management model and benefits for Amazon RDS Custom
- Amazon RDS Custom architecture
- Security in Amazon RDS Custom
- Working with RDS Custom for Oracle
- Working with RDS Custom for SQL Server

Addressing the challenge of database customization

Amazon RDS Custom brings the benefits of Amazon RDS to a market that can't easily move to a fully managed service because of customizations that are required with third-party applications. Amazon RDS Custom saves administrative time, is durable, and scales with your business.

If you need the entire database and operating system to be fully managed by AWS, we recommend Amazon RDS. If you need administrative rights to the database and underlying operating system to make dependent applications available, Amazon RDS Custom is the better choice. If you want full management responsibility and simply need a managed compute service, the best option is self-managing your commercial databases on Amazon EC2.

To deliver a managed service experience, Amazon RDS doesn't let you access the underlying host. Amazon RDS also restricts access to some procedures and objects that require high-level privileges. However, for some applications, you might need to perform operations as a privileged operating system (OS) user.

For example, you might need to do the following:

- Install custom database and OS patches and packages.

- Configure specific database settings.
- Configure file systems to share files directly with their applications.

Previously, if you needed to customize your application, you had to deploy your database on-premises or on Amazon EC2. In this case, you bear most or all of the responsibility for database management, as summarized in the following table.

Feature	On-premises responsibility	Amazon EC2 responsibility	Amazon RDS responsibility
Application optimization	Customer	Customer	Customer
Scaling	Customer	Customer	AWS
High availability	Customer	Customer	AWS
Database backups	Customer	Customer	AWS
Database software patching	Customer	Customer	AWS
Database software install	Customer	Customer	AWS
OS patching	Customer	Customer	AWS
OS installation	Customer	Customer	AWS
Server maintenance	Customer	AWS	AWS
Hardware lifecycle	Customer	AWS	AWS
Power, network, and cooling	Customer	AWS	AWS

When you manage database software yourself, you gain more control, but you're also more prone to user errors. For example, when you make changes manually, you might accidentally

cause application downtime. You might spend hours checking every change to identify and fix an issue. Ideally, you want a managed database service that automates common DBA tasks, but also supports privileged access to the database and underlying operating system.

Management model and benefits for Amazon RDS Custom

Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. RDS Custom automates setup, operation, and scaling of databases in the AWS Cloud while granting you access to the database and underlying operating system. With this access, you can configure settings, install patches, and enable native features to meet the dependent application's requirements. With RDS Custom, you can run your database workload using the AWS Management Console or the AWS CLI.

RDS Custom supports only the Oracle Database and Microsoft SQL Server DB engines.

Topics

- Shared responsibility model in RDS Custom
- Support perimeter and unsupported configurations in RDS Custom
- Key benefits of RDS Custom

Shared responsibility model in RDS Custom

With RDS Custom, you use the managed features of Amazon RDS, but you manage the host and customize the OS as you do in Amazon EC2. You take on additional database management responsibilities beyond what you do in Amazon RDS. The result is that you have more control over database and DB instance management than you do in Amazon RDS, while still benefiting from RDS automation.

Shared responsibility means the following:

1. You own part of the process when using an RDS Custom feature.

   For example, in RDS Custom for Oracle, you control which Oracle database patches to use and when to apply them to your DB instances.
2. You are responsible for making sure that any customizations to RDS Custom features work correctly.

To help protect against invalid customization, RDS Custom has automation software that runs outside of your DB instance. If your underlying Amazon EC2 instance becomes impaired, RDS Custom attempts to resolve these problems automatically by either rebooting or replacing the EC2 instance. The only user-visible change is a new IP address. For more information, see Amazon RDS Custom host replacement.

The following table details the shared responsibility model for different features of RDS Custom.

Feature	Amazon EC2 responsibility	Amazon RDS responsibility	RDS Custom for Oracle responsibility	RDS Custom for SQL Server responsibility
Application optimization	Customer	Customer	Customer	Customer
Scaling	Customer	AWS	Shared	Shared
High availability	Customer	AWS	AWS	AWS
Database backups	Customer	AWS	Shared	AWS
Database software patching	Customer	AWS	Shared	AWS for RPEV, Customer for CEV[1]
Database software install	Customer	AWS	Shared	AWS for RPEV, Customer for CEV[1]
OS patching	Customer	AWS	Customer	AWS for RPEV, Customer for CEV[1]
OS installation	Customer	AWS	Shared	AWS
Server maintenance	AWS	AWS	AWS	AWS

Feature	Amazon EC2 responsibility	Amazon RDS responsibility	RDS Custom for Oracle responsibility	RDS Custom for SQL Server responsibility
Hardware lifecycle	AWS	AWS	AWS	AWS
Power, network, and cooling	AWS	AWS	AWS	AWS

[1] A custom engine version (CEV) is a binary volume snapshot of a database version and Amazon Machine Image (AMI). An RDS provided engine version (RPEV) is the default Amazon Machine Image (AMI) and Microsoft SQL Server installation.

You can create an RDS Custom DB instance using Microsoft SQL Server. In this case:

- You can choose from two licensing models: License Included (LI) and Bring Your Own Media (BYOM).
- With LI, you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software.
- With BYOM, you provide and install your own Microsoft SQL Server binaries and licensing.

You can create an RDS Custom DB instance using Oracle Database. In this case, you do the following:

- Manage your own media.

  When using RDS Custom, you upload your own database installation files and patches. You create a custom engine version (CEV) from these files. Then you can create an RDS Custom DB instance by using this CEV.
- Manage your own licenses.

  You bring your own Oracle Database licenses and manage licenses by yourself.

Support perimeter and unsupported configurations in RDS Custom

RDS Custom provides a monitoring capability called the *support perimeter*. This feature ensures that your host and database environment are configured correctly. If you make a change that causes your DB instance to go outside the support perimeter, RDS Custom changes the instance status to `unsupported-configuration` until you manually fix the configuration problems. For more information, see RDS Custom support perimeter.

Key benefits of RDS Custom

With RDS Custom, you can do the following:

- Automate many of the same administrative tasks as Amazon RDS, including the following:
  - Lifecycle management of databases
  - Automated backups and point-in-time recovery (PITR)
  - Monitoring the health of RDS Custom DB instances and observing changes to the infrastructure, operating system, and database processes.
  - Notification or taking action to fix issues depending on disruption to the DB instance
- Install third-party applications.

  You can install software to run custom applications and agents. Because you have privileged access to the host, you can modify file systems to support legacy applications.
- Install custom patches.

  You can apply custom database patches or modify OS packages on your RDS Custom DB instances.
- Stage an on-premises database before moving it to a fully managed service.

  If you manage your own on-premises database, you can stage the database to RDS Custom as-is. After you familiarize yourself with the cloud environment, you can migrate your database to a fully managed Amazon RDS DB instance.
- Create your own automation.

  You can create, schedule, and run custom automation scripts for reporting, management, or diagnostic tools.

Amazon RDS Custom architecture

Amazon RDS Custom architecture is based on Amazon RDS, with important differences. The following diagram shows the key components of the RDS Custom architecture.

Topics

- VPC
- RDS Custom automation and monitoring
- Amazon S3
- AWS CloudTrail

VPC

As in Amazon RDS, your RDS Custom DB instance resides in a virtual private cloud (VPC).

Your RDS Custom DB instance consists of the following main components:

- Amazon EC2 instance
- Instance endpoint
- Operating system installed on the Amazon EC2 instance
- Amazon EBS storage, which contains any additional file systems

RDS Custom automation and monitoring

RDS Custom has automation software that runs outside of the DB instance. This software communicates with agents on the DB instance and with other components within the overall RDS Custom environment.

The RDS Custom monitoring and recovery features offer similar functionality to Amazon RDS. By default, RDS Custom is in full automation mode. The automation software has the following primary responsibilities:

- Collect metrics and send notifications
- Perform automatic instance recovery

An important responsibility of RDS Custom automation is responding to problems with your Amazon EC2 instance. For various reasons, the host might become impaired or unreachable. RDS Custom resolves these problems by either rebooting or replacing the Amazon EC2 instance.

Topics

- Amazon RDS Custom host replacement
- RDS Custom support perimeter

Amazon RDS Custom host replacement

If the Amazon EC2 host becomes impaired, RDS Custom attempts to reboot it. If this effort fails, RDS Custom uses the same stop and start feature included in Amazon EC2. The only customer-visible change when a host is replaced is a new public IP address.

Topics

- Stopping and starting the host
- Effects of host replacement
- Best practices for Amazon EC2 hosts

Stopping and starting the host

RDS Custom automatically takes the following steps, with no user intervention required:

1. Stops the Amazon EC2 host.

   The EC2 instance performs a normal shutdown and stops running. Any Amazon EBS volumes remain attached to the instance, and their data persists. Any data stored in the instance store volumes (not supported on RDS Custom) or RAM of the host computer is gone.

   For more information, see Stop and start your instance in the *Amazon EC2 User Guide*.
2. Starts the Amazon EC2 host.

   The EC2 instance migrates to a new underlying host hardware. In some cases, the RDS Custom DB instance remains on the original host.

Effects of host replacement

In RDS Custom, you have full control over the root device volume and Amazon EBS storage volumes. The root volume can contain important data and configurations that you don't want to lose.

RDS Custom for Oracle retains all database and customer data after the operation, including root volume data. No user intervention is required. On RDS Custom for SQL Server, database data is retained, but any data on the C: drive, including operating system and customer data, is lost.

After the host replacement process, the Amazon EC2 host has a new public IP address. The new host retains the data and metadata shown in the following table.

Metadata or data	RDS Custom for Oracle retention	RDS Custom for SQL Server retention
EC2 instance ID	Yes	No
EC2 instance metadata	Yes	Yes
Data storage volume data	Yes	Yes
Root volume data	Yes	No
Private IP addresses	Yes	Yes
Elastic IP addresses	Yes	Yes

Best practices for Amazon EC2 hosts

The Amazon EC2 host replacement feature covers the majority of Amazon EC2 impairment scenarios. We recommend that you adhere to the following best practices:

- Before you change your configuration or the operating system, back up your data. If the root volume or operating system becomes corrupt, host replacement can't repair it. Your only options are restoring from a DB snapshot or point-in-time recovery.
- Don't manually stop or terminate the physical Amazon EC2 host. Both actions result in the instance being put outside the RDS Custom support perimeter.
- (RDS Custom for SQL Server) If you attach additional volumes to the Amazon EC2 host, configure them to remount upon restart. If the host is impaired, RDS Custom might stop and start the host automatically.

RDS Custom support perimeter

RDS Custom provides additional monitoring capability called the *support perimeter*. This additional monitoring ensures that your RDS Custom DB instance uses a supported AWS infrastructure, operating system, and database.

The support perimeter checks that your DB instance conforms to the requirements listed in Fixing unsupported configurations in RDS Custom for Oracle and Fixing unsupported configurations in RDS Custom for SQL Server. If any of these requirements aren't met, RDS Custom considers your DB instance to be outside of the support perimeter.

Topics

- Unsupported configurations in RDS Custom
- Troubleshooting unsupported configurations

Unsupported configurations in RDS Custom

When your DB instance is outside the support perimeter, RDS Custom changes the DB instance status to `unsupported-configuration` and sends event notifications. After you fix the configuration problems, RDS Custom changes the DB instance status back to `available`.

While your DB instance is in the `unsupported-configuration` state, the following is true:

- Your database is reachable. An exception is when the DB instance is in the `unsupported-configuration` because the database is shutting down unexpectedly.
- You can't modify your DB instance.
- You can't take DB snapshots.
- Automatic backups aren't created.
- For RDS Custom for SQL Server DB instances only, RDS Custom doesn't replace the underlying Amazon EC2 instance if it becomes impaired. For more information about host replacement, see Amazon RDS Custom host replacement.
- You can delete your DB instance, but most other RDS Custom API operations aren't available.
- RDS Custom continues to support point-in-time recovery (PITR) by archiving redo log files and uploading them to Amazon S3. PITR in an `unsupported-configuration` state differs in the following ways:

- PITR can take a long time to completely restore to a new RDS Custom DB instance. This situation occurs because you can't take either automated or manual snapshots while the instance is in the `unsupported-configuration` state.
- PITR has to replay more redo logs starting from the most recent snapshot taken before the instance entered the `unsupported-configuration` state.
- In some cases, the DB instance is in the `unsupported-configuration` state because you made a change that prevented the uploading of archived redo log files. Examples include stopping the EC2 instance, stopping the RDS Custom agent, and detaching EBS volumes. In such cases, PITR can't restore the DB instance to the latest restorable time.

Troubleshooting unsupported configurations

RDS Custom provides troubleshooting guidance for the `unsupported-configuration` state. Although some guidance applies to both RDS Custom for Oracle and RDS Custom for SQL Server, other guidance depends on your DB engine. For engine-specific troubleshooting information, see the following topics:

- Fixing unsupported configurations in RDS Custom for Oracle
- Fixing unsupported configurations in RDS Custom for SQL Server

Amazon S3

If you use RDS Custom for Oracle, you upload installation media to a user-created Amazon S3 bucket. RDS Custom for Oracle uses the media in this bucket to create a custom engine version (CEV). A *CEV* is a binary volume snapshot of a database version and Amazon Machine Image (AMI). From the CEV, you can create an RDS Custom DB instance. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle.

For both RDS Custom for Oracle and RDS Custom for SQL Server, RDS Custom automatically creates an Amazon S3 bucket prefixed with the string `do-not-delete-rds-custom-`. RDS Custom uses the `do-not-delete-rds-custom-` S3 bucket to store the following types of files:

- AWS CloudTrail logs for the trail created by RDS Custom
- Support perimeter artifacts (see RDS Custom support perimeter)
- Database redo log files (RDS Custom for Oracle only)
- Transaction logs (RDS Custom for SQL Server only)

- Custom engine version artifacts (RDS Custom for Oracle only)

RDS Custom creates the `do-not-delete-rds-custom-` S3 bucket when you create either of the following resources:

- Your first CEV for RDS Custom for Oracle
- Your first DB instance for RDS Custom for SQL Server

RDS Custom creates one bucket for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

For example, if you create RDS Custom for Oracle CEVs in a single AWS Region, one `do-not-delete-rds-custom-` bucket exists. If you create multiple RDS Custom for SQL Server instances, and they reside in different AWS Regions, one `do-not-delete-rds-custom-` bucket exists in each AWS Region. If you create one RDS Custom for Oracle instance and two RDS Custom for SQL Server instances in a single AWS Region, two `do-not-delete-rds-custom-` buckets exist.

AWS CloudTrail

RDS Custom automatically creates an AWS CloudTrail trail whose name begins with `do-not-delete-rds-custom-`. The RDS Custom support perimeter relies on the events from CloudTrail to determine whether your actions affect RDS Custom automation. For more information, see Troubleshooting unsupported configurations.

RDS Custom creates the trail when you create your first DB instance. RDS Custom creates one trail for each combination of the following:

- AWS account ID
- Engine type (either RDS Custom for Oracle or RDS Custom for SQL Server)
- AWS Region

When you delete an RDS Custom DB instance, the CloudTrail for this instance isn't automatically removed. In this case, your AWS account continues to be billed for the undeleted CloudTrail. RDS

Custom is not responsible for the deletion of this resource. To learn how to remove the CloudTrail manually, see Deleting a trail in the *AWS CloudTrail User Guide*.

Security in Amazon RDS Custom

Familiarize yourself with the security considerations for RDS Custom.

For more information about security for RDS Custom, see the following topics.

- Securing your Amazon S3 bucket against the confused deputy problem
- Rotating RDS Custom for Oracle credentials for compliance programs

How RDS Custom securely manages tasks on your behalf

RDS Custom uses the following tools and techniques to securely run operations on your behalf:

AWSServiceRoleForRDSCustom service-linked role

A *service-linked role* is predefined by the service and includes all permissions that the service needs to call other AWS services on your behalf. For RDS Custom, `AWSServiceRoleForRDSCustom` is a service-linked role that is defined according to the principle of least privilege. RDS Custom uses the permissions in `AmazonRDSCustomServiceRolePolicy`, which is the policy attached to this role, to perform most provisioning and all off-host management tasks. For more information, see AmazonRDSCustomServiceRolePolicy.

When it performs tasks on the host, RDS Custom automation uses credentials from the service-linked role to run commands using AWS Systems Manager. You can audit the command history through the Systems Manager command history and AWS CloudTrail. Systems Manager connects to your RDS Custom DB instance using your networking setup. For more information, see Step 4: Configure IAM for RDS Custom for Oracle.

Temporary IAM credentials

When provisioning or deleting resources, RDS Custom sometimes uses temporary credentials derived from the credentials of the calling IAM principal. These IAM credentials are restricted by the IAM policies attached to that principal and expire after the operation is completed. To learn about the permissions required for IAM principals who use RDS Custom, see Step 5: Grant required permissions to your IAM user or role.

Amazon EC2 instance profile

An EC2 instance profile is a container for an IAM role that you can use to pass role information to an EC2 instance. An EC2 instance underlies an RDS Custom DB instance. You provide an

instance profile when you create an RDS Custom DB instance. RDS Custom uses EC2 instance profile credentials when it performs host-based management tasks such as backups. For more information, see Create your IAM role and instance profile manually.

SSH key pair

When RDS Custom creates the EC2 instance that underlies a DB instance, it creates an SSH key pair on your behalf. The key uses the naming prefix `do-not-delete-rds-custom-ssh-privatekey-db-` or `rds-custom!oracle-do-not-delete-`*`db_resource_id-uuid`*`-ssh-privatekey`. AWS Secrets Manager stores this SSH private key as a secret in your AWS account. Amazon RDS doesn't store, access, or use these credentials. For more information, see Amazon EC2 key pairs and Linux instances.

SSL certificates

RDS Custom DB instances don't support managed SSL certificates. If you want to deploy SSL, you can self-manage SSL certificates in your own wallet and create an SSL listener to secure the connections between the client database or for database replication. For more information, see Configuring Transport Layer Security Authentication in the Oracle Database documentation.

Securing your Amazon S3 bucket against the confused deputy problem

When you create an Amazon RDS Custom for Oracle custom engine version (CEV) or an RDS Custom for SQL Server DB instance, RDS Custom creates an Amazon S3 bucket. The S3 bucket stores files such as CEV artifacts, redo (transaction) logs, configuration items for the support perimeter, and AWS CloudTrail logs.

You can make these S3 buckets more secure by using the global condition context keys to prevent the *confused deputy problem*. For more information, see Preventing cross-service confused deputy problems.

The following RDS Custom for Oracle example shows the use of the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in an S3 bucket policy. For RDS Custom for Oracle, make sure to include the Amazon Resource Names (ARNs) for the CEVs and the DB instances. For RDS Custom for SQL Server, make sure to include the ARN for the DB instances.

Rotating RDS Custom for Oracle credentials for compliance programs

Some compliance programs require database user credentials to change periodically, for example, every 90 days. RDS Custom for Oracle automatically rotates credentials for some predefined database users.

Topics

- Automatic rotation of credentials for predefined users
- Guidelines for rotating user credentials
- Rotating user credentials manually

Automatic rotation of credentials for predefined users

If your RDS Custom for Oracle DB instance is hosted in Amazon RDS, credentials for the following predefined Oracle users rotate every 30 days automatically. Credentials for the preceding users reside in AWS Secrets Manager.

Database user	Created by	Supported engine versions	Notes
SYS	Oracle	custom-oracle-ee custom-oracle-ee-cdb custom-oracle-se2 custom-oracle-se2-cdb	
SYSTEM	Oracle	custom-oracle-ee custom-oracle-ee-cdb custom-oracle-se2 custom-oracle-se2-cdb	
RDSADMIN	RDS	custom-oracle-ee custom-oracle-se2	
C##RDSADMIN	RDS	custom-oracle-ee-cdb custom-oracle-se2-cdb	User names with a C## prefix exist only in CDBs. For more information about CDBs, see Overview of Amazon RDS Custom for Oracle architecture.
RDS_DATAGUARD	RDS	custom-oracle-ee	This user exists only in read replicas, source databases for read replicas, and databases that you have physically

Database user	Created by	Supported engine versions	Notes
			migrated into RDS Custom using Oracle Data Guard.
C##RDS_DATAGUARD	RDS	custom-oracle-ee-cdb	This user exists only in read replicas, source databases for read replicas, and databases that you have physically migrated into RDS Custom using Oracle Data Guard. User names with a C## prefix exist only in CDBs. For more information about CDBs, see Overview of Amazon RDS Custom for Oracle architecture.

An exception to the automatic credential rotation is an RDS Custom for Oracle DB instance that you have manually configured as a standby database. RDS only rotates credentials for read replicas that you have created using the `create-db-instance-read-replica` CLI command or `CreateDBInstanceReadReplica` API.

Guidelines for rotating user credentials

To make sure that your credentials rotate according to your compliance program, note the following guidelines:

- If your DB instance rotates credentials automatically, don't manually change or delete a secret, password file, or password for users listed in Predefined Oracle users. Otherwise, RDS Custom might place your DB instance outside of the support perimeter, which suspends automatic rotation.
- The RDS master user is not predefined, so you are responsible for either changing the password manually or setting up automatic rotation in Secrets Manager. For more information, see Rotate AWS Secrets Manager secrets.

Rotating user credentials manually

For the following categories of databases, RDS doesn't automatically rotate the credentials for the users listed in Predefined Oracle users:

- A database that you configured manually to function as a standby database.
- An on-premises database.
- A DB instance that is outside of the support perimeter or in a state in which the RDS Custom automation can't run. In this case, RDS Custom also doesn't rotate keys.

If your database is in any of the preceding categories, you must rotate your user credentials manually.

To rotate user credentials manually for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In **Databases**, make sure that RDS isn't currently backing up your DB instance or performing operations such configuring high availability.
3. In the database details page, choose **Configuration** and note the Resource ID for the DB instance. Or you can use the AWS CLI command `describe-db-instances`.
4. Open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
5. In the search box, enter the resource ID of your database and search for a secret using either of the following naming conventions:

   ```
   do-not-delete-rds-custom-resource_id-uuid
   rds-custom!oracle-do-not-delete-resource_id-uuid
   ```

   This secret stores the password for RDSADMIN, SYS, and SYSTEM. The following sample keys are for the DB instance with the resource ID db-ABCDEFG12HIJKLNMNOPQRS3TUVWX and UUID 123456:

   ```
   do-not-delete-rds-custom-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-123456
   rds-custom!oracle-do-not-delete-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-123456
   ```

Important

If your DB instance is a read replica and uses the `custom-oracle-ee-cdb` engine, two secrets exist with the suffix *db-resource_id-uuid*, one for the master user and the other for RDSADMIN, SYS, and SYSTEM. To find the correct secret, run the following command on the host:

```
cat /opt/aws/rdscustomagent/config/database_metadata.json | python3 -c
 "import sys,json; print(json.load(sys.stdin)['dbMonitoringUserPassword'])"
```

The dbMonitoringUserPassword attribute indicates the secret for RDSADMIN, SYS, and SYSTEM.

6. If your DB instance exists in an Oracle Data Guard configuration, search for a secret using either of the following naming conventions:

```
do-not-delete-rds-custom-resource_id-uuid-dg
rds-custom!oracle-do-not-delete-resource_id-uuid-dg
```

This secret stores the password for RDS_DATAGUARD. The following sample keys are for the DB instance with the DB resource ID db-ABCDEFG12HIJKLNMNOPQRS3TUVWX and UUID **789012**:

```
do-not-delete-rds-custom-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-789012-dg
rds-custom!oracle-do-not-delete-db-ABCDEFG12HIJKLNMNOPQRS3TUVWX-789012-dg
```

7. For all database users listed in Predefined Oracle users, update the passwords by following the instructions in Modify an AWS Secrets Manager secret.
8. If your database is a standalone database or a source database in an Oracle Data Guard configuration:

   a. Start your Oracle SQL client and log in as SYS.

   b. Run a SQL statement in the following form for each database user listed in Predefined Oracle users:

```
ALTER USER user-name IDENTIFIED BY pwd-from-secrets-manager ACCOUNT UNLOCK;
```

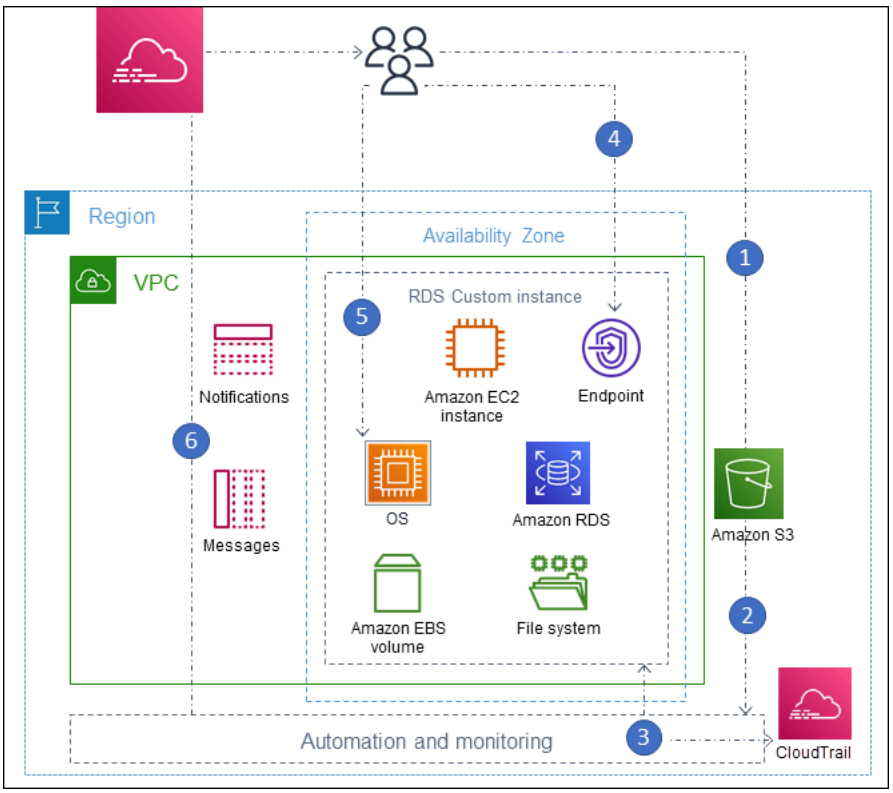
For example, if the new password for RDSADMIN stored in Secrets Manager is pwd-123, run the following statement:

```
ALTER USER RDSADMIN IDENTIFIED BY pwd-123 ACCOUNT UNLOCK;
```

9. If your DB instance runs Oracle Database 12c Release 1 (12.1) and is managed by Oracle Data Guard, manually copy the password file (orapw) from the primary DB instance to each standby DB instance.

   If your DB instance is hosted in Amazon RDS, the password file location is /rdsdbdata/config/orapw. For databases that aren't hosted in Amazon RDS, the default location is $ORACLE_HOME/dbs/orapw$ORACLE_SID on Linux and UNIX and %ORACLE_HOME%\database\PWD%ORACLE_SID%.ora on Windows.

Working with RDS Custom for Oracle



Following, you can find instructions for creating, managing, and maintaining your RDS Custom for Oracle DB instances.

Topics

- RDS Custom for Oracle workflow
- Database architecture for Amazon RDS Custom for Oracle
- Feature availability and support for RDS Custom for Oracle
- RDS Custom for Oracle requirements and limitations
- Setting up your environment for Amazon RDS Custom for Oracle
- Working with custom engine versions for Amazon RDS Custom for Oracle
- Configuring a DB instance for Amazon RDS Custom for Oracle
- Managing an Amazon RDS Custom for Oracle DB instance
- Managing a Multi-AZ deployment for RDS Custom for Oracle
- Working with Oracle replicas for RDS Custom for Oracle
- Backing up and restoring an Amazon RDS Custom for Oracle DB instance
- Working with option groups in RDS Custom for Oracle
- Migrating an on-premises database to RDS Custom for Oracle
- Upgrading a DB instance for Amazon RDS Custom for Oracle
- Troubleshooting DB issues for Amazon RDS Custom for Oracle
- Known issues for Amazon RDS Custom for Oracle

RDS Custom for Oracle workflow

The following diagram shows the typical workflow for RDS Custom for Oracle.

The steps are as follows:

1. Upload your database software to your Amazon S3 bucket.

   For more information, see Step 3: Upload your installation files to Amazon S3.

2. Create an RDS Custom for Oracle custom engine version (CEV) from your media.

   Choose either the CDB architecture or the traditional non-CDB architecture. For more information, see Creating a CEV.

3. Create an RDS Custom for Oracle DB instance from a CEV.

   For more information, see Creating an RDS Custom for Oracle DB instance.

4. Connect your application to the DB instance endpoint.

   For more information, see Connecting to your RDS Custom DB instance using SSH and Connecting to your RDS Custom DB instance using Session Manager.

5. (Optional) Access the host to customize your software.

6. Monitor notifications and messages generated by RDS Custom automation.

Database installation files

Your responsibility for media is a key difference between Amazon RDS and RDS Custom. Amazon RDS, which is a fully managed service, supplies the Amazon Machine Image (AMI) and database software. The Amazon RDS database software is preinstalled, so you need only choose a database engine and version, and create your database.

For RDS Custom, you supply your own media. When you create a custom engine version, RDS Custom installs the media that you provide. RDS Custom media contains your database installation files and patches. This service model is called *Bring Your Own Media (BYOM)*.

Custom engine versions for RDS Custom for Oracle

An *RDS Custom for Oracle custom engine version* (CEV) is a binary volume snapshot of a database version and AMI. By default, RDS Custom for Oracle uses the most recent AMI that Amazon EC2 makes available. You can also choose to reuse an existing AMI.

CEV manifest

After you download Oracle database installation files from Oracle, you upload them to an Amazon S3 bucket. When you create your CEV, you specify the file names in a JSON document called a *CEV manifest*. RDS Custom for Oracle uses the specified files and the AMI to create your CEV.

RDS Custom for Oracle provides JSON manifest templates with our recommended .zip files for each supported Oracle Database release. For example, the following template is for the 19.17.0.0.0 RU.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p34419443_190000_Linux-x86-64.zip",
        "p34411846_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p28852325_190000_Linux-x86-64.zip",
```

```
        "p29997937_190000_Linux-x86-64.zip",
        "p31335037_190000_Linux-x86-64.zip",
        "p32327201_190000_Linux-x86-64.zip",
        "p33613829_190000_Linux-x86-64.zip",
        "p34006614_190000_Linux-x86-64.zip",
        "p34533061_190000_Linux-x86-64.zip",
        "p34533150_190000_Generic.zip",
        "p28730253_190000_Linux-x86-64.zip",
        "p29213893_1917000DBRU_Generic.zip",
        "p33125873_1917000DBRU_Linux-x86-64.zip",
        "p34446152_1917000DBRU_Linux-x86-64.zip"
    ]
}
```

You can also specify installation parameters in the JSON manifest. For example, you can set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. For more information, see JSON fields in the CEV manifest.

CEV naming format

Name your RDS Custom for Oracle CEV using a customer-specified string. The name format is the following, depending on your Oracle Database release:

- `19.`*`customized_string`*
- `18.`*`customized_string`*
- `12.2.`*`customized_string`*
- `12.1.`*`customized_string`*

You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might name your CEV `19.my_cev1`.

Oracle multitenant architecture in RDS Custom for Oracle

The Oracle multitenant architecture enables an Oracle database to function as a container database (CDB). A CDB includes zero, one, or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas and objects that appears to an application as a traditional non-CDB.

When you create an RDS Custom for Oracle CEV, you specify the either the CDB or non-CDB architecture. You can create an RDS Custom for Oracle CDB only when the CEV that you used to

create it uses the Oracle multitenant architecture. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle.

Creating a DB instance for RDS Custom for Oracle

After you create your CEV, it's available for use. You can create multiple CEVs, and you can create multiple RDS Custom for Oracle DB instances from any CEV. You can also change the status of a CEV to make it available or inactive.

You can either create your RDS Custom for Oracle DB instance with the Oracle multitenant architecture (`custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type) or with the traditional non-CDB architecture (`custom-oracle-ee` or `custom-oracle-se2` engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

To create your RDS Custom for Oracle DB instance, use the `create-db-instance` command. In this command, specify which CEV to use. The procedure is similar to creating an Amazon RDS DB instance. However, some parameters are different. For more information, see Configuring a DB instance for Amazon RDS Custom for Oracle.

Database connection

Like an Amazon RDS DB instance, an RDS Custom DB instance resides in a virtual private cloud (VPC). Your application connects to the Oracle database using an Oracle listener.

If your database is a CDB, you can use the listener `L_RDSCDB_001` to connect to the CDB root and to a PDB. If you plug a non-CDB into a CDB, make sure to set `USE_SID_AS_SERVICE_LISTENER = ON` so that migrated applications keep the same settings.

When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming your RDS Custom DB instance.

Database architecture for Amazon RDS Custom for Oracle

RDS Custom for Oracle supports both the Oracle multitenant and non-multitenant architecture.

Topics

- Supported Oracle database architectures
- Supported engine types
- Supported features in the Oracle multitenant architecture

Supported Oracle database architectures

The *Oracle multitenant architecture*, also called the *CDB architecture*, allows an Oracle database to function as a container database (CDB). A CDB includes pluggable databases (PDBs). A PDB is a collection of schemas and objects that appears to an application as a traditional Oracle database. For more information, see Introduction to the Multitenant Architecture in the *Oracle Multitenant Administrator's Guide*.

The CDB and non-CDB architectures are mutually exclusive. If an Oracle database isn't a CDB, it's a non-CDB and so can't contain PDBs. In RDS Custom for Oracle, only Oracle Database 19c supports the CDB architecture. Thus, if you create DB instances using previous Oracle database releases, you can create only non-CDBs. For more information, see Multitenant architecture considerations.

Supported engine types

When you create an Amazon RDS Custom for Oracle CEV or DB instance, choose either a CDB engine type or a non-CDB engine type:

- `custom-oracle-ee-cdb` and `custom-oracle-se2-cdb`

  These engine types specify the Oracle multitenant architecture. This option is available only for Oracle Database 19c. When you create an RDS for Oracle DB instance using the multitenant architecture, your CDB includes the following containers:

  - CDB root (`CDB$ROOT`)
  - PDB seed (`PDB$SEED`)
  - Initial PDB

  You can create more PDBs using the Oracle SQL command `CREATE PLUGGABLE DATABASE`. You can't use RDS APIs to create or delete PDBs.

- `custom-oracle-ee` and `custom-oracle-se2`

  These engine types specify the traditional non-CDB architecture. A non-CDB can't contain pluggable databases (PDBs).

For more information, see Multitenant architecture considerations.

Supported features in the Oracle multitenant architecture

An RDS Custom for Oracle CDB instance supports the following features:

- Backups
- Restoring and point-time-restore (PITR) from backups
- Read replicas
- Minor version upgrades

Feature availability and support for RDS Custom for Oracle

In this topic, you can find a summary of the RDS Custom for Oracle feature availability and support for quick reference.

Topics

- AWS Region and database version support for RDS Custom for Oracle
- Database version support for RDS Custom for Oracle
- Edition and licensing support for RDS Custom for Oracle
- DB instance class support for RDS Custom for Oracle
- Option group support for RDS Custom for Oracle

AWS Region and database version support for RDS Custom for Oracle

Feature availability and support vary across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS Custom for Oracle, see Supported Regions and DB engines for RDS Custom.

Database version support for RDS Custom for Oracle

RDS Custom for Oracle supports the following Oracle database versions:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

Edition and licensing support for RDS Custom for Oracle

RDS Custom for Oracle supports Enterprise Edition (EE) and Standard Edition 2 (SE2) on the BYOL model.

Note the following limitations for Standard Edition 2:

- Oracle Data Guard isn't supported. Thus, you can't create Oracle read replicas.
- You can only use DB instance classes that have 16 or fewer vCPUs (up to 4xlarge).
- A CDB instance on Standard Edition 2 supports a maximum of 3 tenant databases.

- You can't migrate data between Enterprise Edition and Standard Edition 2.

DB instance class support for RDS Custom for Oracle

RDS Custom for Oracle supports the following DB instance classes. If you create a DB instance on Standard Edition 2, you can only use instance classes with 16 or fewer vCPUs (up to 4x large).

Type	Size
db.m7i	db.m7i.large |db.m7i.xlarge |db.m7i.2xlarge |db.m7i.4xlarge |db.m7i.8xlarge |db.m7i.12xlarge |db.m7i.16xlarge |db.m7i.24xlarge |db.m7i.48xlarge |db.m7i.metal-24xl |db.m7i.metal-48xl
db.m6i	db.m6i.large |db.m6i.xlarge |db.m6i.2xlarge |db.m6i.4xlarge |db.m6i.8xlarge |db.m6i.12xlarge |db.m6i.16xlarge |db.m6i.24xlarge |db.m6i.32xlarge |db.m6i.metal
db.m6ic	db.m6id.metal
db.m6ir	db.m6in.metal
db.m5	db.m5.large |db.m5.xlarge |db.m5.2xlarge |db.m5.4xlarge | db.m5.8xlarge |db.m5.12xlarge |db.m5.16xlarge |db.m5.24xlarge
db.r7i	db.r7i.large |db.r7i.xlarge |db.r7i.2xlarge |db.r7i.4xlarge |db.r7i.8xlarge |db.r7i.12xlarge |db.r7i.16xlarge |db.r7i.24xlarge |db.r7i.48xlarge |db.r7i.metal-24xl |db.r7i.metal-48xl
db.r6i	db.r6i.large |db.r6i.xlarge |db.r6i.2xlarge |db.r6i.4xlarge |db.r6i.8xlarge |db.r6i.12xlarge |db.r6i.16xlarge |db.r6i.24xlarge |db.r6i.32xlarge |db.r6i.metal
db.r6id	db.r6id.metal
db.r6in	db.r6in.metal
db.r5b	db.r5b.large |db.r5b.xlarge |db.r5b.2xlarge |db.r5b.4xlarge |db.r5b.8xlarge |db.r5b.12xlarge |db.r5b.16xlarge |db.r5b.24xlarge

Type	Size
db.r5	db.r5.large |db.r5.xlarge |db.r5.2xlarge |db.r5.4xlarge | db.r5.8xlarge |db.r5.12xlarge |db.r5.16xlarge |db.r5.24xlarge
db.x2iec	db.x2iedn.xlarge |db.x2iedn.2xlarge |db.x2iedn.4xlarge | db.x2iedn.8xlarge |db.x2iedn.16xlarge |db.x2iedn.24xlarge | db.x2iedn.32xlarge |db.x2iedn.metal
db.x2idr	db.x2idn.metal
db.x2iez	db.x2iezn.2xlarge |db.x2iezn.4xlarge |db.x2iezn.6xlarge | db.x2iezn.8xlarge |db.x2iezn.12xlarge |db.x2iezn.metal
db.t3	db.t3.medium |db.t3.large |db.t3.xlarge |db.t3.2xlarge

Option group support for RDS Custom for Oracle

You can specify an option group when you create or modify an RDS Custom for Oracle DB instance. For more information, see Working with option groups in RDS Custom for Oracle.

RDS Custom for Oracle requirements and limitations

In this topic, you can find a summary of the Amazon RDS Custom for Oracle feature availability and requirements for quick reference.

Topics

- General requirements for RDS Custom for Oracle
- General limitations for RDS Custom for Oracle
- CEV and AMI limitations for RDS Custom for Oracle
- Unsupported settings for create and modify workflows
- DB instance quotas for your AWS account

General requirements for RDS Custom for Oracle

Make sure to meet the following requirements for Amazon RDS Custom for Oracle:

- You have access to My Oracle Support and Oracle Software Delivery Cloud to download the supported list of installation files and patches for RDS Custom for Oracle. If you use an unknown patch, custom engine version (CEV) creation fails. In this case, contact the RDS Custom support team and ask it to add the missing patch. For more information, see Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud.
- You have access to Amazon S3. You need this service for the following reasons:
  - You upload your Oracle installation files to S3 buckets. You use the uploaded installation files to create your RDS Custom CEV.
  - RDS Custom for Oracle uses scripts downloaded from internally defined S3 buckets to perform actions on your DB instances. These scripts are necessary for onboarding and RDS Custom automation.
  - RDS Custom for Oracle uploads certain files to S3 buckets located in your customer account. These buckets use the following naming format: `do-not-delete-rds-custom-`*`account_id`*`-`*`region`*`-`*`uuid`*. For example, you might have a bucket named `do-not-delete-rds-custom-123456789012-us-east-1-12a3b4`.

  For more information, see Step 3: Upload your installation files to Amazon S3 and Creating a CEV.
- You use the DB instance classes listed in DB instance class support for RDS Custom for Oracle to create your RDS Custom for Oracle DB instances.

- Your RDS Custom for Oracle DB instances run Oracle Linux 8 (recommended) or Oracle Linux 7. If you require Oracle Linux 7, contact Support. For more information, see Considerations for RDS Custom for Oracle database upgrades.
- You specify the gp2, gp3, or io1 solid state drives for Amazon EBS storage. The maximum storage size is 64 TiB.
- You have an AWS KMS key to create an RDS Custom for Oracle DB instance. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key.
- You have the AWS Identity and Access Management (IAM) role and instance profile required for creating RDS Custom for Oracle DB instances. For more information, see Step 4: Configure IAM for RDS Custom for Oracle.
- The AWS Identity and Access Management (IAM) user that creates a CEV or RDS Custom DB instance has the required permissions for IAM, CloudTrail, and Amazon S3.

  For more information, see Step 5: Grant required permissions to your IAM user or role.
- You supply your own virtual private cloud (VPC) and security group configuration. For more information, see Step 6: Configure your VPC for RDS Custom for Oracle.
- You supply a networking configuration that RDS Custom for Oracle can use to access other AWS services. For specific requirements, see Step 4: Configure IAM for RDS Custom for Oracle.

General limitations for RDS Custom for Oracle

The following limitations apply to RDS Custom for Oracle:

- You can't modify the DB instance identifier of an existing RDS Custom for Oracle DB instance.
- You can't specify the Oracle multitenant architecture for any release except Oracle Database 19c.
- You can't create multiple Oracle databases on a single RDS Custom for Oracle DB instance.
- You can’t stop your RDS Custom for Oracle DB instance or its underlying Amazon EC2 instance. Billing for an RDS Custom for Oracle DB instance can't be stopped.
- You can't use automatic shared memory management because RDS Custom for Oracle supports automatic memory management only. For more information, see Automatic Memory Management in the *Oracle Database Administrator’s Guide*.
- Make sure not to change the `DB_UNIQUE_NAME` for the primary DB instance. Changing the name causes any restore operation to become stuck.
- You can't make more than 20 snapshot copies at the same time in the same Region.

- You can't use the `describe-reserved-db-instances` API for RDS Custom for Oracle DB instances.

For limitations specific to modifying an RDS Custom for Oracle DB instance, see Modifying your RDS Custom for Oracle DB instance. For replication limitations, see General limitations for RDS Custom for Oracle replication.

CEV and AMI limitations for RDS Custom for Oracle

The following limitations apply to RDS Custom for Oracle CEVs and AMIs:

- You can't provide your own AMI for use in an RDS Custom for Oracle CEV. You can specify either the default AMI, which uses Oracle Linux 8, or an AMI that has been previously used by an RDS Custom for Oracle CEV.

  > **Note**
  >
  > RDS Custom for Oracle releases a new default AMI when common vulnerabilities and exposures are discovered. No fixed schedule is available or guaranteed. RDS Custom for Oracle tends to publish a new default AMI every 30 days.

- You can't modify a CEV to use a different AMI.
- You can't create a CDB instance from a CEV that uses the `custom-oracle-ee` or `custom-oracle-se2` engine types. The CEV must use `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`.
- RDS Custom for Oracle doesn't currently allow you to upgrade the OS of your RDS Custom for Oracle DB instance with RDS API calls. As a workaround, you can update your OS manually with the following command: `sudo yum update --security`.

Unsupported settings for create and modify workflows

When you create or modify an RDS Custom for Oracle DB instance, you can't do the following:

- Change the number of CPU cores and threads per core on the DB instance class.
- Turn on storage autoscaling.
- Set backup retention to `0`.
- Configure Kerberos authentication.

- Specify your own DB parameter group or option group.
- Turn on Performance Insights.
- Turn on automatic minor version upgrade.

DB instance quotas for your AWS account

Make sure that the combined number of RDS Custom and Amazon RDS DB instances doesn't exceed your quota limit. For example, if your quota for Amazon RDS is 40 DB instances, you can have 20 RDS Custom for Oracle DB instances and 20 Amazon RDS DB instances.

Setting up your environment for Amazon RDS Custom for Oracle

Before you create an Amazon RDS Custom for Oracle DB instance, perform the following tasks.

Topics

- Step 1: Create or reuse a symmetric encryption AWS KMS key
- Step 2: Download and install the AWS CLI
- Step 3: Extract the CloudFormation templates for RDS Custom for Oracle
- Step 4: Configure IAM for RDS Custom for Oracle
- Step 5: Grant required permissions to your IAM user or role
- Step 6: Configure your VPC for RDS Custom for Oracle

Step 1: Create or reuse a symmetric encryption AWS KMS key

Customer managed keys are AWS KMS keys in your AWS account that you create, own, and manage. A customer managed symmetric encryption KMS key is required for RDS Custom. When you create an RDS Custom for Oracle DB instance, you supply the KMS key identifier. For more information, see Configuring a DB instance for Amazon RDS Custom for Oracle.

You have the following options:

- If you have an existing customer managed KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a customer managed symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing customer managed symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the *AWS Key Management Service Developer Guide*.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

> **Important**
>
> RDS Custom doesn't support AWS managed KMS keys.

Make sure that your symmetric encryption key grants access to the `kms:Decrypt` and `kms:GenerateDataKey` operations to the AWS Identity and Access Management (IAM) role in your IAM instance profile. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy grants access to these operations.

For more information, see Step 4: Configure IAM for RDS Custom for Oracle.

For more information about configuring IAM for RDS Custom for Oracle, see Step 4: Configure IAM for RDS Custom for Oracle.

Step 2: Download and install the AWS CLI

AWS provides you with a command-line interface to use RDS Custom features. You can use either version 1 or version 2 of the AWS CLI.

For information about downloading and installing the AWS CLI, see Installing or updating the latest version of the AWS CLI.

Skip this step if either of the following is true:

- You plan to access RDS Custom only from the AWS Management Console.
- You have already downloaded the AWS CLI for Amazon RDS or a different RDS Custom DB engine.

Step 3: Extract the CloudFormation templates for RDS Custom for Oracle

To simplify setup, we strongly recommend that you use CloudFormation templates to create CloudFormation stacks. If you plan to configure IAM and your VPC manually, skip this step.

Topics

- Step 3a: Download the CloudFormation template files
- Step 3b: Extract custom-oracle-iam.json
- Step 3c: Extract custom-vpc.json

Step 3a: Download the CloudFormation template files

A *CloudFormation template* is a declaration of the AWS resources that make up a stack. The template is stored as a JSON file.

To download the CloudFormation template files

1. Open the context (right-click) menu for the link custom-oracle-iam.zip and choose **Save Link As**.
2. Save the file to your computer.
3. Repeat the previous steps for the link custom-vpc.zip.

   If you already configured your VPC for RDS Custom, skip this step.

Step 3b: Extract custom-oracle-iam.json

Open the `custom-oracle-iam.zip` file that you downloaded, and then extract the file `custom-oracle-iam.json`. The beginning of the file looks like the following.

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters": {
    "EncryptionKey": {
      "Type": "String",
      "Default": "*",
      "Description": "KMS Key ARN for encryption of data managed by RDS Custom and by
 DB Instances."
    }
  },
  "Resources": {
    "RDSCustomInstanceServiceRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "RoleName": { "Fn::Sub": "AWSRDSCustomInstanceRole-${AWS::Region}" },
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Action": "sts:AssumeRole",
              "Effect": "Allow",
              "Principal": {
                "Service": "ec2.amazonaws.com"
              }
            }
          ]
        },...
```

Step 3c: Extract custom-vpc.json

> **Note**
>
> If you already configured an existing VPC for RDS Custom for Oracle, skip this step. For more information, see Configure your VPC manually for RDS Custom for Oracle.

Open the `custom-vpc.zip` file that you downloaded, and then extract the file `custom-vpc.json`. The beginning of the file looks like the following.

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters": {
    "PrivateVpc": {
      "Type": "AWS::EC2::VPC::Id",
      "Description": "Private VPC Id to use for RDS Custom DB Instances"
    },
    "PrivateSubnets": {
      "Type": "List<AWS::EC2::Subnet::Id>",
      "Description": "Private Subnets to use for RDS Custom DB Instances"
    },
    "RouteTable": {
      "Type": "String",
      "Description": "Route Table that must be associated with the PrivateSubnets and
 used by S3 VPC Endpoint",
      "AllowedPattern": "rtb-[0-9a-z]+"
    }
  },
  "Resources": {
    "DBSubnetGroup": {
      "Type": "AWS::RDS::DBSubnetGroup",
      "Properties": {
        "DBSubnetGroupName": "rds-custom-private",
        "DBSubnetGroupDescription": "RDS Custom Private Network",
        "SubnetIds": {
          "Ref": "PrivateSubnets"
        }
      }
    },...
```

Step 4: Configure IAM for RDS Custom for Oracle

You use an IAM role or IAM user (known as an *IAM entity*) to create an RDS Custom DB instance using the console or AWS CLI. This IAM entity must have the necessary permissions for instance creation.

You can configure IAM using either CloudFormation or manual steps.

> **Important**
>
> We strongly recommend that you configure your RDS Custom for Oracle environment using CloudFormation. This technique is the easiest and least error-prone.

Topics

- Configure IAM using CloudFormation
- Create your IAM role and instance profile manually

Configure IAM using CloudFormation

When you use the CloudFormation template for IAM, it creates the following required resources:

- An instance profile named `AWSRDSCustomInstanceProfile-`*`region`*
- A service role named `AWSRDSCustomInstanceRole-`*`region`*
- An access policy named `AWSRDSCustomIamRolePolicy` that is attached to the service role

To configure IAM using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Start the Create Stack wizard, and choose **Create Stack**.
3. On the **Create stack** page, do the following:
   a. For **Prepare template**, choose **Template is ready**.
   b. For **Template source**, choose **Upload a template file**.
   c. For **Choose file**, navigate to, then choose **custom-oracle-iam.json**.
   d. Choose **Next**.

4. On the **Specify stack details** page, do the following:

   a. For **Stack name**, enter **`custom-oracle-iam`**.

   b. Choose **Next**.

5. On the **Configure stack options page**, choose **Next**.

6. On the **Review custom-oracle-iam** page, do the following:

   a. Select the **I acknowledge that CloudFormation might create IAM resources with custom names** check box.

   b. Choose **Submit**.

   CloudFormation creates the IAM roles that RDS Custom for Oracle requires. In the left panel, when **custom-oracle-iam** shows **CREATE_COMPLETE**, proceed to the next step.

7. In the left panel, choose **custom-oracle-iam**. In the right panel, do the following:

   a. Choose **Stack info**. Your stack has an ID in the format **arn:aws:cloudformation:*region*:*account-no*:stack/custom-oracle-iam/*identifier***.

   b. Choose **Resources**. You should see the following:

      - An instance profile named **AWSRDSCustomInstanceProfile-*region***
      - A service role named **AWSRDSCustomInstanceRole-*region***

      When you create your RDS Custom DB instance, you need to supply the instance profile ID.

Create your IAM role and instance profile manually

Configuration is easiest when you use CloudFormation. However, you can also configure IAM manually. For manual setup, do the following:

- Step 1: Create the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance.
- Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
- Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
- Step 4: Add AWSRDSCustomInstanceRoleForRdsCustomInstance to AWSRDSCustomInstanceProfile.

Step 1: Create the IAM role AWSRDSCustomInstanceRoleForRdsCustomInstance

In this step, you create the role using the naming format `AWSRDSCustomInstanceRole-`*`region`*. Using the trust policy, Amazon EC2 can assume the role. The following example assumes that you have set the environment variable `$REGION` to the AWS Region in which you want to create your DB instance.

```
aws iam create-role \
  --role-name AWSRDSCustomInstanceRole-$REGION \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
      "Statement": [
        {
          "Action": "sts:AssumeRole",
          "Effect": "Allow",
          "Principal": {
              "Service": "ec2.amazonaws.com"
          }
        }
      ]
    }'
```

Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance

When you embed an inline policy in an IAM role, the inline policy is used as part of the role's access (permissions) policy. You create the `AWSRDSCustomIamRolePolicy` policy that permits Amazon EC2 to send and receive messages and perform various actions.

The following example creates the access policy named `AWSRDSCustomIamRolePolicy`, and adds it to the IAM role `AWSRDSCustomInstanceRole-`*`region`*. This example assumes that you have set the following environment variables:

`$REGION`

Set this variable to the AWS Region in which you plan to create your DB instance.

`$ACCOUNT_ID`

Set this variable to your AWS account number.

$KMS_KEY

Set this variable to the Amazon Resource Name (ARN) of the AWS KMS key that you want to use for your RDS Custom DB instances. To specify more than one KMS key, add it to the `Resources` section of statement ID (Sid) 11.

```
aws iam put-role-policy \
  --role-name AWSRDSCustomInstanceRole-$REGION \
  --policy-name AWSRDSCustomIamRolePolicy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "1",
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeAssociation",
                "ssm:GetDeployablePatchSnapshotForInstance",
                "ssm:GetDocument",
                "ssm:DescribeDocument",
                "ssm:GetManifest",
                "ssm:GetParameter",
                "ssm:GetParameters",
                "ssm:ListAssociations",
                "ssm:ListInstanceAssociations",
                "ssm:PutInventory",
                "ssm:PutComplianceItems",
                "ssm:PutConfigurePackageResult",
                "ssm:UpdateAssociationStatus",
                "ssm:UpdateInstanceAssociationStatus",
                "ssm:UpdateInstanceInformation",
                "ssm:GetConnectionStatus",
                "ssm:DescribeInstanceInformation",
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": [
                "*"
            ]
        },
```

```
        {
            "Sid": "2",
            "Effect": "Allow",
            "Action": [
                "ec2messages:AcknowledgeMessage",
                "ec2messages:DeleteMessage",
                "ec2messages:FailMessage",
                "ec2messages:GetEndpoint",
                "ec2messages:GetMessages",
                "ec2messages:SendReply"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "3",
            "Effect": "Allow",
            "Action": [
                "logs:PutRetentionPolicy",
                "logs:PutLogEvents",
                "logs:DescribeLogStreams",
                "logs:DescribeLogGroups",
                "logs:CreateLogStream",
                "logs:CreateLogGroup"
            ],
            "Resource": [
                "arn:aws:logs:'$REGION':'$ACCOUNT_ID':log-group:rds-custom-instance*"
            ]
        },
        {
            "Sid": "4",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3:GetObjectVersion"
            ],
            "Resource": [
                "arn:aws:s3:::do-not-delete-rds-custom-*/*"
            ]
        },
        {
            "Sid": "5",
```

```
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData"
            ],
            "Resource": [
                "*"
            ],
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": [
                        "RDSCustomForOracle/Agent"
                    ]
                }
            }
        },
        {
            "Sid": "6",
            "Effect": "Allow",
            "Action": [
                "events:PutEvents"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "7",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue",
                "secretsmanager:DescribeSecret"
            ],
            "Resource": [
                "arn:aws:secretsmanager:'$REGION':'$ACCOUNT_ID':secret:do-not-delete-
rds-custom-*",
                "arn:aws:secretsmanager:'$REGION':'$ACCOUNT_ID':secret:rds-custom!
oracle-do-not-delete-*"
            ]
        },
        {
           "Sid": "8",
           "Effect": "Allow",
           "Action": [
             "s3:ListBucketVersions"
```

```
            ],
            "Resource": [
              "arn:aws:s3:::do-not-delete-rds-custom-*"
            ]
          },
          {
             "Sid": "9",
             "Effect": "Allow",
             "Action": "ec2:CreateSnapshots",
             "Resource": [
                 "arn:aws:ec2:*:*:instance/*",
                 "arn:aws:ec2:*:*:volume/*"
             ],
             "Condition": {
                 "StringEquals": {
                     "ec2:ResourceTag/AWSRDSCustom": "custom-oracle"
                 }
             }
           },
           {
             "Sid": "10",
             "Effect": "Allow",
             "Action": "ec2:CreateSnapshots",
             "Resource": [
                 "arn:aws:ec2:*::snapshot/*"
             ]
           },
           {
             "Sid": "11",
             "Effect": "Allow",
             "Action": [
               "kms:Decrypt",
               "kms:GenerateDataKey"
             ],
             "Resource": [
               "arn:aws:kms:'$REGION':'$ACCOUNT_ID':key/'$KMS_KEY'"
             ]
           },
           {
             "Sid": "12",
             "Effect": "Allow",
             "Action": "ec2:CreateTags",
             "Resource": "*",
             "Condition": {
```

```
                "StringLike": {
                    "ec2:CreateAction": [
                        "CreateSnapshots"
                    ]
                }
            }
        },
        {
            "Sid": "13",
            "Effect": "Allow",
            "Action": [
                "sqs:SendMessage",
                "sqs:ReceiveMessage",
                "sqs:DeleteMessage",
                "sqs:GetQueueUrl"
            ],
            "Resource": "arn:aws:sqs:'$REGION':'$ACCOUNT_Id':do-not-delete-rds-custom-
*",
            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/AWSRDSCustom": "custom-oracle"
                }
            }
        }
    ]
}'
```

Step 3: Create the RDS Custom instance profile AWSRDSCustomInstanceProfile

An instance profile is a container that includes a single IAM role. RDS Custom uses the instance profile to pass the role to the instance.

If you use the CLI to create a role, you create the role and instance profile as separate actions, with potentially different names. Create your IAM instance profile as follows, naming it using the format `AWSRDSCustomInstanceProfile-`*`region`*. The following example assumes that you have set the environment variable `$REGION` to the AWS Region in which you want to create your DB instance.

```
aws iam create-instance-profile \
    --instance-profile-name AWSRDSCustomInstanceProfile-$REGION
```

Step 4: Add AWSRDSCustomInstanceRoleForRdsCustomInstance to AWSRDSCustomInstanceProfile

Add your IAM role to the instance profile that you previously created. The following example assumes that you have set the environment variable `$REGION` to the AWS Region in which you want to create your DB instance.

```
aws iam add-role-to-instance-profile \
    --instance-profile-name AWSRDSCustomInstanceProfile-$REGION \
    --role-name AWSRDSCustomInstanceRole-$REGION
```

Step 5: Grant required permissions to your IAM user or role

Make sure that the IAM principal (user or role) that creates the CEV or RDS Custom DB instance has either of the following policies:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with required permissions for Amazon S3 and AWS KMS, CEV creation, and DB instance creation

Topics

- IAM permissions required for Amazon S3 and AWS KMS
- IAM permissions required for creating a CEV
- IAM permissions required for creating a DB instance from a CEV

IAM permissions required for Amazon S3 and AWS KMS

To create CEVs or RDS Custom for Oracle DB instances, your IAM principal needs to access Amazon S3 and AWS KMS. The following sample JSON policy grants the required permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
```

```
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateKmsGrant",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about the `kms:CreateGrant` permission, see AWS KMS key management.

IAM permissions required for creating a CEV

To create a CEV, your IAM principal needs the following additional permissions:

```
s3:GetObjectAcl
s3:GetObject
s3:GetObjectTagging
s3:ListBucket
mediaimport:CreateDatabaseBinarySnapshot
```

The following sample JSON policy grants the additional permissions necessary to access bucket *`my-custom-installation-files`* and its contents.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
```

```
            "Sid": "AccessToS3MediaBucket",
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectAcl",
                "s3:GetObject",
                "s3:GetObjectTagging",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::my-custom-installation-files",
                "arn:aws:s3:::my-custom-installation-files/*"
            ]
        },
        {
            "Sid": "PermissionForByom",
            "Effect": "Allow",
            "Action": [
                "mediaimport:CreateDatabaseBinarySnapshot"
            ],
            "Resource": "*"
        }
    ]
}
```

You can grant similar permissions for Amazon S3 to caller accounts using an S3 bucket policy.

IAM permissions required for creating a DB instance from a CEV

To create an RDS Custom for Oracle DB instance from an existing CEV, the IAM principal needs the following additional permissions.

```
iam:SimulatePrincipalPolicy
cloudtrail:CreateTrail
cloudtrail:StartLogging
```

The following sample JSON policy grants the permissions necessary to validate an IAM role and log information to an AWS CloudTrail.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
            "Effect": "Allow",
            "Action": [
                "cloudtrail:CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
        }
    ]
}
```

Step 6: Configure your VPC for RDS Custom for Oracle

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Unlike RDS Custom for SQL Server, RDS Custom for Oracle doesn't create an access control list or security groups. You must attach you own security group, subnets, and route tables.

You can configure your virtual private cloud (VPC) using either CloudFormation or a manual process.

> **Important**
>
> We strongly recommend that you configure your RDS Custom for Oracle environment using CloudFormation. This technique is the easiest and least error-prone.

Topics

- Configure your VPC using CloudFormation (recommended)
- Configure your VPC manually for RDS Custom for Oracle

Configure your VPC using CloudFormation (recommended)

If you've already configured your VPC for a different RDS Custom engine, and want to reuse the existing VPC, skip this step. This section assumes the following:

- You've already used CloudFormation to create your IAM instance profile and role.
- You know your route table ID.

  For a DB instance to be private, it must be in a private subnet. For a subnet to be private, it must not be associated with a route table that has a default internet gateway. For more information, see Configure route tables in the *Amazon VPC User Guide*.

When you use the CloudFormation template for your VPC, it creates the following resources:

- A private VPC
- A subnet group named `rds-custom-private`
- The following VPC endpoints, which your DB instance uses to communicate with dependent AWS services:
  - `com.amazonaws.region.ec2messages`
  - `com.amazonaws.region.events`
  - `com.amazonaws.region.logs`
  - `com.amazonaws.region.monitoring`
  - `com.amazonaws.region.s3`
  - `com.amazonaws.region.secretsmanager`
  - `com.amazonaws.region.ssm`
  - `com.amazonaws.region.ssmmessages`

  If you're creating a Multi-AZ deployment:

  - `com.amazonaws.region.sqs`

> **Note**
>
> For a complex networking setup with existing accounts, we recommend that you configure access to dependent services manually if access doesn't already exist. For more information, see Make sure your VPC can access dependent AWS services.

To configure your VPC using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. Start the Create Stack wizard, and choose **Create Stack** and then **With new resources (standard)**.
3. On the **Create stack** page, do the following:
   a. For **Prepare template**, choose **Template is ready**.
   b. For **Template source**, choose **Upload a template file**.
   c. For **Choose file**, navigate to, then choose `custom-vpc.json`.
   d. Choose **Next**.
4. On the **Specify stack details** page, do the following:
   a. For **Stack name**, enter **`custom-vpc`**.
   b. For **Parameters**, choose the private subnets to use for RDS Custom DB instances.
   c. Choose the private VPC ID to use for RDS Custom DB instances.
   d. Enter the route table associated with the private subnets.
   e. Choose **Next**.
5. On the **Configure stack options page**, choose **Next**.
6. On the **Review custom-vpc** page, choose **Submit**.

   CloudFormation configures your private VPC. In the left panel, when **custom-vpc** shows **CREATE_COMPLETE**, proceed to the next step.
7. (Optional) Review the details of your VPC. In the **Stacks** pane, choose **custom-vpc**. In the right pane, do the following:
   a. Choose **Stack info**. Your stack has an ID in the format **arn:aws:cloudformation:*region*:*account-no*:stack/custom-vpc/*identifier***.
   b. Choose **Resources**. You should see a subnet group named **rds-custom-private** and several VPC endpoints that use the naming format **vpce-*string***. Each endpoint corresponds to an AWS service that RDS Custom needs to communicate with. For more information, see Make sure your VPC can access dependent AWS services.
   c. Choose **Parameters**. You should see the private subnets, private VPC, and the route table that you specified when you created the stack. When you create a DB instance, you need to supply the VPC ID and subnet group.

Configure your VPC manually for RDS Custom for Oracle

As an alternative to automating VPC creation with CloudFormation, you can configure your VPC manually. This option might be best when you have a complex networking setup that uses existing resources.

Topics

- Make sure your VPC can access dependent AWS services
- Configure the instance metadata service

Make sure your VPC can access dependent AWS services

RDS Custom sends communication from your DB instance to other AWS services. Make sure the following services are accessible from the subnet in which you create your RDS Custom DB instances:

- Amazon CloudWatch (`com.amazonaws.`*`region`*`.monitoring`)
- Amazon CloudWatch Logs (`com.amazonaws.`*`region`*`.logs`)
- Amazon CloudWatch Events (`com.amazonaws.`*`region`*`.events`)
- Amazon EC2 (`com.amazonaws.`*`region`*`.ec2` and `com.amazonaws.`*`region`*`.ec2messages`)
- Amazon S3 (`com.amazonaws.`*`region`*`.s3`)
- AWS Secrets Manager (`com.amazonaws.`*`region`*`.secretsmanager`)
- AWS Systems Manager (`com.amazonaws.`*`region`*`.ssm` and `com.amazonaws.`*`region`*`.ssmmessages`)

If creating Multi-AZ deployments

- Amazon Simple Queue Service (`com.amazonaws.`*`region`*`.sqs`)

If RDS Custom can't communicate with the necessary services, it publishes the following events:

```
Database instance in incompatible-network. SSM Agent connection not available. Amazon
 RDS can't connect to the dependent AWS services.
```

```
Database instance in incompatible-network. Amazon RDS can't connect to dependent AWS
 services. Make sure port 443 (HTTPS) allows outbound connections, and try again.
 "Failed to connect to the following services: s3 events"
```

To avoid `incompatible-network` errors, make sure that VPC components involved in communication between your RDS Custom DB instance and AWS services satisfy the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your RDS Custom DB instance.
- RDS Custom can correctly resolve the domain names of endpoints for each AWS service.

If you already configured a VPC for a different RDS Custom DB engine, you can reuse that VPC and skip this process.

Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see Use IMDSv2 in the *Amazon EC2 User Guide*.

RDS Custom for Oracle automation uses IMDSv2 by default, by setting `HttpTokens=enabled` on the underlying Amazon EC2 instance. However, you can use IMDSv1 if you want. For more information, see Configure the instance metadata options in the *Amazon EC2 User Guide*.

Working with custom engine versions for Amazon RDS Custom for Oracle

A *custom engine version (CEV)* for Amazon RDS Custom for Oracle is a binary volume snapshot of a database engine and specific Amazon Machine Image (AMI). By default, RDS Custom for Oracle uses the latest available AMI managed by RDS Custom, but you can specify an AMI that was used in a previous CEV. You store your database installation files in Amazon S3. RDS Custom uses the installation files and the AMI to create your CEV for you.

Topics

- Preparing to create a CEV
- Creating a CEV
- Modifying CEV status
- Viewing CEV details for Amazon RDS Custom for Oracle
- Deleting a CEV

Preparing to create a CEV

To create a CEV, access the installation files and patches that are stored in your Amazon S3 bucket for any of the following releases:

- Oracle Database 19c
- Oracle Database 18c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

For example, you can use the April 2021 RU/RUR for Oracle Database 19c, or any valid combination of installation files and patches. For more information on the versions and Regions supported by RDS Custom for Oracle, see RDS Custom with RDS for Oracle.

Topics

- Step 1 (Optional): Download the manifest templates
- Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud
- Step 3: Upload your installation files to Amazon S3

- Step 4 (Optional): Share your installation media in S3 across AWS accounts
- Step 5: Prepare the CEV manifest
- Step 6 (Optional): Validate the CEV manifest
- Step 7: Add necessary IAM permissions

Step 1 (Optional): Download the manifest templates

A *CEV manifest* is a JSON document that includes the list of database installation .zip files for your CEV. To create a CEV, do the following:

1. Identify the Oracle database installation files that you want to include in your CEV.
2. Download the installation files.
3. Create a JSON manifest that lists the installation files.

RDS Custom for Oracle provides JSON manifest templates with our recommended .zip files for each supported Oracle Database release. For example, the following template is for the 19.17.0.0.0 RU.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p34419443_190000_Linux-x86-64.zip",
        "p34411846_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p28852325_190000_Linux-x86-64.zip",
        "p29997937_190000_Linux-x86-64.zip",
        "p31335037_190000_Linux-x86-64.zip",
        "p32327201_190000_Linux-x86-64.zip",
        "p33613829_190000_Linux-x86-64.zip",
        "p34006614_190000_Linux-x86-64.zip",
        "p34533061_190000_Linux-x86-64.zip",
        "p34533150_190000_Generic.zip",
```

```
        "p28730253_190000_Linux-x86-64.zip",
        "p29213893_1917000DBRU_Generic.zip",
        "p33125873_1917000DBRU_Linux-x86-64.zip",
        "p34446152_1917000DBRU_Linux-x86-64.zip"
    ]
}
```

Each template has an associated readme that includes instructions for downloading the patches, URLs for the .zip files, and file checksums. You can use these templates as they are or modify them with your own patches. To review the templates, download custom-oracle-manifest.zip to your local disk and then open it with a file archiving application. For more information, see Step 5: Prepare the CEV manifest.

Step 2: Download your database installation files and patches from Oracle Software Delivery Cloud

When you have identified the installation files that you want for your CEV, download them to your local system. The Oracle Database installation files and patches are hosted on Oracle Software Delivery Cloud. Each CEV requires a base release, such as Oracle Database 19c or Oracle Database 12c Release 2 (12.2), and an optional list of patches.

To download the database installation files for Oracle Database

1. Go to https://edelivery.oracle.com/ and sign in.
2. In the search box, enter **`Oracle Database Enterprise Edition`** or **`Oracle Database Standard Edition 2`** and choose **Search**.
3. Choose one of the following base releases:

Database version	Enterprise Edition	Standard Edition 2
Oracle Database 19c	**DLP: Oracle Database 19c Enterprise Edition 19.3.0.0.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database 19c Standard Edition 2 19.3.0.0.0 (Oracle Database Standard Edition 2)**
Oracle Database 18c	**DLP: Oracle Database 18c Enterprise Edition 18.0.0.0.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database Standard Edition 2 18.0.0.0.0 (Oracle Database Standard Edition 2)**

Database version	Enterprise Edition	Standard Edition 2
Oracle Database 12c Release 2 (12.2.0.1)	**DLP: Oracle Database 12c Enterprise Edition 12.2.0.1.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database Standard Edition 2 12.2.0.1.0 (Oracle Database Standard Edition 2)**
Oracle Database 12c Release 1 (12.1.0.2)	**DLP: Oracle Database 12c Enterprise Edition 12.1.0.2.0 (Oracle Database Enterprise Edition)**	**DLP: Oracle Database Standard Edition 2 12.1.0.2.0 (Oracle Database Standard Edition 2)**

4. Choose **Continue**.
5. Clear the **Download Queue** check box.
6. Choose the option that corresponds to your base release:
   - **Oracle Database 19.3.0.0.0 - Long Term Release**.
   - **Oracle Database 18.0.0.0.0**
   - **Oracle Database 12.2.0.1.0**.
   - **Oracle Database 12.1.0.2.0**.
7. Choose **Linux x86-64** in **Platform/Languages**.
8. Choose **Continue**, and then sign the Oracle License Agreement.
9. Choose the .zip file that corresponds to your database release:

Database release and edition	Zip files	SHA-256 hash
19c EE and SE2	**V982063-01.zip**	`BA8329C757133DA313ED3B6D7F86C5AC42CD9970A28BF2E6233F3235233AA8D8`
18c EE and SE2	**V978967-01.zip**	`C96A4FD768787AF98272008833FE10B172691CF84E42816B138C12D4DE63AB96`

Database release and edition	Zip files	SHA-256 hash
12.2.0.1 EE and SE2	**V839960-01.zip**	96ED97D21F15C1AC0CCE3749DA6C3DAC7059BB60672D76B008103FC754D22DDE
12.1.0.2 EE	**V46095-01_1of2.zip** **V46095-01_2of2.zip**	31FDC2AF41687B4E547A3A18F796424D8C1AF36406D2160F65B0AF6A9CD47355 for V46095-01_1of2.zip 03DA14F5E875304B28F0F3BB02AF0EC33227885B99C9865DF70749D1E220ACCD for V46095-01_2of2.zip
12.1.0.2 SE2	**V77388-01_1of2.zip** **V77388-01_2of2.zip**	73873369753230F5A0921F95ACEADB591388CB06ED72A7F3AEA7BCBCEA2403BC for V77388-01_1of2.zip 2492E1BE1E3E3531DA83D0843C09C08E435AC8CEFD9A00C0DF56BE4F15CEEBF3 for V77388-01_2of2.zip

10. Download your desired Oracle patches from `updates.oracle.com` or `support.oracle.com` to your local system. You can find the URLs for the patches in the following locations:

    - The readme files in the .zip file that you downloaded in Step 1 (Optional): Download the manifest templates
    - The patches listed in each Release Update (RU) in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle

Step 3: Upload your installation files to Amazon S3

Upload your Oracle installation and patch files to Amazon S3 using the AWS CLI. The S3 bucket that contains your installation files must be in the same AWS Region as your CEV.

Examples in this section use the following placeholders:

- *install-or-patch-file.zip* – Oracle installation media file. For example, p32126828_190000_Linux-x86-64.zip is a patch.
- *amzn-s3-demo-destination-bucket* – Your Amazon S3 bucket designated for your uploaded installation files.
- *123456789012/cev1* – An optional prefix in your Amazon S3 bucket.
- *amzn-s3-demo-source-bucket* – An Amazon S3 bucket where you can optionally stage files.

Topics

- Step 3a: Verify that your S3 bucket is in the correct AWS Region
- Step 3b: Make sure that your S3 bucket policy has the correct permissions
- Step 3c: Upload your files using the cp or sync commands
- Step 3d: List the files in your S3 bucket

Step 3a: Verify that your S3 bucket is in the correct AWS Region

Verify that your S3 bucket is in the AWS Region where you plan to run the `create-custom-db-engine-version` command.

```
aws s3api get-bucket-location --bucket amzn-s3-demo-destination-bucket
```

Step 3b: Make sure that your S3 bucket policy has the correct permissions

You can create a CEV from scratch or from a source CEV. If you plan to create new CEV from source CEVs, make sure that your S3 bucket policy has the correct permissions:

1. Identify the S3 bucket reserved by RDS Custom. The bucket name has the format `do-not-delete-rds-custom-account-region-string`. For example, the bucket might be named `do-not-delete-rds-custom-123456789012-us-east-1-abc123EXAMPLE`.
2. Make sure that the following permission is appended to your S3 bucket policy. Replace `do-not-delete-rds-custom-123456789012-us-east-1-abc123EXAMPLE` with the name of your bucket.

```
{
    "Sid": "AWSRDSCustomForOracleCustomEngineVersionGetObject",
```

```
    "Effect": "Allow",
    "Principal": {
        "Service": "custom.rds.amazonaws.com"
    },
    "Action": [
        "s3:GetObject",
        "s3:GetObjectTagging"
    ],
    "Resource": "arn:aws:s3:::do-not-delete-rds-custom-123456789012-us-
east-1-abc123EXAMPLE/CustomEngineVersions/*"
}, ...
```

Step 3c: Upload your files using the cp or sync commands

Choose either of the following options:

- Use `aws s3 cp` to upload a single .zip file.

  Upload each installation .zip file separately. Don't combine the .zip files into a single .zip file.
- Use `aws s3 sync` to upload a directory.

Example

The following example uploads *install-or-patch-file.zip* to the *123456789012/cev1* folder in the RDS Custom Amazon S3 bucket. Run a separate `aws s3` command for each .zip that you want to upload.

For Linux, macOS, or Unix:

```
aws s3 cp install-or-patch-file.zip \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

For Windows:

```
aws s3 cp install-or-patch-file.zip ^
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Example

The following example uploads the files in your local *cev1* folder to the *123456789012/cev1* folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync cev1 \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

For Windows:

```
aws s3 sync cev1 ^
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Example

The following example uploads all files in *amzn-s3-demo-source-bucket* to the *123456789012/cev1* folder in your Amazon S3 bucket.

For Linux, macOS, or Unix:

```
aws s3 sync s3://amzn-s3-demo-source-bucket/ \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

For Windows:

```
aws s3 sync s3://amzn-s3-demo-source-bucket/ ^
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Step 3d: List the files in your S3 bucket

The following example uses the `s3 ls` command to list the files in your RDS Custom Amazon S3 bucket.

```
aws s3 ls \
    s3://amzn-s3-demo-destination-bucket/123456789012/cev1/
```

Step 4 (Optional): Share your installation media in S3 across AWS accounts

For the purposes of this section, the Amazon S3 bucket that contains your uploaded Oracle installation files is your *media bucket*. Your organization might use multiple AWS accounts in an AWS Region. If so, you might want to use one AWS account to populate your media bucket and a different AWS account to create CEVs. If you don't intend to share your media bucket, skip to the next section.

This section assumes the following:

- You can access the account that created your media bucket and a different account in which you intend to create CEVs.
- You intend to create CEVs in only one AWS Region. If you intend to use multiple Regions, create a media bucket in each Region.
- You're using the CLI. If you're using the Amazon S3 console, adapt the following steps.

To configure your media bucket for sharing across AWS accounts

1. Log in to the AWS account that contains the S3 bucket into which you uploaded your installation media.
2. Start with either a blank JSON policy template or an existing policy that you can adapt.

   The following command retrieves an existing policy and saves it as *my-policy.json*. In this example, the S3 bucket containing your installation files is named *amzn-s3-demo-bucket*.

   ```
   aws s3api get-bucket-policy \
       --bucket amzn-s3-demo-bucket \
       --query Policy \
       --output text > my-policy.json
   ```

3. Edit the media bucket permissions as follows:

   - In the `Resource` element of your template, specify the S3 bucket into which you uploaded your Oracle Database installation files.
   - In the `Principal` element, specify the ARNs for all AWS accounts that you intend to use to create CEVs. You can add the root, a user, or a role to the S3 bucket allow list. For more information, see IAM identifiers in the *AWS Identity and Access Management User Guide*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "GrantAccountsAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:root",
                    "arn:aws:iam::444455556666:user/user-name-with-path",
                    "arn:aws:iam::123456789012:role/role-name-with-path"
                ]
            },
            "Action": [
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:GetObjectTagging",
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

4. Attach the policy to your media bucket.

   In the following example, *amzn-s3-demo-bucket* is the name of the S3 bucket that contains your installation files, and *my-policy.json* is the name of your JSON file.

   ```
   aws s3api put-bucket-policy \
       --bucket amzn-s3-demo-bucket \
       --policy file://my-policy.json
   ```

5. Log in to an AWS account in which you intend to create CEVs.

6. Verify that this account can access the media bucket in the AWS account that created it.

```
aws s3 ls --query "Buckets[].Name"
```

   For more information, see aws s3 ls in the *AWS CLI Command Reference*.

7. Create a CEV by following the steps in Creating a CEV.

Step 5: Prepare the CEV manifest

A CEV manifest is a JSON document that includes the following:

- (Required) The list of installation .zip files that you uploaded to Amazon S3. RDS Custom applies the patches in the order in which they're listed in the manifest.
- (Optional) Installation parameters that set nondefault values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. Be aware that you can't modify the installation parameters for an existing CEV or an existing DB instance. You also can't upgrade from one CEV to another CEV when the installation parameters have different settings.

For sample CEV manifests, see the JSON templates that you downloaded in Step 1 (Optional): Download the manifest templates. You can also review the samples in CEV manifest examples.

Topics

- JSON fields in the CEV manifest
- Creating the CEV manifest
- CEV manifest examples

JSON fields in the CEV manifest

The following table describes the JSON fields in the manifest.

JSON field	Description
`MediaImportTemplateVersion`	Version of the CEV manifest. The date is in the format `YYYY-MM-DD` .

JSON field	Description
`databaseInstallationFileNames`	Ordered list of installation files for the database.
`opatchFileNames`	Ordered list of OPatch installers used for the Oracle DB engine. Only one value is valid. Values for `opatchFileNames` must start with `p6880880_`.
`psuRuPatchFileNames`	The PSU and RU patches for this database. **Important** If you include `psuRuPatchFileNames`, `opatchFileNames` is required. Values for `opatchFileNames` must start with `p6880880_`.
`OtherPatchFileNames`	The patches that aren't in the list of PSU and RU patches. RDS Custom applies these patches after applying the PSU and RU patches. **Important** If you include `OtherPatchFileNames`, `opatchFileNames` is required. Values for `opatchFileNames` must start with `p6880880_`.

JSON field	Description
`installationParameters`	Nondefault settings for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. You can set the following parameters: **oracleBase** The directory under which your Oracle binaries are installed. It is the mount point of the binary volume that stores your files. The Oracle base directory can include multiple Oracle homes. For example, if `/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1` is one of your Oracle home directories, then `/home/oracle` is the Oracle base directory. A user-specified Oracle base directory is not a symbolic link. If you don't specify the Oracle base, the default directory is `/rdsdbbin`. **oracleHome** The directory in which your Oracle database binaries are installed. For example, if you specify `/home/oracle/` as your Oracle base, then you might specify `/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1/` as your Oracle home. A user-specified Oracle home directory is not a symbolic link. The Oracle home value is referenced by the `$ORACLE_HOME` environment variable. If you don't specify the Oracle home, the default naming format is `/rdsdbbin/oracle.` *`major-engine-version`* `.custom.r1.` *`engine-edition`* `.1`. **unixUname** The name of the UNIX user that owns the Oracle software. RDS Custom assumes this user when running local database commands. If you specify both `unixUid` and `unixUname`, RDS Custom creates the user if it doesn't exist, and then

JSON field	Description
	assigns the UID to the user if it's not the same as the initial UID. The default user name is `rdsdb`. **unixUid** The ID (UID) of the UNIX user that owns the Oracle software. If you specify both `unixUid` and `unixUname` , RDS Custom creates the user if it doesn't exist, and then assigns the UID to the user if it's not the same as the initial UID. The default UID is `61001`. This is the UID of the user `rdsdb`. **unixGroupName** The name of the UNIX group. The UNIX user that owns the Oracle software belongs to this group. The default group name is `rdsdb`. **unixGroupId** The ID of the UNIX group to which the UNIX user belongs. The default group ID is `1000`. This is the ID of the group `rdsdb`.

Each Oracle Database release has a different list of supported installation files. When you create your CEV manifest, make sure to specify only files that are supported by RDS Custom for Oracle. Otherwise, CEV creation fails with an error. All patches listed in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle are supported.

Creating the CEV manifest

To create a CEV manifest

1. List all installation files that you plan to apply, in the order that you want to apply them.
2. Correlate the installation files with the JSON fields described in JSON fields in the CEV manifest.

3. Do either of the following:

   - Create the CEV manifest as a JSON text file.
   - Edit the CEV manifest template when you create the CEV in the console. For more information, see Creating a CEV.

CEV manifest examples

The following examples show CEV manifest files for different Oracle Database releases. If you include a JSON field in your manifest, make sure that it isn't empty. For example, the following CEV manifest isn't valid because `otherPatchFileNames` is empty.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [

Example Sample CEV manifest for Oracle Database 12c Release 1 (12.1)

In the following example for the July 2021 PSU for Oracle Database 12c Release 1 (12.1), RDS Custom applies the patches in the order specified. Thus, RDS Custom applies p32768233, then

p32876425, then p18759211, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```

```
    ],
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/oracle.12.2.0.1",
        "oracleBase": "/home/oracle"
    }
}
```

Example Sample CEV manifest for Oracle Database 18c

In following example for the October 2021 PSU for Oracle Database 18c, RDS Custom applies p32126855, then p28730253, then p27539475, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```
{
    "mediaImportTemplateVersion":"2020-08-14",
    "databaseInstallationFileNames":[
        "V978967-01.zip"
    ],
    "opatchFileNames":[
        "p6880880_180000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames":[
        "p32126855_180000_Linux-x86-64.zip"
    ],

        "p28730253_180000_Linux-x86-64.zip",
        "p27539475_1813000DBRU_Linux-x86-64.zip",
        "p29213893_180000_Generic.zip",
        "p29374604_1813000DBRU_Linux-x86-64.zip",
        "p29782284_180000_Generic.zip",
        "p28125601_180000_Linux-x86-64.zip",
        "p28852325_180000_Linux-x86-64.zip",
        "p29997937_180000_Linux-x86-64.zip",
        "p31335037_180000_Linux-x86-64.zip",
        "p31335142_180000_Generic.zip"
    ]
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
```

```
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/18.0.0.0.ru-2020-10.rur-2020-10.r1",
        "oracleBase": "/home/oracle/"
    }
}
```

Example Sample CEV manifest for Oracle Database 19c

In the following example for Oracle Database 19c, RDS Custom applies p32126828, then p29213893, then p29782284, and so on. The example sets new values for the UNIX user and group, and the Oracle home and Oracle base.

```
{
    "mediaImportTemplateVersion": "2020-08-14",
    "databaseInstallationFileNames": [
        "V982063-01.zip"
    ],
    "opatchFileNames": [
        "p6880880_190000_Linux-x86-64.zip"
    ],
    "psuRuPatchFileNames": [
        "p32126828_190000_Linux-x86-64.zip"
    ],
    "otherPatchFileNames": [
        "p29213893_1910000DBRU_Generic.zip",
        "p29782284_1910000DBRU_Generic.zip",
        "p28730253_190000_Linux-x86-64.zip",
        "p29374604_1910000DBRU_Linux-x86-64.zip",
        "p28852325_190000_Linux-x86-64.zip",
        "p29997937_190000_Linux-x86-64.zip",
        "p31335037_190000_Linux-x86-64.zip",
        "p31335142_190000_Generic.zip"
    ],
    "installationParameters": {
        "unixGroupName": "dba",
        "unixGroupId": 12345,
        "unixUname": "oracle",
        "unixUid": 12345,
        "oracleHome": "/home/oracle/oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1",
        "oracleBase": "/home/oracle"
    }
}
```

Step 6 (Optional): Validate the CEV manifest

Optionally, verify that manifest is a valid JSON file by running the `json.tool` Python script. For example, if you change into the directory containing a CEV manifest named `manifest.json`, run the following command.

```
python -m json.tool < manifest.json
```

Step 7: Add necessary IAM permissions

Make sure that the IAM principal that creates the CEV has the necessary policies described in Step 5: Grant required permissions to your IAM user or role.

Creating a CEV

You can create a CEV using the AWS Management Console or the AWS CLI. Specify either the multitenant or non-multitenant architecture. For more information, see Multitenant architecture considerations.

Typically, creating a CEV takes about two hours. After you have created the CEV, you can use it to create or upgrade an RDS Custom DB instance. For more information, see Creating an RDS Custom for Oracle DB instance and Upgrading an RDS Custom for Oracle DB instance.

> **Note**
>
> If your DB instance currently uses Oracle Linux 7.9, create a new CEV that uses the latest AMI, which uses Oracle Linux 8. Then modify your instance to use the new CEV.

Note the following requirements and limitations for creating a CEV:

- The Amazon S3 bucket containing your installation files must be in the same AWS Region as your CEV. Otherwise, the creation process fails.
- The CEV name must be in the format *`major-engine-version`*`.`*`customized_string`*, as in `19.cdb_cev1`.
- The CEV name must contain 1–50 alphanumeric characters, underscores, dashes, or periods.
- The CEV name can't contain consecutive periods, as in `19..cdb_cev1`.

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose **Create custom engine version**.
4. In **Engine options**, do the following:

   a. For **Engine type**, choose **Oracle**.

   b. For **Architecture settings**, optionally choose **Multitenant architecture** to create an Oracle multitenant CEV, which uses the DB engine `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`. You can create an RDS Custom for Oracle CDB with a Multitenant CEV only. If you don't choose this option, your CEV is a non-CDB, which uses the engine `custom-oracle-ee` or `custom-oracle-se2`.

   > **Note**
   >
   > The architecture that you choose is a permanent characteristic of your CEV. You can't modify your CEV to use a different architecture later.

   c. Choose either of the following options:

   - **Create new CEV** – Create a CEV from scratch. In this case, you must specify a JSON manifest specifying the database binaries.
   - **Create CEV from source** – In **Specify the CEV that you want to copy**, choose an existing CEV to use as the source CEV. In this case, you can specify a new Amazon Machine Image (AMI), but you can't specify different database binaries.

   d. For **Engine version**, choose the major engine version.
5. In **Version details**, do the following:

   a. Enter a valid name in **Custom engine version name**. For example, you might enter the name **`19.cdb_cev1`**.

b. (Optional) Enter a description for your CEV.

6. In **Installation media**, do the following:

   a. (Optional) For **AMI ID**, either leave the field blank to use the latest service-provided AMI, or enter an AMI that you previously used to create a CEV. To obtain valid AMI IDs, use either of the following techniques:

      - In the console, choose **Custom engine versions** in the left navigation pane, and choose the name of a CEV. The AMI ID used by the CEV appears in the **Configuration** tab.
      - In the AWS CLI, use the `describe-db-engine-versions` command. Search the output for `ImageID`.

   b. For **S3 location of manifest files**, enter the location of the Amazon S3 bucket that you specified in Step 3: Upload your installation files to Amazon S3. For example, enter **`s3://my-custom-installation-files/123456789012/cev1/`**.

      > **Note**
      >
      > The AWS Region in which you create the CEV must be in the same Region as the S3 bucket.

   c. (Create new CEV only) For **CEV manifest**, enter the JSON manifest that you created in Creating the CEV manifest.

7. In the **KMS key** section, select **Enter a key ARN** to list the available AWS KMS keys. Then select your KMS key from the list.

   An AWS KMS key is required for RDS Custom. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key.

8. (Optional) Choose **Add new tag** to create a key-value pair for your CEV.

9. Choose **Create custom engine version**.

   If the JSON manifest is in an invalid format, the console displays **Error validating the CEV manifest**. Fix the problems, and try again.

The **Custom engine versions** page appears. Your CEV is shown with the status **Creating**. The process to create a CEV takes approximately two hours.

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command.

The following options are required:

- `--engine` – Specify the engine type. For a CDB, specify either `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`. For a non-CDB, specify either `custom-oracle-ee` or `custom-oracle-se2`. You can create CDBs only from a CEV created with `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb`. You can create non-CDBs only from a CEV created with `custom-oracle-ee` or `custom-oracle-se2`.
- `--engine-version` – Specify the engine version. The format is *`major-engine-version.customized_string`*. The CEV name must contain 1–50 alphanumeric characters, underscores, dashes, or periods. The CEV name can't contain consecutive periods, as in `19..cdb_cev1`.
- `--kms-key-id` – Specify an AWS KMS key.
- `--manifest` – Specify either *`manifest_json_string`* or `--manifest file:`*`file_name`*. Newline characters aren't permitted in *`manifest_json_string`*. Make sure to escape double quotes (") in the JSON code by prefixing them with a backslash (\).

  The following example shows the *`manifest_json_string`* for 19c from Step 5: Prepare the CEV manifest. The example sets new values for the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group. If you copy this string, remove all newline characters before you paste it into your command.

```
"{\"mediaImportTemplateVersion\": \"2020-08-14\",
\"databaseInstallationFileNames\": [\"V982063-01.zip\"],
\"opatchFileNames\": [\"p6880880_190000_Linux-x86-64.zip\"],
\"psuRuPatchFileNames\": [\"p32126828_190000_Linux-x86-64.zip\"],
\"otherPatchFileNames\": [\"p29213893_1910000DBRU_Generic.zip\",
\"p29782284_1910000DBRU_Generic.zip\",\"p28730253_190000_Linux-
x86-64.zip\",\"p29374604_1910000DBRU_Linux-x86-64.zip\",
\"p28852325_190000_Linux-x86-64.zip\",\"p29997937_190000_Linux-x86-64.zip
\",\"p31335037_190000_Linux-x86-64.zip\",\"p31335142_190000_Generic.zip
\"]\"installationParameters\":{ \"unixGroupName\":\"dba\",
\ \"unixUname\":\"oracle\", \ \"oracleHome\":\"/home/oracle/
oracle.19.0.0.0.ru-2020-04.rur-2020-04.r1.EE.1\", \ \"oracleBase\":\"/
home/oracle/\"}}"
```

- `--database-installation-files-s3-bucket-name` – Specify the same bucket name that you specified in Step 3: Upload your installation files to Amazon S3. The AWS Region in which you run `create-custom-db-engine-version` must be the same Region as your Amazon S3 bucket.

You can also specify the following options:

- `--description` – Specify a description of your CEV.
- `--database-installation-files-s3-prefix` – Specify the folder name that you specified in Step 3: Upload your installation files to Amazon S3.
- `--image-id` – Specify an AMI ID that want to reuse. To find valid IDs, run the `describe-db-engine-versions` command, and then search the output for `ImageID`. By default, RDS Custom for Oracle uses the most recent available AMI.

The following example creates an Oracle multitenant CEV named `19.cdb_cev1`. The example reuses an existing AMI rather than use the latest available AMI. Make sure that the name of your CEV starts with the major engine version number.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-oracle-se2-cdb \
    --engine-version 19.cdb_cev1 \
    --database-installation-files-s3-bucket-name us-east-1-123456789012-custom-
installation-files \
    --database-installation-files-s3-prefix 123456789012/cev1 \
    --kms-key-id my-kms-key \
    --description "test cev" \
    --manifest manifest_string \
    --image-id ami-012a345678901bcde
```

For Windows:

```
aws rds create-custom-db-engine-version ^
    --engine custom-oracle-se2-cdb ^
    --engine-version 19.cdb_cev1 ^
```

```
    --database-installation-files-s3-bucket-name us-east-1-123456789012-custom-
installation-files ^
    --database-installation-files-s3-prefix 123456789012/cev1 ^
    --kms-key-id my-kms-key ^
    --description "test cev" ^
    --manifest manifest_string ^
    --image-id ami-012a345678901bcde
```

Example

Get details about your CEV by using the `describe-db-engine-versions` command.

```
aws rds describe-db-engine-versions \
    --engine custom-oracle-se2-cdb \
    --include-all
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```
{
    "DBEngineVersions": [
        {
            "Engine": "custom-oracle-se2-cdb",
            "EngineVersion": "19.cdb_cev1",
            "DBParameterGroupFamily": "custom-oracle-se2-cdb-19",
            "DBEngineDescription": "Containerized Database for Oracle Custom SE2",
            "DBEngineVersionDescription": "test cev",
            "Image": {
                "ImageId": "ami-012a345678901bcde",
                "Status": "active"
            },
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": true,
            "SupportedFeatureNames": [],
            "Status": "available",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "MajorEngineVersion": "19",
            "DatabaseInstallationFilesS3BucketName": "us-east-1-123456789012-custom-
installation-files",

            "TagList": [],
            "SupportsBabelfish": false,
...
```

Failure to create a CEV

If the process to create a CEV fails, RDS Custom issues `RDS-EVENT-0198` with the message `Creation failed for custom engine version` *`major-engine-version.cev_name`*, and includes details about the failure. For example, the event prints missing files.

You can't modify a failed CEV. You can only delete it, then try again to create a CEV after fixing the causes of the failure. For information about troubleshooting the reasons for CEV creation failure, see Troubleshooting custom engine version creation for RDS Custom for Oracle.

Modifying CEV status

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- `available` – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- `inactive` – You can't create or upgrade an RDS Custom instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV from any supported status to any other supported status. You might change status to prevent the accidental use of a CEV or make a discontinued CEV eligible for use again. For example, you might change the status of your CEV from `available` to `inactive`, and from `inactive` back to `available`.

Console

To modify a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to modify.
4. For **Actions**, choose **Modify**.
5. Make any of the following changes:
   - For **CEV status settings**, choose a new availability status.
   - For **Version description**, enter a new description.
6. Choose **Modify CEV**.

   If the CEV is in use, the console displays **You can't modify the CEV status**. Fix the problems, and try again.

The **Custom engine versions** page appears.

AWS CLI

To modify a CEV by using the AWS CLI, run the modify-custom-db-engine-version command. You can find CEVs to modify by running the describe-db-engine-versions command.

The following options are required:

- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version that you want to modify
- `--status` *`status`*, where *`status`* is the availability status that you want to assign to the CEV

The following example changes a CEV named `19.my_cev1` from its current status to `inactive`.

Example

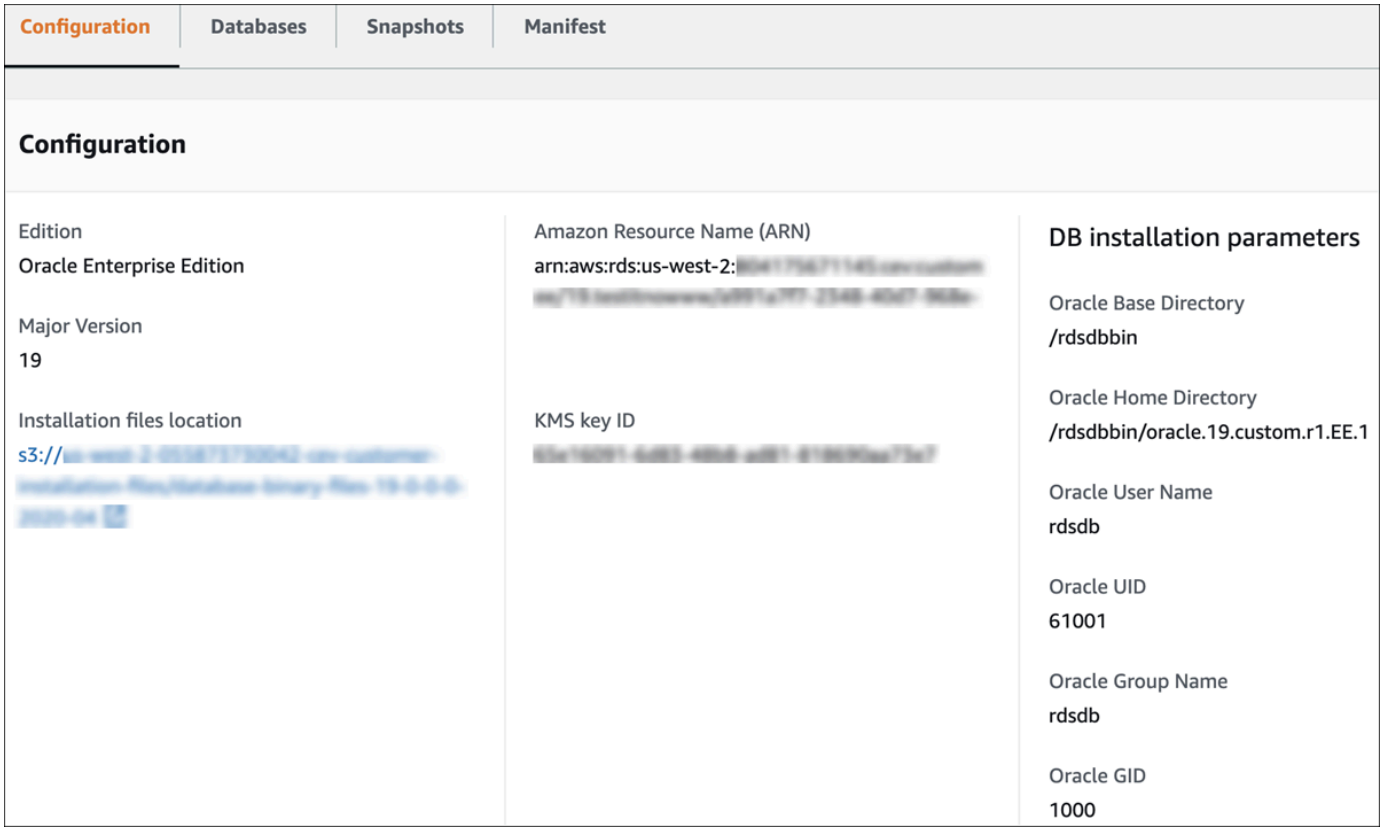
For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \
    --engine custom-oracle-se2 \
    --engine-version 19.my_cev1 \
    --status inactive
```

For Windows:

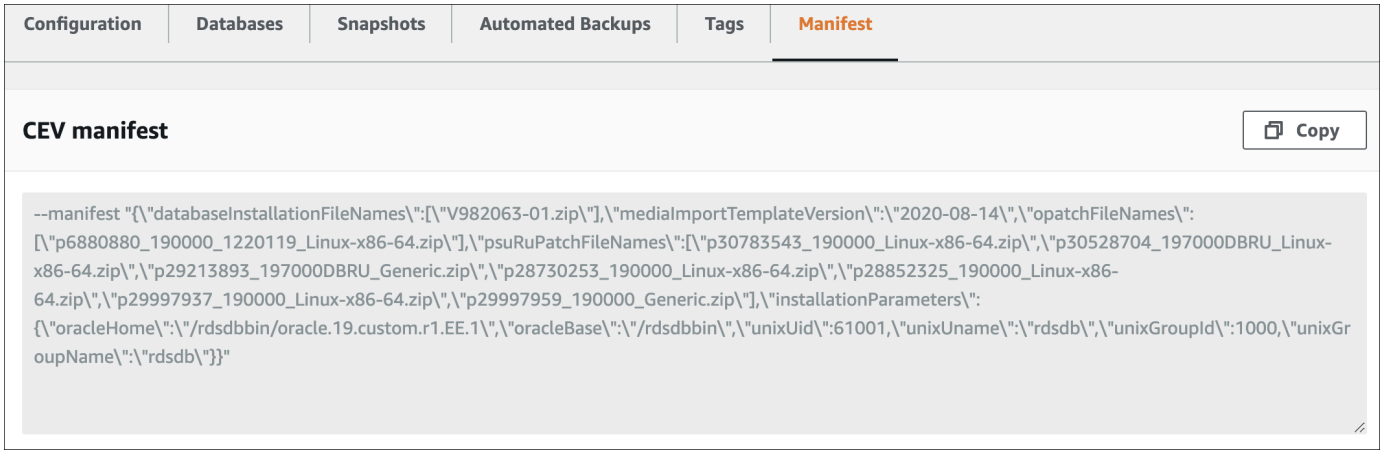
```
aws rds modify-custom-db-engine-version ^
    --engine custom-oracle-se2 ^
    --engine-version 19.my_cev1 ^
    --status inactive
```

Viewing CEV details for Amazon RDS Custom for Oracle



You can view details about your CEV manifest and the command used to create your CEV by using the AWS Management Console or the AWS CLI.

Console



To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose the name of the CEV that you want to view.
4. Choose **Configuration** to view the installation parameters specified in your manifest.

5. Choose **Manifest** to view the installation parameters specified in the `--manifest` option of the `create-custom-db-engine-version` command. You can copy this text, replace values as needed, and use them in a new command.

AWS CLI

To view details about a CEV by using the AWS CLI, run the describe-db-engine-versions command.

The following options are required:

- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`major-engine-version`*`.`*`customized_string`*

The following example creates a non-CDB CEV that uses Enterprise Edition. The CEV name `19.my_cev1` starts with the major engine version number, which is required.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev1
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev1
```

The following partial sample output shows the engine, parameter groups, manifest, and other information.

```
"DBEngineVersions": [
    {
        "Engine": "custom-oracle-ee",
        "MajorEngineVersion": "19",
        "EngineVersion": "19.my_cev1",
        "DatabaseInstallationFilesS3BucketName": "us-east-1-123456789012-cev-customer-
installation-files",

            "IsMajorVersionUpgrade": false
        }
]
```

Deleting a CEV

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, deletion takes a few minutes.

To delete a CEV, it can't be in use by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

Console

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to delete.
4. For **Actions**, choose **Delete**.

The **Delete *cev_name*?** dialog box appears.

5. Enter **`delete me`**, and then choose **Delete**.

   In the **Custom engine versions** page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the delete-custom-db-engine-version command.

The following options are required:

- `--engine` *engine-type*, where *engine-type* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *cev*, where *cev* is the name of the custom engine version to be deleted

The following example deletes a CEV named `19.my_cev1`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev1
```

For Windows:

```
aws rds delete-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev1
```

Configuring a DB instance for Amazon RDS Custom for Oracle

You can create an RDS Custom DB instance, and then connect to it using Secure Shell (SSH) or AWS Systems Manager.

For more information about connecting and logging in to a RDS Custom for Oracle DB instance, see the following topics.

- Connecting to your RDS Custom DB instance using Session Manager
- Connecting to your RDS Custom DB instance using SSH
- Logging in to your RDS Custom for Oracle database as SYS

Creating an RDS Custom for Oracle DB instance

Create an Amazon RDS Custom for Oracle DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance. For more information, see Creating an Amazon RDS DB instance.

If you included installation parameters in your CEV manifest, then your DB instance uses the Oracle base, Oracle home, and the ID and name of the UNIX/Linux user and group that you specified. The `oratab` file, which is created by Oracle Database during installation, points to the real installation location rather than to a symbolic link. When RDS Custom for Oracle runs commands, it runs as the configured OS user rather than the default user `rdsdb`. For more information, see Step 5: Prepare the CEV manifest.

Before you attempt to create or connect to an RDS Custom DB instance, complete the tasks in Setting up your environment for Amazon RDS Custom for Oracle.

Console

To create an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**.
4. In **Choose a database creation method**, select **Standard create**.

5. In the **Engine options** section, do the following:

   a. For **Engine type**, choose **Oracle**.

   b. For **Database management type**, choose **Amazon RDS Custom**.

   c. For **Architecture settings**, do one of the following:

   - Select **Multitenant architecture** to create a container database (CDB). At creation, your CDB contains one PDB seed and one initial PDB.

     > **Note**
     >
     > The **Multitenant architecture** setting is supported only for Oracle Database 19c.

   - Clear **Multitenant architecture** to create a non-CDB. A non-CDB can't contain PDBs.

   d. For **Edition**, choose **Oracle Enterprise Edition** or **Oracle Standard Edition 2**.

   e. For **Custom engine version**, choose an existing RDS Custom custom engine version (CEV). A CEV has the following format: *`major-engine-version.customized_string`*. An example identifier is `19.cdb_cev1`.

   If you chose **Multitenant architecture** in the previous step, you can only specify a CEV that uses the `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type. The console filters out CEVs that were created with different engine types.

6. In **Templates**, choose **Production**.

7. In the **Settings** section, do the following:

   a. For **DB instance identifier**, enter a unique name for your DB instance.

   b. For **Master username**, enter a username. You can retrieve this value from the console later.

   When you connect to a non-CDB, the master user is the user for the non-CDB. When you connect to a CDB, the master user is the user for the PDB. To connect to the CDB root, log in to the host, start a SQL client, and create an administrative user with SQL commands.

   c. Clear **Auto generate a password**.

8. Choose a **DB instance class**.

   For supported classes, see DB instance class support for RDS Custom for Oracle.

9. In the **Storage** section, do the following:

a. For **Storage type**, choose an SSD type: io1, io2, gp2, or gp3. You have the following additional options:

- For io1, io2, or gp3, choose a rate for **Provisioned IOPS**. The default is 1000 for io1 and io2 and 12000 for gp3.
- For gp3, choose a rate for **Storage throughput**. The default is 500 MiBps.

b. For **Allocated storage**, choose a storage size. The default is 40 GiB.

10. For **Connectivity**, specify your **Virtual private cloud (VPC)**, **DB subnet group**, and **VPC security group (firewall)**.
11. For **RDS Custom security**, do the following:

a. For **IAM instance profile**, choose the instance profile for your RDS Custom for Oracle DB instance.

The IAM instance profile must begin with `AWSRDSCustom`, for example *`AWSRDSCustomInstanceProfileForRdsCustomInstance`*.

b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

An AWS KMS key is required for RDS Custom. For more information, see Step 1: Create or reuse a symmetric encryption AWS KMS key.

12. For **Database options**, do the following:

a. (Optional) For **System ID (SID)**, enter a value for the Oracle SID, which is also the name of your CDB. The SID is the name of the Oracle database instance that manages your database files. In this context, the term "Oracle database instance" refers exclusively to the system global area (SGA) and Oracle background processes. If you don't specify a SID, the value defaults to **RDSCDB**.

b. (Optional) For **Initial database name**, enter a name. The default value is **ORCL**. In the multitenant architecture, the initial database name is the PDB name.

> **Note**
>
> The SID and PDB name must be different.

c. For **Option group**, choose an option group or accept the default.

> **Note**
>
> The only supported option for RDS Custom for Oracle is `Timezone`. For more information, see Oracle time zone.

d. For **Backup retention period** choose a value. You can't choose **0 days**.

e. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see Settings for DB instances. The following settings don't appear in the console and aren't supported:

- **Processor features**
- **Storage autoscaling**
- **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
- **Performance Insights**
- **Log exports**
- **Enable auto minor version upgrade**
- **Deletion protection**

13. Choose **Create database**.

> **Important**
>
> When you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

> **Important**
>
> You can't view the master user password again in the console. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, log in to the database and run an `ALTER USER` command. You can't reset the password using the **Modify** option in the console.

14. Choose **Databases** to view the list of RDS Custom DB instances.
15. Choose the RDS Custom DB instance that you just created.

    On the RDS console, the details for the new RDS Custom DB instance appear:

    - The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
    - **Role** has the value **Instance (RDS Custom)**.
    - **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

AWS CLI

You create an RDS Custom DB instance by using the create-db-instance AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see DB instance class support for RDS Custom for Oracle)
- `--engine` *`engine-type`*, where *`engine-type`* is `custom-oracle-ee`, `custom-oracle-se2`, `custom-oracle-ee-cdb`, or `custom-oracle-se2-cdb`
- `--engine-version` *`cev`* (where *`cev`* is the name of the custom engine version that you specified in Creating a CEV)
- `--kms-key-id` *`my-kms-key`*
- `--backup-retention-period` *`days`* (where *`days`* is a value greater than `0`)

- `--no-auto-minor-version-upgrade`
- `--custom-iam-instance-profile AWSRDSCustomInstanceProfile-`*`us-east-1`* (where *`region`* is the AWS Region where you are creating your DB instance)

The following example creates an RDS Custom DB instance named `my-cfo-cdb-instance`. The database is a CDB with the nondefault name *`MYCDB`*. The nondefault PDB name is *`MYPDB`*. The backup retention period is three days.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine custom-oracle-ee-cdb \
    --db-instance-identifier my-cfo-cdb-instance \
    --engine-version 19.cdb_cev1 \
    --db-name MYPDB \
    --db-system-id MYCDB \
    --allocated-storage 250 \
    --db-instance-class db.m5.xlarge \
    --db-subnet-group mydbsubnetgroup \
    --master-username myuser \
    --master-user-password mypassword \
    --backup-retention-period 3 \
    --port 8200 \
    --kms-key-id my-kms-key \
    --no-auto-minor-version-upgrade \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfile-us-east-1
```

For Windows:

```
aws rds create-db-instance ^
    --engine custom-oracle-ee-cdb ^
    --db-instance-identifier my-cfo-cdb-instance ^
    --engine-version 19.cdb_cev1 ^
    --db-name MYPDB ^
    --db-system-id MYCDB ^
    --allocated-storage 250 ^
    --db-instance-class db.m5.xlarge ^
    --db-subnet-group mydbsubnetgroup ^
    --master-username myuser ^
```

```
    --master-user-password mypassword ^
    --backup-retention-period 3 ^
    --port 8200 ^
    --kms-key-id my-kms-key ^
    --no-auto-minor-version-upgrade ^
    --custom-iam-instance-profile AWSRDSCustomInstanceProfile-us-east-1
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Get details about your instance by using the `describe-db-instances` command.

Example

```
aws rds describe-db-instances --db-instance-identifier my-cfo-cdb-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
        {
            "DBInstanceIdentifier": "my-cfo-cdb-instance",
            "DBInstanceClass": "db.m5.xlarge",
            "Engine": "custom-oracle-ee-cdb",
            "DBInstanceStatus": "available",
            "MasterUsername": "admin",
            "DBName": "MYPDB",
            "DBSystemID": "MYCDB",
            "Endpoint": {
                "Address": "my-cfo-cdb-instance.abcdefghijkl.us-
east-1.rds.amazonaws.com",
                "Port": 1521,
                "HostedZoneId": "A1B2CDEFGH34IJ"
            },
            "AllocatedStorage": 100,
            "InstanceCreateTime": "2023-04-12T18:52:16.353000+00:00",
            "PreferredBackupWindow": "08:46-09:16",
            "BackupRetentionPeriod": 7,
            "DBSecurityGroups": [],
            "VpcSecurityGroups": [
                {
                    "VpcSecurityGroupId": "sg-0a1bcd2e",
```

```
                    "Status": "active"
                }
            ],
            "DBParameterGroups": [
                {
                    "DBParameterGroupName": "default.custom-oracle-ee-cdb-19",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
...
```

Multitenant architecture considerations

If you create an Amazon RDS Custom for Oracle DB instance with the Oracle multitenant architecture (`custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type), your database is a container database (CDB). If you don't specify the Oracle multitenant architecture, your database is a traditional non-CDB that uses the `custom-oracle-ee` or `custom-oracle-se2` engine type. A non-CDB can't contain pluggable databases (PDBs). For more information, see Database architecture for Amazon RDS Custom for Oracle.

When you create an RDS Custom for Oracle CDB instance, consider the following:

- You can create a multitenant database only from an Oracle Database 19c CEV.
- You can create a CDB instance only if the CEV uses the `custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type.
- If you create a CDB instance using Standard Edition 2, the CDB can contain a maximum of 3 PDBs.
- By default, your CDB is named `RDSCDB`, which is also the name of the Oracle System ID (Oracle SID). You can choose a different name.
- You CDB contains only one initial PDB. The PDB name defaults to `ORCL`. You can choose a different name for your initial PDB, but the Oracle SID and the PDB name can't be the same.
- RDS Custom for Oracle doesn't supply APIs for PDBs. To create additional PDBs, use the Oracle SQL command `CREATE PLUGGABLE DATABASE`. RDS Custom for Oracle doesn't restrict the number of PDBs that you can create. In general, you are responsible for creating and managing PDBs, as in an on-premises deployment.
- You can't use RDS APIs to create, modify, and delete PDBs: you must use Oracle SQL statements. When you create a PDB using Oracle SQL, we recommend that you take a manual snapshot afterward in case you need to perform point-in-time recovery (PITR).

- You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.
- The open mode for the CDB root is `READ WRITE` on the primary and `MOUNTED` on a mounted standby database. RDS Custom for Oracle attempts to open all PDBs when opening the CDB. If RDS Custom for Oracle can't open all PDBs, it issues the event `tenant database shutdown`.

RDS Custom service-linked role

A *service-linked role* gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS.

The first time that you create an RDS Custom for Oracle DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Installing additional software components on your RDS Custom for Oracle DB instance

In a newly created DB instance, your database environment includes Oracle binaries, a database, and a database listener. You might want to install additional software on the host operating system of the DB instance. For example, you might want to install Oracle Application Express (APEX), the Oracle Enterprise Manager (OEM) agent, or the Guardium S-TAP agent. For guidelines and high-level instructions, see the detailed AWS blog post Install additional software components on Amazon RDS Custom for Oracle.

Connecting to your RDS Custom DB instance using Session Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. This is the preferred technique when your DB instance isn't publicly accessible.

Session Manager allows you to access Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** for your DB instance. For example, the resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then click the instance ID associated with it. For example, the instance ID might be `i-abcdefghijklm01234`.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

    A window opens for your session.

AWS CLI

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses db-ABCDEFGHIJKLMNOPQRS0123456 for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
    --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefghijklm01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

Connecting to your RDS Custom DB instance using SSH

The Secure Shell Protocol (SSH) is a network protocol that supports encrypted communication over an unsecured network. After you create your RDS Custom DB instance, you can connect to it using an ssh client. For more information, see Connecting to your Linux instance using SSH.

Your SSH connection technique depends on whether your DB instance is private, meaning that it doesn't accept connections from the public internet. In this case, you must use SSH tunneling to connect the ssh utility to your instance. This technique transports data with a dedicated data stream (tunnel) inside an existing SSH session. You can configure SSH tunneling using AWS Systems Manager.

> **Note**
>
> Various strategies are supported for accessing private instances. To learn how to connect an ssh client to private instances using bastion hosts, see Linux Bastion Hosts on AWS. To learn how to configure port forwarding, see Port Forwarding Using AWS Systems Manager Session Manager.

If your DB instance is in a public subnet and has the publicly available setting, then no SSH tunneling is required. You can connect with SSH just as would to a public Amazon EC2 instance.

To connect an ssh client to your DB instance, complete the following steps:

1. Step 1: Configure your DB instance to allow SSH connections
2. Step 2: Retrieve your SSH secret key and EC2 instance ID
3. Step 3: Connect to your EC2 instance using the ssh utility

Step 1: Configure your DB instance to allow SSH connections

To make sure that your DB instance can accept SSH connections, do the following:

- Make sure that your DB instance security group permits inbound connections on port 22 for TCP.

  To learn how to configure the security group for your DB instance, see Controlling access with security groups.
- If you don't plan to use SSH tunneling, make sure your DB instance resides in a public subnet and is publicly accessible.

  In the console, the relevant field is **Publicly accessible** on the **Connectivity & security** tab of the database details page. To check your settings in the CLI, run the following command:

  ```
  aws rds describe-db-instances \
  --query 'DBInstances[*].
  {DBInstanceIdentifier:DBInstanceIdentifier,PubliclyAccessible:PubliclyAccessible}' \
  --output table
  ```

  To change the accessibility settings for your DB instance, see Modifying an Amazon RDS DB instance.

Step 2: Retrieve your SSH secret key and EC2 instance ID

To connect to the DB instance using SSH, you need the SSH key pair associated with the instance. RDS Custom creates the SSH key pair on your behalf, using the naming convention `do-not-delete-rds-custom-ssh-privatekey-`*`resource_id`*`-`*`uuid`* or `rds-custom!oracle-do-not-delete-`*`resource_id`*`-`*`uuid`*`-ssh-privatekey`. AWS Secrets Manager stores your SSH private key as a secret.

Retrieve your SSH secret key using either AWS Management Console or the AWS CLI. If your instance has a public DNS, and you don't intend to use SSH tunneling, then also retrieve the DNS name. You specify the DNS name for public connections.

Console

To retrieve the secret SSH key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value. For example, the DB instance resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. Find the name of your EC2 instance, and choose the instance ID associated with it. For example, the EC2 instance ID might be `i-abcdefghijklm01234`.
8. In **Details**, find **Key pair name**. The pair name includes the DB instance resource ID. For example, the pair name might be `do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c` or `rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey`.
9. If your EC2 instance is public, note the **Public IPv4 DNS**. For the example, the public Domain Name System (DNS) address might be `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.
10. Open the AWS Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
11. Choose the secret that has the same name as your key pair.

12. Choose **Retrieve secret value**.
13. Copy the SSH private key into a text file, and then save the file with the `.pem` extension. For example, save the file as `/tmp/do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem` or `/tmp/rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey.pem`.

AWS CLI

To retrieve the SSH private key and save it in a .pem file, you can use the AWS CLI.

1. Find the DB resource ID of your RDS Custom DB instance using `aws rds describe-db-instances`.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

   The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

2. Find the EC2 instance ID of your DB instance using `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRS0123456` for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
    --query 'Reservations[*].Instances[*].InstanceId'
```

   The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

3. To find the key name, specify the EC2 instance ID. The following example describes EC2 instance `i-0bdc4219e66944afa`.

```
aws ec2 describe-instances \
    --instance-ids i-0bdc4219e66944afa \
```

```
    --output text \
    --query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the naming format `do-not-delete-rds-custom-ssh-privatekey-`*`resource_id`*`-`*`uuid`* or `rds-custom!oracle-do-not-delete-`*`resource_id`*`-`*`uuid`*`-ssh-privatekey`.

```
do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c
rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey
```

4. Save the private key in a .pem file named after the key using `aws secretsmanager`.

   The following example saves the key `do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c` to a file in your `/tmp` directory.

```
aws secretsmanager get-secret-value \
    --secret-id do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c \
    --query SecretString \
    --output text >/tmp/do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
```

   The following example saves the key `rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey` to a file in your `/tmp` directory.

```
aws secretsmanager get-secret-value \
    --secret-id rds-custom!oracle-do-not-delete-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey \
    --query SecretString \
    --output text >/tmp/rds-custom!oracle-do-not-delete-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey.pem
```

Step 3: Connect to your EC2 instance using the ssh utility

Your connection technique depends on whether you are connecting to a private DB instance or connecting to a public instance. A private connection requires you to configure SSH tunneling through AWS Systems Manager.

To connect to an EC2 instance using the ssh utility

1. For private connections, modify your SSH configuration file to proxy commands to AWS Systems Manager Session Manager. For public connections, skip to Step 2.

   Add the following lines to `~/.ssh/config`. These lines proxy SSH commands for hosts whose names begin with `i-` or `mi-`.

   ```
   Host i-* mi-*
       ProxyCommand sh -c "aws ssm start-session --target %h --document-name AWS-
   StartSSHSession --parameters 'portNumber=%p'"
   ```

2. Change to the directory that contains your .pem file. Using `chmod`, set the permissions to `400`.

   The following example changes to the `/tmp` directory and sets permissions for .pem file `do-not-delete-rds-custom-ssh-privatekey-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem`.

   ```
   cd /tmp
   chmod 400 do-not-delete-rds-custom-ssh-privatekey-db-
   ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem
   ```

   The following example changes to the `/tmp` directory and sets permissions for .pem file `rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-privatekey.pem`.

   ```
   cd /tmp
   chmod 400 rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-
   privatekey.pem
   ```

3. Run the ssh utility, specifying the .pem file and either the public DNS name (for public connections) or the EC2 instance ID (for private connections). Log in as user `ec2-user`.

   The following example connects to a public instance using the DNS name `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.

   ```
   # .pem file using naming prefix do-not-delete
   ssh -i \
     "do-not-delete-rds-custom-ssh-privatekey-db-
   ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem" \
     ec2-user@ec2-12-345-678-901.us-east-2.compute.amazonaws.com
   ```

```
# .pem file using naming prefix rds-custom!oracle-do-not-delete
ssh -i \
  "rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-
privatekey.pem" \
  ec2-user@ec2-12-345-678-901.us-east-2.compute.amazonaws.com
```

The following example connects to a private instance using the EC2 instance ID `i-0bdc4219e66944afa`.

```
# .pem file using naming prefix do-not-delete
ssh -i \
  "do-not-delete-rds-custom-ssh-privatekey-db-
ABCDEFGHIJKLMNOPQRS0123456-0d726c.pem" \
  ec2-user@i-0bdc4219e66944afa

# .pem file using naming prefix rds-custom!oracle-do-not-delete
ssh -i \
  "rds-custom!oracle-do-not-delete-db-ABCDEFGHIJKLMNOPQRS0123456-0d726c-ssh-
privatekey.pem" \
  ec2-user@i-0bdc4219e66944afa
```

Logging in to your RDS Custom for Oracle database as SYS

After you create your RDS Custom DB instance, you can log in to your Oracle database as user SYS, which gives you SYSDBA privileges. You have the following login options:

- Get the SYS password from Secrets Manager, and specify this password in your SQL client.
- Use OS authentication to log in to your database. In this case, you don't need a password.

Finding the SYS password for your RDS Custom for Oracle database

Your can log in to your Oracle database as SYS or SYSTEM or by specifying the master user name in an API call. The password for SYS and SYSTEM is stored in Secrets Manager.

The secret uses the naming format `do-not-delete-rds-custom-`*`resource_id`*`-`*`uuid`* or `rds-custom!oracle-do-not-delete-`*`resource_id`*`-`*`uuid`*. You can find the password using the AWS Management Console.

Console

To find the SYS password for your database in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the RDS console, complete the following steps:
   a. In the navigation pane, choose **Databases**.
   b. Choose the name of your RDS Custom for Oracle DB instance.
   c. Choose **Configuration**.
   d. Copy the value underneath **Resource ID**. For example, you resource ID might be **db-ABC12CDE3FGH4I5JKLMNO6PQR7**.
3. Open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
4. In the Secrets Manager console, complete the following steps:
   a. In the left navigation pane, choose **Secrets**.
   b. Filter the secrets by the resource ID that you copied in step 2.d.
   c. Choose the secret that uses the naming format **do-not-delete-rds-custom-*`resource_id`*-*`uuid`*** or **rds-custom!oracle-do-not-delete-*`resource_id`*-*`uuid`***. The *`resource_id`* is the resource ID that you copied in step 2.d.

      For example, if your resource ID is **db-ABC12CDE3FGH4I5JKLMNO6PQR7** and your UUID is **1234ab**, your secret is named **do-not-delete-rds-custom-db-ABC12CDE3FGH4I5JKLMNO6PQR7-1234ab** or **rds-custom!oracle-do-not-delete-db-ABC12CDE3FGH4I5JKLMNO6PQR7-1234ab**.
   d. In **Secret value**, choose **Retrieve secret value**.
   e. In **Key/value**, copy the value for **password**.
5. Install SQL*Plus on your DB instance and log in to your database as SYS. For more information, see Step 3: Connect your SQL client to an Oracle DB instance.

Logging in to your RDS Custom for Oracle database using OS authentication

The OS user `rdsdb` owns the Oracle database binaries. You can switch to the `rdsdb` user and log in to your RDS Custom for Oracle database without a password.

1. Connect to your DB instance with AWS Systems Manager. For more information, see Connecting to your RDS Custom DB instance using Session Manager.
2. Switch to the `rdsdb` user.

```
sudo su - rdsdb
```

3. Log in to your database using OS authentication. You can use `sqlplus / as sysdba` or the `sql` alias.

```
$ sqlplus / as sysdba

SQL*Plus: Release 21.0.0.0.0 - Production on Wed Apr 12 20:11:08 2023
Version 21.9.0.0.0

Copyright (c) 1982, 2020, Oracle.  All rights reserved.

Connected to:
Oracle Database 19c Enterprise Edition Release 19.0.0.0.0 - Production
Version 19.10.0.0.0
```

Alternatively, you can use the `sql` alias:

```
$ sql
```

Managing an Amazon RDS Custom for Oracle DB instance

Amazon RDS Custom supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for Oracle management tasks using the AWS Management Console and the AWS CLI.

Topics

- Working with container databases (CDBs) in RDS Custom for Oracle
- Working with high availability features for RDS Custom for Oracle
- Customizing your RDS Custom environment
- Modifying your RDS Custom for Oracle DB instance
- Changing the character set of an RDS Custom for Oracle DB instance
- Setting the NLS_LANG value in RDS Custom for Oracle
- Support for Transparent Data Encryption
- Tagging RDS Custom for Oracle resources
- Deleting an RDS Custom for Oracle DB instance

Working with container databases (CDBs) in RDS Custom for Oracle

You can either create your RDS Custom for Oracle DB instance with the Oracle multitenant architecture (`custom-oracle-ee-cdb` or `custom-oracle-se2-cdb` engine type) or with the traditional non-CDB architecture (`custom-oracle-ee` or `custom-oracle-se2` engine type). When you create a container database (CDB), it contains one pluggable database (PDB) and one PDB seed. You can create additional PDBs manually using Oracle SQL.

PDB and CDB names

When you create an RDS Custom for Oracle CDB instance, you specify a name for the initial PDB. By default, your initial PDB is named `ORCL`. You can choose a different name.

By default, your CDB is named `RDSCDB`. You can choose a different name. The CDB name is also the name of your Oracle system identifier (SID), which uniquely identifies the memory and processes that manage your CDB. For more information about the Oracle SID, see Oracle System Identifier (SID) in *Oracle Database Concepts*.

You can't rename existing PDBs using Amazon RDS APIs. You also can't rename the CDB using the `modify-db-instance` command.

PDB management

In the RDS Custom for Oracle shared responsibility model, you are responsible for managing PDBs and creating any additional PDBs. RDS Custom doesn't restrict the number of PDBs. You can manually create, modify, and delete PDBs by connecting to the CDB root and running a SQL statement. Create PDBs on an Amazon EBS data volume to prevent the DB instance from going outside the support perimeter.

To modify your CDBs or PDBs, complete the following steps:

1. Pause automation to prevent interference with RDS Custom actions.
2. Modify your CDB or PDBs.
3. Back up any modified PDBs.
4. Resume RDS Custom automation.

Automatic recovery of the CDB root

RDS Custom keeps the CDB root open in the same way as it keeps a non-CDB open. If the state of the CDB root changes, the monitoring and recovery automation attempts to recover the CDB root to the desired state. You receive RDS event notifications when the root CDB is shut down (`RDS-EVENT-0004`) or restarted (`RDS-EVENT-0006`), similar to the non-CDB architecture. RDS Custom attempts to open all PDBs in `READ WRITE` mode at DB instance startup. If some PDBs can't be opened, RDS Custom publishes the following event: `tenant database shutdown`.

Working with high availability features for RDS Custom for Oracle

RDS Custom for Oracle provides built-in high availability through Multi-AZ deployments. Alternatively, you can use Oracle Data Guard as a customer-managed option based on your use cases.

Multi-AZ deployments (fully-managed)

With Multi-AZ deployments for RDS Custom for Oracle, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone (AZ). The primary DB instance is synchronously replicated across AZs to a standby replica for data redundancy. Multi-AZ deployment is supported in both the Enterprise Edition and the Standard Edition 2. See the section called “Managing a Multi-AZ deployment for RDS Custom for Oracle” for details.

Oracle Data Guard (customer-managed)

Alternatively, you can achieve high availability by manually configuring Oracle Data Guard to replicate data between RDS Custom for Oracle DB instances. The primary DB instance automatically synchronizes data to the standby instances. Oracle Data Guard is supported only in the Enterprise Edition.

You can configure your high availability environment in the following ways:

- Configure standby instances in different AZs to be resilient to AZ failures.
- Place your standby databases in mounted or read-only mode. Read-only mode requires an Oracle Active Data Guard license.
- Fail over or switch over from the primary database to a standby database with no data loss.
- Migrate data by configuring high availability for your on-premises instance, and then failing over or switching over to the RDS Custom for Oracle standby database.

To learn how to configure Oracle Data Guard for high availability, see the AWS blog Build high availability for RDS Custom for Oracle using read replicas. You can perform the following tasks:

- Use a virtual private network (VPN) tunnel to encrypt data in transit for your high availability instances. Encryption in transit isn't configured automatically by RDS Custom for Oracle.
- Configure Oracle Fast-Failover Observer (FSFO) to monitor your high availability instances.
- Allow the observer to perform automatic failover when necessary conditions are met.

Customizing your RDS Custom environment

RDS Custom for Oracle includes built-in features that allow you to customize your DB instance environment without pausing automation. For example, you can use RDS APIs to customize your environment as follows:

- Create and restore DB snapshots to create a clone environment.
- Create read replicas.
- Modify storage settings.
- Change the CEV to apply release updates

For some customizations, such as changing the character set, you can't use the RDS APIs. In these cases, you need to change the environment manually by accessing your Amazon EC2 instance as the root user or logging in to your Oracle database as SYSDBA.

To customize your instance manually, you must pause and resume RDS Custom automation. This pause ensures that your customizations don't interfere with RDS Custom automation. In this way, you avoid breaking the support perimeter, which places the instance in the `unsupported-configuration` state until you fix the underlying issues. Pausing and resuming are the only supported automation tasks when you modify an RDS Custom for Oracle DB instance.

General steps for customizing your RDS Custom environment

To customize your RDS Custom DB instance, complete the following steps:

1. Pause RDS Custom automation for a specified period using the console or CLI.
2. Identify your underlying Amazon EC2 instance.
3. Connect to your underlying Amazon EC2 instance using SSH keys or AWS Systems Manager.
4. Verify your current configuration settings at the database or operating system layer.

   You can validate your changes by comparing the initial configuration to the changed configuration. Depending on the type of customization, use OS tools or database queries.
5. Customize your RDS Custom for Oracle DB instance as needed.
6. Reboot your instance or database, if required.

> **Note**
>
> In an on-premises Oracle CDB, you can preserve a specified open mode for PDBs using a built-in command or after a startup trigger. This mechanism brings PDBs to a specified state when the CDB restarts. When opening your CDB, RDS Custom automation discards any user-specified preserved states and attempts to open all PDBs. If RDS Custom can't open all PDBs, the following event is issued: `The following PDBs failed to open: list-of-PDBs`.

7. Verify your new configuration settings by comparing them with the previous settings.
8. Resume RDS Custom automation in either of the following ways:
   - Resume automation manually.

- Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

9. Verify the RDS Custom automation framework

   If you followed the preceding steps correctly, RDS Custom starts an automated backup. The status of the instance in the console shows **Available**.

For best practices and step-by-step instructions, see the AWS blog posts Make configuration changes to an Amazon RDS Custom for Oracle instance: Part 1 and Recreate an Amazon RDS Custom for Oracle database: Part 2.

Pausing and resuming your RDS Custom DB instance

You can pause and resume automation for your DB instance using the console or CLI.

Console

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:

   - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
   - **Full automation** resumes automation.

5. Choose **Continue** to check the summary of modifications.

   A message indicates that RDS Custom will apply the changes immediately.

6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.

7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in *num* minutes**.

AWS CLI

To pause or resume RDS Custom automation, use the `modify-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.
- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

> **Note**
>
> Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 90
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 30
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 30
```

The following example resumes full automation for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode full \
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode full
```

In the following partial sample output, the pending `AutomationMode` value is `full`.

```
{
    "DBInstance": {
        "PubliclyAccessible": true,
        "MasterUsername": "admin",

    }
```

Modifying your RDS Custom for Oracle DB instance

Modifying an RDS Custom for Oracle DB instance is similar to modifying an Amazon RDS DB instance. You can change settings such as the following:

- DB instance class
- Storage allocation and type
- Backup retention period
- Deletion protection
- Option group
- CEV (see Upgrading an RDS Custom for Oracle DB instance)
- Port

Topics

- Requirements and limitations when modifying your DB instance storage
- Requirements and limitations when modifying your DB instance class

- How RDS Custom creates your DB instance when you modify the instance class
- Modifying your RDS Custom for Oracle DB instance

Requirements and limitations when modifying your DB instance storage

Consider the following requirements and limitations when you modify the storage for an RDS Custom for Oracle DB instance:

- The minimum allocated storage for RDS Custom for Oracle is 40 GiB, and the maximum is 64 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon EBS volumes.
- Storage autoscaling isn't supported for RDS Custom DB instances.
- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

  For more information, see RDS Custom support perimeter.
- Magnetic (standard) Amazon EBS storage isn't supported for RDS Custom. You can choose only the io1, io2, gp2, or gp3 SSD storage types.

For more information about Amazon EBS storage, see Amazon RDS DB instance storage. For general information about storage modification, see Working with storage for Amazon RDS DB instances.

Requirements and limitations when modifying your DB instance class

Consider the following requirements and limitations when you modify the instance class for an RDS Custom for Oracle DB instance:

- Your DB instance must be in the `available` state.
- Your DB instance must have a minimum of 100 MiB of free space on the root volume, data volume, and binary volume.
- You can assign only a single elastic IP (EIP) to your RDS Custom for Oracle DB instance when using the default elastic network interface (ENI). If you attach multiple ENIs to your DB instance, the modify operation fails.
- All RDS Custom for Oracle tags must be present.
- If you use RDS Custom for Oracle replication, note the following requirements and limitations:

- For primary DB instances and read replicas, you can change the instance class for only one DB instance at a time.
- If your RDS Custom for Oracle DB instance has an on-premises primary or replica database, make sure to manually update private IP addresses on the on-premises DB instance after the modification completes. This action is necessary to preserve Oracle DataGuard functionality. RDS Custom for Oracle publishes an event when the modification succeeds.
- You can't modify your RDS Custom for Oracle DB instance class when the primary or read replica DB instances have FSFO (Fast-Start Failover) configured.

How RDS Custom creates your DB instance when you modify the instance class

When you modify your instance class, RDS Custom creates your DB instance as follows:

- Creates the Amazon EC2 instance.
- Creates the root volume from the latest DB snapshot. RDS Custom for Oracle doesn't retain information added to the root volume after the latest DB snapshot.
- Creates Amazon CloudWatch alarms.
- Creates an Amazon EC2 SSH key pair if you have deleted the original key pair. Otherwise, RDS Custom for Oracle retains the original key pair.
- Creates new resources using the tags that are attached to your DB instance when you initiate the modification. RDS Custom doesn't transfer tags to the new resources when they are attached directly to underlying resources.
- Transfers the binary and data volumes with the most recent modifications to the new DB instance.
- Transfers the elastic IP address (EIP). If the DB instance is publicly accessible, then RDS Custom temporarily attaches a public IP address to the new DB instance before transferring the EIP. If the DB instance isn't publicly accessible, RDS Custom doesn't create public IP addresses.

Modifying your RDS Custom for Oracle DB instance

You can modify the DB instance class or storage using the console, AWS CLI, or RDS API.

Console

To modify an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. (Optional) In **Instance configuration**, choose a value for **DB instance class**. For supported classes, see DB instance class support for RDS Custom for Oracle.
6. (Optional) In **Storage**, make the following changes as needed:
    a. Enter a new value for **Allocated storage**. It must be greater than the current value, and from 40 GiB–64 TiB.
    b. Change the value for **Storage type** to **General Purpose SSD (gp2)**, **General Purpose SSD (gp3)**, **Provisioned IOPS (io1)**, or **Provisioned IOPS (io2)**.
    c. If you specified a storage type other than **General Purpose SSD (gp2)**, you can change the **Provisioned IOPS** value.
7. (Optional) In **Additional configuration**, make the following changes as needed:
    - For **Option group**, choose a new option group. For more information, see Working with option groups in RDS Custom for Oracle.
8. Choose **Continue**.
9. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
10. Choose **Modify DB instance**.

AWS CLI

To modify the storage for an RDS Custom for Oracle DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- `--db-instance-class` – A new instance class. For supported classes, see DB instance class support for RDS Custom for Oracle.
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 40–65,536 GiB.

- `--storage-type` – The storage type: gp2, gp3, io1, or io2.
- `--iops` – Provisioned IOPS for the DB instance, if using the io1, io2, or gp3 storage types.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

  Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

The following example changes the DB instance class of `my-cfo-instance` to `db.m5.16xlarge`. The command also changes the storage size to `1024` (1 TiB), storage type to `io2`, Provisioned IOPS to `3000`, and option group to `cfo-ee-19-mt`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-cfo-instance \
    --db-instance-class db.m5.16xlarge \
    --storage-type io2 \
    --iops 3000 \
    --allocated-storage 1024 \
    --option-group cfo-ee-19-mt \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-cfo-instance ^
    --db-instance-class db.m5.16xlarge ^
    --storage-type io2 ^
    --iops 3000 ^
    --allocated-storage 1024 ^
    --option-group cfo-ee-19-mt ^
    --apply-immediately
```

Changing the character set of an RDS Custom for Oracle DB instance

RDS Custom for Oracle defaults to the character set US7ASCII. You might want to specify different character sets to meet language or multibyte character requirements. When you use RDS Custom

for Oracle, you can pause automation and then change the character set of your database manually.

Changing the character set of an RDS Custom for Oracle DB instance has the following requirements:

- You can only change the character on a newly provisioned RDS Custom instance that has an empty or starter database with no application data. For all other scenarios, change the character set using DMU (Database Migration Assistant for Unicode).
- You can only change to a character set supported by RDS for Oracle. For more information, see Supported DB character sets.

To change the character set of an RDS Custom for Oracle DB instance

1. Pause RDS Custom automation. For more information, see Pausing and resuming your RDS Custom DB instance.
2. Log in to your database as a user with SYSDBA privileges.
3. Restart the database in restricted mode, change the character set, and then restart the database in normal mode.

   Run the following script in your SQL client:

   ```
   SHUTDOWN IMMEDIATE;
   STARTUP RESTRICT;
   ALTER DATABASE CHARACTER SET INTERNAL_CONVERT AL32UTF8;
   SHUTDOWN IMMEDIATE;
   STARTUP;
   SELECT VALUE FROM NLS_DATABASE_PARAMETERS WHERE PARAMETER = 'NLS_CHARACTERSET';
   ```

   Verify that the output shows the correct character set:

   ```
   VALUE
   --------
   AL32UTF8
   ```

4. Resume RDS Custom automation. For more information, see Pausing and resuming your RDS Custom DB instance.

Setting the NLS_LANG value in RDS Custom for Oracle

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. To specify locale behavior for Oracle software, set the NLS_LANG environment variable on your client host. This variable sets the language, territory, and character set used by the client application in a database session.

For RDS Custom for Oracle, you can set only the language in the NLS_LANG variable: the territory and character use defaults. The language is used for Oracle database messages, collation, day names, and month names. Each supported language has a unique name, for example, American, French, or German. If language is not specified, the value defaults to American.

After you create your RDS Custom for Oracle database, you can set NLS_LANG on your client host to a language other than English. To see a list of languages supported by Oracle Database, log in to your RDS Custom for Oracle database and run the following query:

```
SELECT VALUE FROM V$NLS_VALID_VALUES WHERE PARAMETER='LANGUAGE' ORDER BY VALUE;
```

You can set NLS_LANG on the host command line. The following example sets the language to German for your client application using the Z shell on Linux.

```
export NLS_LANG=German
```

Your application reads the NLS_LANG value when it starts and then communicates it to the database when it connects.

For more information, see Choosing a Locale with the NLS_LANG Environment Variable in the *Oracle Database Globalization Support Guide*.

Support for Transparent Data Encryption

RDS Custom supports Transparent Data Encryption (TDE) for RDS Custom for Oracle DB instances.

However, you can't enable TDE using an option in a custom option group as you can in RDS for Oracle. You turn on TDE manually. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption in the Oracle documentation.

Tagging RDS Custom for Oracle resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the `AWSRDSCustom` tag that's required for RDS Custom automation. If you do, you might break the automation.
- The `Name` tag is added to RDS Custom resources with prefix value of `do-not-delete-rds-custom` or `rds-custom!oracle-do-not-delete`. Any customer-passed value for the key is overwritten.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see Tagging Amazon RDS resources.

Deleting an RDS Custom for Oracle DB instance

Warning

Deleting a DB instance is a permanent action. You can't recover a DB instance after deletion unless you have a backup or snapshot.
When you delete an RDS Custom DB instance, AWS automatically deletes the underlying Amazon EC2 instance and EBS volumes. Don't manually terminate the Amazon EC2 instance or delete the EBS volumes before deleting the DB instance through Amazon RDS. Manual deletion of these resources causes DB instance deletion and final snapshot creation to fail, preventing any possibility of recovery.

To delete an RDS Custom DB instance, do the following:

- Provide the name of the DB instance.
- Clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete) and how much data is deleted.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to delete. RDS Custom DB instances show the role **Instance (RDS Custom)**.
3. For **Actions**, choose **Delete**.
4. To retain automated backups, choose **Retain automated backups**.
5. Enter **`delete me`** in the box.
6. Choose **Delete**.

AWS CLI

You delete an RDS Custom DB instance by using the delete-db-instance AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance, with the following exceptions:

- `--skip-final-snapshot` is required.
- `--no-skip-final-snapshot` isn't supported.
- `--final-db-snapshot-identifier` isn't supported.

The following example deletes the RDS Custom DB instance named `my-custom-instance`, and retains automated backups.

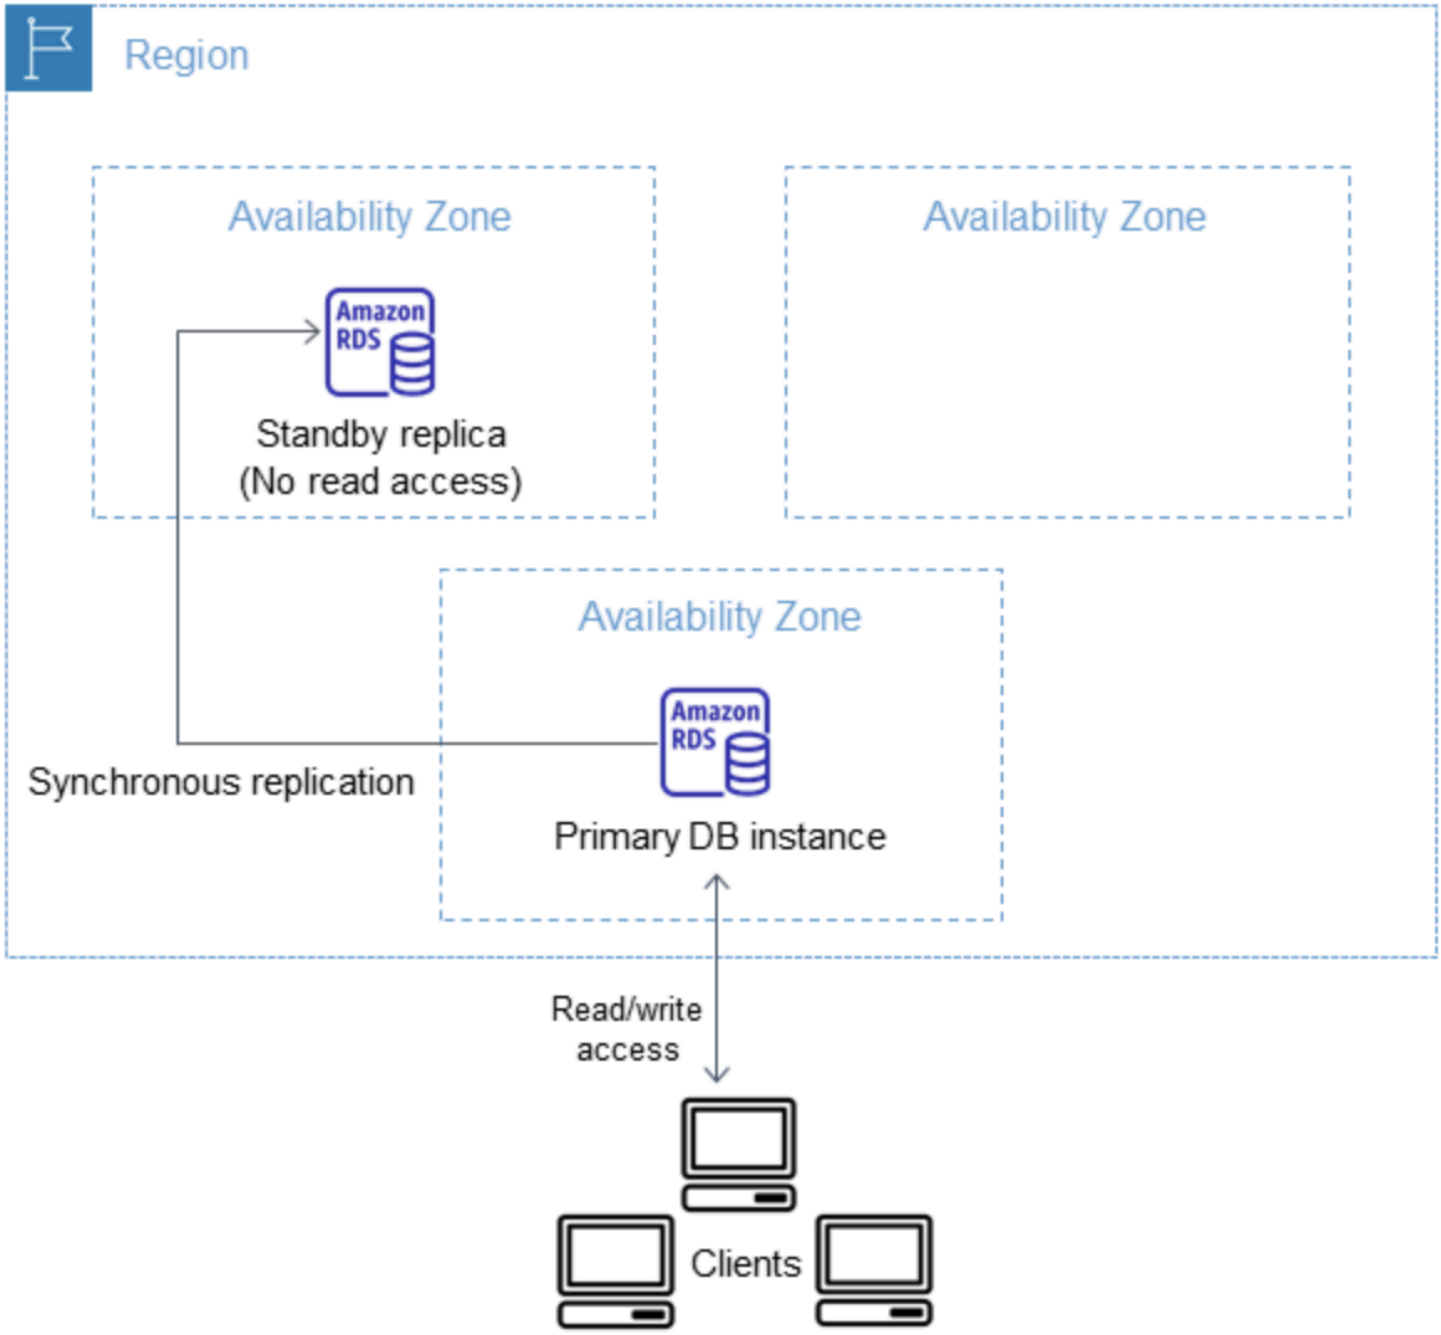
Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier my-custom-instance \
```

```
    --skip-final-snapshot \
    --no-delete-automated-backups
```

For Windows:



```
aws rds delete-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --skip-final-snapshot ^
    --no-delete-automated-backups
```

Managing a Multi-AZ deployment for RDS Custom for Oracle

In a Multi-AZ DB instance deployment for RDS Custom for Oracle, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone (AZ). The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy.

A Multi-AZ DB instance deployment enhances availability during planned system maintenance. If planned database maintenance or unplanned service disruption occurs, Amazon RDS automatically fails over to the up-to-date standby DB instance. Database operations can resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the standby replica as part of the failover process. You don't need to reconfigure your application when a failover occurs.

The following diagram shows the Multi-AZ architecture for RDS Custom for Oracle:

The Amazon RDS console shows the Availability Zone of the standby replica (the secondary AZ). You can also use the `describe-db-instances` CLI command or the `DescribeDBInstances` API operation to find the secondary AZ.

Region and version availability for a Multi-AZ deployment for RDS Custom for Oracle

Multi-AZ deployments for RDS Custom for Oracle are supported for the following releases for both Enterprise Edition (EE) and Standard Edition 2 (SE2):

- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

> **Note**
>
> Multi-AZ deployments for RDS Custom for Oracle aren't supported on Oracle Database 18c.

Multi-AZ deployments for RDS Custom for Oracle are available in all Regions where RDS Custom for Oracle is available. For more information on Region availability of Multi-AZ deployments for RDS Custom for Oracle, see the section called “Supported Regions and DB engines for RDS Custom for Oracle”.

Limitations for a Multi-AZ deployment in RDS Custom for Oracle

Multi-AZ deployments with RDS Custom for Oracle have the following limitations:

- If your DB instance was created before June 30, 2025, you can't convert from a Single-AZ to Multi-AZ deployment. Your underlying Custom Engine Version (CEV) was built with an older service-provided AMI that lacks Multi-AZ support. You must migrate your database to a new DB instance using a CEV that you create with a service-provided AMI after June 30, 2025. For details, see the section called “Migration for CEVs before 06.30.2025”.
- You can't create cross-Region Multi-AZ deployments.
- You can't configure the standby DB instance to accept database read activity.
- When you use a Custom Engine Version (CEV) with a Multi-AZ deployment, your standby DB instance uses the same CEV. The standby DB instance can't use a different CEV.
- You can't create a read replica on a Multi-AZ deployment instance and you also cannot modify the primary instance of the read replica to have a Multi-AZ deployment.

- RDS Custom for Oracle DB instances with Multi-AZ deployment can have increased write and commit latency compared to a Single-AZ deployment. This increase can happen because of the synchronous data replication between DB instances. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones.

Creating a Multi-AZ deployment in RDS Custom for Oracle

To create an RDS Custom for Oracle DB instance with a Multi-AZ deployment, follow the steps in the section called "Setting up your RDS Custom for Oracle environment" to set up your environment with the prerequisites.

> **Important**
>
> To simplify setup, we recommend that you use the latest CloudFormation template file provided in the network setup instructions. For more information, see the section called "Deploy with CloudFormation".

You can create an RDS Custom for Oracle instance with a Multi-AZ deployment by choosing the **Multi-AZ** option during the database instance creation in the Amazon RDS console. Alternatively, you can specify the `--multi-az` parameter in the Amazon RDS `create-db-instance` command in the AWS CLI.

Prerequisites for a Multi-AZ deployment in RDS Custom for Oracle

A Multi-AZ deployment for RDS Custom for Oracle is different from Multi-AZ for RDS for Oracle. Unlike Multi-AZ for RDS for Oracle, you must meet the prerequisites for RDS Custom for Oracle before you create your Multi-AZ DB instance. This is because RDS Custom runs inside your own account, which requires permissions. Also, you need to create the Multi-AZ instance on the CEV with the latest service-provided AMI, which supports the Multi-AZ deployments.

If you don't complete the prerequisites, your Multi-AZ DB instance might fail to run, or automatically revert to a Single-AZ DB instance. For more information about prerequisites, see the section called "Prerequisites".

RDS Custom for Oracle requires specific prerequisites when converting from Single-AZ to Multi-AZ deployment. Incomplete prerequisites cause Multi-AZ setup to fail. Use either manual setup

or the latest CloudFormation template file provided in the network setup instructions. For more information, see Step 3: Extract the CloudFormation templates for RDS Custom for Oracle.

To complete the prerequisites manually, follow the steps in the section called "Converting Single-AZ to Multi-AZ" and note the following:

- Make sure your RDS Custom for Oracle DB instance uses a CEV created after June 30, 2025 with the latest service-provided AMI.
- Update the Amazon RDS security group inbound and outbound rules to allow port 1120.
- Create new Amazon SQS VPC endpoints that allow the Amazon RDS RDS Custom for Oracle DB instance to communicate with Amazon SQS.
- Update the Amazon SQS permissions in the instance profile role.

> **Important**
>
> Don't reboot your Multi-AZ primary DB instance manually by logging into the instance without pausing RDS Custom for Oracle automation.

Migration steps for DB instances using CEVs created before June 30, 2025

If you created your RDS Custom for Oracle DB instance before June 30, 2025, you can't directly modify it to Multi-AZ deployment because the underlying CEV was built with an older service-provided AMI that lacks Multi-AZ support. You must migrate your database to a new instance using a CEV you create after June 30, 2025. Do the following for the migration.

1. **Create CEV from source** with the latest service-provided AMI (after June 30, 2025).
2. **Launch a new DB instance** with the new CEV.
3. **Migrate your database** from the existing DB instance that doesn't support Multi-AZ deployment to the newly created instance using one of following methods:
   - Physical migration of Oracle databases to Amazon RDS Custom using Data Guard
   - Physical migration of Oracle databases to Amazon RDS Custom using RMAN duplication

Converting a Single-AZ deployment to a Multi-AZ deployment in RDS Custom for Oracle

You can convert an existing multi-AZ compatible RDS Custom for Oracle instance from a Single-AZ deployment to a Multi-AZ deployment. When you modify the DB instance, Amazon RDS performs several actions:

- Takes a snapshot of the primary DB instance.
- Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
- Turns on synchronous block-level replication between the primary and standby DB instances.

> **Important**
>
> We recommend that you avoid modifying your RDS Custom for Oracle DB instance from a Single-AZ to a Multi-AZ deployment on a production DB instance during periods of peak activity.

AWS uses a snapshot to create the standby instance to avoid downtime when you convert from Single-AZ to Multi-AZ, but performance might be impacted during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency. While this capability allows large volumes to quickly be restored from snapshots, it can cause increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation

Follow Step 3: Extract the CloudFormation templates for RDS Custom for Oracle to setup your VPC and IAM profile again to add SQS VPC endpoint and SQS permission in IAM profile.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually

If you choose to configure the prerequisites manually, perform the following tasks.

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/
2. Choose **Endpoint**. The **Create Endpoint** page appears.

3. For **Service Category**, choose **AWS services**.
4. In **Services**, search for SQS.
5. In **VPC**, choose the VPC where your RDS Custom for Oracle DB instance is deployed.
6. In **Subnets**, choose the subnets where your RDS Custom for Oracle DB instance is deployed.
7. In **Security Groups**, choose the security group where your RDS Custom for Oracle DB instance is deployed.
8. For **Policy**, choose **Custom**.
9. In your custom policy, replace the `AWS partition`, `Region`, `accountId`, and `IAM-Instance-role` with your own values.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/AWSRDSCustom": "custom-oracle"
                }
            },
            "Action": [
                "SQS:SendMessage",
                "SQS:ReceiveMessage",
                "SQS:DeleteMessage",
                "SQS:GetQueueUrl"
            ],
            "Resource": "arn:aws:sqs:us-east-1:111122223333:do-not-delete-rds-
custom-*",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/{IAM-Instance-role}"
            }
        }
    ]
}
```

Update the **Instance profile** with permission to access Amazon SQS. Replace the `AWS partition`, `Region`, and `accountId` with your own values.

```
{
    "Sid": "13",
    "Effect": "Allow",
    "Action": [
        "SQS:SendMessage",
        "SQS:ReceiveMessage",
        "SQS:DeleteMessage",
        "SQS:GetQueueUrl"
    ],
    "Resource": [
        {
            "Fn::Sub": "arn:${AWS::Partition}:sqs:${AWS::Region}:${AWS::AccountId}:do-
not-delete-rds-custom-*"
        }
    ],
    "Condition": {
        "StringLike": {
            "aws:ResourceTag/AWSRDSCustom": "custom-oracle"
        }
    }
}
```

Update the Amazon RDS security group inbound and outbound rules to allow port 1120.

- In **Security Groups**, choose the group where your RDS Custom for Oracle DB instance is deployed.
- For **Inbound Rules**, create a **Custom TCP** rule to allow port `1120` from the source group.
- For **Outbound Rules**, create a **Custom TCP** rule to allow port `1120` to the destination group.

Modify using the RDS console, AWS CLI, or RDS API

After you've completed the prerequisites, you can modify an RDS Custom for Oracle DB instance from a Single-AZ to Multi-AZ deployment using the Amazon RDS console, AWS CLI, or Amazon RDS API.

Console

To modify an existing RDS Custom for Oracle Single-AZ to Multi-AZ deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**. The **Databases** pane appears.
3. Choose the RDS Custom for Oracle DB instance that you want to modify.
4. For **Actions**, choose **Convert to Multi-AZ deployment**.
5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see the section called "Scheduling modifications".
6. On the **Confirmation** page, choose **Convert to Multi-AZ**.

AWS CLI

To convert to a Multi-AZ DB instance deployment by using the AWS CLI, call the modify-db-instance command and set the `--multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see the section called "Available settings".

Example

The following code modifies `mycustomdbinstance` by including the `--multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see the section called "Scheduling modifications".

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mycustomdbinstance \
    --multi-az \
    [--no-apply-immediately | --apply-immediately]
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mycustomdbinstance ^
    --multi-az ^
    [--no-apply-immediately | --apply-immediately]
```

RDS API

To convert to a Multi-AZ DB instance deployment with the Amazon RDS API, call the ModifyDBInstance operation and set the `MultiAZ` parameter to true.

Converting a Multi-AZ deployment to a Single-AZ deployment in RDS Custom for Oracle

You can modify an existing RDS Custom for Oracle DB instance from a Multi-AZ to a Single-AZ deployment.

Console

To modify an RDS Custom for Oracle DB instance from a Multi-AZ to Single-AZ deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**. The **Databases** pane appears.
3. Choose the RDS Custom for Oracle DB instance that you want to modify.
4. For **Multi-AZ deployment**, choose **No**.
5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see the section called “Scheduling modifications”.
6. On the **Confirmation** page, choose **Modify DB Instance**.

AWS CLI

To modify a Multi-AZ deployment to a Single-AZ deployment by using the AWS CLI, call the modify-db-instance command and include the `--no-multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see the section called “Available settings”.

Example

The following code modifies `mycustomdbinstance` by including the `--no-multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see the section called "Scheduling modifications".

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mycustomdbinstance \
    --no-multi-az \
    [--no-apply-immediately | --apply-immediately]
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mycustomdbinstance ^
    --no-multi-az ^
    [--no-apply-immediately | --apply-immediately]
```

RDS API

To modify a Multi-AZ deployment to a Single-AZ deployment by using the Amazon RDS API, call the ModifyDBInstance operation and set the `MultiAZ` parameter to `false`.

Customizing the OS in an RDS Custom for Oracle Multi-AZ deployment

With RDS Custom for Oracle Multi-AZ deployments, you can customize the operating system and install third-party software on both primary and standby EC2 instances. Unlike Amazon RDS, RDS Custom for Oracle provides administrative access to the database environment and underlying operating system, allowing you to install monitoring tools, security agents, or custom applications in addition to Oracle databases.

When you customize the OS on a Multi-AZ deployment, you're responsible for ensuring that customizations exist on both primary and standby instances. This approach ensures application continuity during Multi-AZ failover and maintains consistent functionality across both instances.

Requirements for customizing the OS in an RDS Custom for Oracle Multi-AZ deployment

Before you customize the OS in a Multi-AZ deployment, be aware of the following requirements:

- Install third-party software only on the `/rdsdbdata` mount point. The data volume (`/rdsdbdata`) is the only data that is replicated in a Multi-AZ deployment. The root volume (`/`) is replaced during OS patching, and the binary volume (`/rdsdbbin`) is replaced during database patching. Software installed on the root and binary volumes is lost during patching.
- Ensure all customizations comply with AWS and Oracle licensing terms and conditions.
- Before you convert from Single-AZ to Multi-AZ, make sure the HugePages settings in `/etc/sysctl.conf` work correctly.

Identifying EC2 instances in an RDS Custom for Oracle Multi-AZ deployment

When customizing your Multi-AZ instances, identify which Amazon EC2 instances serve as the primary and standby for your RDS Custom for Oracle deployment.

To identify primary and standby EC2 instances

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose your Multi-AZ RDS Custom for Oracle DB instance.
4. In the **Configuration** section, note the **Resource ID** (format: db-*nnnnnnn*).
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. In the search box, enter the Resource ID from step 4.
8. The search results show two instances: your primary and secondary. The instance with the active RDS Custom for Oracle database is the primary.

Customizing the OS before creating an RDS Custom for Oracle Multi-AZ deployment

In this scenario, your current deployment is a Single-AZ DB instance. You can customize the OS and then convert your DB instance to a Multi-AZ deployment. If you're installing third-party software, and you have modified files on multiple volumes, this technique is recommended.

To customize the OS before converting your Single-AZ to Multi-AZ

1. Connect to the EC2 instance in your Single-AZ deployment using AWS Systems Manager Session Manager or SSH.
2. Perform either of the following customizations:

- Install third-party software on the data volume (`/rdsdbdata`).
- Customize files on the root volume (`/`).

3. Test your software or root volume customizations to ensure they work correctly.
4. Convert the Single-AZ DB instance to a Multi-AZ deployment by following the instructions in Converting a Single-AZ deployment to a Multi-AZ deployment in RDS Custom for Oracle.
5. Verify that your customizations exist on both instances in the Multi-AZ deployment. For more information, see Identifying EC2 instances in an RDS Custom for Oracle Multi-AZ deployment.

Customizing the OS after creating an RDS Custom for Oracle Multi-AZ deployment

If you have an exiting Multi-AZ deployment, you can deploy your customizations using AWS Systems Manager or using manual techniques.

Customizing the OS in a Multi-AZ deployment using AWS Systems Manager

For existing Multi-AZ DB instances, we recommend Systems Manager as the most reliable way to apply customizations simultaneously to both primary and standby instances. This approach ensures consistency. For a general introduction to this service, see What is AWS Systems Manager?. To learn how to install software on both DB instances simultaneously, see Install or update Distributor packages.

Customizing the OS in a Multi-AZ deployment manually

In this scenario, your Multi-AZ deployment already exists, but you don't use AWS Systems Manager to deploy the customizations. You can customize your OS manually in either of the following ways:

Customize the OS on the primary instance and replicate the changes

Multi-AZ deployment automatically replicates the `rdsdbdata` volume. You can customize the OS in the following ways:

- Install third-party software directly on the `/rdsdbdata` mount point.
- To modify files on the root volume (`/`), create files on the data volume and then create a symbolic link from the root volume files to the data volume files.

Customize the OS on the primary and standby instances separately

In this approach, you customize the OS on the primary instance. Then you perform the same customizations on the standby instance.

To customize the OS on the primary instance so that they are replicated automatically

1. Identify the primary and standby DB instances using the procedure in Identifying EC2 instances in an RDS Custom for Oracle Multi-AZ deployment.
2. Connect to the primary EC2 instance using Session Manager or SSH.
3. Use either of the following techniques, depending on your business requirements:

   Install third-party software

   Install your software on the `/rdsdbdata` mount point.

   ```
   sudo mkdir -p /rdsdbdata/custom-software
   cd /rdsdbdata/custom-software
   # Install your software here
   ```

   Customize the root volume

   Create symbolic links from OS configuration files on the root volume to files on the data volume. For example, create file `/rdsdbdata/customizations/sysctl.conf`, and then create a symbolic link at `/etc/sysctl.conf` that points to `/rdsdbdata/customizations/sysctl.conf`.

   ```
   sudo mkdir -p /rdsdbdata/customizations
   sudo mv /etc/sysctl.conf /rdsdbdata/customizations/sysctl.conf
   sudo ln -sf /rdsdbdata/customizations/sysctl.conf /etc/sysctl.conf
   ```

4. Test your software or root volume customizations to ensure they work correctly.
5. Connect to the standby instance and verify that the synchronous replication has copied your software or root volume customizations to the `/rdsdbdata` directory.

Customizing the binary volume in an RDS Custom for Oracle Multi-AZ deployment

You can apply a database patch to the binary volume (`/rdsdbbin`) in an RDS Custom for Oracle Multi-AZ deployment. You must apply the patch to the primary and standby instances. Consider the following guidelines:

- When you perform a one-off patch, we recommend that you create a new CEV with the new one-off patch included in the manifest.

- To apply a one-off patch manually, make sure to unzip the one-off patch in both the primary and secondary EC2 instances. Applying the patch and running `datapatch` is required only on the primary Multi-AZ instance.
- If you patch the database using a different CEV, the binary volume is replaced. Make sure to include the one-off patch in the manifest of the new CEV.

Best practices for customizing the OS

Follow these best practices when customizing the OS on RDS Custom for Oracle Multi-AZ instances:

Test in non-production environments

Always test customizations in a non-production environment before applying them to production instances.

Document all changes

Maintain detailed documentation of all customizations for future reference and troubleshooting. We recommend that you store your customizations in a script that you can be applied anytime, just in case.

Verify on both instances

Regularly verify that customizations are present and functioning correctly on both primary and standby instances.

Use Systems Manager for consistency

Use Systems Manager for consistent application of changes across instances, especially for existing Multi-AZ deployments.

Deploying RDS Custom for Oracle with AWS CloudFormation

Automate your RDS Custom for Oracle deployment using the provided AWS CloudFormation template. Complete the following prerequisites before deploying the resources.

Prerequisites

Download required Oracle files

You need specific Oracle installation files before you can create the CloudFormationtemplate. Download these files before you deploy.

1. Navigate to Oracle Database 19c (19.3)
2. Locate and download the file `LINUX.X64_193000_db_home.zip`
3. Rename the file to`V982063-01.zip`
4. Download the remaining patches, selecting **Platform or Language** as `Linux x86-64`

Latest OPatch utility

Patch 6880880

January 2023 PSU Patches

Database PSU & RU Patches

- Patch 34765931
- Patch 34786990

Additional Required Patches

- Patch 35099667
- Patch 35099674
- Patch 28730253
- Patch 29213893
- Patch 35012866

April 2023 PSU Patches

Database PSU & RU Patches

- Patch 35042068
- Patch 35050341

Additional Required Patches

- Patch 29213893
- Patch 33125873
- Patch 35220732
- Patch 35239280

Amazon S3 bucket setup

1. Create an Amazon S3 bucket in your AWS account, or choose an existing bucket.
2. Create a folder structure in the bucket similar to example below.

```
<bucket-name>/
### oracle_cev/
    ### V982063-01.zip
    ### p6880880_190000_Linux-x86-64.zip
    ### p34765931_190000_Linux-x86-64.zip
    ### p34786990_190000_Linux-x86-64.zip

    ### p35239280_190000_Generic.zip
```

3. Upload all of Oracle files that you previously downloaded to the appropriate folders.

Deploy RDS Custom for Oracle using AWS CloudFormation

Step 1: Prepare the CloudFormation template

Before you can deploy RDS Custom for Oracle, you need to download and configure the CloudFormation template that creates the necessary prerequisites.

Copy and save the template

1. Go to Deploying RDS Custom for Oracle with single and multiple Availability Zones
2. Copy the template in your preferred format (YAML or JSON)
3. Save the file in YAML or JSON format. For example, `rds-custom-oracle-prereqs.yaml`

Launch the stack in the AWS console

1. Open the AWS Console and navigate to AWS CloudFormation
2. Choose **Create stack** > **With new resources (standard)**
3. Select **Choose an existing template**
4. Select **Upload a template file** > **Choose file**
5. Select the template file you previously downloaded
6. Keep the default parameter values
7. Select **Next** to create the stack

Alternative: Using AWS CLI

Instead of using the console, you can create the stack using the AWS CLI:

```
aws cloudformation create-stack \
  --stack-name rds-custom-oracle \
  --template-body file://rds-custom-oracle-prereqs.yaml \
  --capabilities CAPABILITY_NAMED_IAM
```

Step 2: Create the Custom Engine Versions (CEVs) and Amazon RDS instances

Copy and save the template

1. Go to Deploying RDS Custom for Oracle with single and multiple Availability Zones
2. Copy the template in your preferred format (YAML or JSON)
3. Update the following parameters in the template if needed:
   - `BucketName`
   - `CEVS3Prefix`
   - Database master password (replace **********)

4. Save the file in YAML or JSON format

Step 3: Deploy using the AWS console

1. Open the AWS Console and navigate to AWS CloudFormation
2. Choose **Create stack** > **With new resources (standard)**
3. Select **Choose an existing template**
4. Select **Upload a template file** > **Choose file**
5. Select the template file you previously downloaded
6. Leave the parameters as default values
7. Fill in the parameters as follows:

```
BucketName: rds-custom-id
CEVS3Prefix: oracle_cev
CEVCreation: Yes
```

8. Review the configuration and select **Next** to create the stack

Optional: Deploy Using AWS CLI

```
aws cloudformation create-stack \
  --stack-name rds-custom-oracle \
  --template-body file://rds-custom-oracle.yaml \
  --parameters \
    ParameterKey=BucketName,ParameterValue=rds-custom-id \
    ParameterKey=CEVS3Prefix,ParameterValue=oracle_cev \
    ParameterKey=CEVCreation,ParameterValue=Yes \
  --capabilities CAPABILITY_NAMED_IAM
```

Deployment resources created

The template creates the following resources:

- Amazon VPC with public and private subnets
- Security groups
- Amazon VPC endpoints
- IAM roles and policies

- AWS KMS key for encryption
- Custom Engine Versions (CEVs)
- RDS Custom for Oracle instances for both single-AZ and multi-AZ configurations

Monitor your deployment progress

After you create the CloudFormation stack, monitor its progress to ensure successful deployment. The deployment process includes creating Custom Engine Versions (CEVs) and RDS instances.

To monitor deployment progress:

1. Open the CloudFormation console.
2. Choose your stack name.
3. Choose the **Events** tab to view progress and identify any errors.

> **Note**
>
> CEV creation typically requires 2-3 hours. After CEV creation completes successfully, Amazon RDS automatically begins creating the Amazon RDS instance.

Post-Deployment

After the stack creation process completes, perform the following post-deployment verification and configuration steps:

1. From the Amazon RDS console page, navigate to **Custom engine versions** to verify CEV creation.
2. Confirm Amazon RDS instances are created and available
3. Test connectivity to the Amazon RDS instances
4. Set up monitoring and backup strategies as needed

Cleanup

To remove all resources, run the following AWS CLI command:

```
aws cloudformation delete-stack --stack-name rds-custom-oracle
```

Troubleshooting

If you encounter issues during deployment, use the following solutions to resolve common problems.

CEV creation fails

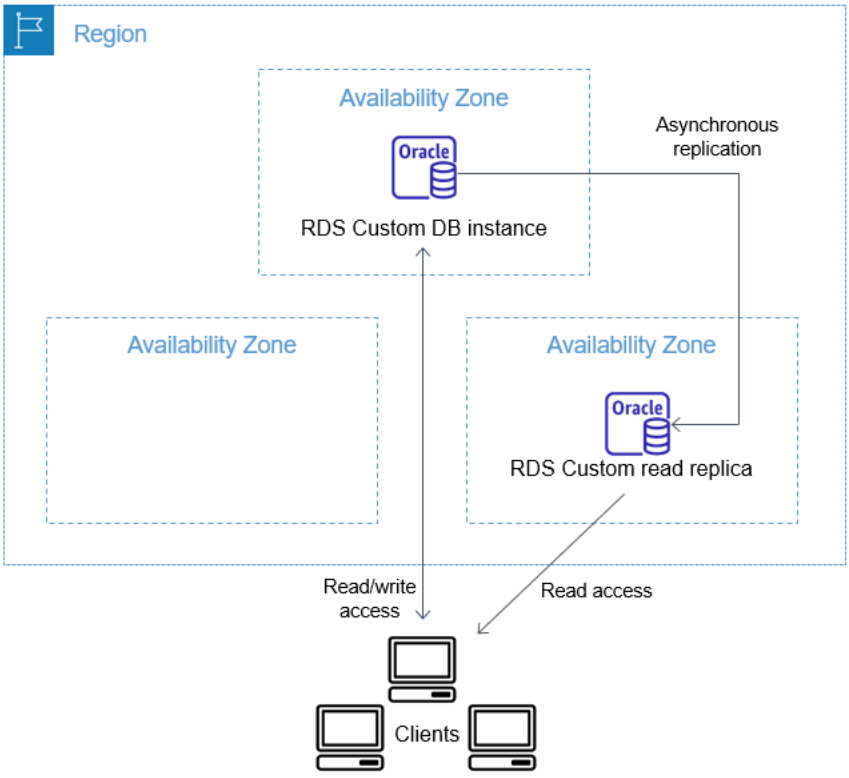
- Verify all required patches are uploaded to Amazon S3
- Check IAM permissions
- Verify the patch versions are correct; see the the section called “Prerequisites” for the list of required patches.

Amazon RDS instance creation fails

- Check VPC/subnet configurations
- Verify security group rules
- Confirm CEV is available

Working with Oracle replicas for RDS Custom for Oracle

You can create Oracle replicas for RDS Custom for Oracle DB instances that run Oracle Enterprise Edition. Both container databases (CDBs) and non-CDBs are supported. Standard Edition 2 doesn't support Oracle Data Guard.



Creating an RDS Custom for Oracle replica is similar to creating an RDS for Oracle replica, but with important differences. For general information about creating and managing Oracle replicas, see Working with DB instance read replicas and Working with read replicas for Amazon RDS for Oracle.

Topics

- Overview of RDS Custom for Oracle replication
- Guidelines and limitations for RDS Custom for Oracle replication
- Promoting an RDS Custom for Oracle replica to a standalone DB instance
- Configuring a VPN tunnel between RDS Custom for Oracle primary and replica instances

Overview of RDS Custom for Oracle replication

The architecture of RDS Custom for Oracle replication is analogous to RDS for Oracle replication. A primary DB instance replicates asynchronously to one or more Oracle replicas.

Maximum number of replicas

As with RDS for Oracle, you can create up to five managed Oracle replicas of your RDS Custom for Oracle primary DB instance. You can also create your own manually configured (external) Oracle replicas. External replicas don't count toward your DB instance limit. They also lie outside the RDS Custom support perimeter. For more information about the support perimeter, see RDS Custom support perimeter.

Replica naming convention

Oracle replica names are based on the database unique name. The format is *DB_UNIQUE_NAME_X*, with letters appended sequentially. For example, if your database unique name is ORCL, the first two replicas are named ORCL_A and ORCL_B. The first six letters, A–F, are reserved for RDS Custom. RDS Custom copies database parameters from your primary DB instance to the replicas. For more information, see DB_UNIQUE_NAME in the Oracle documentation.

Replica backup retention

By default, RDS Custom Oracle replicas use the same backup retention period as your primary DB instance. You can modify the backup retention period to 1–35 days. RDS Custom supports backing up, restoring, and point-in-time recovery (PITR). For more information about backing up and restoring RDS Custom DB instances, see Backing up and restoring an Amazon RDS Custom for Oracle DB instance.

> **Note**
>
> While creating a Oracle replica, RDS Custom temporarily pauses the cleanup of redo log files. In this way, RDS Custom ensures that it can apply these logs to the new Oracle replica after it becomes available.

Replica promotion

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, `promote-read-replica` AWS CLI command, or `PromoteReadReplica` API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. You can only promote external Oracle replicas manually.

Guidelines and limitations for RDS Custom for Oracle replication

When you create RDS Custom for Oracle replicas, not all RDS Oracle replica options are supported.

Topics

- General guidelines for RDS Custom for Oracle replication
- General limitations for RDS Custom for Oracle replication
- Networking requirements and limitations for RDS Custom for Oracle replication
- External replica limitations for RDS Custom for Oracle

General guidelines for RDS Custom for Oracle replication

When working with RDS Custom for Oracle, follow these guidelines:

- You can use RDS Custom for Oracle replication only in Oracle Enterprise Edition. Standard Edition 2 isn't supported.
- We strongly recommend that you implement a VPN tunnel to encrypt communication between your primary and standby instances. For more information, see Configuring a VPN tunnel between RDS Custom for Oracle primary and replica instances.
- Don't modify the `RDS_DATAGUARD` user. This user is reserved for RDS Custom for Oracle automation. Modifying this user can result in undesired outcomes, such as an inability to create Oracle replicas for your RDS Custom for Oracle DB instance.
- Don't change the replication user password. It is required to administer the Oracle Data Guard configuration on the RDS Custom host. If you change the password, RDS Custom for Oracle might put your Oracle replica outside the support perimeter. For more information, see RDS Custom support perimeter.

  The password is stored in AWS Secrets Manager, tagged with the DB resource ID. Each Oracle replica has its own secret in Secrets Manager. The secret uses either of the following naming formats.

  ```
  do-not-delete-rds-custom-db-DB_resource_id-uuid-dg
  rds-custom!oracle-do-not-delete-DB_resource_id-uuid-dg
  ```

- Don't change the `DB_UNIQUE_NAME` for the primary DB instance. Changing the name causes any restore operation to become stuck.

- Don't specify the clause `STANDBYS=NONE` in a `CREATE PLUGGABLE DATABASE` command in an RDS Custom CDB. This way, if a failover occurs, your standby CDB contains all PDBs.

General limitations for RDS Custom for Oracle replication

RDS Custom for Oracle replicas have the following limitations:

- You can't create RDS Custom for Oracle replicas in read-only mode. However, you can manually change the mode of mounted replicas to read-only, and from read-only to mounted. For more information, see the documentation for the create-db-instance-read-replica AWS CLI command.
- You can't create cross-Region RDS Custom for Oracle replicas.
- You can't change the value of the Oracle Data Guard `CommunicationTimeout` parameter. This parameter is set to 15 seconds for RDS Custom for Oracle DB instances.

Networking requirements and limitations for RDS Custom for Oracle replication

Make sure that your network configuration supports RDS Custom for Oracle replicas. Consider the following:

- Make sure to enable port 1140 for both inbound and outbound communication within your virtual private cloud (VPC) for the primary DB instance and all of its replicas. This is required for Oracle Data Guard communication between read replicas.
- RDS Custom for Oracle validates the network while creating a Oracle replica. If the primary DB instance and the new replica can't connect over the network, RDS Custom for Oracle doesn't create the replica and places it in the `INCOMPATIBLE_NETWORK` state.
- For external Oracle replicas, such as those you create on Amazon EC2 or on-premises, use another port and listener for Oracle Data Guard replication. Trying to use port 1140 could cause conflicts with RDS Custom automation.
- The `/rdsdbdata/config/tnsnames.ora` file contains network service names mapped to listener protocol addresses. Note the following requirements and recommendations:
  - Entries in `tnsnames.ora` prefixed with `rds_custom_` are reserved for RDS Custom when handling Oracle replica operations.

    When creating manual entries in `tnsnames.ora`, don't use this prefix.
  - In some cases, you might want to switch over or fail over manually, or use failover technologies such as Fast-Start Failover (FSFO). If so, make sure to manually synchronize

`tnsnames.ora` entries from the primary DB instance to all of the standby instances. This recommendation applies to both Oracle replicas managed by RDS Custom and to external Oracle replicas.

RDS Custom automation updates `tnsnames.ora` entries on only the primary DB instance. Make sure also to synchronize when you add or remove a Oracle replica.

If you don't synchronize the `tnsnames.ora` files and switch over or fail over manually, Oracle Data Guard on the primary DB instance might not be able to communicate with the Oracle replicas.

External replica limitations for RDS Custom for Oracle

RDS Custom for Oracle external replicas, which include on-premises replicas, have the following limitations:

- RDS Custom for Oracle doesn't detect instance role changes upon manual failover, such as FSFO, for external Oracle replicas.

  RDS Custom for Oracle does detect changes for managed replicas. The role change is noted in the event log. You can also see the new state by using the describe-db-instances AWS CLI command.
- RDS Custom for Oracle doesn't detect high replication lag for external Oracle replicas.

  RDS Custom for Oracle does detect lag for managed replicas. High replication lag produces the `Replication has stopped` event. You can also see the replication status by using the describe-db-instances AWS CLI command, but there might be a delay for it to be updated.
- RDS Custom for Oracle doesn't promote external Oracle replicas automatically if you delete your primary DB instance.

  The automatic promotion feature is available only for managed Oracle replicas. For information about promoting Oracle replicas manually, see the white paper Enabling high availability with Data Guard on Amazon RDS Custom for Oracle.

Promoting an RDS Custom for Oracle replica to a standalone DB instance

Just as with RDS for Oracle, you can promote an RDS Custom for Oracle replica to a standalone DB instance. When you promote a Oracle replica, RDS Custom for Oracle reboots the DB instance

before it becomes available. For more information about promoting Oracle replicas, see Promoting a read replica to be a standalone DB instance.

When promoting a replica, note the following guidelines:

- Don't initiate a failover while RDS Custom for Oracle is promoting your replica. Otherwise, the promotion workflow could become stuck.
- Don't switch over your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.
- Don't shut down your primary DB instance while RDS Custom for Oracle is promoting your Oracle replica. Otherwise, the promotion workflow could become stuck.
- Don't try to restart replication with your newly promoted DB instance as a target. After RDS Custom for Oracle promotes your Oracle replica, it becomes a standalone DB instance and no longer has the replica role.

Note the following limitations for RDS Custom for Oracle replica promotion:

- You can't promote a replica while RDS Custom for Oracle is backing it up.
- You can't change the backup retention period to `0` when you promote your Oracle replica.
- You can't promote your replica when it isn't in a healthy state.

  If you issue `delete-db-instance` on the primary DB instance, RDS Custom for Oracle validates that each managed Oracle replica is healthy and available for promotion. A replica might be ineligible for promotion because automation is paused or it is outside the support perimeter. In such cases, RDS Custom for Oracle publishes an event explaining the issue so that you can repair your Oracle replica manually.

The following steps show the general process for promoting a Oracle replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance.
2. Wait for RDS Custom for Oracle to apply all updates to your Oracle replica.
3. Promote your Oracle replica by choosing the **Promote** option on the Amazon RDS console, the AWS CLI command `promote-read-replica`, or the `PromoteReadReplica` Amazon RDS API operation.

Promoting a Oracle replica takes a few minutes to complete. During the process, RDS Custom for Oracle stops replication and reboots your replica. When the reboot completes, the Oracle replica is available as a standalone DB instance. For information about troubleshooting replica promotion, see Troubleshooting replica promotion for RDS Custom for Oracle.

Console

To promote an RDS Custom for Oracle replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each Oracle replica shows **Replica** in the **Role** column.
3. Choose the RDS Custom for Oracle replica that you want to promote.
4. For **Actions**, choose **Promote**.
5. On the **Promote Oracle replica** page, enter the backup retention period and the backup window for the newly promoted DB instance. You can't set this value to **0**.
6. When the settings are as you want them, choose **Promote Oracle replica**.

AWS CLI

To promote your RDS Custom for Oracle replica to a standalone DB instance, use the AWS CLI `promote-read-replica` command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \
--db-instance-identifier my-custom-read-replica \
--backup-retention-period 2 \
--preferred-backup-window 23:00-24:00
```

For Windows:

```
aws rds promote-read-replica ^
--db-instance-identifier my-custom-read-replica ^
```

```
--backup-retention-period 2 ^
--preferred-backup-window 23:00-24:00
```

RDS API

To promote your RDS Custom for Oracle replica to be a standalone DB instance, call the Amazon RDS API `PromoteReadReplica` operation with the required parameter `DBInstanceIdentifier`.

Configuring a VPN tunnel between RDS Custom for Oracle primary and replica instances

A VPN tunnel is an encrypted connection between two or more devices over a network. To ensure the highest level of security for your Oracle Data Guard instances in RDS Custom for Oracle, we strongly recommend that you implement a VPN tunnel to encrypt communication between your primary and standby instances. The tunnel serves as a safeguard for sensitive data as it travels the network between instances. While this configuration is optional, we recommend it as a best practice to achieve data security and regulatory compliance.

Make sure you meet the following prerequisites:

- You have root access to the primary and standby hosts.
- You have the technical expertise to run the `ipsec` command.

To configure a VPN tunnel between a primary and replica in RDS Custom for Oracle

1. Add the security groups for both the primary instance and standby instance to the allow list using the following rules:

```
ACTION FLOW SOURCE PROTO PORT

ALLOW ingress this-SG 50 (ESP) all (N/A)
ALLOW egress this-SG 50 (ESP) all (N/A)

ALLOW ingress this-SG 17 (UDP) 500 (IKE)
ALLOW egress this-SG 17 (UDP) 500 (IKE)
```

2. Switch to the root user.

```
$ sudo su - root
```

3. Run the following commands on both the primary instance and the standby instance to initialize the Network Security Services (NSS) database under the user `root`.

```
ipsec initnss --nssdir /etc/ipsec.d
```

4. Generate RSA keys as follows:

   a. On the primary instance, generate the keys using either of the following `ipsec` commands, depending on your OS version.

```
ipsec newhostkey --nssdir /etc/ipsec.d       ## for Oracle Linux Version 8
ipsec newhostkey --output /etc/ipsec.secrets ## for Oracle Linux version 7.9
```

   b. Obtain the public key, which you need to create the configuration. In the following example, the primary instance is `left` because in `ipsec` parlance, `left` refers to the device you are currently configuring, and `right` refers to the device at the other end of the tunnel.

```
ipsec showhostkey --left --ckaid ckaid-returned-in-last-statement
```

   c. On the standby instance, generate keys for the standby instance.

```
ipsec newhostkey --nssdir /etc/ipsec.d       ## for Oracle Linux Version 8
ipsec newhostkey --output /etc/ipsec.secrets ## for Oracle Linux version 7.9
```

   d. Obtain the public key for the standby instance, which you need to create the configuration. In the following example, the standby instance is `right` because it refers to the device at the other end of the tunnel.

```
ipsec showhostkey --right --ckaid ckaid-returned-in-last-statement
```

5. Based on the RSA keys that you obtained, generate the configuration. The configuration is identical for both the primary instance and the standby instance. You can find the primary instance IPv4 address and standby instance IPv4 address in the AWS console.

   On both the primary instance and the standby instance, save the following configuration to the file `/etc/ipsec.d/custom-fb-tunnel.conf`.

```
conn custom-db-tunnel
 type=transport
```

```
 auto=add
 authby=rsasig
 left=IPV4-for-primary
 leftrsasigkey=RSA-key-generated-on-primary
 right=IPV4-for-standby
 rightrsasigkey=RSA-key-generated-on-standby
```

6. On both the primary instance and the standby instance, start the `ipsec` daemon on both hosts.

```
ipsec setup start
```

7. Start the tunnel on either the primary instance or the standby instance. The output should look similar to the following.

```
[root@ip-172-31-6-81 ~]# ipsec auto --up custom-db-tunnel
181 "custom-db-tunnel" #1: initiating IKEv2 connection
181 "custom-db-tunnel" #1: sent IKE_SA_INIT request to 172.31.32.196:500
182 "custom-db-tunnel" #1: sent IKE_AUTH request {cipher=AES_GCM_16_256 integ=n/a
 prf=HMAC_SHA2_512 group=DH19}
003 "custom-db-tunnel" #1: initiator established IKE SA; authenticated peer '3584-
bit PKCS#1 1.5 RSA with SHA1' signature using preloaded certificate '172.31.32.196'
004 "custom-db-tunnel" #2: initiator established Child SA using #1; IPsec transport
 [172.31.6.81-172.31.6.81:0-65535 0] -> [172.31.32.196-172.31.32.196:0-65535 0]
 {ESP/ESN=>0xda9c4815 <0xb742ca42 xfrm=AES_GCM_16_256-NONE DPD=passive}
[root@ip-172-31-6-81 ~]#
```

Backing up and restoring an Amazon RDS Custom for Oracle DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for Oracle DB instance during the backup window of your DB instance. You can also back up your DB instance manually.

The procedure is identical to taking a snapshot of an Amazon RDS DB instance. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots are incremental.

Restore DB snapshots using either the AWS Management Console or the AWS CLI.

Topics

- Creating an RDS Custom for Oracle snapshot
- Restoring from an RDS Custom for Oracle DB snapshot
- Restoring an RDS Custom for Oracle instance to a point in time
- Deleting an RDS Custom for Oracle snapshot
- Deleting RDS Custom for Oracle automated backups

Creating an RDS Custom for Oracle snapshot

RDS Custom for Oracle creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When your DB instance contains a container database (CDB), the snapshot of the instance includes the root CDB and all PDBs.

When you create an RDS Custom for Oracle snapshot, specify which RDS Custom DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for Oracle creates an Amazon EBS snapshot for every volume attached to the DB instance. RDS Custom for Oracle uses the EBS snapshot of the root volume to register a new Amazon Machine Image (AMI). To make snapshots easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DbiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the size of your database. Because the snapshot includes the entire

storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

Create an RDS Custom for Oracle snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

   The **Take DB snapshot** window appears.
5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

AWS CLI

You create a snapshot of an RDS Custom DB instance by using the create-db-snapshot AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up
- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called *`my-custom-snapshot`* for an RDS Custom DB instance called *`my-custom-instance`*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier my-custom-instance \
    --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier my-custom-instance ^
    --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for Oracle DB snapshot

When you restore an RDS Custom for Oracle DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for Oracle DB instance is created when you restore.

The restore process differs in the following ways from restore in Amazon RDS:

- Before restoring a snapshot, RDS Custom for Oracle backs up existing configuration files. These files are available on the restored instance in the directory `/rdsdbdata/config/backup`. RDS Custom for Oracle restores the DB snapshot with default parameters and overwrites the previous database configuration files with existing ones. Thus, the restored instance doesn't preserve custom parameters and changes to database configuration files.
- The restored database has the same name as in the snapshot. You can't specify a different name. (For RDS Custom for Oracle, the default is `ORCL`.)

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore DB instance** page, for **DB instance identifier**, enter the name for your restored RDS Custom DB instance.

6. Choose **Restore DB instance**.

AWS CLI

You restore an RDS Custom DB snapshot by using the restore-db-instance-from-db-snapshot AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct `db-subnet-group-name` and `no-publicly-accessible`. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- `db-snapshot-identifier` – Identifies the snapshot from which to restore
- `db-instance-identifier` – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- `custom-iam-instance-profile` – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot \
  --db-instance-identifier my-custom-instance \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
  --no-publicly-accessible
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
  --no-publicly-accessible
```

Restoring an RDS Custom for Oracle instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention set to a nonzero value.

The latest restorable time for an RDS Custom for Oracle DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI describe-db-instances command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see Restoring a DB instance to a specified time for Amazon RDS.

Topics

- PITR considerations for RDS Custom for Oracle

PITR considerations for RDS Custom for Oracle

In RDS Custom for Oracle, PITR differs in the following important ways from PITR in Amazon RDS:

- The restored database has the same name as in the source DB instance. You can't specify a different name. The default is `ORCL`.
- `AWSRDSCustomIamRolePolicy` requires new permissions. For more information, see Step 2: Add an access policy to AWSRDSCustomInstanceRoleForRdsCustomInstance.
- All RDS Custom for Oracle DB instances must have backup retention set to a nonzero value.
- If you change the operating system or DB instance time zone, PITR might not work. For information about changing time zones, see Oracle time zone.
- If you set automation to `ALL_PAUSED`, RDS Custom pauses the upload of archived redo log files, including logs created before the latest restorable time (LRT). We recommend that you pause automation for a brief period.

  To illustrate, assume that your LRT is 10 minutes ago. You pause automation. During the pause, RDS Custom doesn't upload archived redo logs. If your DB instance crashes, you can only recover

to a time before the LRT that existed when you paused. When you resume automation, RDS Custom resumes uploading logs. The LRT advances. Normal PITR rules apply.

- In RDS Custom, you can manually specify an arbitrary number of hours to retain archived redo logs before RDS Custom deletes them after upload. Specify the number of hours as follows:

  1. Create a text file named `/opt/aws/rdscustomagent/config/redo_logs_custom_configuration.json`.
  2. Add a JSON object in the following format: `{"archivedLogRetentionHours" : "num_of_hours"}`. The number must be an integer in the range 1–840.

- Assume that you plug a non-CDB into a container database (CDB) as a PDB and then attempt PITR. The operation succeeds only if you previously backed up the PDB. After you create or modify a PDB, we recommend that you always back it up.
- We recommend that you don't customize database initialization parameters. For example, modifying the following parameters affects PITR:
  - `CONTROL_FILE_RECORD_KEEP_TIME` affects the rules for uploading and deleting logs.
  - `LOG_ARCHIVE_DEST_`*n* doesn't support multiple destinations.
  - `ARCHIVE_LAG_TARGET` affects the latest restorable time. `ARCHIVE_LAG_TARGET` is set to `300` because the recovery point objective (RPO) is 5 minutes. To honor this objective, RDS switches the online redo log every 5 minutes and stores it in an Amazon S3 bucket. If the frequency of the log switch causes a performance issue for your RDS Custom for Oracle database, you can scale your DB instance and storage to one with higher IOPS and throughput. If necessary for your recovery plan, you can adjust the setting of the `ARCHIVE_LAG_TARGET` initialization parameter to a value from 60–7200.
- If you customize database initialization parameters, we strongly recommend that you customize only the following:
  - `COMPATIBLE`
  - `MAX_STRING_SIZE`
  - `DB_FILES`
  - `UNDO_TABLESPACE`
  - `ENABLE_PLUGGABLE_DATABASE`
  - `CONTROL_FILES`
  - `AUDIT_TRAIL`
  - `AUDIT_TRAIL_DEST`

For all other initialization parameters, RDS Custom restores the default values. If you modify a parameter that isn't in the preceding list, it might have an adverse effect on PITR and lead to unpredictable results. For example, `CONTROL_FILE_RECORD_KEEP_TIME` affects the rules for uploading and deleting logs.

You can restore an RDS Custom DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore an RDS Custom DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the instance.

   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

AWS CLI

You restore a DB instance to a specified time by using the restore-db-instance-to-point-in-time AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier mysourcedbinstance`
- `--source-dbi-resource-id dbinstanceresourceID`
- `--source-db-instance-automated-backups-arn backupARN`

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my-custom-db-instance\
    --target-db-instance-identifier my-restored-custom-db-instance \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
    --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-identifier my-custom-db-instance ^
    --target-db-instance-identifier my-restored-custom-db-instance ^
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
    --restore-time 2022-10-14T23:45:00.000Z
```

Deleting an RDS Custom for Oracle snapshot

You can delete DB snapshots managed by RDS Custom for Oracle when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for Oracle snapshots. These EBS snapshots are automatically deleted after they're no longer related to any existing RDS Custom for Oracle resources (DB instances or backups).

Console

To delete a snapshot of an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

To delete an RDS Custom snapshot, use the AWS CLI command delete-db-snapshot.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for Oracle automated backups

You can delete retained automated backups for RDS Custom for Oracle when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **`delete me`** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command delete-db-instance-automated-backup.

The following option is used to delete a retained automated backup:

- `--dbi-resource-id` – The resource identifier for the source RDS Custom DB instance.

  You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command describe-db-instance-automated-backups.

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

Working with option groups in RDS Custom for Oracle

RDS Custom uses option groups to enable and configure additional features. An *option group* specifies features, called options, that are available for an RDS Custom for Oracle DB instance. Options can have settings that specify how the option works. When you associate an RDS Custom for Oracle DB instance with an option group, the specified options and option settings are enabled for this instance. For general information about option groups in Amazon RDS, see Working with option groups.

Topics

- Overview of option groups in RDS Custom for Oracle
- Oracle time zone

Overview of option groups in RDS Custom for Oracle

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups.

Topics

- Summary of RDS Custom for Oracle options
- Basic steps for adding an option to an RDS Custom for Oracle DB instance
- Creating an option group for in RDS Custom for Oracle
- Associating an option group with an RDS Custom for Oracle DB instance

Summary of RDS Custom for Oracle options

RDS Custom for Oracle supports the following options for a DB instance.

Option	Option ID	Description
Oracle time zone	`Timezone`	The time zone used by your RDS Custom for Oracle DB instance.

Basic steps for adding an option to an RDS Custom for Oracle DB instance

The general procedure for adding an option to your RDS Custom for Oracle DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with your DB instance when you create or modify it.

Creating an option group for in RDS Custom for Oracle

You can create a new option group that derives its settings from the default option group. You then add one or more options to the new option group. Or, if you already have an existing option group, you can copy that option group with all of its options to a new option group. To learn how to copy an option group, see Copying an option group.

The default option groups for RDS Custom for Oracle are the following:

- `default:custom-oracle-ee`
- `default:custom-oracle-se2`
- `default:custom-oracle-ee-cdb`
- `default:custom-oracle-se2-cdb`

When you create an option group, the settings are derived from the default option group. After you have added the `TIME_ZONE` option, you can then associate the option group with your DB instance.

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:

a. For **Name**, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.

b. For **Description**, type a brief description of the option group. The description is used for display purposes.

c. For **Engine**, choose any of the following RDS Custom for Oracle DB engines:

- **custom-oracle-ee**
- **custom-oracle-se2**
- **custom-oracle-ee-cdb**
- **custom-oracle-se2-cdb**

d. For **Major engine version**, choose a major engine version supported by RDS Custom for Oracle. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.

5. To continue, choose **Create**. To cancel the operation instead, choose **Cancel**.

AWS CLI

To create an option group, use the AWS CLI `create-option-group` command with the following required parameters.

- `--option-group-name`
- `--engine-name`
- `--major-engine-version`
- `--option-group-description`

Example

The following example creates an option group named `testoptiongroup`, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name testoptiongroup \
    --engine-name custom-oracle-ee-cdb \
    --major-engine-version 19 \
```

```
    --option-group-description "Test option group for a Custom Oracle CDB"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name testoptiongroup ^
    --engine-name custom-oracle-ee-cdb ^
    --major-engine-version 19 ^
    --option-group-description "Test option group for a Custom Oracle CDB"
```

RDS API

To create an option group, call the Amazon RDS API `CreateOptionGroup` operation.

Associating an option group with an RDS Custom for Oracle DB instance

You can associate your option group with a new or existing DB instance:

- For a new DB instance, apply the option group when you create the instance. For more information, see Creating an RDS Custom for Oracle DB instance.
- For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying your RDS Custom for Oracle DB instance.

Oracle time zone

To change the system time zone used by your RDS Custom for Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including `SYSDATE` and `SYSTIMESTAMP`.

Topics

- Time zone option settings in RDS Custom for Oracle
- Available time zones in RDS Custom for Oracle
- Considerations for setting the time zone in RDS Custom for Oracle
- Limitations for the time zone setting in RDS Custom for Oracle
- Adding the time zone option to an option group
- Removing the time zone option

Time zone option settings in RDS Custom for Oracle

Amazon RDS supports the following settings for the time zone option.

Option setting	Valid values	Description
TIME_ZONE	One of the available time zones. For the full list, see Available time zones in RDS Custom for Oracle.	The new time zone for your DB instance.

Available time zones in RDS Custom for Oracle

You can use the following values for the time zone option.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde

Zone	Time zone
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Considerations for setting the time zone in RDS Custom for Oracle

If you choose to set the time zone for your DB instance, consider the following:

- When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.
- If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. For this reason, we strongly suggest that you to use one of the following strategies before you add the time zone option to your instance:
  - If your RDS Custom for Oracle DB instance uses the default option group, take a snapshot of your DB instance. For more information, see Creating an RDS Custom for Oracle snapshot.
  - If your DB instance currently uses a nondefault option group, take a snapshot of your DB instance, and then create a new option group with the time zone option.
- We strongly recommend that you back up your DB instance manually after applying the `Timezone` option.

- We strongly recommend that you to test the time zone option on a test DB instance before you add it to a production DB instance. Adding the time zone option can cause problems with tables that use system date to add dates or times. We recommend that you analyze your data and applications to assess the impact of changing the time zone.

Limitations for the time zone setting in RDS Custom for Oracle

Note the following limitations:

- You can't change your timezone directly on your host without moving it outside the support perimeter. To change your database timezone, you must create an option group.
- Because the time zone option is a persistent option (but not a permanent option), you can't do the following:
  - Remove the option from an option group after you add the option.
  - Modify the time zone setting of the option to a different time zone.
- You can't associate multiple option groups with your RDS Custom for Oracle DB instance.
- You can't set the time zone for individual PDBs within a CDB.

Adding the time zone option to an option group

The default option groups for RDS Custom for Oracle are the following:

- `default:custom-oracle-ee`
- `default:custom-oracle-se2`
- `default:custom-oracle-ee-cdb`
- `default:custom-oracle-se2-cdb`

When you create an option group, the settings are derived from the default option group. For general information about option groups in Amazon RDS, see Working with option groups.

Console

To add the time zone option to an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you want to modify, and then choose **Add option**.
4. In the **Add option** window, do the following:
   a. Choose **Timezone**.
   b. In **Option settings**, choose a time zone.
   c. To enable the option on all associated RDS Custom for Oracle DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instances during its next maintenance window.
   d.

> **Important**
>
> If you add the time zone option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

5. When the settings are as you want them, choose **Add option**.
6. Back up the RDS Custom for Oracle DB instances whose time zones were updated. For more information, see Creating an RDS Custom for Oracle snapshot.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `Timezone` option and the `TIME_ZONE` option setting to an option group called `testoptiongroup`. The time zone is set to `America/Los_Angeles`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "testoptiongroup" \
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=America/
Los_Angeles}]" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "testoptiongroup" ^
```

```
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=America/
Los_Angeles}]" ^
    --apply-immediately
```

Removing the time zone option

The time zone option is a persistent option, but not a permanent option. You can't remove the option from an option group after you add it. To disassociate the old option group from your DB instance:

1. Create a new option group with an updated `Timezone` option.
2. Associate the new option group with your DB instance when you modify the instance.

Migrating an on-premises database to RDS Custom for Oracle

Before you migrate an on-premises Oracle database to RDS Custom for Oracle, consider the following factors:

- The amount of downtime the application can afford
- The size of the source database
- Network connectivity
- A requirement for a fallback plan
- The source and target Oracle database version and DB instance OS types
- Available replication tools, such as AWS Database Migration Service, Oracle GoldenGate, or third-party replication tools

Based on these factors, you can choose physical migration, logical migration, or a combination. If you choose physical migration, you can use the following techniques:

RMAN duplication

Active database duplication doesn't require a backup of your source database. It duplicates the live source database to the destination host by copying database files over the network to the auxiliary instance. The RMAN `DUPLICATE` command copies the required files as image copies or backup sets. To learn this technique, see the AWS blog post Physical migration of Oracle databases to Amazon RDS Custom using RMAN duplication.

Oracle Data Guard

In this technique, you back up a primary on-premises database and copy the backups to an Amazon S3 bucket. You then copy the backups to your RDS Custom for Oracle standby DB instance. After performing the necessary configuration, you manually switch over your primary database to your RDS Custom for Oracle standby database. To learn this technique, see the AWS blog post Physical migration of Oracle databases to Amazon RDS Custom using Data Guard.

For general information about logically importing data into RDS for Oracle, see Importing data into Oracle on Amazon RDS.

Upgrading a DB instance for Amazon RDS Custom for Oracle

You can upgrade an Amazon RDS Custom DB instance by modifying it to use a new custom engine version (CEV). For general information about upgrades, see Upgrading a DB instance engine version.

Topics

- Overview of upgrades in RDS Custom for Oracle
- Requirements for RDS Custom for Oracle upgrades
- Considerations for RDS Custom for Oracle database upgrades
- Considerations for RDS Custom for Oracle OS upgrades
- Viewing valid CEV upgrade targets for RDS Custom for Oracle DB instances
- Upgrading an RDS Custom for Oracle DB instance
- Viewing pending database upgrades for RDS Custom DB instances
- Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance

Overview of upgrades in RDS Custom for Oracle

With RDS Custom for Oracle, you can patch either your Oracle database or your DB instance operating system (OS) by creating new CEVs and then modifying your instance to use the new CEV.

Topics

- CEV upgrade options
- Patching without CEVs
- General steps for patching your DB instance with a CEV

CEV upgrade options

When you create a CEV for an upgrade, you have the following mutually exclusive options:

Database only

Reuse the Amazon Machine Image (AMI) currently in use by your DB instance, but specify different database binaries. RDS Custom allocates a new binary volume and then attaches it to

the existing Amazon EC2 instance. RDS Custom replaces the entire database volume with a new volume that uses your target database version.

OS only

Reuse the database binaries currently in use by your DB instance, but specify a different AMI. RDS Custom allocates a new Amazon EC2 instance, and then attaches the existing binary volume to the new instance. The existing database volume is retained.

If you want to upgrade both the OS and database, you must upgrade the CEV twice. You can either upgrade the OS and then the database or upgrade the database and then the OS.

> **Warning**
>
> When you patch your OS, you lose your root volume data and any existing OS customization. Thus, we strongly recommend that you don't use the root volume for installations or for storing permanent data or files. We also recommend that you back up your data before the upgrade.

Patching without CEVs

We strongly recommend that you upgrade your RDS Custom for Oracle DB instance using CEVs. RDS Custom for Oracle automation synchronizes the patch metadata with the database binary on your DB instance.

In special circumstances, RDS Custom supports applying a "one-off" database patch directly to the underlying Amazon EC2 instance directly using the OPatch utility. A valid use case might be a database patch that you want to apply immediately, but the RDS Custom team is upgrading the CEV feature, causing a delay. To apply a database patch manually, perform the following steps:

1. Pause RDS Custom automation.
2. Apply your patch to the database binaries on the Amazon EC2 instance.
3. Resume RDS Custom automation.

A disadvantage of the preceding technique is that you must apply the database patch manually to every instance that you want to upgrade. In contrast, when you create a new CEV, you can create or upgrade multiple DB instances using the same CEV.

General steps for patching your DB instance with a CEV

Whether you patch the OS or your database, perform the following basic steps:

1. Create a CEV that contains either of the following, depending on whether you're patching the database or OS:
   - The Oracle Database RU that you want to apply to your DB instance
   - A different AMI–either the latest available or one that you specify–and an existing CEV to use as a source

   Follow the steps in Creating a CEV.
2. (Optional for database patching) Check available engine version upgrades by running `describe-db-engine-versions`.
3. Start the patching process by running `modify-db-instance`.

   The status of the instance being patched differs as follows:
   - While RDS is patching the database, the status of the DB instance changes to **Upgrading**.
   - While RDS is patching the OS, the status of the DB instance changes to **Modifying**.

   When the DB instance has the status **Available**, patching is complete.
4. Confirm that your DB instance uses the new CEV by running `describe-db-instances`.

Requirements for RDS Custom for Oracle upgrades

When upgrading your RDS Custom for Oracle DB instance to a target CEV, make sure you meet the following requirements:

- The target CEV to which you are upgrading must exist.
- You must upgrade either the OS or the database in a single operation. Upgrading both the OS and the database in a single API call isn't supported.
- The target CEV must use the installation parameter settings that are in the manifest of the current CEV. For example, you can't upgrade a database that uses the default Oracle home to a CEV that uses a nondefault Oracle home.
- For database upgrades, the target CEV must use a new minor database version, not a new major version. For example, you can't upgrade from an Oracle Database 12c CEV to an Oracle Database 19c CEV. But you can upgrade from version 21.0.0.0.ru-2023-04.rur-2023-04.r1 to version 21.0.0.0.ru-2023-07.rur-2023-07.r1.

- For OS upgrades, the target CEV must use a different AMI but have the same major version.

Considerations for RDS Custom for Oracle database upgrades

If you plan to upgrade your database, consider the following:

- The currently supported operating system (OS) version is Oracle Linux 8. To continue receiving the latest security updates and patches from RDS Custom for Oracle, upgrade your DB instances to Oracle Linux 8 by specifying a CEV based on this OS. Oracle Database 12c Release 1 (12.1), Oracle Database Release 2 (12.2), and Oracle Database 19c are the only releases that support Oracle Linux 8. To migrate to the latest Oracle Linux 8 AMI, upgrade your OS to the latest AMI. For more information, see Upgrading an RDS Custom for Oracle DB instance.

  Oracle Linux 7.9 ended support on Dec 31, 2024. To continue running Oracle Linux 7 after the end of support, purchase an Oracle Extended Support license. You're responsible for security updates and must patch your RDS Custom for Oracle instances manually. For more information, see Lifetime Support Policy: Coverage for Oracle Open Source Service Offerings.
- When you upgrade the database binaries in your primary DB instance, RDS Custom for Oracle upgrades your read replicas automatically. When you upgrade the OS, however, you must upgrade the read replicas manually.
- When you upgrade a container database (CDB) to a new database version, RDS Custom for Oracle checks that all PDBs are open or could be opened. If these conditions aren't met, RDS Custom stops the check and returns the database to its original state without attempting the upgrade. If the conditions are met, RDS Custom patches the CDB root first, and then patches all other PDBs (including `PDB$SEED`) in parallel.

  After patching completes, RDS Custom attempts to open all PDBs. If any PDBs fail to open, you receive the following event: `The following PDBs failed to open: list-of-PDBs`. If RDS Custom fails to patch the CDB root or any PDBs, the instance is put into the `PATCH_DB_FAILED` state.
- You might want to perform a major database version upgrade and a conversion of non-CDB to CDB at the same time. In this case, we recommend that you proceed as follows:

  1. Create a new RDS Custom for Oracle DB instance that uses the Oracle multitenant architecture.
  2. Plug in a non-CDB into your CDB root, creating it as a PDB. Make sure that the non-CDB is the same major version as your CDB.

3. Convert your PDB by running the `noncdb_to_pdb.sql` Oracle SQL script.
4. Validate your CDB instance.
5. Upgrade your CDB instance.

Considerations for RDS Custom for Oracle OS upgrades

When you plan an OS upgrade, consider the following:

- You can't provide your own AMI for use in an RDS Custom for Oracle CEV. You can specify either the default AMI, which uses Oracle Linux 8, or an AMI that has been previously used by an RDS Custom for Oracle CEV.

  > **Note**
  >
  > RDS Custom for Oracle releases a new default AMI when common vulnerabilities and exposures are discovered. No fixed schedule is available or guaranteed. RDS Custom for Oracle tends to publish a new default AMI every 30 days.

- When you upgrade the OS in your primary DB instance, you must upgrade its associated read replicas manually.
- Reserve sufficient Amazon EC2 compute capacity for your instance type in your AZ before you begin patching the OS.

  When you create a Capacity Reservation, you specify the AZ, number of instances, and instance attributes (including instance type). For example, if your DB instance uses the underlying EC2 instance type r5.large, we recommend that you reserve EC2 capacity for r5.large in your AZ. During OS patching, RDS Custom creates one new host of type db.r5.large, which can become stuck if the AZ lacks EC2 capacity for this instance type. If you reserve EC2 capacity, you lower the risk of blocked patching caused by capacity constraints. For more information, see On-Demand Capacity Reservations in the *Amazon EC2 User Guide*.
- Back up your DB instance before you upgrade its OS. The upgrade removes your root volume data and any existing OS customizations.
- In the shared responsibility model, you're responsible for keeping your OS up to date. RDS Custom for Oracle doesn't mandate which patches you apply to your OS. If your RDS Custom for Oracle is functional, you can use the AMI associated with this CEV indefinitely.

Viewing valid CEV upgrade targets for RDS Custom for Oracle DB instances

You can see existing CEVs on the **Custom engine versions** page in the AWS Management Console.

You can also use the describe-db-engine-versions AWS CLI command to find valid CEVs to use when you upgrade your DB instances, as shown in the following example. This example assumes that you created a DB instance using the engine version `19.my_cev1`, and that the upgrade versions `19.my_cev2` and `19.my_cev` exist.

```
aws rds describe-db-engine-versions --engine custom-oracle-ee --engine-version
 19.my_cev1
```

The output resembles the following. The `ImageId` field shows the AMI ID.

```
{
    "DBEngineVersions": [
        {
            "Engine": "custom-oracle-ee",
            "EngineVersion": "19.my_cev1",
            ...
            "Image": {
                "ImageId": "ami-2345",
                "Status": "active"
            },
            "DBEngineVersionArn": "arn:aws:rds:us-west-2:123456789012:cev:custom-
oracle-ee/19.my_cev1/12a34b5c-67d8-90e1-2f34-gh56ijk78lm9"
            "ValidUpgradeTarget": [
                {
                    "Engine": "custom-oracle-ee",
                    "EngineVersion": "19.my_cev2",
                    "Description": "19.my_cev2 description",
                    "AutoUpgrade": false,
                    "IsMajorVersionUpgrade": false
                },
                {
                    "Engine": "custom-oracle-ee",
                    "EngineVersion": "19.my_cev3",
                    "Description": "19.my_cev3 description",
                    "AutoUpgrade": false,
                    "IsMajorVersionUpgrade": false
                }
            ]
```

```
...
```

Upgrading an RDS Custom for Oracle DB instance

To upgrade your RDS Custom for Oracle DB instance, modify it to use a new CEV. This CEV can contain either new database binaries or a new AMI. For example, to upgrade your Oracle Linux 7.9 DB instance to Oracle Linux 8, specify the latest AMI, which uses Oracle Linux 8. To upgrade the database and OS, you must perform two separate upgrades.

> **Note**
>
> If you upgrade the database, RDS Custom automatically upgrades read replicas after it upgrades the primary DB instance. If you upgrade the OS, you must upgrade the replicas manually.

Before you begin, review Requirements for RDS Custom for Oracle upgrades and Considerations for RDS Custom for Oracle database upgrades.

Console

To upgrade an RDS Custom for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom for Oracle DB instance that you want to upgrade.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **DB engine version**, choose a new CEV. Do the following:
   - If you are patching the database, make sure that the CEV specifies database binaries that are different from those used by your DB instance, and doesn't specify an AMI that is different from the AMI currently used by your DB instance.
   - If you are patching the OS, make sure that the CEV specifies an AMI that is different from the AMI currently used by your DB instance, and doesn't specify different database binaries.

> **Warning**
>
> When you patch your OS, you lose your root volume data and any existing OS customization.

5. Choose **Continue** to check the summary of modifications.

   Choose **Apply immediately** to apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

The following examples show possible upgrade scenarios. The examples assume that you created an RDS Custom for Oracle DB instance with the following characteristics:

- DB instance named `my-custom-instance`
- CEV named `19.my_cev1`
- Oracle Database 19c using the non-CDB architecture
- Oracle Linux 8 using AMI `ami-1234`

The latest service-provided AMI is `ami-2345`. You can find AMIs by running the CLI command `describe-db-engine-versions`.

Topics

- Upgrading the OS
- Upgrading the database

Upgrading the OS

In this example, you want to upgrade `ami-1234` to `ami-2345`, which is the latest service-provided AMI. Because you are upgrading the OS, the database binaries for `ami-1234` and `ami-2345` must be the same. You create a new CEV named `19.my_cev2` based on `19.my_cev1`.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev2 \
    --description "Non-CDB CEV based on ami-2345" \
    --kms-key-id key-name \
    --source-custom-db-engine-version-identifer arn:aws:rds:us-
west-2:123456789012:cev:custom-oracle-ee/19.my_cev1/12345678-ab12-1234-cde1-
abcde123456789 \
    --image-id ami-2345
```

For Windows:

```
aws rds create-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev2 ^
    --description "Non-CDB CEV based on ami-2345" ^
    --kms-key-id key-name ^
    --source-custom-db-engine-version-identifer arn:aws:rds:us-
west-2:123456789012:cev:custom-oracle-ee/19.my_cev1/12345678-ab12-1234-cde1-
abcde123456789 ^
    --image-id ami-2345
```

To upgrade an RDS Custom DB instance, use the modify-db-instance AWS CLI command with the following parameters:

- `--db-instance-identifier` – Specify the RDS Custom for Oracle DB instance to be upgraded.
- `--engine-version` – Specify the CEV that has the new AMI.
- `--no-apply-immediately` | `--apply-immediately` – Specify whether to perform the upgrade immediately or wait until the scheduled maintenance window.

The following example upgrades `my-custom-instance` to version `19.my_cev2`. Only the OS is upgraded.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
```

```
    --engine-version 19.my_cev2 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --engine-version 19.my_cev2 ^
    --apply-immediately
```

Upgrading the database

In this example, you want to apply Oracle patch p35042068 to your RDS for Oracle DB instance. Because you upgraded your OS in Upgrading the OS, your DB instance is currently using `19.my_cev2`, which is based on `ami-2345`. You create a new CEV named `19.my_cev3` that also uses `ami-2345`, but you specify a new JSON manifest in the `$MANIFEST` environment variable. Thus, only the database binaries different in your new CEV and the CEV that your instance is currently using.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-oracle-ee \
    --engine-version 19.my_cev3 \
    --description "Non-CDB CEV with p35042068 based on ami-2345" \
    --kms-key-id key-name \
    --image-id ami-2345 \
    --manifest $MANIFEST
```

For Windows:

```
aws rds create-custom-db-engine-version ^
    --engine custom-oracle-ee ^
    --engine-version 19.my_cev3 ^
    --description "Non-CDB CEV with p35042068 based on ami-2345" ^
    --kms-key-id key-name ^
    --image-id ami-2345 ^
    --manifest $MANIFEST
```

The following example upgrades `my-custom-instance` to engine version `19.my_cev3`. Only the database is upgraded.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --engine-version 19.my_cev3 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --engine-version 19.my_cev3 ^
    --apply-immediately
```

Viewing pending database upgrades for RDS Custom DB instances

You can see pending database upgrades for your Amazon RDS Custom DB instances by using the describe-db-instances or describe-pending-maintenance-actions AWS CLI command.

However, this approach doesn't work if you used the `--apply-immediately` option or if the upgrade is in progress.

The following `describe-db-instances` command shows pending database upgrades for `my-custom-instance`.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{
    "DBInstances": [
        {
           "DBInstanceIdentifier": "my-custom-instance",
            "EngineVersion": "19.my_cev1",
            ...
```

```
            "PendingModifiedValues": {
                "EngineVersion": "19.my_cev3"
            ...
            }
        }
    ]
}
```

Troubleshooting an upgrade failure for an RDS Custom for Oracle DB instance

If an RDS Custom DB instance upgrade fails, an RDS event is generated and the DB instance status becomes `upgrade-failed`.

You can see this status by using the describe-db-instances AWS CLI command, as shown in the following example.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The output resembles the following.

```
{
    "DBInstances": [
        {
           "DBInstanceIdentifier": "my-custom-instance",
            "EngineVersion": "19.my_cev1",
            ...
            "PendingModifiedValues": {
                "EngineVersion": "19.my_cev3"
            ...
            }
            "DBInstanceStatus": "upgrade-failed"
        }
    ]
}
```

After an upgrade failure, all database actions are blocked except for modifying the DB instance to perform the following tasks:

- Retrying the same upgrade
- Pausing and resuming RDS Custom automation
- Point-in-time recovery (PITR)

- Deleting the DB instance

> **Note**
>
> If automation has been paused for the RDS Custom DB instance, you can't retry the upgrade until you resume automation.
> The same actions apply to an upgrade failure for an RDS-managed read replica as for the primary.

For more information, see Troubleshooting upgrades for RDS Custom for Oracle.

Troubleshooting DB issues for Amazon RDS Custom for Oracle

The shared responsibility model of RDS Custom provides OS shell–level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom DB instances.

> **Note**
>
> This section explains how to troubleshoot RDS Custom for Oracle. For troubleshooting RDS Custom for SQL Server, see Troubleshooting DB issues for Amazon RDS Custom for SQL Server.

Topics

- Viewing RDS Custom events
- Subscribing to RDS Custom events
- Troubleshooting DB instance creation issues
- Troubleshooting custom engine version creation for RDS Custom for Oracle
- Fixing unsupported configurations in RDS Custom for Oracle
- Troubleshooting upgrades for RDS Custom for Oracle
- Troubleshooting replica promotion for RDS Custom for Oracle

Viewing RDS Custom events

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events.

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages.

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \
```

```
    --source-identifier my-custom-instance \
    --source-type db-instance
```

Subscribing to RDS Custom events

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification.

To subscribe to RDS Custom event notification using the CLI, use the `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \
    --subscription-name my-instance-events \
    --source-type db-instance \
    --event-categories '["backup","recovery"]' \
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:interesting-events
```

Troubleshooting DB instance creation issues

If your environment isn't properly configured or required permissions are missing, you can't create or restore RDS Custom for Oracle DB instances. When you attempt to create or restore a DB instance, Amazon RDS validates your environment and returns specific error messages if it detects any issues.

After you resolve all issues, try again to create or restore your RDS Custom for Oracle DB instance.

Common permissions issues

When you create or restore a RDS Custom for Oracle instance, Amazon RDS validates that your environment has the required permissions. If permissions are missing or denied, the operation fails with a specific error message.

Issue type	Error message	Action
IAM role access policy	You can't create the DB instance because of incompatible resources . The host environment validation failed for the following permissions: <permission> on resource: <resource > due to permissions issue with message: User: <user> is not authorize d to perform: <permission> on resource: <resource> because no identity-based policy allows the <permission> action.	Ensure that the listed required permissions are present and set to `Allow` in the access policy with the appropriate resources included.
Permission boundary	You can't create the DB instance because of incompatible resources . The host environment validation failed for the following permissions: <permission> on resource: <resource > due to permissions issue with message: User: <user> is not authorize d to perform: <permission> on resource: <resource> with an explicit deny in a permissions boundary.	Verify that the permissions boundary attached to the instance role isn't restricting the listed required permissions and resources.
Service control policy	You can't create the DB instance because of incompatible resources . The host environment validation failed for the following permissions: <permission> on resource: <resource > due to permissions issue with message: User: <user> is not authorize d to perform: <permission> on resource: <resource> with an explicit deny in a service control policy.	Contact your AWS Organizations administrator and verify that the service control policy attached to your account isn't restricting the listed required permissions and resources.

Issue type	Error message	Action
Resource control policy	You can't create the DB instance because of incompatible resources . The host environment validation failed for the following permissions: <permission> on resource: <resource > due to permissions issue with message: User: <user> is not authorize d to perform: <permission> on resource: <resource> with an explicit deny in a resource control policy.	Contact your AWS Organizations administrator and verify that the resource control policy attached to your account isn't restricting the listed required permissions and resources.
VPC endpoint policy	You can't create the DB instance because of incompatible resources . The host environment validation failed for the following permissions: <permission> on resource: <resource > due to permissions issue with message: User: <user> is not authorize d to perform: <permission> on resource: <resource> with an explicit deny in a VPC endpoint policy.	Ensure that the required VPC endpoints exist and the policies attached to them aren't restricting the listed required permissions and resources.

Networking issues

In addition to reviewing Step 6: Configure your VPC for RDS Custom for Oracle, verify that the following are configured correctly and not restricting access to the required AWS services:

Security group attached to the Amazon EC2 instance

Ensure that the security group allows all necessary inbound and outbound traffic for RDS Custom operations.

Security group attached to your VPC

Verify that VPC security groups permit traffic to and from the required AWS services.

VPC endpoints

Confirm that all required VPC endpoints are properly configured and accessible.

Networking access control lists

Check that network ACLs aren't blocking traffic needed for RDS Custom functionality.

Troubleshooting custom engine version creation for RDS Custom for Oracle

When CEV creation fails, RDS Custom issues `RDS-EVENT-0198` with the message `Creation failed for custom engine version` *`major-engine-version.cev_name`*, and includes details about the failure. For example, the event prints missing files.

CEV creation might fail because of the following issues:

- The Amazon S3 bucket containing your installation files isn't in the same AWS Region as your CEV.
- When you request CEV creation in an AWS Region for the first time, RDS Custom creates an S3 bucket for storing RDS Custom resources (such as CEV artifacts, AWS CloudTrail logs, and transaction logs).

  CEV creation fails if RDS Custom can't create the S3 bucket. Either the caller doesn't have S3 permissions as described in Step 5: Grant required permissions to your IAM user or role, or the number of S3 buckets has reached the limit.
- The caller doesn't have permissions to get files from your S3 bucket that contains the installation media files. These permissions are described in Step 7: Add necessary IAM permissions.
- Your IAM policy has an `aws:SourceIp` condition. Make sure to follow the recommendations in AWS Denies access to AWS based on the source IP in the *AWS Identity and Access Management User Guide*. Also make sure that the caller has the S3 permissions described in Step 5: Grant required permissions to your IAM user or role.
- Installation media files listed in the CEV manifest aren't in your S3 bucket.
- The SHA-256 checksums of the installation files are unknown to RDS Custom.

  Confirm that the SHA-256 checksums of the provided files match the SHA-256 checksum on the Oracle website. If the checksums match, contact AWS Support and provide the failed CEV name, file name, and checksum.

- The OPatch version is incompatible with your patch files. You might get the following message: `OPatch is lower than minimum required version. Check that the version meets the requirements for all patches, and try again`. To apply an Oracle patch, you must use a compatible version of the OPatch utility. You can find the required version of the Opatch utility in the readme file for the patch. Download the most recent OPatch utility from My Oracle Support, and try creating your CEV again.
- The patches specified in the CEV manifest are in the wrong order.

You can view RDS events either on the RDS console (in the navigation pane, choose **Events**) or by using the `describe-events` AWS CLI command. The default duration is 60 minutes. If no events are returned, specify a longer duration, as shown in the following example.

```
aws rds describe-events --duration 360
```

Currently, the MediaImport service that imports files from Amazon S3 to create CEVs isn't integrated with AWS CloudTrail. Therefore, if you turn on data logging for Amazon RDS in CloudTrail, calls to the MediaImport service such as the `CreateCustomDbEngineVersion` event aren't logged.

However, you might see calls from the API gateway that accesses your Amazon S3 bucket. These calls come from the MediaImport service for the `CreateCustomDbEngineVersion` event.

Fixing unsupported configurations in RDS Custom for Oracle

In the shared responsibility model, it's your responsibility to fix configuration issues that put your RDS Custom for Oracle DB instance into the `unsupported-configuration` state. If the issue is with the AWS infrastructure, use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, log in to the host to fix it.

> **Note**
>
> This section explains how to fix unsupported configurations in RDS Custom for Oracle. For information about RDS Custom for SQL Server, see Fixing unsupported configurations in RDS Custom for SQL Server.

The following tables includes descriptions of the notifications and events that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to

change. For background on the support perimeter, see RDS Custom support perimeter. For event descriptions, see Amazon RDS event categories and event messages.

Event ID	Configuration	RDS event message	Action
SP-00000	Manual unsupported configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: *reason*.	To resolve this issue, create an Support case.

AWS resources (infrastructure)

Event ID	Configuration	RDS event message	Action
SP-O100	Amazon Elastic Block Store (Amazon EBS) volumes	The following EBS volumes were added to EC2 instance *ec2_id*: *volume_id* . To resolve the issue, detach the specified volumes from the instance.	RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance: • The binary volume where the database software binaries are located • The data volumes where database files are located When you create your DB instance, the storage configurations that you specify configure the data volumes. The support perimeter monitors the following: • The initial EBS volumes created with the DB instance are still associated with the instance.

Event ID	Configuration	RDS event message	Action

			• The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput.
			• No additional EBS volumes are attached to the DB instance.
			
			Use the following CLI command to compare the volume type of the EBS volume details and the RDS Custom for Oracle DB instance details:
			
			`aws rds describe-db-instances \`
			`--db-instance-identifier db-instance-name | grep StorageType`

Event ID	Configuration	RDS event message	Action
SP-O100	Amazon Elastic Block Store (Amazon EBS) volumes	EBS volume *volume_id* has been detached from EC2 instance [*ec2_id*]. You can't detach the original volume from this instance. To resolve the issue, re-attach *volume_id* to *ec2_id*.	RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance: • The binary volume where the database software binaries are located • The data volumes where database files are located When you create your DB instance, the storage configurations that you specify configure the data volumes. The support perimeter monitors the following: • The initial EBS volumes created with the DB instance are still associated with the instance. • The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. • No additional EBS volumes are attached to the DB instance. Use the following CLI command to compare the volume type of the EBS volume details and the RDS Custom for Oracle DB instance details: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageType`

Event ID	Configuration	RDS event message	Action
SP-O100	Amazon Elastic Block Store (Amazon EBS) volumes	The original EBS volume *volume_id* attached to EC2 instance *ec2_id* has been modified as follows: size [*X*] to [*Y*], type [*N*] to [*M*], or IOPS [*J*] to [*K*]. To resolve the issue, revert the modification.	RDS Custom creates two types of EBS volume, besides the root volume created from the Amazon Machine Image (AMI), and associates them with the EC2 instance: • The binary volume where the database software binaries are located • The data volumes where database files are located When you create your DB instance, the storage configurations that you specify configure the data volumes. The support perimeter monitors the following: • The initial EBS volumes created with the DB instance are still associated with the instance. • The initial EBS volumes still have the same configurations as initially set: storage type, size, Provisioned IOPS, and storage throughput. • No additional EBS volumes are attached to the DB instance. Use the following CLI command to compare the volume type of the EBS volume details and the RDS Custom for Oracle DB instance details: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageType`

Event ID	Configuration	RDS event message	Action
SP-O1004	Amazon EC2 instance state	Automated recovery left EC2 instance [*ec2_id*] in an impaired state. To resolve the issue, see Troubleshooting instance recovery failures.	To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep DBInstanceStatus`
SP-O1005	Amazon EC2 instance attributes	EC2 instance [*ec2_id*] was modified as follows: attribute [*att1*] changed from [*val-old*] to [*val-new*], attribute [*att2*] changed from [*val-old*] to [*val-new*]. To resolve the issue, revert to the original value.	

Event ID	Configuration	RDS event message	Action
SP-O1006	Amazon EC2 instance state	EC2 instance [*ec2_id*] was terminated or can't be found. To resolve the issue, delete the RDS Custom DB instance.	The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running. **To delete your DB instance** 1. To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep DBInstanceStatus` 2. Delete your RDS Custom for Oracle DB instance.
SP-O1007	Amazon EC2 instance state	EC2 instance [*ec2_id*] was stopped. To resolve the issue, start the instance.	The support perimeter monitors EC2 instance state-change notifications. The EC2 instance must always be running. **To restart your DB instance** 1. To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep DBInstanceStatus` 2. Start your DB instance. 3. Remount the binary and data volumes.

Event ID	Configuration	RDS event message	Action

SP-10	Amazon SQS permission	Permissions are missing for Amazon SQS. Check the permissions for the IAM instance profile, VPC endpoint policy, and dependent service connections, and then try again.	You can resolve this by making sure the IAM profile associated with the host has the following permissions:
			`"SQS:SendMessage"`
			`"SQS:ReceiveMessage"`
			`"SQS:DeleteMessage"`
			`"SQS:GetQueueUrl"`

SP-10	Amazon Simple Queue Service (Amazon SQS)	The SQS queue [%s] was deleted and couldn't be recovered. To resolve this issue, recreate the queue.	Recreate the Amazon SQS queue.

Operating system

Event ID	Configuration	RDS event message	Action
SP-O200	RDS Custom agent status	The RDS Custom agent isn't running on EC2 instance [*ec2_id*]. Make sure the agent is running on [*ec2_id*].	On RDS Custom for Oracle, the DB instance goes outside the support perimeter if the RDS Custom agent stops. The agent publishes the `IamAlive` metric to Amazon CloudWatch every 30 seconds. An alarm is triggered if the metric hasn't been published for 30 seconds. The support perimeter also monitors the RDS Custom agent process state on the host every 30 minutes.

Event ID	Configuration	RDS event message	Action

			To restart the RDS Custom agent
			
			1. Log in to your host and make sure that the RDS Custom agent is running.
			2. Run the following command to find the status of the agent.
			
			`service rdscustomagent status`
			
			3. Use the following command to start the agent.
			
			`service rdscustomagent start`
			
			When the RDS Custom agent is running again, the `IamAlive` metric is published to Amazon CloudWatch, and the alarm switches to the OK state. This switch notifies the support perimeter that the agent is running.

Event ID	Configuration	RDS event message	Action
SP-02002	AWS Systems Manager agent (SSM agent) status	The Systems Manager agent on EC2 instance [*ec2_id*] is unreachable. Make sure that you that have correctly configured the network, agent, and IAM permissions.	SSM Agent must always be running. The RDS Custom agent is responsible for making sure that the Systems Manager agent is running. If SSM Agent was terminated and then restarted, the RDS Custom agent publishes the metric `SSM_Agent_Restarted_Or_NotFound` to CloudWatch. The RDS Custom agent has an alarm on the metric `do-not-delete-rds-custom-ssm-agent-restarted-or-notfound-` *ec2-id* configured to trigger when there has been a restart in each of the previous three minutes. The support perimeter also monitors the process state of SSM Agent on the host every 30 minutes. For more information, see Troubleshooting SSM Agent.
SP-02003	AWS Systems Manager agent (SSM agent) status	The Systems Manager agent on EC2 instance [*ec2_id*] crashed multiple times. For more information, see the SSM Agent troubleshooting documentation.	For more information, see Troubleshooting SSM Agent.

Event ID	Configuration	RDS event message	Action
SP-O200	OS time zone	The time zone on EC2 instance [*ec2_id*] was changed. To resolve this issue, revert the timezone to the previous setting of [*previous-time-zone*]. Then use an RDS options group to change the time zone.	RDS automation detected that the time zone on the host was changed without the use of an option group. This host-level change can cause RDS automation failures, so the EC2 instance is placed in the `unsupported-configuration` state. **To fix the time zone setting** 1. Log in to your EC2 host and check the OS time zone as follows: `timedatectl` 2. Pause RDS Custom automation. For more information, see Pausing and resuming your RDS Custom DB instance. 3. Stop the DB instance. 4. Revert the time zone change on the operating system. 5. Start the DB instance. 6. Resume RDS Custom automation. Your DB instance becomes available within 30 minutes. To prevent moving out of perimeter in the future, modify your timezone through an options group. For more information, see Oracle time zone.

Event ID	Configuration	RDS event message	Action
SP-O200	sudo configurations	The sudo configurations on EC2 instance [*ec2_id*] lack necessary permissions. To resolve this issue, revert the recent changes to the sudo configurations.	The support perimeter verifies that certain OS users are allowed to run certain commands on the host. It monitors sudo configurations and compares them to the supported state. If the sudo configurations aren't supported, RDS Custom tries to overwrite them and return to the previous supported state. If the attempt is successful, RDS Custom sends the following notification: RDS Custom successfully overwrote your configuration. If the overwrite isn't successful, your DB instance remains in the unsupported configuration state. To resolve this problem, either revert the changes within the `sudoers.d/` file or fix the permissions. **To investigate changes to the sudo configurations** 1. Log in to your host. 2. Run the following command. `visudo -c -f /etc/sudoers.d/ individual_sudo_files` 3. Modify the sudo configurations as necessary. After the support perimeter determines that the sudo configurations are supported, your RDS Custom for Oracle DB instance becomes available within 30 minutes.

Event ID	Configuration	RDS event message	Action
SP-O2006	S3 bucket accessibility	RDS Custom automation can't download files from the S3 bucket on EC2 instance [*ec2_id*]. Check your networking configuration and make sure the instance allows connections to and from S3.	
SP-20	High Availability Software Solution Version	The HA solution of your instance differs from the expected version. To resolve this issue, create an AWS Support case.	Create an AWS Support case.

Database

Event ID	Configuration	RDS event message	Action
SP-O300	Database archive lag target	The ARCHIVE_LAG_TARGET parameter on EC2 instance [*ec2_id*] is out of the recommended range *value_ran*	The support perimeter monitors the `ARCHIVE_LAG_TARGET` database parameter to verify that the latest restorable time of the DB instance is within reasonable bounds. **To change the lag target for archived redo logs** 1. Log in to your EC2 host

Event ID	Configuration	RDS event message	Action
		ge . To resolve the issue, set the parameter to a value within value_range.	2. Connect to your RDS Custom for Oracle DB instance 3. Change the ARCHIVE_LAG_TARGET parameter to a value from 60–7200. For example, use the following SQL statement. `ALTER SYSTEM SET ARCHIVE_LAG_TARGET=300 SCOPE=BOTH;` Your DB instance becomes available within 30 minutes.

Event ID	Configuration	RDS event message	Action

SP-O300	Oracle Data Guard role	The database role [*role_name*] isn't supported for Oracle Data Guard on EC2 instance [*ec2_id*]. To resolve the issue, set the DATABASE_ROLE parameter to either PRIMARY or PHYSICAL STANDBY.	The support perimeter monitors the current database role every 15 seconds and sends a CloudWatch notification if the database role has changed. The Oracle Data Guard DATABASE_ROLE parameter must be either PRIMARY or PHYSICAL STANDBY.
			
			To restore your Oracle Data Guard database role to a supported value
			
			1. Check the Oracle Data Guard role by running the following statement:
			
			`SELECT DATABASE_ROLE FROM V$DATABASE;`
			
			2. If your DB instance is standalone, use either of the following statements to change it back to the PRIMARY role:
			
			`ALTER DATABASE COMMIT TO SWITCHOVER PRIMARY;`
			`ALTER DATABASE ACTIVATE STANDBY DATABASE;`
			
			If your DB instance is a replica, use the following statement to change it back to the PHYSICAL STANDBY role:
			
			`ALTER DATABASE CONVERT TO PHYSICAL STANDBY;`
			
			After the support perimeter determines that the database role is supported, your RDS Custom for Oracle DB instance becomes available within 15 seconds.

Event ID	Configuration	RDS event message	Action
SP-O300	Database health	The SMON process of the Oracle database is in a zombie state. To resolve the issue, manually recover the database on EC2 instance [*ec2_id*], open the database, and then immediately back it up. For more help, contact Support.	The support perimeter monitors the DB instance state. It also monitors how many restarts occurred during the previous hour and day. You're notified when the instance is in a state where it still exists, but you can't interact with it. **To make the support perimeter evaluate your instance state** 1. Log in to your host and determine the database state. `ps -eo pid,state,command | grep smon` 2. If necessary, restart your DB instance. If the restart fails, proceed to the next step. 3. If necessary, restart your EC2 host. After your DB instance restarts, the RDS Custom agent detects that your DB instance is no longer in an unresponsive state. It then notifies the support perimeter to reevaluate your DB instance state.

Event ID	Configuration	RDS event message	Action

SP-O3004	Database log mode	The database log mode on EC2 instance [*ec2_id*] was changed to [*value_b*]. To resolve the issue, set the log mode to [*value_a*].	**To change your DB instance log mode to ARCHIVELOG**
			1. Log in to your EC2 host.
			2. Connect to your database and run the following statement:
			`SELECT LOG_MODE FROM V$DATABASE;`
			Or you can run the follow command in SQL*Plus:
			`ARCHIVE LOG LIST`
			3. Run the following SQL*Plus command to initiate a consistent shutdown.
			`SHUTDOWN IMMEDIATE`
			The RDS Custom agent automatically restarts your DB instance and sets the log mode to ARCHIVELOG . Your DB instance becomes available within 30 minutes.

SP-O3005	Oracle home path	The Oracle home on EC2 instance [*ec2_id*] was changed to *new_path*. To resolve the issue, revert the setting to *old_path*.	

Event ID	Configuration	RDS event message	Action

SP-O3006	Database unique name	The database unique name on EC2 instance [*ec2_id*] was changed to *new_value* . To resolve the issue, revert the name to *old_value* .	**To change the database unique name for your DB instance**
			1. Log in to your EC2 host.
			2. Connect to the database and run the following statement:
			`SELECT DB_UNIQUE_NAME FROM V$DATABASE;`
			3. Specify the original database unique name using the command `ALTER SYSTEM SET DB_UNIQUE_NAME` .
			4. Run the following SQL statement to initiate a consistent shutdown.
			`SHUTDOWN IMMEDIATE;`
			The RDS Custom agent automatically restarts your DB instance and sets the log mode to `ARCHIVELOG` . Your DB instance becomes available within 30 minutes.

Troubleshooting upgrades for RDS Custom for Oracle

Your upgrade of an RDS Custom for Oracle instance might fail. Following, you can find techniques that you can use during upgrades of RDS Custom DB for Oracle DB instances:

- Examine the upgrade output log files in the `/tmp` directory on your DB instance. The names of the logs depend on your DB engine version. For example, you might see logs that contain the strings `catupgrd` or `catup`.
- Examine the `alert.log` file located in the `/rdsdbdata/log/trace` directory.

- Run the following `grep` command in the `root` directory to track the upgrade OS process. This command shows where the log files are being written and determine the state of the upgrade process.

```
ps -aux | grep upg
```

The following shows sample output.

```
root     18884  0.0  0.0 235428  8172 ?        S<   17:03   0:00 /usr/bin/
sudo -u rdsdb /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-
UPGRADE/2.upgrade.sh
rdsdb    18886  0.0  0.0 153968 12164 ?        S<   17:03   0:00 /usr/bin/perl -T -
w /rdsdbbin/scripts/oracle-control ORCL op_apply_upgrade_sh RDS-UPGRADE/2.upgrade.sh
rdsdb    18887  0.0  0.0 113196  3032 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/
oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb    18900  0.0  0.0 113196  1812 ?        S<   17:03   0:00 /bin/sh /rdsdbbin/
oracle/rdbms/admin/RDS-UPGRADE/2.upgrade.sh
rdsdb    18901  0.1  0.0 167652 20620 ?        S<   17:03   0:07 /rdsdbbin/oracle/
perl/bin/perl catctl.pl -n 4 -d /rdsdbbin/oracle/rdbms/admin -l /tmp catupgrd.sql
root     29944  0.0  0.0 112724  2316 pts/0    S+   18:43   0:00 grep --color=auto
 upg
```

- Run the following SQL query to verify the current state of the components to find the database version and the options installed on the DB instance.

```
SET LINESIZE 180
COLUMN COMP_ID FORMAT A15
COLUMN COMP_NAME FORMAT A40 TRUNC
COLUMN STATUS FORMAT A15 TRUNC
SELECT COMP_ID, COMP_NAME, VERSION, STATUS FROM DBA_REGISTRY ORDER BY 1;
```

The output resembles the following.

```
COMP_NAME                                STATUS               PROCEDURE
---------------------------------------- --------------------
 ------------------------------------------------
Oracle Database Catalog Views            VALID
 DBMS_REGISTRY_SYS.VALIDATE_CATALOG
Oracle Database Packages and Types       VALID
 DBMS_REGISTRY_SYS.VALIDATE_CATPROC
Oracle Text                              VALID                VALIDATE_CONTEXT
```

```
Oracle XML Database                        VALID                DBMS_REGXDB.VALIDATEXDB

4 rows selected.
```

- Run the following SQL query to check for invalid objects that might interfere with the upgrade process.

```
SET PAGES 1000 LINES 2000
COL OBJECT FOR A40
SELECT SUBSTR(OWNER,1,12) OWNER,
       SUBSTR(OBJECT_NAME,1,30) OBJECT,
       SUBSTR(OBJECT_TYPE,1,30) TYPE, STATUS,
       CREATED
FROM   DBA_OBJECTS
WHERE  STATUS <>'VALID'
AND    OWNER IN ('SYS','SYSTEM','RDSADMIN','XDB');
```

Troubleshooting replica promotion for RDS Custom for Oracle

You can promote managed Oracle replicas in RDS Custom for Oracle using the console, `promote-read-replica` AWS CLI command, or `PromoteReadReplica` API. If you delete your primary DB instance, and all replicas are healthy, RDS Custom for Oracle promotes your managed replicas to standalone instances automatically. If a replica has paused automation or is outside the support perimeter, you must fix the replica before RDS Custom can promote it automatically. For more information, see Promoting an RDS Custom for Oracle replica to a standalone DB instance.

The replica promotion workflow might become stuck in the following situation:

- The primary DB instance is in the state `STORAGE_FULL`.
- The primary database can't archive all of its online redo logs.
- A gap exists between the archived redo log files on your Oracle replica and the primary database.

To respond to the stuck workflow

1. Synchronize the redo log gap on your Oracle replica DB instance.
2. Force the promotion of your read replica to the latest applied redo log. Run the following commands in SQL*Plus:

```
ALTER DATABASE ACTIVATE STANDBY DATABASE;
```

```
SHUTDOWN IMMEDIATE
STARTUP
```

3. Contact Support and ask them to move your DB instance to `available` status.

Known issues for Amazon RDS Custom for Oracle

When working with RDS Custom for Oracle, note the following issues for DB instances:

- Resizing the root or dbbin volumes isn't supported.

  > **Warning**
  >
  > We strongly recommend that you don't resize the root or dbbin volumes manually. We recommend that you store all configurations in the data volume, which persists after patching, and that you resize the volume using only the RDS scale storage API.

- Some RDS APIs can be blocked when a database instance is on an older AMI, for example, an AMI that uses Oracle Linux 7. To resolve this issue, patch your DB instance to the latest AMI using OS patching. For more information, see CEV upgrade options.
- Before you perform RDS operations, make sure that your AWS account has enough quota for compute and storage.
- If the database is in the creation state, and you actively log in to the database or Amazon EC2 host and run commands, database creation might not complete.
- Control file multiplexing isn't currently supported because of a read replica issue. Before you create a read replica, make sure to specify only one file name in the `CONTROL_FILES` initialization parameter on the source database.
- You can't change the database mode from `PHYSICAL STANDBY` (mounted or read-only) to `SNAPSHOT STANDBY` (converting to read/write).
- If an AWS account is part of an AWS Organization with a service control policy (SCP), and the SCP contains a condition key, an RDS Custom for Oracle DB instance might fail to create with the following error:

```
You can't create the DB instance because of incompatible resources.
The IAM instance profile role [AWSRDSCustomInstanceRole1-us-east-1] is missing the
 following permissions:
EFFECT [Allow] on ACTION(S) [ssm:DescribeAssociation, ssm:DescribeDocument,
 ssm:GetConnectionStatus,
  ssm:GetDeployablePatchSnapshotForInstance, ssmmessages:OpenControlChannel,
 ssm:GetParameters,
  ssm:ListInstanceAssociations, ssm:PutConfigurePackageResult,
 ssmmessages:CreateControlChannel,
```

```
 ssm:GetParameter, ssm:UpdateAssociationStatus, ssm:GetManifest,
ssmmessages:CreateDataChannel,
 ssm:PutInventory, ssm:UpdateInstanceInformation, ssm:DescribeInstanceInformation,
 ssmmessages:OpenDataChannel, ssm:GetDocument, ssm:ListAssociations,
ssm:PutComplianceItems,
 ssm:UpdateInstanceAssociationStatus] for RESOURCE(S) [], EFFECT [Allow] on
ACTION(S) [ec2messages:DeleteMessage,
 ec2messages:FailMessage, ec2messages:GetEndpoint, ec2messages:AcknowledgeMessage,
ec2messages:GetMessages,
 ec2messages:SendReply] for RESOURCE(S) [], EFFECT [Allow] on ACTION(S)
[logs:CreateLogStream,
 logs:DescribeLogStreams, logs:PutRetentionPolicy, logs:PutLogEvents]
```

To resolve this issue, create a ticket with Support.

Known issues with database user accounts

Note the following issues:

- Don't remove database user accounts that begin with the string RDS, such as RDSADMIN and RDS_DATAGUARD. RDS Custom for Oracle uses the RDS account for automation. If you remove this user account, RDS Custom moves the instance to the unsupported configuration state.
- You can't change the master username for your RDS Custom for Oracle DB instance using the ModifyDBInstance API.
- RDS Custom for Oracle rotates user account credentials on all DB instances. For more information, see Rotating RDS Custom for Oracle credentials for compliance programs. If you use an on-premises primary/standby configuration, credential rotation might affect the following resources:
  - Manually created standby RDS Custom for Oracle instances

    To resolve this issue, drop the manual standby databases, and then create an Oracle read replica using an API call. Manage the secrets manually for the manual standby databases so that they match the source DB instance.
  - Manually created cross-Region read replicas

    To resolve this issue, manually keep the secrets so that they match the primary DB instance.

Known issues with parameter and configuration files

- You must configure the `crontab` file after scale compute, OS upgrades, and other operations where RDS Custom replaces the root volume. We highly recommend that you keep a backup of `crontab`.
- Note the following guidelines when you configure the `listener.ora` file:
  - Make sure that every entry in the file is on a single line. This approach avoids issues with indentation during instance creation.
  - Make sure that `GLOBAL_DBNAME` is equal to the value of `SID_NAME`.
  - Make sure the value for `LISTENER` follows the naming convention `L_`*`dbname`*`_001`.
  - Make sure the `listener.ora` file maintains a connection to the database name. RDS Custom uses this connection to verify database startup. If you modify this file incorrectly, operations such as scale compute or patching might fail.

    The following example shows a `listener.ora` that is configured correctly:

    ```
    ADR_BASE_L_ORCL_001=/rdsdbdata/log/
    USE_SID_AS_SERVICE_L_ORCL_001=ON
    SID_LIST_L_ORCL_001=(SID_LIST = (SID_DESC = (SID_NAME = ORCL)(GLOBAL_DBNAME = ORCL)
     (ORACLE_HOME = /rdsdbbin/oracle.19.custom.r1.EE.1)))
    SUBSCRIBE_FOR_NODE_DOWN_EVENT_L_ORCL_001=OFF
    L_ORCL_001=(DESCRIPTION_LIST = (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(PORT =
     XXXX)(HOST = x.x.x.x))) (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(PORT = XXXX)
    (HOST = 127.0.0.1))))
    ```
- Comments aren't supported in a server parameter file or initialization parameter file.
- You must declare the following initialization parameters in the server parameter file (`/rdsdbdata/config/oracle_pfile`):
  - `MEMORY_MAX_TARGET`
  - `MEMORY_TARGET`
  - `PGA_AGGREGATE_TARGET`
  - `PROCESSES`
  - `SGA_TARGET`
  - `USE_LARGE_PAGES`

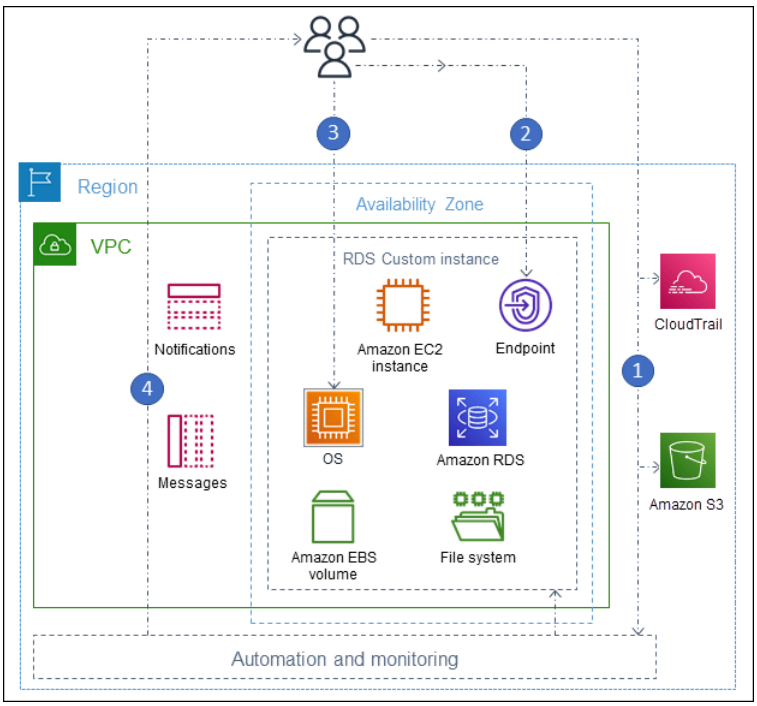
If the preceding parameters aren't declared in `/rdsdbdata/config/oracle_pfile`, read replica creation and scale compute might fail.

- You can't delete the symbolic links for configuration files such as the server parameter file, audit files, `listener.ora`, `tnsnames.ora`, or `sqlnet.ora`. You also can't modify the directory structure for these files. RDS Custom automation expects these files to exist in a specific directory structure.

  To create a server parameter file from an initialization parameter file, use the following syntax.

```
CREATE SPFILE='/rdsdbdata/admin/$ORACLE_SID/pfile/spfile$ORACLE_SID.ora'
    FROM PFILE='/rdsdbdata/config/oracle_pfile';
```

Working with RDS Custom for SQL Server



Following, you can find instructions for creating, managing, and maintaining your RDS Custom for SQL Server DB instances.

RDS Custom for SQL Server workflow

The following diagram shows the typical workflow for RDS Custom for SQL Server.

The steps are as follows:

1. Create an RDS Custom for SQL Server DB instance from an engine version offered by RDS Custom.

   For more information, see Creating an RDS Custom for SQL Server DB instance.

2. Connect your application to the RDS Custom DB instance endpoint.

   For more information, see Connecting to your RDS Custom DB instance using AWS Systems Manager and Connecting to your RDS Custom DB instance using RDP.

3. (Optional) Access the host to customize your software.

4. Monitor notifications and messages generated by RDS Custom automation.

Creating a DB instance for RDS Custom

You create your RDS Custom DB instance using the `create-db-instance` command. The procedure is similar to creating an Amazon RDS instance. However, some of the parameters are different. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

Database connection

Like an Amazon RDS DB instance, your RDS Custom for SQL Server DB instance resides in a VPC. Your application connects to the RDS Custom instance using a client such as SQL Server Management Suite (SSMS), just as in RDS for SQL Server.

RDS Custom customization

You can access the RDS Custom host to install or customize software. To avoid conflicts between your changes and the RDS Custom automation, you can pause the automation for a specified period. During this period, RDS Custom doesn't perform monitoring or instance recovery. At the end of the period, RDS Custom resumes full automation. For more information, see Pausing and resuming RDS Custom automation.

Requirements and limitations for Amazon RDS Custom for SQL Server

Following, you can find a summary of the Amazon RDS Custom for SQL Server requirements and limitations for quick reference. Requirements and limitations also appear in the relevant sections.

Topics

- Region and version availability
- General requirements for RDS Custom for SQL Server
- DB instance class support for RDS Custom for SQL Server
- Limitations for RDS Custom for SQL Server
- Setting character sets and collations for RDS Custom for SQL Server DB instances
- Local time zone for RDS Custom for SQL Server DB instances
- Using a Service Master Key with RDS Custom for SQL Server
- Change data capture (CDC) support with RDS Custom for SQL Server

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Amazon RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

General requirements for RDS Custom for SQL Server

Make sure to follow these requirements for Amazon RDS Custom for SQL Server:

- Use the instance classes shown in DB instance class support for RDS Custom for SQL Server. The only storage types supported are solid state drives (SSD) of types gp2, gp3, io1, and io2 Block Express. The maximum storage limit for io1, gp2, and gp3 is 16 TiB while io2 supports 64 TiB.
- Make sure that you have a symmetric encryption AWS KMS key to create an RDS Custom DB instance. For more information, see Make sure that you have a symmetric encryption AWS KMS key.
- Make sure that you create an AWS Identity and Access Management (IAM) role and instance profile. For more information, see Creating your IAM role and instance profile manually and Automated instance profile creation using the AWS Management Console.

- Make sure to supply a networking configuration that RDS Custom can use to access other AWS services. For specific requirements, see Step 2: Configure networking, instance profile, and encryption.
- The combined number of RDS Custom and Amazon RDS DB instances can't exceed your quota limit. For example, if your quota is 40 DB instances, you can have 20 RDS Custom for SQL Server DB instances and 20 Amazon RDS DB instances.
- RDS Custom automatically creates an AWS CloudTrail trail whose name begins with `do-not-delete-rds-custom-`. The RDS Custom support perimeter relies on the events from CloudTrail to determine whether your actions affect RDS Custom automation. RDS Custom creates the trail when you create your first DB instance. To use an already existing CloudTrail, contact AWS Support. For more information, see AWS CloudTrail.

DB instance class support for RDS Custom for SQL Server

Check if the DB instance class is supported in your Region by using the describe-orderable-db-instance-options command.

RDS Custom for SQL Server supports the DB instance classes shown in the following table:

SQL Server edition	RDS Custom support
Enterprise Edition	db.r5.xlarge–db.r5.24xlarge db.r5b.xlarge–db.r5b.24xlarge db.m5.xlarge–db.m5.24xlarge db.r6i.xlarge–db.r6i.32xlarge db.m6i.xlarge–db.m6i.32xlarge db.x2iedn.xlarge–db.x2iedn.32xlarge
Standard Edition	db.r5.large–db.r5.24xlarge db.r5b.large–db.r5b.8xlarge

SQL Server edition	RDS Custom support
	db.m5.large–db.m5.24xlarge db.r6i.large–db.r6i.8xlarge db.m6i.large–db.m6i.8xlarge db.x2iedn.xlarge–db.x2iedn.8xlarge
Developer Edition	db.r5.xlarge–db.r5.24xlarge db.r5b.xlarge–db.r5b.24xlarge db.m5.xlarge–db.m5.24xlarge db.r6i.xlarge–db.r6i.32xlarge db.m6i.xlarge–db.m6i.32xlarge db.x2iedn.xlarge–db.x2iedn.32xlarge
Web Edition	db.r5.large–db.r5.4xlarge db.m5.large–db.m5.4xlarge db.r6i.large–db.r6i.4xlarge db.m6i.large–db.m6i.4xlarge db.r5b.large–db.r5b.4xlarge

The following recommendations apply to db.x2iedn class types:

- At creation, local storage is a raw and unallocated device. Before using a DB instance with this instance class, you must mount and format the local storage. Afterward, configure `tempdb` on it to ensure optimal performance. For more information, see Optimize tempdb performance in Amazon RDS Custom for SQL Server using local instance storage.

- Local storage reverts to its raw and unallocated state when you run DB instance operations such as scale compute, instance replacement, snapshot restore, or point-in-time recovery (PITR). In these situations, you must remount, reformat, and reconfigure the drive and `tempdb` to restore functionality.
- For Multi-AZ instances, we recommend that you perform the configuration on a standby DB instance. This way, if a failover occurs, the system continues to operate without issues because the configuration is already in place on the standby instance.

Limitations for RDS Custom for SQL Server

The following limitations apply to RDS Custom for SQL Server:

- You can't create read replicas in Amazon RDS for RDS Custom for SQL Server DB instances. However, you can configure high availability automatically with a Multi-AZ deployment. For more information, see Managing a Multi-AZ deployment for RDS Custom for SQL Server.
- You can't modify the DB instance identifier of an existing RDS Custom for SQL Server DB instance.
- For an RDS Custom for SQL Server DB instance that wasn't created with a custom engine version (CEV), changes to the Microsoft Windows operating system aren't guaranteed to persist. For example, you lose these changes when you initiate a snapshot or point-in-time restore operation. If the RDS Custom for SQL Server DB instance was created with a CEV, then those changes are persisted.
- Not all options are supported. For example, when you create an RDS Custom for SQL Server DB instance, you can't do the following:
  - Change the number of CPU cores and threads per core on the DB instance class.
  - Turn on storage autoscaling.
  - Specify your own DB parameter group, option group, or character set.
  - Turn on Performance Insights or Database Insights.
  - Turn on automatic minor version upgrade.
- The maximum DB instance storage is 64 TiB.
- You can't use RDS Proxy with RDS Custom for SQL Server.
- You can't use the `describe-reserved-db-instances` API for RDS Custom for SQL Server DB instances.

Setting character sets and collations for RDS Custom for SQL Server DB instances

Overview

With RDS Custom for SQL Server DB instances, you can configure the character set and collation settings that determine how data is stored and sorted. Character sets define which characters are allowed, while collations specify the rules for sorting and comparing data. It't important to set the appropriate character sets and collations for applications that work with multilingual data or have specific sorting requirements. For example, you might need to handle accented characters and define language-specific sorting rules, or maintain data integrity across different locales. The following sections provide information on character set and collation support for your RDS Custom for SQL Server DB instances.

RDS Custom for SQL Server supports a wide range of server collations, both in traditional and UTF-8 encoding, for the SQL_Latin, Japanese, German, and Arabic locales. The default server collation is `SQL_Latin1_General_CP1_CI_AS`, however, you can select another supported collation to use. You can select a collation using the same procedure that RDS for SQL Server uses. For more information, see Managing collations and character sets for Amazon RDS for Microsoft SQL Server.

Considerations

The following requirements and limitations apply when working with server collations on RDS Custom for SQL Server:

- You can set the server collation when you create an RDS Custom for SQL Server DB instance. You can't modify the server-level collation after the DB instance is created.
- You can't modify the server level collation when restoring from a DB snapshot or during a point in time recovery (PITR).
- When you create a DB instance from an RDS Custom for SQL Server CEV, the DB instance doesn't inherit the server collation from the CEV. Instead, the default server collation of `SQL_Latin1_General_CP1_CI_AS` is used. If you've configured a non-default server collation on a RDS Custom for SQL Server CEV and want to use that same server collation on a new DB instance, be sure to select that same collation when you create the DB instance from the CEV.

> **Note**
>
> If the collation you select while creating the DB instance is different from the collation of the CEV, the Microsoft SQL Server system databases on the new RDS Custom for SQL

Server DB instance will be rebuilt to use the updated collation. The rebuild process is only performed on the new RDS Custom for SQL Server DB instance and has no impact on the CEV itself. Any previous modifications that you made to the system databases on the CEV will not be retained on the new RDS Custom for SQL Server DB instance once the system databases are rebuilt. Examples of some modifications include user-defined objects in the `master` database, scheduled jobs in the `msdb` database, or changes to default database settings in the `model` database on your CEV. You can manually recreate your modifications once the new RDS Custom for SQL Server DB instance is created.

- When you create a DB instance from an RDS Custom for SQL Server custom engine version (CEV) and select a different collation from that of the CEV, ensure that your golden image (AMI) used for CEV creation meets the following requirements so the Microsoft SQL Server system databases on the new DB instance can be rebuilt:
  - For SQL Server 2022, ensure the `setup.exe` file is located in the following path: `C:\Program Files\Microsoft SQL Server\160\Setup Bootstrap\SQL2022\setup.exe`
  - For SQL Server 2019, ensure the `setup.exe` file is located in the following path: `C:\Program Files\Microsoft SQL Server\150\Setup Bootstrap\SQL2019\setup.exe`
  - Copies of the data and log templates for the `master`, `model`, and `msdb` databases must exist in their default locations. For more information, see Rebuild system databases in the Microsoft public documentation.
  - Ensure your SQL Server Database Engine uses `NT Service\MSSQLSERVER` or `NT AUTHORITY\NETWORK SERVICE` as the service account. Any other account will not have the required permissions on the `C:\` drive when configuring a non-default server collation for the DB instance.
- If the server collation selected for a new DB instance is the same as that configured on your CEV, the Microsoft SQL Server system databases on the new RDS Custom for SQL Server DB instance do not undergo the rebuild process. Any previous modifications that you made to the system databases on the CEV will automatically persist to the new RDS Custom for SQL Server DB instance.

Supported collations

You can set your collation to one of the values listed in the following table.

Collation	Description
Arabic_100_BIN	Arabic-100, binary sort
Arabic_100_BIN2	Arabic-100, binary code point comparison sort
Arabic_100_CI_AI	Arabic-100, case-insensitive, accent-insensitive , kanatype-insensitive, width-insensitive
Arabic_100_CI_AI_KS	Arabic-100, case-insensitive, accent-insensitive , kanatype-sensitive, width-insensitive
Arabic_100_CI_AI_KS_SC	Arabic-100, case-insensitive, accent-insensitive , kanatype-sensitive, width-insensitive, supplementary characters
Arabic_100_CI_AI_KS_SC_UTF8	Arabic-100, case-insensitive, accent-insensitive , kanatype-sensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CI_AI_KS_WS	Arabic-100, case-insensitive, accent-insensitive , kanatype-sensitive, width-sensitive
Arabic_100_CI_AI_KS_WS_SC	Arabic-100, case-insensitive, accent-in sensitive, kanatype-sensitive, width-sensitive, supplementary characters
Arabic_100_CI_AI_KS_WS_SC_UTF8	Arabic-100, case-insensitive, accent-in sensitive, kanatype-sensitive, width-sensitive, supplementary characters, UTF8
Arabic_100_CI_AI_SC	Arabic-100, case-insensitive, accent-insensitive , kanatype-insensitive, width-insensitive, supplementary characters
Arabic_100_CI_AI_SC_UTF8	Arabic-100, case-insensitive, accent-insensitive , kanatype-insensitive, width-insensitive, supplementary characters, UTF8

Collation	Description
Arabic_100_CI_AI_WS	Arabic-100, case-insensitive, accent-insensitive , kanatype-insensitive, width-sensitive
Arabic_100_CI_AI_WS_SC	Arabic-100, case-insensitive, accent-insensitive , kanatype-insensitive, width-sensitive, supplementary characters
Arabic_100_CI_AI_WS_SC_UTF8	Arabic-100, case-insensitive, accent-insensitive , kanatype-insensitive, width-sensitive, supplementary characters, UTF8
Arabic_100_CI_AS	Arabic-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Arabic_100_CI_AS_KS	Arabic-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive
Arabic_100_CI_AS_KS_SC	Arabic-100, case-insensitive, accent-se nsitive, kanatype-sensitive, width-insensitive, supplementary characters
Arabic_100_CI_AS_KS_SC_UTF8	Arabic-100, case-insensitive, accent-se nsitive, kanatype-sensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CI_AS_KS_WS	Arabic-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-sensitive
Arabic_100_CI_AS_KS_WS_SC	Arabic-100, case-insensitive, accent-se nsitive, kanatype-sensitive, width-sensitive, supplementary characters
Arabic_100_CI_AS_KS_WS_SC_UTF8	Arabic-100, case-insensitive, accent-se nsitive, kanatype-sensitive, width-sensitive, supplementary characters, UTF8

Collation	Description
Arabic_100_CI_AS_SC	Arabic-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters
Arabic_100_CI_AS_SC_UTF8	Arabic-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CI_AS_WS	Arabic-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-sensitive
Arabic_100_CI_AS_WS_SC	Arabic-100, case-insensitive, accent-se nsitive, kanatype-insensitive, width-sensitive, supplementary characters
Arabic_100_CI_AS_WS_SC_UTF8	Arabic-100, case-insensitive, accent-se nsitive, kanatype-insensitive, width-sensitive, supplementary characters, UTF8
Arabic_100_CS_AI	Arabic-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-insensitive
Arabic_100_CS_AI_KS	Arabic-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-insensitive
Arabic_100_CS_AI_KS_SC	Arabic-100, case-sensitive, accent-insensitive , kanatype-sensitive, width-insensitive, supplementary characters
Arabic_100_CS_AI_KS_SC_UTF8	Arabic-100, case-sensitive, accent-insensitive , kanatype-sensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CS_AI_KS_WS	Arabic-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-sensitive

Collation	Description
Arabic_100_CS_AI_KS_WS_SC	Arabic-100, case-sensitive, accent-insensitive , kanatype-sensitive, width-sensitive, supplementary characters
Arabic_100_CS_AI_KS_WS_SC_UTF8	Arabic-100, case-sensitive, accent-insensitive , kanatype-sensitive, width-sensitive, supplementary characters, UTF8
Arabic_100_CS_AI_SC	Arabic-100, case-sensitive, accent-insensitive , kanatype-insensitive, width-insensitive, supplementary characters
Arabic_100_CS_AI_SC_UTF8	Arabic-100, case-sensitive, accent-insensitive , kanatype-insensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CS_AI_WS	Arabic-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-sensitive
Arabic_100_CS_AI_WS_SC	Arabic-100, case-sensitive, accent-insensitive , kanatype-insensitive, width-sensitive, supplementary characters
Arabic_100_CS_AI_WS_SC_UTF8	Arabic-100, case-sensitive, accent-insensitive , kanatype-insensitive, width-sensitive, supplementary characters, UTF8
Arabic_100_CS_AS	Arabic-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Arabic_100_CS_AS_KS	Arabic-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive
Arabic_100_CS_AS_KS_SC	Arabic-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters

Collation	Description
Arabic_100_CS_AS_KS_SC_UTF8	Arabic-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CS_AS_KS_WS	Arabic-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-sensitive
Arabic_100_CS_AS_KS_WS_SC	Arabic-100, case-sensitive, accent-se nsitive, kanatype-sensitive, width-sensitive, supplementary characters
Arabic_100_CS_AS_KS_WS_SC_UTF8	Arabic-100, case-sensitive, accent-se nsitive, kanatype-sensitive, width-sensitive, supplementary characters, UTF8
Arabic_100_CS_AS_SC	Arabic-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters
Arabic_100_CS_AS_SC_UTF8	Arabic-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, UTF8
Arabic_100_CS_AS_WS	Arabic-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-sensitive
Arabic_100_CS_AS_WS_SC	Arabic-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-sensitive, supplementary characters
Arabic_100_CS_AS_WS_SC_UTF8	Arabic-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-sensitive, supplementary characters, UTF8
Arabic_BIN	Arabic, binary sort
Arabic_BIN2	Arabic, binary code point comparison sort

Collation	Description
Arabic_CI_AI	Arabic, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive
Arabic_CI_AI_KS	Arabic, case-insensitive, accent-insensitive, kanatype-sensitive, width-insensitive
Arabic_CI_AI_KS_WS	Arabic, case-insensitive, accent-insensitive, kanatype-sensitive, width-sensitive
Arabic_CI_AI_WS	Arabic, case-insensitive, accent-insensitive, kanatype-insensitive, width-sensitive
Arabic_CI_AS	Arabic, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Arabic_CI_AS_KS	Arabic, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive
Arabic_CI_AS_KS_WS	Arabic, case-insensitive, accent-sensitive, kanatype-sensitive, width-sensitive
Arabic_CI_AS_WS	Arabic, case-insensitive, accent-sensitive, kanatype-insensitive, width-sensitive
Arabic_CS_AI	Arabic, case-sensitive, accent-insensitive, kanatype-insensitive, width-insensitive
Arabic_CS_AI_KS	Arabic, case-sensitive, accent-insensitive, kanatype-sensitive, width-insensitive
Arabic_CS_AI_KS_WS	Arabic, case-sensitive, accent-insensitive, kanatype-sensitive, width-sensitive
Arabic_CS_AI_WS	Arabic, case-sensitive, accent-insensitive, kanatype-insensitive, width-sensitive
Arabic_CS_AS	Arabic, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive

Collation	Description
Arabic_CS_AS_KS	Arabic, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive
Arabic_CS_AS_KS_WS	Arabic, case-sensitive, accent-sensitive, kanatype-sensitive, width-sensitive
Arabic_CS_AS_WS	Arabic, case-sensitive, accent-sensitive, kanatype-insensitive, width-sensitive
Chinese_PRC_BIN2	Chinese-PRC, binary code point comparison sort
Chinese_PRC_CI_AS	Chinese-PRC, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Chinese_Taiwan_Stroke_CI_AS	Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Danish_Norwegian_CI_AS	Danish-Norwegian, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Finnish_Swedish_CI_AS	Finnish-Swedish, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
French_CI_AS	French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
German_PhoneBook_100_BIN	German-PhoneBook-100, binary sort
German_PhoneBook_100_BIN2	German-PhoneBook-100, binary code point comparison sort
German_PhoneBook_100_CI_AI	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive

Collation	Description
German_PhoneBook_100_CI_AI_KS	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-sensitive, width-insensitive
German_PhoneBook_100_CI_AI_KS_SC	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-sensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CI_AI_KS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-sensitive, width-insensitive, supplementary characters, UTF8
German_PhoneBook_100_CI_AI_KS_WS	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-sensitive, width-sensitive
German_PhoneBook_100_CI_AI_KS_WS_SC	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-sensitive, width-sensitive, supplementary characters
German_PhoneBook_100_CI_AI_KS_WS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-sensitive, width-sensitive, supplementary characters, UTF8
German_PhoneBook_100_CI_AI_SC	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CI_AI_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive, supplementary characters, UTF8
German_PhoneBook_100_CI_AI_WS	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-sensitive

Collation	Description
German_PhoneBook_100_CI_AI_WS_SC	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-sensitive, supplementary characters
German_PhoneBook_100_CI_AI_WS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-sensitive, supplementary characters, UTF8
German_PhoneBook_100_CI_AS	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
German_PhoneBook_100_CI_AS_KS	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive
German_PhoneBook_100_CI_AS_KS_SC	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CI_AS_KS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, UTF8
German_PhoneBook_100_CI_AS_KS_WS	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-sensitive
German_PhoneBook_100_CI_AS_KS_WS_SC	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-sensitive, supplementary characters
German_PhoneBook_100_CI_AS_KS_WS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-sensitive, width-sensitive, supplementary characters, UTF8

Collation	Description
German_PhoneBook_100_CI_AS_SC	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CI_AS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, UTF8
German_PhoneBook_100_CI_AS_WS	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-sensitive
German_PhoneBook_100_CI_AS_WS_SC	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-sensitive, supplementary characters
German_PhoneBook_100_CI_AS_WS_SC_UTF8	German-PhoneBook-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-sensitive, supplementary characters, UTF8
German_PhoneBook_100_CS_AI	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-insensitive
German_PhoneBook_100_CS_AI_KS	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-insensitive
German_PhoneBook_100_CS_AI_KS_SC	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CS_AI_KS_SC_UTF8	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-insensitive, supplementary characters, UTF8

Collation	Description
German_PhoneBook_100_CS_AI_KS_WS	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-sensitive
German_PhoneBook_100_CS_AI_KS_WS_SC	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-sensitive, supplementary characters
German_PhoneBook_100_CS_AI_KS_WS_SC_UTF8	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-sensitive, width-sensitive, supplementary characters, UTF8
German_PhoneBook_100_CS_AI_SC	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CS_AI_SC_UTF8	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-insensitive, supplementary characters, UTF8
German_PhoneBook_100_CS_AI_WS	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-sensitive
German_PhoneBook_100_CS_AI_WS_SC	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-sensitive, supplementary characters
German_PhoneBook_100_CS_AI_WS_SC_UTF8	German-PhoneBook-100, case-sensitive, accent-insensitive, kanatype-insensitive, width-sensitive, supplementary characters, UTF8
German_PhoneBook_100_CS_AS	German-PhoneBook-100, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive

Collation	Description
German_PhoneBook_100_CS_AS_KS	German-PhoneBook-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive
German_PhoneBook_100_CS_AS_KS_SC	German-PhoneBook-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters
German_PhoneBook_100_CS_AS_KS_SC_UTF8	German-PhoneBook-100, case-sensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, UTF8

Local time zone for RDS Custom for SQL Server DB instances

The time zone of an RDS Custom for SQL Server DB instance is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment, then when you fail over, your time zone remains the local time zone that you set.

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time for Amazon RDS.

The following are limitations to setting the local time zone on your DB instance:

- You can configure the time zone for a DB instance during instance creation, but you can't modify the time zone of an existing RDS Custom for SQL Server DB instance.
- If the time zone is modified for an existing RDS Custom for SQL Server DB instance, RDS Custom changes the DB instance status to `unsupported-configuration`, and sends event notifications.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Supported time zones

You can set your local time zone to one of the values listed in the following table.

Time zone	Standard time offset	Description	Notes
Afghanistan Standard Time	(UTC+04:30)	Kabul	This time zone doesn't observe daylight saving time.
Alaskan Standard Time	(UTC–09:00)	Alaska	
Aleutian Standard Time	(UTC–10:00)	Aleutian Islands	
Altai Standard Time	(UTC+07:00)	Barnaul, Gorno-Altaysk	
Arab Standard Time	(UTC+03:00)	Kuwait, Riyadh	This time zone doesn't observe daylight saving time.
Arabian Standard Time	(UTC+04:00)	Abu Dhabi, Muscat	

Time zone	Standard time offset	Description	Notes
Arabic Standard Time	(UTC+03:00)	Baghdad	This time zone doesn't observe daylight saving time.
Argentina Standard Time	(UTC–03:00)	City of Buenos Aires	This time zone doesn't observe daylight saving time.
Astrakhan Standard Time	(UTC+04:00)	Astrakhan, Ulyanovsk	
Atlantic Standard Time	(UTC–04:00)	Atlantic Time (Canada)	
AUS Central Standard Time	(UTC+09:30)	Darwin	This time zone doesn't observe daylight saving time.
Aus Central W. Standard Time	(UTC+08:45)	Eucla	
AUS Eastern Standard Time	(UTC+10:00)	Canberra, Melbourne, Sydney	
Azerbaijan Standard Time	(UTC+04:00)	Baku	
Azores Standard Time	(UTC–01:00)	Azores	
Bahia Standard Time	(UTC–03:00)	Salvador	
Bangladesh Standard Time	(UTC+06:00)	Dhaka	This time zone doesn't observe daylight saving time.

Time zone	Standard time offset	Description	Notes
Belarus Standard Time	(UTC+03:00)	Minsk	This time zone doesn't observe daylight saving time.
Bougainville Standard Time	(UTC+11:00)	Bougainville Island	
Canada Central Standard Time	(UTC–06:00)	Saskatchewan	This time zone doesn't observe daylight saving time.
Cape Verde Standard Time	(UTC–01:00)	Cabo Verde Is.	This time zone doesn't observe daylight saving time.
Caucasus Standard Time	(UTC+04:00)	Yerevan	
Cen. Australia Standard Time	(UTC+09:30)	Adelaide	
Central America Standard Time	(UTC–06:00)	Central America	This time zone doesn't observe daylight saving time.

Using a Service Master Key with RDS Custom for SQL Server

RDS Custom for SQL Server supports using a Service Master Key (SMK). RDS Custom retains the same SMK throughout the lifespan of your RDS Custom for SQL Server DB instance. By retaining the same SMK, your DB instance can use objects that are encrypted with the SMK, such as linked server passwords and credentials. If you use a Multi-AZ deployment, RDS Custom also synchronizes and maintains the SMK between primary and secondary DB instances.

Topics

- Region and version availability
- Supported features
- Using TDE
- Configuring features
- Requirements and limitations

Region and version availability

Using an SMK is supported in all Regions where RDS Custom for SQL Server is available, for all SQL Server versions available on RDS Custom. For more information on version and Region availability

of Amazon RDS with RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

Supported features

When using a SMK with RDS Custom for SQL Server, the following features are supported:

- Transparent Data Encryption (TDE)
- Column-level encryption
- Database Mail
- Linked Servers
- SQL Server Integration Services (SSIS)

Using TDE

An SMK enables the ability to configure Transparent Data Encryption (TDE), which encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage. Unlike RDS for SQL Server, configuring TDE on an RDS Custom for SQL Server DB instance doesn't require using option groups. Instead, once you've created a certificate and database encryption key, you can run the following command to turn on TDE at the database level:

```
ALTER DATABASE [myDatabase] SET ENCRYPTION ON;
```

For more information on using TDE with RDS for SQL Server, see Support for Transparent Data Encryption in SQL Server.

For detailed information on TDE in Microsoft SQL Server, see Transparent data encryption in the Microsoft documentation.

Configuring features

For detailed steps on configuring features that use a SMK with RDS Custom for SQL Server, you can use the following posts in the Amazon RDS database blog:

- Linked servers: Configuring linked servers on RDS Custom for SQL Server.
- SSIS: Migrate SSIS packages to RDS Custom for SQL Server.
- TDE: Secure your data using TDE on RDS Custom for SQL Server.

Requirements and limitations

When using an SMK with an RDS Custom for SQL Server DB instance, keep in mind the following requirements and limitations:

- If you re-generate the SMK on your DB instance, you should immediately perform a manual DB snapshot. We recommend avoiding re-generating the SMK if possible.
- You must maintain backups of the server certificates and database master key passwords. If you don't maintain backups of these, it may result in data loss.
- If you configure SSIS, you should use an SSM document to join the RDS Custom for SQL Server DB instance to the domain in case of a scale compute or host replacement.
- When TDE or column-encryption is enabled, database backups are automatically encrypted. When you perform a snapshot restore or point in time recovery, the SMK from the source DB instance will be restored to decrypt data for the restore, and a new SMK will be generated to re-encrypt data on the restored instance.

For more information on Service Master Keys in Microsoft SQL Server, see SQL Server and Database Encryption Keys in the Microsoft documentation.

Change data capture (CDC) support with RDS Custom for SQL Server

Overview

RDS Custom for SQL Server provides native support for Change data capture (CDC), enabling you to track and capture data modifications in your SQL Server tables. CDC stores detailed metadata about these changes for subsequent retrieval and analysis. For detailed information about CDC functionality, see Change data capture in the Microsoft documentation.

CDC operation in SQL Server requires matching values between the *local server* (that has `server_id` = 0) in `sys.servers` and `SERVERPROPERTY('ServerName')` identifiers. RDS Custom for SQL Server automatically maintains this synchronization throughout the instance's lifecycle to ensuring continuous CDC functioning even if hosts are replaced during maintenance or recovery operations.

> **Important**
>
> Following a Multi-AZ instance failover, the `SERVERPROPERTY('Servername')` function automatically reflects changes in the network/computer name. However, the

@@SERVERNAME function retains the old server name until the MSSQLSERVER service is restarted. Querying @@SERVERNAME returns the previous server name after a failover. To obtain the accurate server name after a failover, use the following SQL query:

```
SELECT name FROM sys.servers WHERE server_id=0
```

This query provides the most up-to-date server name information without requiring a service restart.

Region and version availability

CDC functionality is supported in all AWS Regions where RDS Custom for SQL Server is available, for all SQL Server versions supported by RDS Custom. For more information about supported versions and Region availability of RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

Requirements and limitations

When implementing CDC on RDS Custom for SQL Server, be aware the following key considerations:

- If you manually set `@@SERVERNAME` and/or *local server* in `sys.servers` to use features like MS Replication, if the value of the local server (that has `server_id = 0`) in `sys.servers` is set to a format that matches `*.rds.amazonaws.com` or `*.awsrds.*.com`, RDS Custom for SQL Server does not attempt to modify it to match `SERVERPROPERTY('ServerName')`.
- RDS cannot modify the local server (that has `server_id = 0`) in `sys.servers` to a new hostname while remote logins or linked servers are actively using the old hostname. This limitation applies in two scenarios:
  - When a linked server establishes a connection to the local server using a remote login associated with the old hostname
  - When an RDS Custom for SQL Server instance acts as a publisher or distributor and has linked logins associated with the old hostname to its subscriber instances.

Troubleshooting

To identify remote logins or linked logins associated with the old server name, use the following queries. Validate the results and remove these logins to ensure proper CDC functionality.

```
SELECT * FROM sys.remote_logins WHERE server_id=0
```

or

```
select sss.srvname,ssp.name,srl.remote_name  from sys.server_principals ssp
inner join sys.remote_logins srl on srl.local_principal_id=ssp.principal_id
inner join sys.sysservers sss  on srl.server_id = sss.srvid
where sss.srvname = @@SERVERNAME
```

Setting up your environment for Amazon RDS Custom for SQL Server

Before you create and manage a DB instance for Amazon RDS Custom for SQL Server DB instance, make sure to perform the following tasks.

Contents

- Prerequisites for setting up RDS Custom for SQL Server
  - Automated instance profile creation using the AWS Management Console
- Step 1: Grant required permissions to your IAM principal
- Step 2: Configure networking, instance profile, and encryption
  - Configuring with CloudFormation
    - Parameters required by CloudFormation
    - Download CloudFormation template file
    - Configuring resources using CloudFormation
  - Configuring manually
    - Make sure that you have a symmetric encryption AWS KMS key
    - Creating your IAM role and instance profile manually
      - Create the AWSRDSCustomSQLServerInstanceRole IAM role
      - Add an access policy to AWSRDSCustomSQLServerInstanceRole
      - Create your RDS Custom for SQL Server instance profile
      - Add AWSRDSCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile
    - Configuring your VPC manually
      - Configure your VPC security group
      - Configure endpoints for dependent AWS services
      - Configure the instance metadata service
- Cross-instance restriction

> **Note**
>
> For a step-by-step tutorial on how to set up prerequisites and launch Amazon RDS Custom for SQL Server, see Get started with Amazon RDS Custom for SQL Server using an

CloudFormation template (Network setup) and Explore the prerequisites required to create an Amazon RDS Custom for SQL Server instance.

Prerequisites for setting up RDS Custom for SQL Server

Before creating an RDS Custom for SQL Server DB instance, make sure that your environment meets the requirements described in this topic. You can also use the CloudFormation template to set up the prerequisites within your AWS account. For more information, see Configuring with CloudFormation

RDS Custom for SQL Server requires that you configure the following prerequisites:

- Configure the AWS Identity and Access Management (IAM) permissions required for instance creation. This is the AWS Identity and Access Management (IAM) user or role needed to make a `create-db-instance` request to RDS.
- Configure prerequisite resources required by RDS Custom for SQL Server DB instance:
  - Configure the AWS KMS key required for encryption of RDS Custom instance. RDS Custom requires a customer managed key at the time of instance creation for encryption. The KMS key ARN, ID, alias ARN, or alias name is passed as `kms-key-id` parameter in the request to create the RDS Custom DB instance.
  - Configure the permissions required inside RDS Custom for SQL Server DB instance. RDS Custom attaches an instance profile to DB instance at creation and uses it for automation within the DB instance. The instance profile name is set to `custom-iam-instance-profile` in the RDS Custom create request. You can create an instance profile from the AWS Management Console or manually create your instance profile. For more information, see Automated instance profile creation using the AWS Management Console and Creating your IAM role and instance profile manually.
  - Configure the networking setup as per the requirements of RDS Custom for SQL Server. RDS Custom instances reside in the subnets (configured with DB subnet group) that you provide at instance creation. These subnets must allow RDS Custom instances to communicate with services required for RDS automation.

Note

For the requirements mentioned above, make sure there aren't any service control policies (SCPs) restricting account level permissions.

If the account that you're using is part of an AWS Organization, it might have service control policies (SCPs) restricting account level permissions. Make sure that the SCPs don't restrict the permissions on users and roles that you create using the following procedures. For more information about SCPs, see Service control policies (SCPs) in the *AWS Organizations User Guide*. Use the describe-organization AWS CLI command to check whether your account is part of an AWS Organization.
For more information about AWS Organizations, see What is AWS Organizations in the *AWS Organizations User Guide*.

For general requirements that apply to RDS Custom for SQL Server, see General requirements for RDS Custom for SQL Server.

Automated instance profile creation using the AWS Management Console

RDS Custom requires you to create and configure an instance profile to launch any RDS Custom for SQL Server DB instance. Use the AWS Management Console to create and attach a new instance profile in a single step. This option is available under RDS Custom security section in the **Create database**, **Restore snapshot**, and **Restore to point in time** console pages. Choose **Create a new instance profile** to provide an instance profile name suffix. The AWS Management Console creates a new instance profile that has the permissions required for RDS Custom automation tasks. To automatically create new instance profiles, your logged-in AWS Management Console user must have `iam:CreateInstanceProfile`, `iam:AddRoleToInstanceProfile`, `iam:CreateRole`, and `iam:AttachRolePolicy` permissions.

Note

This option is only available in the AWS Management Console. If you are using the CLI or SDK, use the RDS Custom provided CloudFormation template or manually create an instance profile. For more information, see Creating your IAM role and instance profile manually.

Step 1: Grant required permissions to your IAM principal

Make sure that you have sufficient access to create an RDS Custom instance. The IAM role or IAM user (referred to as the *IAM principal*) for creating an RDS Custom for SQL Server DB instance using the console or CLI must have either of the following policies for successful DB instance creation:

- The `AdministratorAccess` policy
- The `AmazonRDSFullAccess` policy with the following additional permissions:

```
iam:SimulatePrincipalPolicy
cloudtrail:CreateTrail
cloudtrail:StartLogging
s3:CreateBucket
s3:PutBucketPolicy
s3:PutBucketObjectLockConfiguration
s3:PutBucketVersioning
kms:CreateGrant
kms:DescribeKey
kms:Decrypt
kms:ReEncryptFrom
kms:ReEncryptTo
kms:GenerateDataKeyWithoutPlaintext
kms:GenerateDataKey
ec2:DescribeImages
ec2:RunInstances
ec2:CreateTags
```

RDS Custom uses these permissions during instance creation. These permissions configure resources in your account that are required for RDS Custom operations.

For more information about the `kms:CreateGrant` permission, see AWS KMS key management.

The following sample JSON policy grants the required permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ValidateIamRole",
            "Effect": "Allow",
            "Action": "iam:SimulatePrincipalPolicy",
            "Resource": "*"
        },
        {
            "Sid": "CreateCloudTrail",
```

```
            "Effect": "Allow",
            "Action": [
                "cloudtrail:CreateTrail",
                "cloudtrail:StartLogging"
            ],
            "Resource": "arn:aws:cloudtrail:*:*:trail/do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateS3Bucket",
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutBucketPolicy",
                "s3:PutBucketObjectLockConfiguration",
                "s3:PutBucketVersioning"
            ],
            "Resource": "arn:aws:s3:::do-not-delete-rds-custom-*"
        },
        {
            "Sid": "CreateKmsGrant",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

The IAM principal requires the following additional permissions to work with custom engine versions (CEVs):

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ConfigureKmsKeyEncryptionPermission",
            "Effect": "Allow",
```

```
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey",
                "kms:Decrypt",
                "kms:ReEncryptFrom",
                "kms:ReEncryptTo",
                "kms:GenerateDataKeyWithoutPlaintext",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key_id"
        },
        {
            "Sid": "CreateEc2Instance",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeImages",
                "ec2:RunInstances",
                "ec2:CreateTags"
            ],
            "Resource": "*"
        }
    ]
}
```

Replace *111122223333* with the ID of the account that you are using to create your instance. Replace *us-east-1* with the AWS Region you are using to create your instance. Replace *key_id* with your customer managed key ID. You can add multiple keys as required.

For more information about the resource-level permissions that are required to launch an EC2 instance, see Launch instances (RunInstances).

Also, the IAM principal requires the `iam:PassRole` permission on the IAM role. That must be attached to the instance profile passed in the `custom-iam-instance-profile` parameter in the request to create the RDS Custom DB instance. The instance profile and its attached role are created later in Step 2: Configure networking, instance profile, and encryption.

> **Note**
>
> Make sure that the previously listed permissions aren't restricted by service control policies (SCPs), permission boundaries, or session policies associated with the IAM principal.

Step 2: Configure networking, instance profile, and encryption

You can configure your IAM instance profile role, virtual private cloud (VPC), and AWS KMS symmetric encryption key by using either of the following processes:

- Configuring with CloudFormation (recommended)
- Configuring manually

> **Note**
>
> If your account is part of any AWS Organizations, make sure that the permissions required by the instance profile role aren't restricted by service control policies (SCPs).
> The networking configurations in this topic work best with DB instances that aren't publicly accessible. You can't connect directly to such DB instances from outside the VPC.

Configuring with CloudFormation

To simplify setup, you can use an CloudFormation template file to create a CloudFormation stack. A CloudFormation template creates all the networking, instance profiles, and encryption resources according the requirements of RDS Custom.

To learn how to create stacks, see Creating a stack on the CloudFormation console in the *CloudFormation User Guide*.

For a tutorial on how to launch Amazon RDS Custom for SQL Server using an CloudFormation template, see Get started with Amazon RDS Custom for SQL Server using an CloudFormation template in the *AWS Database Blog* .

Topics

- Parameters required by CloudFormation
- Download CloudFormation template file
- Configuring resources using CloudFormation

Parameters required by CloudFormation

The following parameters are required to configure RDS Custom prerequisite resources with CloudFormation:

Parameter group	Parameter name	Default Value	Description
Availability Configuration	Select an availability configuration for prerequisites setup	Multi-AZ	Specify whether to setup prerequisites in Single-AZ or Multi-AZ configuration for RDS Custom instances . You should use Multi-AZ configuration if you require at least one Multi-AZ DB instance in this configuration
Network Configuration	IPv4 CIDR block for VPC	10.0.0.0/16	Specify an IPv4 CIDR block (or IP address range) for your VPC. This VPC is configured to create and work with RDS Custom DB instance.
	IPv4 CIDR block for 1 of 2 private subnets	10.0.128.0/20	Specify an IPv4 CIDR block (or IP address range) for your first private subnet. This is one of the two subnets in which the RDS Custom DB instance can be created. This is a private subnet with no access to internet.
	IPv4 CIDR block for 2 of 2 private subnets	10.0.144.0/20	Specify an IPv4 CIDR block (or IP address range) for

Parameter group	Parameter name	Default Value	Description
			your second private subnet. This is one of the two subnets in which the RDS Custom DB instance can be created. This is a private subnet with no access to internet.
	IPv4 CIDR block for public subnet	10.0.0.0/20	Specify an IPv4 CIDR block (or IP address range) for your public subnet. This is one of the subnet in which the EC2 instance can connect with RDS Custom DB instance can be created. This is a public subnet with access to internet.
RDP Access Configuration	IPv4 CIDR block of your source	-	Specify an IPv4 CIDR block (or IP address range) of your source. This is the IP range from where you make RDP connection to EC2 instance in the public subnet. If not set, RDP connection to EC2 instance is not configured.

Parameter group	Parameter name	Default Value	Description
	Setup RDP access to RDS Custom for SQL Server instance	No	Specify whether to enable the RDP connection from the EC2 instance to the RDS Custom for SQL Server instance. By default, RDP connection from the EC2 instance to the DB instance is not configured.

Resources created by CloudFormation

Successfully creating the CloudFormation stack using default settings creates the following resources in your AWS account:

- Symmetric encryption KMS key for encryption of data managed by RDS Custom.
- The instance profile is is associated to an IAM role with `AmazonRDSCustomInstanceProfileRolePolicy` to provide permissions required by RDS Custom. For more information, see AmazonRDSCustomServiceRolePolicy in the *AWS Managed Policy Reference Guide*.
- VPC with the CIDR range specified as the CloudFormation parameter. The default value is `10.0.0.0/16`.
- Two private subnets with the CIDR range specified in the parameters, and two different Availability Zones in the AWS Region. The default values for the subnet CIDRs are `10.0.128.0/20` and `10.0.144.0/20`.
- One public subnet with the CIDR range specified in the parameters. The default value for the subnet CIDR is 10.0.0.0/20. The EC2 instance resides in this subnet and can be used to connect to the RDS Custom instance.
- DHCP option set for the VPC with domain name resolution to an Amazon Domain Name System (DNS) server.
- Route table to associate with two private subnets and no access to the internet.

- Route table to associate with public subnet and has access to the internet.
- Internet gateway associated with the VPC to allow internet access to public subnet.
- Network access control list (ACL) to associate with two private subnets and access restricted to HTTPS and DB port within VPC.
- VPC security group to be associated with the RDS Custom instance. Access is restricted for outbound HTTPS to AWS service endpoints that are required by RDS Custom and inbound DB port from EC2 instance security group.
- VPC security group to be associated with the EC2 instance in public subnet. Access is restricted for outbound DB port to RDS Custom instance security group.
- VPC security group to be associated with VPC endpoints that are created for AWS service endpoints that are required by RDS Custom.
- DB subnet group in which RDS Custom instances are created. Two private subnets created by this template are added to the DB subnet group.
- VPC endpoints for each of the AWS service endpoints that are required by RDS Custom.

Setting availability configuration to multi-az will create following resources in addition to above list:

- Network ACL rules allowing communication between private subnets.
- Inbound and outbound access to Multi-AZ port within VPC security group associated with the RDS Custom instance.
- VPC endpoints to AWS service endpoint(s) that are required for Multi-AZ communication.

In addition, setting RDP access configuration creates the following resources:

- Configuring RDP access to public subnet from your source IP address:
  - Network ACL rules that allow RDP connection from your source IP to public subnet.
  - Ingress access to RDP port from your source IP to VPC security group associated with the EC2 instance.
- Configuring RDP access from EC2 instance in public subnet to RDS Custom Instance in private subnets:
  - Network ACL rules allowing RDP connection from public subnet to private subnets.
  - Inbound access to RDP port from VPC security group associated with the EC2 instance to VPC security group associated with the RDS Custom Instance.

Use the following procedures to create the CloudFormation stack for RDS Custom for SQL Server.

Download CloudFormation template file

To download the template file

1. Open the context (right-click) menu for the link custom-sqlserver-onboard.zip and choose **Save Link As**.
2. Save and extract the file to your computer.

Configuring resources using CloudFormation

To configure resources using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. To start the Create Stack wizard, choose **Create Stack**.

   The **Create stack** page appears.
3. For **Prerequisite - Prepare template**, choose **Template is ready**.
4. For **Specify template**, do the following:

   a. For **Template source**, choose **Upload a template file**.

   b. For **Choose file**, navigate to and then choose the correct file.
5. Choose **Next**.

   The **Specify stack details** page appears.
6. For **Stack name**, enter **`rds-custom-sqlserver`**.
7. For **Parameters**, do the following:

   a. To keep the default options, choose **Next**.

   b. To change options, choose the appropriate availability configuration, networking configuration, and RDP access configuration, and then choose **Next**.

      Read the description of each parameter carefully before changing parameters.

> **Note**
>
> If you choose to create at least one Multi-AZ instance in this CloudFormation stack, make sure that the CloudFormation stack parameter **Select an availability configuration for prerequisites setup** is set to `Multi-AZ`. If you create the CloudFormation stack as Single-AZ, update the CloudFormation stack to Multi-AZ configuration before creating the first Multi-AZ instance.

8. On the **Configure stack options page**, choose **Next.**
9. On the **Review rds-custom-sqlserver** page, do the following:
   a. For **Capabilities**, select the **I acknowledge that CloudFormation might create IAM resources with custom names** check box.
   b. Choose **Create stack**.

> **Note**
>
> Do not update the resources created from this CloudFormation stack directly from the resource pages. This prevents you from applying future updates to these resources by using a CloudFormation template.

CloudFormation creates the resources that RDS Custom for SQL Server requires. If the stack creation fails, read through the **Events** tab to see which resource creation failed and its status reason.

The **Outputs** tab for this CloudFormation stack in the console should have information about all resources to be passed as parameters for creating an RDS Custom for SQL Server DB instance. Make sure to use the VPC security group and DB subnet group created by CloudFormation for RDS Custom DB instances. By default, RDS tries to attach the default VPC security group, which might not have the access that you need.

If you used CloudFormation to create resources, you can skip Configuring manually.

Updating the CloudFormation stack

You can also update some of the configuration on the CloudFormation stack after creation. The configurations that can be updated are:

- Availability Configuration for RDS Custom for SQL Server
  - **Select an availability configuration for prerequisites setup**: Update this parameter to switch between Single-AZ and Multi-AZ configuration. If you are using this CloudFormation stack for at least one Multi-AZ instance, you must update the stack to choose Multi-AZ configuration.
- RDP Access Configuration for RDS Custom for SQL Server
  - IPv4 CIDR block of your source: You can update the IPv4 CIDR block (or IP address range) of your source by updating this parameter. Setting this parameter to blank removes RDP access configuration from your source CIDR block to public subnet.
  - Setup RDP access to RDS Custom for SQL Server: Enable or disable the RDP connection from the EC2 instance to the RDS Custom for SQL Server instance.

Deleting the CloudFormation stack

You can delete the CloudFormation stack after deleting all the RDS Custom instances that uses resources from the stack. RDS Custom doesn't keep track of the CloudFormation stack, hence it doesn't block deletion of the stack when there are DB instances that uses stack resources. Make sure that there are no RDS Custom DB instances that uses the stack resources when deleting the stack.

> **Note**
>
> When you delete a CloudFormation stack, all of the resources created by the stack are deleted except the KMS key. The KMS key goes into a pending-deletion state and is deleted after 30 days. To keep the KMS key, perform a CancelKeyDeletion operation during the 30-day grace period.

Configuring manually

If you choose to configure resources manually, perform the following tasks.

> **Note**
>
> To simplify setup, you can use the CloudFormation template file to create a CloudFormation stack rather than a manual configuration. For more information, see Configuring with CloudFormation.
> You can also use the AWS CLI to complete this section. If so, download and install the latest CLI.

Topics

- Make sure that you have a symmetric encryption AWS KMS key
- Creating your IAM role and instance profile manually
- Configuring your VPC manually

Make sure that you have a symmetric encryption AWS KMS key

A symmetric encryption AWS KMS key is required for RDS Custom. When you create an RDS Custom for SQL Server DB instance, make sure to supply the KMS key identifier as parameter `kms-key-id`. For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

You have the following options:

- If you have an existing customer managed KMS key in your AWS account, you can use it with RDS Custom. No further action is necessary.
- If you already created a customer managed symmetric encryption KMS key for a different RDS Custom engine, you can reuse the same KMS key. No further action is necessary.
- If you don't have an existing customer managed symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the *AWS Key Management Service Developer Guide*.
- If you're creating a CEV or RDS Custom DB instance, and your KMS key is in a different AWS account, make sure to use the AWS CLI. You can't use the AWS console with cross-account KMS keys.

> **Important**
>
> RDS Custom doesn't support AWS managed KMS keys.

Make sure that your symmetric encryption key grants access to the `kms:Decrypt` and `kms:GenerateDataKey` operations to the AWS Identity and Access Management (IAM) role in your IAM instance profile. If you have a new symmetric encryption key in your account, no changes are required. Otherwise, make sure that your symmetric encryption key's policy grants access to these operations.

For more information, see Step 4: Configure IAM for RDS Custom for Oracle.

Creating your IAM role and instance profile manually

You can manually create an instance profile and use it to launch RDS Custom instances. If you plan to create the instance in the AWS Management Console, skip this section. The AWS Management Console allows you to create and attach an instance profile to your RDS Custom DB instances. For more information, see Automated instance profile creation using the AWS Management Console.

When you manually create an instance profile, pass the instance profile name as the `custom-iam-instance-profile` parameter to your `create-db-instance` CLI command. RDS Custom uses the role associated with this instance profile to run automation to manage the instance.

To create the IAM instance profile and IAM roles for RDS Custom for SQL Server

1. Create the IAM role named `AWSRDSCustomSQLServerInstanceRole` with a trust policy that lets Amazon EC2 assume this role.
2. Add the AWS Managed Policy `AmazonRDSCustomInstanceProfileRolePolicy` to `AWSRDSCustomSQLServerInstanceRole`.
3. Create an IAM instance profile for RDS Custom for SQL Server that is named `AWSRDSCustomSQLServerInstanceProfile`.
4. Add `AWSRDSCustomSQLServerInstanceRole` to the instance profile.

Create the AWSRDSCustomSQLServerInstanceRole IAM role

The following example creates the `AWSRDSCustomSQLServerInstanceRole` role. The trust policy lets Amazon EC2 assume the role.

```
aws iam create-role \
    --role-name AWSRDSCustomSQLServerInstanceRole \
    --assume-role-policy-document '{
        "Version": "2012-10-17",
          "Statement": [
            {
              "Action": "sts:AssumeRole",
              "Effect": "Allow",
              "Principal": {
                  "Service": "ec2.amazonaws.com"
              }
            }
          ]
        }'
```

Add an access policy to AWSRDSCustomSQLServerInstanceRole

To provide the required permissions, attach the AWS managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to `AWSRDSCustomSQLServerInstanceRole`. `AmazonRDSCustomInstanceProfileRolePolicy` allows RDS Custom instances to send and receive messages, and perform various automation actions.

> **Note**
>
> Make sure that the permissions in the access policy aren't restricted by SCPs or permission boundaries associated with the instance profile role.

The following example attaches AWS managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to the `AWSRDSCustomSQLServerInstanceRole` role.

```
aws iam attach-role-policy \
    --role-name AWSRDSCustomSQLServerInstanceRole \
    --policy-arn arn:aws:iam::aws:policy/AmazonRDSCustomInstanceProfileRolePolicy
```

Create your RDS Custom for SQL Server instance profile

An instance profile is a container that includes a single IAM role. RDS Custom uses the instance profile to pass the role to the instance.

If you use the AWS Management Console to create a role for Amazon EC2, the console automatically creates an instance profile and gives it the same name as the role when the role is created. Create your instance profile as follows, naming it `AWSRDSCustomSQLServerInstanceProfile`.

```
aws iam create-instance-profile \
    --instance-profile-name AWSRDSCustomSQLServerInstanceProfile
```

Add AWSRDSCustomSQLServerInstanceRole to your RDS Custom for SQL Server instance profile

Add the `AWSRDSCustomInstanceRoleForRdsCustomInstance` role to the previously created `AWSRDSCustomSQLServerInstanceProfile` profile.

```
aws iam add-role-to-instance-profile \
    --instance-profile-name AWSRDSCustomSQLServerInstanceProfile \
    --role-name AWSRDSCustomSQLServerInstanceRole
```

Configuring your VPC manually

Your RDS Custom DB instance is in a virtual private cloud (VPC) based on the Amazon VPC service, just like an Amazon EC2 instance or Amazon RDS instance. You provide and configure your own VPC. Thus, you have full control over your instance networking setup.

RDS Custom sends communication from your DB instance to other AWS services. Make sure the following services are accessible from the subnet in which you create your RDS Custom DB instances:

- Amazon CloudWatch (`com.amazonaws.`*`region`*`.monitoring`)
- Amazon CloudWatch Logs (`com.amazonaws.`*`region`*`.logs`)
- Amazon CloudWatch Events (`com.amazonaws.`*`region`*`.events`)
- Amazon EC2 (`com.amazonaws.`*`region`*`.ec2` and `com.amazonaws.`*`region`*`.ec2messages`)
- Amazon S3 (`com.amazonaws.`*`region`*`.s3`)
- AWS Secrets Manager (`com.amazonaws.`*`region`*`.secretsmanager`)

- AWS Systems Manager (`com.amazonaws.region.ssm` and `com.amazonaws.region.ssmmessages`)

If creating Multi-AZ deployments

- Amazon Simple Queue Service (`com.amazonaws.region.sqs`)

If RDS Custom can't communicate with the necessary services, it publishes the following events:

```
Database instance in incompatible-network. SSM Agent connection not available. Amazon
 RDS can't connect to the dependent AWS services.
```

```
Database instance in incompatible-network. Amazon RDS can't connect to dependent AWS
 services. Make sure port 443 (HTTPS) allows outbound connections, and try again.
 "Failed to connect to the following services: s3 events"
```

To avoid `incompatible-network` errors, make sure that VPC components involved in communication between your RDS Custom DB instance and AWS services satisfy the following requirements:

- The DB instance can make outbound connections on port 443 to other AWS services.
- The VPC allows incoming responses to requests originating from your RDS Custom DB instance.
- RDS Custom can correctly resolve the domain names of endpoints for each AWS service.

If you already configured a VPC for a different RDS Custom DB engine, you can reuse that VPC and skip this process.

Topics

- Configure your VPC security group
- Configure endpoints for dependent AWS services
- Configure the instance metadata service

Configure your VPC security group

A *security group* acts as a virtual firewall for a VPC instance, controlling both inbound and outbound traffic. An RDS Custom DB instance has a security group attached to its network

interface that protects the instance. Make sure that your security group permits traffic between RDS Custom and other AWS services through HTTPS. You pass this security group as the `vpc-security-group-ids` parameter in the instance creation request.

To configure your security group for RDS Custom

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. Allow RDS Custom to use the default security group, or create your own security group.

   For detailed instructions, see Provide access to your DB instance in your VPC by creating a security group.
3. Make sure that your security group permits outbound connections on port 443. RDS Custom needs this port to communicate with dependent AWS services.
4. If you have a private VPC and use VPC endpoints, make sure that the security group associated with the DB instance allows outbound connections on port 443 to VPC endpoints. Also make sure that the security group associated with the VPC endpoint allows inbound connections on port 443 from the DB instance.

   If incoming connections aren't allowed, the RDS Custom instance can't connect to the AWS Systems Manager and Amazon EC2 endpoints. For more information, see Create a Virtual Private Cloud endpoint in the *AWS Systems Manager User Guide*.
5. For RDS Custom for SQL Server Multi-AZ instances, make sure that the security group associated with the DB instance allows inbound and outbound connections on port 1120 to this security group itself. This is required for peer host connection on a Multi-AZ RDS Custom for SQL Server DB instance.

For more information about security groups, see Security groups for your VPC in the *Amazon VPC Developer Guide*.

Configure endpoints for dependent AWS services

We recommend that you add endpoints for every service to your VPC using the following instructions. However, you can use any solution that lets your VPC communicate with AWS service endpoints. For example, you can use Network Address Translation (NAT) or AWS Direct Connect.

To configure endpoints for AWS services with which RDS Custom works

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. On the navigation bar, use the Region selector to choose the AWS Region.
3. In the navigation pane, choose **Endpoints**. In the main pane, choose **Create Endpoint**.
4. For **Service category**, choose **AWS services**.
5. For **Service Name**, choose the endpoint shown in the table.
6. For **VPC**, choose your VPC.
7. For **Subnets**, choose a subnet from each Availability Zone to include.

   The VPC endpoint can span multiple Availability Zones. AWS creates an elastic network interface for the VPC endpoint in each subnet that you choose. Each network interface has a Domain Name System (DNS) host name and a private IP address.
8. For **Security group**, choose or create a security group.

   You can use security groups to control access to your endpoint, much as you use a firewall. Make sure that the security group allows inbound connections on port 443 from the DB instances. For more information about security groups, see Security groups for your VPC in the *Amazon VPC User Guide*.
9. Optionally, you can attach a policy to the VPC endpoint. Endpoint policies can control access to the AWS service to which you are connecting. The default policy allows all requests to pass through the endpoint. If you're using a custom policy, make sure that requests from the DB instance are allowed in the policy.
10. Choose **Create endpoint**.

The following table explains how to find the list of endpoints that your VPC needs for outbound communications.

Service	Endpoint format	Notes and links
AWS Systems Manager	Use the following endpoint formats: • `ssm.region.amazonaws.com` • `ssmmessages. region.amazonaws.com`	For the list of endpoints in each Region, see AWS Systems Manager endpoints and quotas in the *Amazon Web Services General Reference*.

Service	Endpoint format	Notes and links
AWS Secrets Manager	Use the endpoint format `secretsmanager.` *region* `.amazonaws.com .`	For the list of endpoints in each Region, see AWS Secrets Manager endpoints and quotas in the *Amazon Web Services General Reference*.
Amazon CloudWatch	Use the following endpoint formats: • For CloudWatch metrics, use `monitoring.` *region* `.amazonaws.com` • For CloudWatch Events, use `events.`*region*`.amazonaws.com` • For CloudWatch Logs, use `logs.`*region*`.amazonaws.com`	For the list of endpoints in every Region, see: • Amazon CloudWatch endpoints and quotas in the *Amazon Web Services General Reference* • Amazon CloudWatch Logs endpoints and quotas in the *Amazon Web Services General Reference* • Amazon CloudWatch Events endpoints and quotas in the *Amazon Web Services General Reference*
Amazon EC2	Use the following endpoint formats: • `ec2.`*region*`.amazonaws.com` • `ec2messages.` *region* `.amazonaws.com`	For the list of endpoints in each Region, see Amazon Elastic Compute Cloud endpoints and quotas in the *Amazon Web Services General Reference*.

Service	Endpoint format	Notes and links
Amazon S3	Use the endpoint format `s3.region.amazonaws.com` .	For the list of endpoints in each Region, see Amazon Simple Storage Service endpoints and quotas in the *Amazon Web Services General Reference*. To learn more about gateway endpoints for Amazon S3, see Endpoints for Amazon S3 in the *Amazon VPC Developer Guide*. To learn how to create an access point, see Creating access points in the *Amazon VPC Developer Guide*. To learn how to create a gateway endpoints for Amazon S3, see Gateway VPC endpoints.
Amazon Simple Queue Service	Use the endpoint format `sqs.region.amazonaws.com`	For the list of endpoints in each Region, see Amazon Simple Queue Service endpoints and quotas.

Configure the instance metadata service

Make sure that your instance can do the following:

- Access the instance metadata service using Instance Metadata Service Version 2 (IMDSv2).
- Allow outbound communications through port 80 (HTTP) to the IMDS link IP address.
- Request instance metadata from `http://169.254.169.254`, the IMDSv2 link.

For more information, see Use IMDSv2 in the *Amazon EC2 User Guide*.

Cross-instance restriction

When you create an instance profile by following the steps above, it uses the AWS managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to provide the required permissions to RDS Custom which allows instance management and monitoring automation. The managed policy ensures that the permissions allow access to only those resources which RDS Custom requires to run automation. We recommend using the managed policy to support new features and address security requirements which are automatically applied to existing instance profiles without manual intervention. For more information, see AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy.

The `AmazonRDSCustomInstanceProfileRolePolicy` managed policy restricts the instance profile to have cross-account access but it might allow access to some RDS Custom managed resources across RDS Custom instances within the same account. Based on your requirement, you can use permission boundaries to further restrict cross-instance access. Permission boundaries define the maximum permissions that the identity-based policies can grant to an entity, but doesn't grant permissions by themselves. For more information, see Evaluating effective permissions with boundaries.

For example, the following boundary policy restricts instance profile role to access a specific AWS KMS key and limits access to RDS Custom managed resources across instances which are using different AWS KMS keys.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DenyOtherKmsKeyAccess",
            "Effect": "Deny",
            "Action": "kms:*",
            "NotResource": "arn:aws:kms:us-east-1:111122223333:key/KMS_key_ID"
        }
    ]
}
```

Note

Make sure the permissions boundary does not block any permissions that `AmazonRDSCustomInstanceProfileRolePolicy` grants to RDS Custom.

Bring Your Own Media with RDS Custom for SQL Server

RDS Custom for SQL Server supports two licensing models: License Included (LI) and Bring Your Own Media (BYOM).

With BYOM, you can do the following:

1. Provide and install your own Microsoft SQL Server binaries with supported cumulative updates (CU) on an AWS EC2 Windows AMI.
2. Save the AMI as a golden image, which is a template that you can use to create a custom engine version (CEV).
3. Create a CEV from your golden image.
4. Create new RDS Custom for SQL Server DB instances by using your CEV.

Amazon RDS then manages your DB instances for you.

> **Note**
>
> If you also have a License Included (LI) RDS Custom for SQL Server DB instance, you can't use the SQL Server software from this DB instance with BYOM. You must bring your own SQL Server binaries to BYOM.

Requirements for BYOM for RDS Custom for SQL Server

The same general requirements for custom engine versions with RDS Custom for SQL Server also apply to BYOM. For more information, see Requirements for RDS Custom for SQL Server CEVs.

When using BYOM, make you sure that you meet the following additional requirements:

- Use one of the following supported editions: SQL Server 2022 or 2019 Enterprise, Standard, or Developer edition.
- Grant the SQL Server sysadmin (SA) server role privilege to `NT AUTHORITY\SYSTEM`.
- Open TCP port 1433 and UDP port 1434 to allow SSM connections.

Limitations of BYOM for RDS Custom for SQL Server

The same general limitations for RDS Custom for SQL Server also apply to BYOM. For more information, see Requirements and limitations for Amazon RDS Custom for SQL Server.

With BYOM, the following additional limitations apply:

- Only the default SQL Server instance (MSSQLSERVER) is supported. Named SQL Server instances aren't supported. RDS Custom for SQL Server detects and monitors only the default SQL Server instance.
- Only a single installation of SQL Server is supported on each AMI. Multiple installations of different SQL Server versions aren't supported.
- SQL Server Web edition isn't supported with BYOM.
- Evaluation versions of SQL Server editions aren't supported with BYOM. When you install SQL Server, don't select the checkbox for using an evaluation version.
- Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information, see Region availability for RDS Custom for SQL Server CEVs and Version support for RDS Custom for SQL Server CEVs.

Creating an RDS Custom for SQL Server DB instance with BYOM

To prepare and create an RDS Custom for SQL Server DB instance with BYOM, see Preparing a CEV using Bring Your Own Media (BYOM).

Working with custom engine versions for RDS Custom for SQL Server

A *custom engine version (CEV)* for RDS Custom for SQL Server is an Amazon Machine Image (AMI) that includes Microsoft SQL Server.

The basic steps of the CEV workflow are as follows:

1. Choose an AWS EC2 Windows AMI to use as a base image for a CEV. You have the option to use pre-installed Microsoft SQL Server, or bring your own media to install SQL Server yourself.
2. Install other software on the operating system (OS) and customize the configuration of the OS and SQL Server to meet your enterprise needs.
3. Save the AMI as a golden image
4. Create a custom engine version (CEV) from your golden image.
5. Create new RDS Custom for SQL Server DB instances by using your CEV.

Amazon RDS then manages these DB instances for you.

A CEV allows you to maintain your preferred baseline configuration of the OS and database. Using a CEV ensures that the host configuration, such as any third-party agent installation or other OS customizations, are persisted on RDS Custom for SQL Server DB instances. With a CEV, you can quickly deploy fleets of RDS Custom for SQL Server DB instances with the same configuration.

Topics

- Preparing to create a CEV for RDS Custom for SQL Server
- Creating a CEV for RDS Custom for SQL Server
- Modifying a CEV for RDS Custom for SQL Server
- Viewing CEV details for Amazon RDS Custom for SQL Server
- Deleting a CEV for RDS Custom for SQL Server

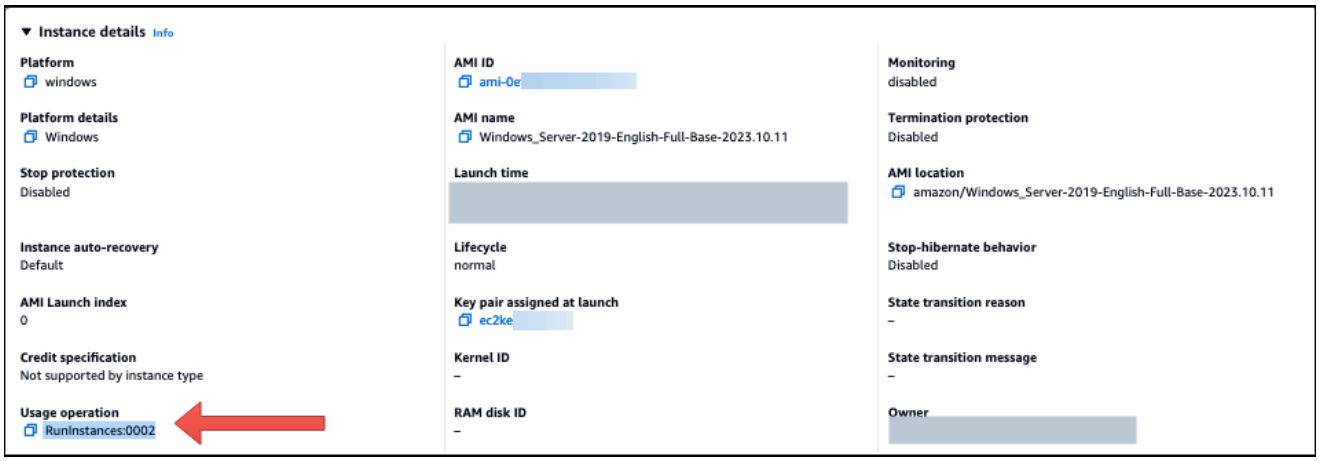
Preparing to create a CEV for RDS Custom for SQL Server

You can create a CEV using an Amazon Machine Image (AMI) that contains pre-installed, License Included (LI) Microsoft SQL Server, or with an AMI on which you install your own SQL Server installation media (BYOM).

Preparing a CEV

Use the following procedures to create a CEV using Bring Your Own Media (BYOM) or pre-installed Microsoft SQL Server (LI).

Preparing a CEV using Bring Your Own Media (BYOM)



The following steps use an AMI with **Windows Server 2019 Base** as an example.

To create a CEV using BYOM

1. On the Amazon EC2 console, choose **Launch Instance**.
2. For **Name**, enter the name of the instance.
3. Under Quick Start, choose **Windows**.
4. Choose **Microsoft Windows Server 2019 Base**.
5. Choose an appropriate instance type, key pair, network and storage settings, and launch the instance.
6. After launching or creating the EC2 instance, ensure the correct Windows AMI was selected from Step 4:

    a. Select the EC2 instance in the Amazon EC2 console.

    b. In the **Details** section, check the **Usage operation** and ensure that it is set to **RunInstances:0002**.

7. Log in to the EC2 instance and copy your SQL Server installation media to it.

> **Note**
>
> If you're building a CEV using SQL Server Developer edition, you may need to obtain the installation media using your Microsoft Visual Studio subscription.

8. Install SQL Server. Make sure that you do the following:

   a. Review Requirements for BYOM for RDS Custom for SQL Server and Version support for RDS Custom for SQL Server CEVs.

   b. Set the instance root directory to the default `C:\Program Files\Microsoft SQL Server\`. Don't change this directory.

   c. Set the SQL Server Database Engine Account Name to either `NT Service\MSSQLSERVER` or `NT AUTHORITY\NETWORK SERVICE`.

   d. Set the SQL Server Startup mode to **Manual**.

   e. Choose SQL Server Authentication mode as **Mixed**.

   f. Leave the current settings for the default Data directories and TempDB locations.

9. Grant the SQL Server sysadmin (SA) server role privilege to `NT AUTHORITY\SYSTEM`:

```
USE [master]
GO
EXEC master..sp_addsrvrolemember @loginame = N'NT AUTHORITY\SYSTEM' , @rolename =
 N'sysadmin'
GO
```

10. Install additional software or customize the OS and database configuration to meet your requirements.

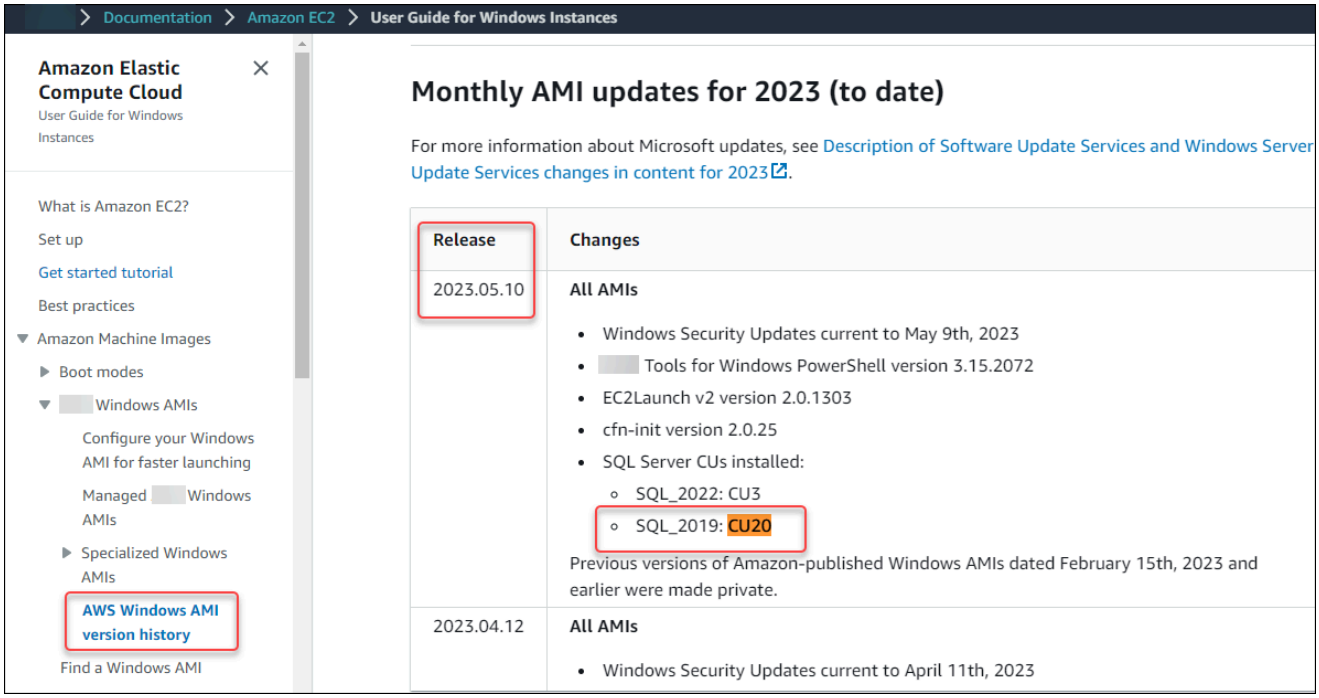
11. Run Sysprep on the EC2 instance. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.

12. Save the AMI that contains your installed SQL Server version, other software, and customizations. This will be your golden image.

13. Create a new CEV by providing the AMI ID of the image that you created. For detailed steps, see Creating a CEV for RDS Custom for SQL Server.

14. Create a new RDS Custom for SQL Server DB instance using the CEV. For detailed steps, see Create an RDS Custom for SQL Server DB instance from a CEV.

Preparing a CEV using pre-installed SQL Server (LI)



The following steps to create a CEV using pre-installed Microsoft SQL Server (LI) use an AMI with **SQL Server CU20** Release number `2023.05.10` as an example. When you create a CEV, choose an AMI with the most recent release number. This ensures that you are using a supported version of Windows Server and SQL Server with the latest Cumulative Update (CU).

To create a CEV using pre-installed Microsoft SQL Server (LI)

1. Choose the latest available AWS EC2 Windows Amazon Machine Image (AMI) with License Included (LI) Microsoft Windows Server and SQL Server.

   a. Search for **CU20** within the Windows AMI version history.

   b. Note the Release number. For SQL Server 2019 CU20, the release number is `2023.05.10`.

   c. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

   d. In the left navigation panel of the Amazon EC2 console choose **Images**, then **AMIs**.

   e. Choose **Public images**.

   f. Enter `2023.05.10` into the search box. A list of AMIs appears.

   g. Enter `Windows_Server-2019-English-Full-SQL_2019` into the search box to filter the results. The following results should appear.

h. Choose the AMI with the SQL Server edition that you want to use.

2. Create or launch an EC2 instance from your chosen AMI.
3. Log in to the EC2 instance and install additional software or customize the OS and database configuration to meet your requirements.
4. Run Sysprep on the EC2 instance. For more information prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.
5. Save the AMI that contains your installed SQL Server version, other software, and customizations. This will be your golden image.
6. Create a new CEV by providing the AMI ID of the image that you created. For detailed steps on creating a CEV, see Creating a CEV for RDS Custom for SQL Server.
7. Create a new RDS Custom for SQL Server DB instance using the CEV. For detailed steps, see Create an RDS Custom for SQL Server DB instance from a CEV.

Region availability for RDS Custom for SQL Server CEVs

Custom engine version (CEV) support for RDS Custom for SQL Server is available in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (Oregon)
- US West (N. California)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)

- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)

Version support for RDS Custom for SQL Server CEVs

CEV creation for RDS Custom for SQL Server is supported for the following AWS EC2 Windows AMIs:

- For CEVs using pre-installed media, AWS EC2 Windows AMIs with License Included (LI) Microsoft Windows Server 2019 (OS) and SQL Server 2022 or 2019
- For CEVs using bring your own media (BYOM), AWS EC2 Windows AMIs with Microsoft Windows Server 2019 (OS)

CEV creation for RDS Custom for SQL Server is supported for the following operating system (OS) and database editions:

- For CEVs using pre-installed media:
  - SQL Server 2022 Enterprise, Standard, or Web, with CU9, CU13, CU14-GDR, CU15-GDR, CU16, CU17, CU18, CU19, CU19-GDR, CU20-GDR, CU21-GDR, CU22 and CU22-GDR.
  - SQL Server 2019 Enterprise, Standard, or Web, with CU8, CU17, CU18, CU20, CU24, CU26, CU28-GDR, CU29-GDR, CU30, CU32, and CU32-GDR.
- For CEVs using bring your own media (BYOM):
  - SQL Server 2022 Enterprise, Standard, or Developer, with CU9, CU13, CU14-GDR, CU15-GDR, CU16, CU17, CU18, CU19, CU19-GDR, CU20-GDR, CU21-GDR, CU22 and CU22-GDR.
  - SQL Server 2019 Enterprise, Standard, or Developer, with CU8, CU17, CU18, CU20, CU24, CU26, CU28-GDR, CU29-GDR, CU30, CU32, and CU32-GDR.

- For CEVs using pre-installed media or bring your own media (BYOM), Windows Server 2019 is the only supported OS.

For more information, see AWS Windows AMI version history.

Requirements for RDS Custom for SQL Server CEVs

The following requirements apply to creating a CEV for RDS Custom for SQL Server:

- The AMI used to create a CEV must be based on an OS and database configuration supported by RDS Custom for SQL Server. For more information on supported configurations, see Requirements and limitations for Amazon RDS Custom for SQL Server.
- The CEV must have a unique name. You can't create a CEV with the same name as an existing CEV.
- You must name the CEV using a naming pattern of SQL Server *major version + minor version + customized string*. The *major version + minor version* must match the SQL Server version provided with the AMI. For example, you can name an AMI with SQL Server 2019 CU17 as **15.00.4249.2.my_cevtest**.
- You must prepare an AMI using Sysprep. For more information about prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.
- You are responsible for maintaining the life cycle of the AMI. An RDS Custom for SQL Server DB instance created from a CEV doesn't store a copy of the AMI. It maintains a pointer to the AMI that you used to create the CEV. The AMI must exist for an RDS Custom for SQL Server DB instance to remain operable.

Limitations for RDS Custom for SQL Server CEVs

The following limitations apply to custom engine versions with RDS Custom for SQL Server:

- You can't delete a CEV if there are resources, such as DB instances or DB snapshots, associated with it.
- To create an RDS Custom for SQL Server DB instance, a CEV must have a status of `pending-validation`, `available`, `failed`, or `validating`. You can't create an RDS Custom for SQL Server DB instance using a CEV if the CEV status is `incompatible-image-configuration`.
- To modify a RDS Custom for SQL Server DB instance to use a new CEV, the CEV must have a status of `available`.

- You can't create an AMI or CEV from an existing RDS Custom for SQL Server DB instance.
- You can't modify an existing CEV to use a different AMI. However, you can modify an RDS Custom for SQL Server DB instance to use a different CEV. For more information, see Modifying an RDS Custom for SQL Server DB instance.
- Encrypting an AMI or CEV with a customer-managed KMS key different than the KMS key provided during DB instance creation is not supported.
- Cross-Region copy of CEVs isn't supported.
- Cross-account copy of CEVs isn't supported.
- You can't restore or recover a CEV after you delete it. However, you can create a new CEV from the same AMI.
- A RDS Custom for SQL Server DB instance stores your SQL Server database files in the *D:*\drive. The AMI associated with a CEV should store the Microsoft SQL Server system database files in the *C:*\ drive.
- An RDS Custom for SQL Server DB instance retains your configuration changes made to SQL Server. Any configuration changes to the OS on a running RDS Custom for SQL Server DB instance created from a CEV aren't retained. If you need to make a permanent configuration change to the OS and have it retained as your new baseline configuration, create a new CEV and modify the DB instance to use the new CEV.

  Important

  Modifying an RDS Custom for SQL Server DB instance to use a new CEV is an offline operation. You can perform the modification immediately or schedule it to occur during a weekly maintenance window.

- When you modify a CEV, Amazon RDS doesn't push those modifications to any associated RDS Custom for SQL Server DB instances. You must modify each RDS Custom for SQL Server DB instance to use the new or updated CEV. For more information, see Modifying an RDS Custom for SQL Server DB instance.
- **Important**

  If an AMI used by a CEV is deleted, any modifications that may require host replacement, for example, scale compute, will fail. The RDS Custom for SQL Server DB instance will then be placed outside of the RDS support perimeter. We recommend that you avoid deleting any AMI that's associated to a CEV.

Creating a CEV for RDS Custom for SQL Server

You can create a custom engine version (CEV) using the AWS Management Console or the AWS CLI. You can then use the CEV to create an RDS Custom for SQL Server DB instance.

Make sure that the Amazon Machine Image (AMI) is in the same AWS account and Region as your CEV. Otherwise, the process to create a CEV fails.

For more information, see Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

> **Important**
>
> The steps to create a CEV are the same for AMIs created with pre-installed SQL Server and those created using bring your own media (BYOM).

Console

To create a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the table is empty.
3. Choose **Create custom engine version**.
4. For **Engine type**, choose **Microsoft SQL Server**.
5. For **Edition**, choose the DB engine edition that you want to use.
6. For **Major version**, choose the major engine version that's installed on your AMI.
7. In **Version details**, enter a valid name in **Custom engine version name**.

   The name format is *major-engine-version*.*minor-engine-version*.*customized_string*. You can use 1–50 alphanumeric characters, underscores, dashes, and periods. For example, you might enter the name **15.00.4249.2.my_cevtest**.

   Optionally, enter a description for your CEV.

8. For **Installation Media**, browse to or enter the AMI ID that you'd like to create the CEV from.
9. In the **Tags** section, add any tags to identify the CEV.
10. Choose **Create custom engine version**.

The **Custom engine versions** page appears. Your CEV is shown with the status **pending-validation**

AWS CLI

To create a CEV by using the AWS CLI, run the create-custom-db-engine-version command.

The following options are required:

- `--engine`
- `--engine-version`
- `--image-id`

You can also specify the following options:

- `--description`
- `--region`
- `--tags`

The following example creates a CEV named `15.00.4249.2.my_cevtest`. Make sure that the name of your CEV begins with the major engine version number.

Example

For Linux, macOS, or Unix:

```
aws rds create-custom-db-engine-version \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4249.2.my_cevtest \
    --image-id ami-0r93cx31t5r596482 \
    --description "Custom SQL Server EE 15.00.4249.2 cev test"
```

The following partial output shows the engine, parameter groups, and other information.

```
"DBEngineVersions": [
    {
    "Engine": "custom-sqlserver-ee",
    "MajorEngineVersion": "15.00",
    "EngineVersion": "15.00.4249.2.my_cevtest",
    "DBEngineDescription": "Microsoft SQL Server Enterprise Edition for RDS Custom for
 SQL Server",
    "DBEngineVersionArn": "arn:aws:rds:us-east-1:<my-account-id>:cev:custom-sqlserver-
ee/15.00.4249.2.my_cevtest/a1234a1-123c-12rd-bre1-1234567890",
    "DBEngineVersionDescription": "Custom SQL Server EE 15.00.4249.2 cev test",

    "Image": [
        "ImageId": "ami-0r93cx31t5r596482",
        "Status": "pending-validation"
     ],
    "CreateTime": "2022-11-20T19:30:01.831000+00:00",
    "SupportsLogExportsToCloudwatchLogs": false,
    "SupportsReadReplica": false,
    "Status": "pending-validation",
    "SupportsParallelQuery": false,
    "SupportsGlobalDatabases": false,
    "TagList": []
    }
]
```

If the process to create a CEV fails, RDS Custom for SQL Server issues `RDS-EVENT-0198` with the message `Creation failed for custom engine version` *`major-engine-version.cev_name`*. The message includes details about the failure, for example, the event prints missing files. To find troubleshooting ideas for CEV creation issues, see Troubleshooting CEV errors for RDS Custom for SQL Server.

Create an RDS Custom for SQL Server DB instance from a CEV

After you successfully create a CEV, the **CEV status** shows `pending-validation`. You can now create a new RDS Custom for SQL Server DB instance using the CEV. To create a new RDS Custom for SQL Server DB instance from a CEV, see Creating an RDS Custom for SQL Server DB instance.

Lifecycle of a CEV

The CEV lifecycle includes the following statuses.

CEV status	Description	Troubleshooting suggestions	
`pending-validation`	A CEV was created and is pending the validation of the associated AMI. A CEV will remain in `pending-validation` until an RDS Custom for SQL Server DB instance is created from it.	If there are no existing tasks, create a new RDS Custom for SQL Server DB instance from the CEV. When creating the RDS Custom for SQL Server DB instance, the system attempts to validate the associated AMI for a CEV.	
`validating`	A creation task for the RDS Custom for SQL Server DB instance based on a new CEV is in progress. When creating the RDS Custom for SQL Server DB instance, the system attempts to validate the associated AMI of a CEV.	Wait for the creation task of the existing RDS Custom for SQL Server DB instance to complete. You can use the RDS EVENTS console to review detailed event messages for troubleshooting.	
`available`	The CEV was successfully validated. A CEV will enter the	The CEV doesn't require any additional validation. It can be used to create additional RDS Custom for SQL Server DB instances or modify existing ones.	

CEV status	Description	Troubleshooting suggestions
	`available` status once an RDS Custom for SQL Server DB instance has been successfu lly created from it.	
`inactive`	The CEV has been modified to an inactive state.	You can't create or upgrade an RDS Custom DB instance with this CEV. Also, you can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV. For information about how to change the state to `ACTIVE`, see Modifying a CEV for RDS Custom for SQL Server.
`failed`	The create DB instance step failed for this CEV before it could validate the AMI. Alternatively, the underlying AMI used by the CEV isn't in an available state.	Troubleshoot the root cause for why the system couldn't create the DB instance. View the detailed error message and try to create a new DB instance again. Ensure that the underlying AMI used by the CEV is in an available state.

CEV status	Description	Troubleshooting suggestions
`incompatible-image-configuration`	There was an error validating the AMI.	View the technical details of the error. You can't attempt to validate the AMI with this CEV again. Review the following: recommendations: • Ensure your CEV is named using the required naming pattern of SQL Server *major version + minor version + customized string*. • Ensure the SQL Server version in the CEV name matches the version provided with the AMI. • Ensure the OS build version meets the minimum required build version. • Ensure the OS major version meets the minimum required major version. Create a new CEV using the correct information. If needed, create a new EC2 instance using a supported AMI and run the Sysprep process on it.

Modifying a CEV for RDS Custom for SQL Server

You can modify a CEV using the AWS Management Console or the AWS CLI. You can modify the CEV description or its availability status. Your CEV has one of the following status values:

- `available` – You can use this CEV to create a new RDS Custom DB instance or upgrade a DB instance. This is the default status for a newly created CEV.
- `inactive` – You can't create or upgrade an RDS Custom DB instance with this CEV. You can't restore a DB snapshot to create a new RDS Custom DB instance with this CEV.

You can change the CEV status from `available` to `inactive` or from `inactive` to `available`. You might change the status to `INACTIVE` to prevent the accidental use of a CEV or to make a discontinued CEV eligible for use again.

Console

To modify a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to modify.
4. For **Actions**, choose **Modify**.
5. Make any of the following changes:
   - For **CEV status settings**, choose a new availability status.
   - For **Version description**, enter a new description.
6. Choose **Modify CEV**.

   If the CEV is in use, the console displays **You can't modify the CEV status**. Fix the problems, then try again.

The **Custom engine versions** page appears.

AWS CLI

To modify a CEV by using the AWS CLI, run the modify-custom-db-engine-version command. You can find CEVs to modify by running the describe-db-engine-versions command.

The following options are required:

- `--engine`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version that you want to modify
- `--status` *`status`*, where *`status`* is the availability status that you want to assign to the CEV

The following example changes a CEV named `15.00.4249.2.my_cevtest` from its current status to `inactive`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-custom-db-engine-version \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4249.2.my_cevtest \
    --status inactive
```

For Windows:

```
aws rds modify-custom-db-engine-version ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4249.2.my_cevtest ^
    --status inactive
```

To modify an RDS Custom for SQL Server DB instance to use a new CEV, see Modifying an RDS Custom for SQL Server DB instance to use a new CEV.

Modifying an RDS Custom for SQL Server DB instance to use a new CEV

You can modify an existing RDS Custom for SQL Server DB instance to use a different CEV. The changes that you can make include:

- Changing the CEV
- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window

Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.

5. Make the following changes as needed:

   a. For **DB engine version**, choose a different CEV.

   b. Change the value for **DB instance class**. For supported classes, see DB instance class support for RDS Custom for SQL Server.

   c. Change the value for **Backup retention period**.

   d. For **Backup window**, set values for the **Start time** and **Duration**.

   e. For **DB instance maintenance window**, set values for the **Start day**, **Start time**, and **Duration**.

6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

> **Note**
>
> When modifying a DB instance from one CEV to an another CEV, for example, when upgrading a minor version, the SQL Server system databases, including their data and configurations, are persisted from the current RDS Custom for SQL Server DB instance.

AWS CLI

To modify a DB instance to use a different CEV by using the AWS CLI, run the modify-db-instance command.

The following options are required:

- `--db-instance-identifier`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version that you want the DB instance to change to.

The following example modifies a DB instance named `my-cev-db-instance` to use a CEV named `15.00.4249.2.my_cevtest_new` and applies the change immediately.

Example

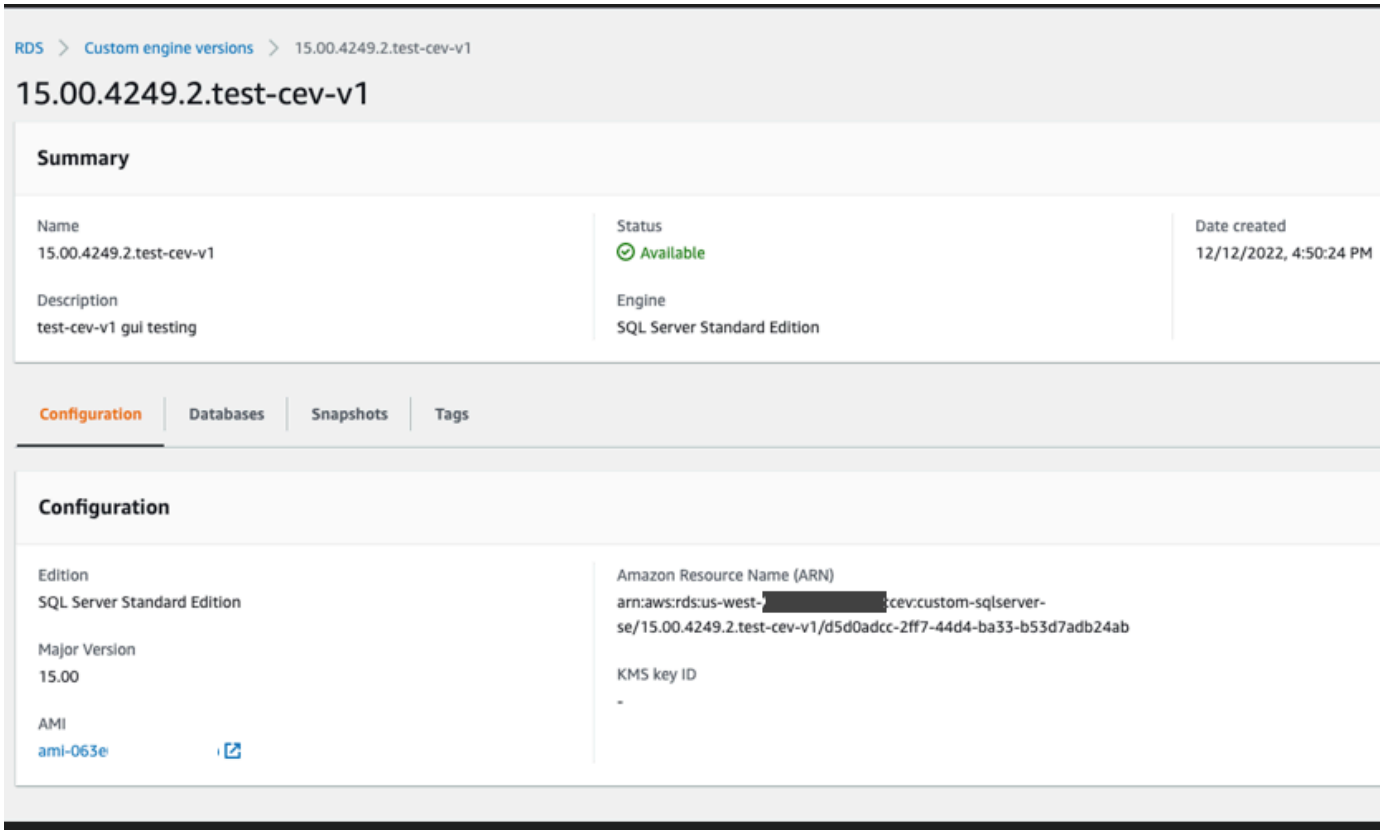
For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-cev-db-instance \
    --engine-version 15.00.4249.2.my_cevtest_new \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-cev-db-instance ^
    --engine-version 15.00.4249.2.my_cevtest_new ^
    --apply-immediately
```

Viewing CEV details for Amazon RDS Custom for SQL Server



You can view details about your CEV by using the AWS Management Console or the AWS CLI.

Console

To view CEV details

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.

   The **Custom engine versions** page shows all CEVs that currently exist. If you haven't created any CEVs, the page is empty.
3. Choose the name of the CEV that you want to view.
4. Choose **Configuration** to view the details.

AWS CLI

To view details about a CEV by using the AWS CLI, run the [describe-db-engine-versions](#) command.

You can also specify the following options:

- `--include-all`, to view all CEVs with any lifecycle state. Without the `--include-all` option, only the CEVs in an `available` lifecycle state will be returned.

```
aws rds describe-db-engine-versions --engine custom-sqlserver-ee --engine-version
 15.00.4249.2.my_cevtest --include-all
{
    "DBEngineVersions": [
        {
            "Engine": "custom-sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "EngineVersion": "15.00.4249.2.my_cevtest",
            "DBParameterGroupFamily": "custom-sqlserver-ee-15.0",
            "DBEngineDescription": "Microsoft SQL Server Enterprise Edition for custom
 RDS",
```

```
            "DBEngineVersionArn": "arn:aws:rds:us-east-1:{my-account-id}:cev:custom-
sqlserver-ee/15.00.4249.2.my_cevtest/a1234a1-123c-12rd-bre1-1234567890",
            "DBEngineVersionDescription": "Custom SQL Server EE 15.00.4249.2 cev test",
            "Image": {
                "ImageId": "ami-0r93cx31t5r596482",
                "Status": "pending-validation"
            },
            "DBEngineMediaType": "AWS Provided",
            "CreateTime": "2022-11-20T19:30:01.831000+00:00",
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": false,
            "SupportedFeatureNames": [],
            "Status": "pending-validation",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "TagList": [],
            "SupportsBabelfish": false
        }
    ]
}
```

You can use filters to view CEVs with a certain lifecycle status. For example, to view CEVs that have a lifecycle status of either `pending-validation`, `available`, or `failed`:

```
aws rds describe-db-engine-versions engine custom-sqlserver-ee
                region us-west-2 include-all query 'DBEngineVersions[?Status ==
 pending-validation ||
                Status == available || Status == failed]'
```

Deleting a CEV for RDS Custom for SQL Server

You can delete a CEV using the AWS Management Console or the AWS CLI. Typically, this task takes a few minutes.

Before deleting a CEV, make sure it isn't being used by any of the following:

- An RDS Custom DB instance
- A snapshot of an RDS Custom DB instance
- An automated backup of your RDS Custom DB instance

Console

To delete a CEV

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Custom engine versions**.
3. Choose a CEV whose description or status you want to delete.
4. For **Actions**, choose **Delete**.

   The **Delete *cev_name*?** dialog box appears.
5. Enter **`delete me`**, and then choose **Delete**.

   In the **Custom engine versions** page, the banner shows that your CEV is being deleted.

AWS CLI

To delete a CEV by using the AWS CLI, run the delete-custom-db-engine-version command.

The following options are required:

- `--engine custom-sqlserver-ee`
- `--engine-version` *`cev`*, where *`cev`* is the name of the custom engine version to be deleted

The following example deletes a CEV named `15.00.4249.2.my_cevtest`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-custom-db-engine-version \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4249.2.my_cevtest
```

For Windows:

```
aws rds delete-custom-db-engine-version ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4249.2.my_cevtest
```

Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server

You can create an RDS Custom DB instance, and then connect to it using AWS Systems Manager or Remote Desktop Protocol (RDP).

Important

Before you can create or connect to an RDS Custom for SQL Server DB instance, make sure to complete the tasks in Setting up your environment for Amazon RDS Custom for SQL Server.

You can tag RDS Custom DB instances when you create them, but don't create or modify the `AWSRDSCustom` tag that's required for RDS Custom automation. For more information, see Tagging RDS Custom for SQL Server resources.

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Topics

- Creating an RDS Custom for SQL Server DB instance
- RDS Custom service-linked role
- Connecting to your RDS Custom DB instance using AWS Systems Manager
- Connecting to your RDS Custom DB instance using RDP

Creating an RDS Custom for SQL Server DB instance

Create an Amazon RDS Custom for SQL Server DB instance using either the AWS Management Console or the AWS CLI. The procedure is similar to the procedure for creating an Amazon RDS DB instance.

For more information, see Creating an Amazon RDS DB instance.

Console

To create an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**.
4. Choose **Standard create** for the database creation method.
5. For **Engine options**, choose **Microsoft SQL Server** for the engine type.
6. For **Database management type**, choose **Amazon RDS Custom**.
7. In the **Edition** section, choose the DB engine edition that you want to use.
8. (Optional) If you intend to create the DB instance from a CEV, check the **Use custom engine version (CEV)** check box. Select your CEV in the drop-down list.
9. For **Database version**, keep the default value version.
10. For **Templates**, choose **Production**.
11. In the **Settings** section, enter a unique name for the **DB instance identifier**.
12. To enter your master password, do the following:

    a. In the **Settings** section, open **Credential Settings**.

    b. Clear the **Auto generate a password** check box.

    c. Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

    By default, the new RDS Custom DB instance uses an automatically generated password for the master user.
13. In the **DB instance size** section, choose a value for **DB instance class**.

    For supported classes, see DB instance class support for RDS Custom for SQL Server.
14. Choose **Storage** settings.
15. For **RDS Custom security**, do the following:

    a. For **IAM instance profile**, you have two options to choose the instance profile for your RDS Custom for SQL Server DB instance.

1. Choose **Create a new instance profile** and provide an instance profile name suffix. For more information, see Automated instance profile creation using the AWS Management Console.
2. Choose an existing instance profile. From the ddropdown list, choose instance profile that begins with `AWSRDSCustom`.

b. For **Encryption**, choose **Enter a key ARN** to list the available AWS KMS keys. Then choose your key from the list.

An AWS KMS key is required for RDS Custom. For more information, see Make sure that you have a symmetric encryption AWS KMS key.

16. For the remaining sections, specify your preferred RDS Custom DB instance settings. For information about each setting, see Settings for DB instances. The following settings don't appear in the console and aren't supported:

- **Processor features**
- **Storage autoscaling**
- **Availability & durability**
- **Password and Kerberos authentication** option in **Database authentication** (only **Password authentication** is supported)
- **Database options** group in **Additional configuration**
- **Performance Insights**
- **Log exports**
- **Enable auto minor version upgrade**
- **Deletion protection**

Backup retention period is supported, but you can't choose **0 days**.

17. Choose **Create database**.

The **View credential details** button appears on the **Databases** page.

To view the master user name and password for the RDS Custom DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

> **Important**
>
> You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the RDS Custom DB instance is available, modify the DB instance. For more information about modifying a DB instance, see Managing an Amazon RDS Custom for SQL Server DB instance.

18. Choose **Databases** to view the list of RDS Custom DB instances.
19. Choose the RDS Custom DB instance that you just created.

    On the RDS console, the details for the new RDS Custom DB instance appear:

    - The DB instance has a status of **creating** until the RDS Custom DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the instance class and storage allocated, it can take several minutes for the new DB instance to be available.
    - **Role** has the value **Instance (RDS Custom)**.
    - **RDS Custom automation mode** has the value **Full automation**. This setting means that the DB instance provides automatic monitoring and instance recovery.

AWS CLI

You create an RDS Custom DB instance by using the create-db-instance AWS CLI command.

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class` (for a list of supported instance classes, see DB instance class support for RDS Custom for SQL Server)
- `--engine` (`custom-sqlserver-ee`, `custom-sqlserver-se`, or `custom-sqlserver-web`)
- `--kms-key-id`
- `--custom-iam-instance-profile`

The following example creates an RDS Custom for SQL Server DB instance named `my-custom-instance`. The backup retention period is 3 days.

> **Note**
>
> To create a DB instance from a custom engine version (CEV), supply an existing CEV name to the `--engine-version` parameter. For example, `--engine-version 15.00.4249.2.my_cevtest`

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine custom-sqlserver-ee \
    --engine-version 15.00.4073.23.v1 \
    --db-instance-identifier my-custom-instance \
    --db-instance-class db.m5.xlarge \
    --allocated-storage 20 \
    --db-subnet-group mydbsubnetgroup \
    --master-username myuser \
    --master-user-password mypassword \
    --backup-retention-period 3 \
    --no-multi-az \
    --port 8200 \
    --kms-key-id mykmskey \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

For Windows:

```
aws rds create-db-instance ^
    --engine custom-sqlserver-ee ^
    --engine-version 15.00.4073.23.v1 ^
    --db-instance-identifier my-custom-instance ^
    --db-instance-class db.m5.xlarge ^
    --allocated-storage 20 ^
    --db-subnet-group mydbsubnetgroup ^
    --master-username myuser ^
    --master-user-password mypassword ^
    --backup-retention-period 3 ^
    --no-multi-az ^
    --port 8200 ^
    --kms-key-id mykmskey ^
```

```
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Get details about your instance by using the `describe-db-instances` command.

```
aws rds describe-db-instances --db-instance-identifier my-custom-instance
```

The following partial output shows the engine, parameter groups, and other information.

```
{
    "DBInstances": [
        {
            "PendingModifiedValues": {},
            "Engine": "custom-sqlserver-ee",
            "MultiAZ": false,
            "DBSecurityGroups": [],
            "DBParameterGroups": [
                {
                    "DBParameterGroupName": "default.custom-sqlserver-ee-15",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
            "AutomationMode": "full",
            "DBInstanceIdentifier": "my-custom-instance",
            "TagList": []
        }
    ]
}
```

RDS Custom service-linked role

A *service-linked role* gives Amazon RDS Custom access to resources in your AWS account. It makes using RDS Custom easier because you don't have to manually add the necessary permissions. RDS Custom defines the permissions of its service-linked roles, and unless defined otherwise, only RDS Custom can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

When you create an RDS Custom DB instance, both the Amazon RDS and RDS Custom service-linked roles are created (if they don't already exist) and used. For more information, see Using service-linked roles for Amazon RDS.

The first time that you create an RDS Custom for SQL Server DB instance, you might receive the following error: The service-linked role is in the process of being created. Try again later. If you do, wait a few minutes and then try again to create the DB instance.

Connecting to your RDS Custom DB instance using AWS Systems Manager

After you create your RDS Custom DB instance, you can connect to it using AWS Systems Manager Session Manager. Session Manager is a Systems Manager capability that you can use to manage Amazon EC2 instances through a browser-based shell or through the AWS CLI. For more information, see AWS Systems Manager Session Manager.

Console

To connect to your DB instance using Session Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose **Configuration**.
4. Note the **Resource ID** value for your DB instance. For example, the resource ID might be `db-ABCDEFGHIJKLMNOPQRS0123456`.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it. For example, the instance ID might be `i-abcdefghijklm01234`.
8. Choose **Connect**.
9. Choose **Session Manager**.
10. Choose **Connect**.

    A window opens for your session.

AWS CLI

You can connect to your RDS Custom DB instance using the AWS CLI. This technique requires the Session Manager plugin for the AWS CLI. To learn how to install the plugin, see Install the Session Manager plugin for the AWS CLI.

To find the DB resource ID of your RDS Custom DB instance, use `describe-db-instances`.

```
aws rds describe-db-instances \
    --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
    --output text
```

The following sample output shows the resource ID for your RDS Custom instance. The prefix is `db-`.

```
db-ABCDEFGHIJKLMNOPQRS0123456
```

To find the EC2 instance ID of your DB instance, use `aws ec2 describe-instances`. The following example uses `db-ABCDEFGHIJKLMNOPQRS0123456` for the resource ID.

```
aws ec2 describe-instances \
    --filters "Name=tag:Name,Values=db-ABCDEFGHIJKLMNOPQRS0123456" \
    --output text \
    --query 'Reservations[*].Instances[*].InstanceId'
```

The following sample output shows the EC2 instance ID.

```
i-abcdefghijklm01234
```

Use the `aws ssm start-session` command, supplying the EC2 instance ID in the `--target` parameter.

```
aws ssm start-session --target "i-abcdefghijklm01234"
```

A successful connection looks like the following.

```
Starting session with SessionId: yourid-abcdefghijklm1234
[ssm-user@ip-123-45-67-89 bin]$
```

Connecting to your RDS Custom DB instance using RDP

After you create your RDS Custom DB instance, you can connect to this instance using an RDP client. The procedure is the same as for connecting to an Amazon EC2 instance. For more information, see Connect to your Windows instance.

To connect to the DB instance, you need the key pair associated with the instance. RDS Custom creates the key pair for you. The pair name uses the prefix `do-not-delete-rds-custom-`*`DBInstanceIdentifier`*. AWS Secrets Manager stores your private key as a secret.

Complete the task in the following steps:

1. Configure your DB instance to allow RDP connections.
2. Retrieve your secret key.
3. Connect to your EC2 instance using the RDP utility.

Configure your DB instance to allow RDP connections

To allow RDP connections, configure your VPC security group and set a firewall rule on the host.

Configure your VPC security group

Make sure that the VPC security group associated with your DB instance permits inbound connections on port 3389 for Transmission Control Protocol (TCP). To learn how to configure your VPC security group, see Configure your VPC security group.

Set the firewall rule on the host

To permit inbound connections on port 3389 for TCP, set a firewall rule on the host. The following examples show how to do this.

We recommend that you use the specific `-Profile` value: `Public`, `Private`, or `Domain`. Using `Any` refers to all three values. You can also specify a combination of values separated by a comma. For more information about setting firewall rules, see Set-NetFirewallRule in the Microsoft documentation.

To use Systems Manager Session Manager to set a firewall rule

1. Connect to Session Manager as shown in Connecting to your RDS Custom DB instance using AWS Systems Manager.
2. Run the following command.

```
Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction
 Inbound -LocalAddress Any -Profile Any
```

To use Systems Manager CLI commands to set a firewall rule

1. Use the following command to open RDP on the host.

```
OPEN_RDP_COMMAND_ID=$(aws ssm send-command --region $AWS_REGION \
    --instance-ids $RDS_CUSTOM_INSTANCE_EC2_ID \
    --document-name "AWS-RunPowerShellScript" \
    --parameters '{"commands":["Set-NetFirewallRule -DisplayName \"Remote Desktop -
 User Mode (TCP-In)\" -Direction Inbound -LocalAddress Any -Profile Any"]}' \
    --comment "Open RDP port" | jq -r ".Command.CommandId")
```

2. Use the command ID returned in the output to get the status of the previous command. To use the following query to return the command ID, make sure that you have the jq plug-in installed.

```
aws ssm list-commands \
    --region $AWS_REGION \
    --command-id $OPEN_RDP_COMMAND_ID
```

Retrieve your secret key

Retrieve your secret key using either AWS Management Console or the AWS CLI.

Console

To retrieve the secret key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance to which you want to connect.
3. Choose the **Configuration** tab.
4. Note the **DB instance ID** for your DB instance, for example, *my-custom-instance*.
5. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

6. In the navigation pane, choose **Instances**.
7. Look for the name of your EC2 instance, and then choose the instance ID associated with it.

   In this example, the instance ID is `i-abcdefghijklm01234`.
8. In **Details**, find **Key pair name**. The pair name includes the DB identifier. In this example, the pair name is `do-not-delete-rds-custom-`*`my-custom-instance`*`-`*`0d726c`*.
9. In the instance summary, find **Public IPv4 DNS**. For the example, the public DNS might be `ec2-12-345-678-901.us-east-2.compute.amazonaws.com`.
10. Open the AWS Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
11. Choose the secret that has the same name as your key pair.
12. Choose **Retrieve secret value**.

AWS CLI

To retrieve the private key

1. Get the list of your RDS Custom DB instances by calling the `aws rds describe-db-instances` command.

   ```
   aws rds describe-db-instances \
       --query 'DBInstances[*].[DBInstanceIdentifier,DbiResourceId]' \
       --output text
   ```
2. Choose the DB instance identifier from the sample output, for example `do-not-delete-rds-custom-`*`my-custom-instance`*.
3. Find the EC2 instance ID of your DB instance by calling the `aws ec2 describe-instances` command. The following example uses the EC2 instance name to describe the DB instance.

   ```
   aws ec2 describe-instances \
       --filters "Name=tag:Name,Values=do-not-delete-rds-custom-my-custom-instance" \
       --output text \
       --query 'Reservations[*].Instances[*].InstanceId'
   ```

   The following sample output shows the EC2 instance ID.

   ```
   i-abcdefghijklm01234
   ```

4. Find the key name by specifying the EC2 instance ID, as shown in the following example.

```
aws ec2 describe-instances \
    --instance-ids i-abcdefghijklm01234 \
    --output text \
    --query 'Reservations[*].Instances[*].KeyName'
```

The following sample output shows the key name, which uses the prefix `do-not-delete-rds-custom-`*`DBInstanceIdentifier`*.

```
do-not-delete-rds-custom-my-custom-instance-0d726c
```

Connect to your EC2 instance using the RDP utility

Follow the procedure in Connect to your Windows instance using RDP in the *Amazon EC2 User Guide*. This procedure assumes that you created a .pem file that contains your private key.

Managing an Amazon RDS Custom for SQL Server DB instance

Amazon RDS Custom for SQL Server supports a subset of the usual management tasks for Amazon RDS DB instances. Following, you can find instructions for the supported RDS Custom for SQL Server management tasks using the AWS Management Console and the AWS CLI.

Topics

- Pausing and resuming RDS Custom automation
- Modifying an RDS Custom for SQL Server DB instance
- Modifying the storage for an RDS Custom for SQL Server DB instance
- Tagging RDS Custom for SQL Server resources
- Deleting an RDS Custom for SQL Server DB instance
- Starting and stopping an RDS Custom for SQL Server DB instance

Pausing and resuming RDS Custom automation

RDS Custom automatically provides monitoring and instance recovery for an RDS Custom for SQL Server DB instance. If you need to customize the instance, do the following:

1. Pause RDS Custom automation for a specified period. The pause ensures that your customizations don't interfere with RDS Custom automation.
2. Customize the RDS Custom for SQL Server DB instance as needed.
3. Do either of the following:
   - Resume automation manually.
   - Wait for the pause period to end. In this case, RDS Custom resumes monitoring and instance recovery automatically.

> **Important**
>
> Pausing and resuming automation are the only supported automation tasks when modifying an RDS Custom for SQL Server DB instance.

Console

To pause or resume RDS Custom automation

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **RDS Custom automation mode**, choose one of the following options:
   - **Paused** pauses the monitoring and instance recovery for the RDS Custom DB instance. Enter the pause duration that you want (in minutes) for **Automation mode duration**. The minimum value is 60 minutes (default). The maximum value is 1,440 minutes.
   - **Full automation** resumes automation.
5. Choose **Continue** to check the summary of modifications.

   A message indicates that RDS Custom will apply the changes immediately.
6. If your changes are correct, choose **Modify DB instance**. Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

   On the RDS console, the details for the modification appear. If you paused automation, the **Status** of your RDS Custom DB instance indicates **Automation paused**.
7. (Optional) In the navigation pane, choose **Databases**, and then your RDS Custom DB instance.

   In the **Summary** pane, **RDS Custom automation mode** indicates the automation status. If automation is paused, the value is **Paused. Automation resumes in *num* minutes**.

AWS CLI

To pause or resume RDS Custom automation, use the `modify-db-instance` AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. Control the automation mode with the following parameters:

- `--automation-mode` specifies the pause state of the DB instance. Valid values are `all-paused`, which pauses automation, and `full`, which resumes it.

- `--resume-full-automation-mode-minutes` specifies the duration of the pause. The default value is 60 minutes.

> **Note**
>
> Regardless of whether you specify `--no-apply-immediately` or `--apply-immediately`, RDS Custom applies modifications asynchronously as soon as possible.

In the command response, `ResumeFullAutomationModeTime` indicates the resume time as a UTC timestamp. When the automation mode is `all-paused`, you can use `modify-db-instance` to resume automation mode or extend the pause period. No other `modify-db-instance` options are supported.

The following example pauses automation for `my-custom-instance` for 90 minutes.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 90
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 90
```

The following example extends the pause duration for an extra 30 minutes. The 30 minutes is added to the original time shown in `ResumeFullAutomationModeTime`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
```

```
    --db-instance-identifier my-custom-instance \
    --automation-mode all-paused \
    --resume-full-automation-mode-minutes 30
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode all-paused ^
    --resume-full-automation-mode-minutes 30
```

The following example resumes full automation for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --automation-mode full \
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --automation-mode full
```

In the following partial sample output, the pending `AutomationMode` value is `full`.

```
{
    "DBInstance": {

Modifying an RDS Custom for SQL Server DB instance

Modifying an RDS Custom for SQL Server DB instance is similar to doing this for Amazon RDS, but the changes that you can make are limited to the following:

- Changing the DB instance class
- Changing the backup retention period and backup window
- Changing the maintenance window
- Upgrading the DB engine version when a new version becomes available
- Changing the allocated storage, provisioned IOPS, and storage type
- Allowing and removing Multi-AZ deployments

The following limitations apply to modifying an RDS Custom for SQL Server DB instance:

- Custom DB option and parameter groups aren't supported.
- Any storage volumes that you attach manually to your RDS Custom DB instance are outside the support perimeter.

  For more information, see RDS Custom support perimeter.

Console

To modify an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:

a. For **DB engine version**, choose the new version.

b. Change the value for **DB instance class**. For supported classes, see DB instance class support for RDS Custom for SQL Server

c. Change the value for **Backup retention period**.

d. For **Backup window**, set values for the **Start time** and **Duration**.

e. For **DB instance maintenance window**, set values for the **Start day**, **Start time**, and **Duration**.

6. Choose **Continue**.
7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- `--db-instance-class` – For supported classes, see DB instance class support for RDS Custom for SQL Server
- `--engine-version` – The version number of the database engine to which you're upgrading.
- `--backup-retention-period` – How long to retain automated backups, from 0–35 days.
- `--preferred-backup-window` – The daily time range during which automated backups are created.
- `--preferred-maintenance-window` – The weekly time range (in UTC) during which system maintenance can occur.
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

  Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

Modifying the storage for an RDS Custom for SQL Server DB instance

Modifying storage for an RDS Custom for SQL Server DB instance is similar to modifying storage for an Amazon RDS DB instance, but you can only do the following:

- Increase the allocated storage size.
- Change the storage type. You can use available storage types such as General Purpose or Provisioned IOPS. Provisioned IOPS is supported for the gp3, io1, and io2 Block Express storage types.
- Change the provisioned IOPS, if you're using the volume types that support Provisioned IOPS.

The following limitations apply to modifying the storage for an RDS Custom for SQL Server DB instance:

- The minimum allocated storage size for RDS Custom for SQL Server is 20 GiB. The maximum storage limit for io1, gp2, and gp3 is 16 TiB while io2 supports 64 TiB.
- As with Amazon RDS, you can't decrease the allocated storage. This is a limitation of Amazon Elastic Block Store (Amazon EBS) volumes. For more information, see Working with storage for Amazon RDS DB instances
- Storage autoscaling isn't supported for RDS Custom for SQL Server DB instances.
- Any storage volumes that you manually attach to your RDS Custom DB instance are not considered for storage scaling. Only the RDS-provided default data volumes, i.e., the D drive, are considered for storage scaling.

  For more information, see RDS Custom support perimeter.
- Scaling storage usually doesn't cause any outage or performance degradation of the DB instance. After you modify the storage size for a DB instance, the status of the DB instance is **storage-optimization**.
- Storage optimization can take several hours. You can't make further storage modifications for either six (6) hours or until storage optimization has completed on the instance, whichever is longer. For more information, see Working with storage for Amazon RDS DB instances

For more information about storage, see Amazon RDS DB instance storage.

For general information about storage modification, see Working with storage for Amazon RDS DB instances.

Important

Do not modify storage for your RDS Custom for SQL Server DB instance using Amazon EC2 or Amazon EBS consoles or APIs. Direct storage modifications outside of Amazon RDS console or APIs result in an `unsupported-configuration` state for your database. When you make direct storage changes using Amazon EC2 or Amazon EBS, Amazon RDS cannot track or manage your database instance state. This might cause:

- High availability failover mechanisms from functioning correctly
- Database replication setups to break
- Redundancy features to fail

Modify storage only through Amazon RDS console or APIs to keep your database in a supported state. See Fixing unsupported configurations in RDS Custom for SQL Server for recovery steps.

Console

To modify the storage for an RDS Custom for SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Make the following changes as needed:
   a. Enter a new value for **Allocated storage**. It must be greater than the current value, and from 20 GiB–16 TiB.
   b. Change the value for **Storage type**. You can choose from the available General Purpose or Provisioned IOPS storage types. Provisioned IOPS is supported for the gp3, io1, and io2 Block Express storage types.
   c. If you're specifying a storage type that supports Provisioned IOPS, you can define the **Provisioned IOPS** value.
6. Choose **Continue**.

7. Choose **Apply immediately** or **Apply during the next scheduled maintenance window**.
8. Choose **Modify DB instance**.

AWS CLI

To modify the storage for an RDS Custom for SQL Server DB instance, use the modify-db-instance AWS CLI command. Set the following parameters as needed:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes. It must be greater than the current value, and from 20–16,384 GiB.
- `--storage-type` – The storage type, for example, gp2, gp3, io1, or io2.
- `--iops` – Provisioned IOPS for the DB instance. You can specify this only for storage types that support Provisioned IOPS (gp3, io1, and io2).
- `--apply-immediately` – Use `--apply-immediately` to apply the storage changes immediately.

  Or use `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

The following example changes the storage size of my-custom-instance to 200 GiB, storage type to io1, and Provisioned IOPS to 3000.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --storage-type io1 \
    --iops 3000 \
    --allocated-storage 200 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --storage-type io1 ^
```

```
    --iops 3000 ^
    --allocated-storage 200 ^
    --apply-immediately
```

Tagging RDS Custom for SQL Server resources

You can tag RDS Custom resources as with Amazon RDS resources, but with some important differences:

- Don't create or modify the `AWSRDSCustom` tag that's required for RDS Custom automation. If you do, you might break the automation.
- The `Name` tag is added to RDS Custom resources with the prefix `do-not-delete-rds-custom`. Any customer-passed value for the key is overwritten.
- Tags added to RDS Custom DB instances during creation are propagated to all other related RDS Custom resources.
- Tags aren't propagated when you add them to RDS Custom resources after DB instance creation.

For general information about resource tagging, see Tagging Amazon RDS resources.

Deleting an RDS Custom for SQL Server DB instance

To delete an RDS Custom for SQL Server DB instance, do the following:

- Provide the name of the DB instance.
- Choose or clear the option to take a final DB snapshot of the DB instance.
- Choose or clear the option to retain automated backups.

You can delete an RDS Custom for SQL Server DB instance using the console or the CLI. The time required to delete the DB instance can vary depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

> **Warning**
>
> Deleting a RDS Custom for SQL Server DB instance will permanently delete the EC2 instance and the associated Amazon EBS volumes. You shouldn’t terminate or delete these resources at any time, otherwise, the deletion and the final snapshot creation may fail.

Note

You can't create a final DB snapshot of your DB instance if it has a status of `creating`, `failed`, `incompatible-create`, `incompatible-restore`, or `incompatible-network`. For more information, see Viewing Amazon RDSDB instance status.

Important

When you choose to take a final snapshot, we recommend that you avoid writing data to your DB instance while the DB instance deletion is in progress. Once the DB instance deletion is initiated, data changes are not guaranteed to be captured by the final snapshot.

Console

To delete an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the RDS Custom for SQL Server DB instance that you want to delete. RDS Custom for SQL Server DB instances show the role **Instance (RDS Custom for SQL Server)**.
3. For **Actions**, choose **Delete**.
4. To take a final snapshot, choose **Create final snapshot**, and provide a name for the **Final snapshot name**.
5. To retain automated backups, choose **Retain automated backups**.
6. Enter **`delete me`** in the box.
7. Choose **Delete**.

AWS CLI

You delete an RDS Custom for SQL Server DB instance by using the delete-db-instance AWS CLI command. Identify the DB instance using the required parameter `--db-instance-identifier`. The remaining parameters are the same as for an Amazon RDS DB instance.

The following example deletes the RDS Custom for SQL Server DB instance named `my-custom-instance`, takes a final snapshot, and retains automated backups.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier my-custom-instance \
    --no-skip-final-snapshot \
    --final-db-snapshot-identifier my-custom-instance-final-snapshot \
    --no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --no-skip-final-snapshot ^
    --final-db-snapshot-identifier my-custom-instance-final-snapshot ^
    --no-delete-automated-backups
```

To take a final snapshot, the `--final-db-snapshot-identifier` option is required and must be specified.

To skip the final snapshot, specify the `--skip-final-snapshot` option instead of the `--no-skip-final-snapshot` and `--final-db-snapshot-identifier` options in the command.

To delete automated backups, specify the `--delete-automated-backups` option instead of the `--no-delete-automated-backups` option in the command.

Starting and stopping an RDS Custom for SQL Server DB instance

You can start and stop your RDS Custom for SQL Server DB instance. The same general requirements and limitations for RDS for SQL Server DB instances apply to stopping and starting your RDS Custom for SQL Server DB instances. For more information, see Stopping an Amazon RDS DB instance temporarily.

The following considerations also apply to starting and stopping your RDS Custom for SQL Server DB instance:

- Modifying an EC2 instance attribute of an RDS Custom for SQL Server DB instance while the DB instance is STOPPED isn't supported.

- You can stop and start an RDS Custom for SQL Server DB instance only if it's configured for a single Availability Zone. You can't stop an RDS Custom for SQL Server DB instance in a Multi-AZ configuration.
- A `SYSTEM` snapshot will be created when you stop an RDS Custom for SQL Server DB instance. The snapshot will be automatically deleted when you start the RDS Custom for SQL Server DB instance again.
- If you delete your EC2 instance while your RDS Custom for SQL Server DB instance is stopped, the `C:` drive will be replaced when you start the RDS Custom for SQL Server DB instance again.
- The `C:\` drive, hostname, and your custom configurations are persisted when you stop an RDS Custom for SQL Server DB instance, as long as you don't modify the instance type.
- The following actions will result in RDS Custom placing the DB instance outside the support perimeter, and you're still charged for DB instance hours:
  - Starting the underlying EC2 instance while Amazon RDS is stopped. To resolve, you can call the `start-db-instance` Amazon RDS API, or stop the EC2 so the RDS Custom instance returns to `STOPPED`.
  - Stopping underlying EC2 instance when the RDS Custom for SQL Server DB instance is `ACTIVE`.

For more details about stopping and starting DB instances, see Stopping an Amazon RDS DB instance temporarily, and Starting an Amazon RDS DB instance that was previously stopped.

Working with Microsoft Active Directory with RDS Custom for SQL Server

RDS Custom for SQL Server allows to join your instances to a Self-Managed Active Directory (AD) or AWS Managed Microsoft AD. This is regardless of where your AD is hosted, like an On-premises data center, Amazon EC2 or with any other cloud service providers.

For authentication of users and services, you can use NTLM or Kerberos authentication on your RDS Custom for SQL Server DB instance without using intermediary domains and forest trusts. When a user tries to authenticate on your RDS Custom for SQL Server DB instance with a self joined Active Directory, requests for authentication are forwarded to a self-managed AD or AWS Managed Microsoft AD that you specify.

In the following sections, you can find information about working with Self Managed Active Directory and AWS Managed Active Directory for RDS Custom for SQL Server.

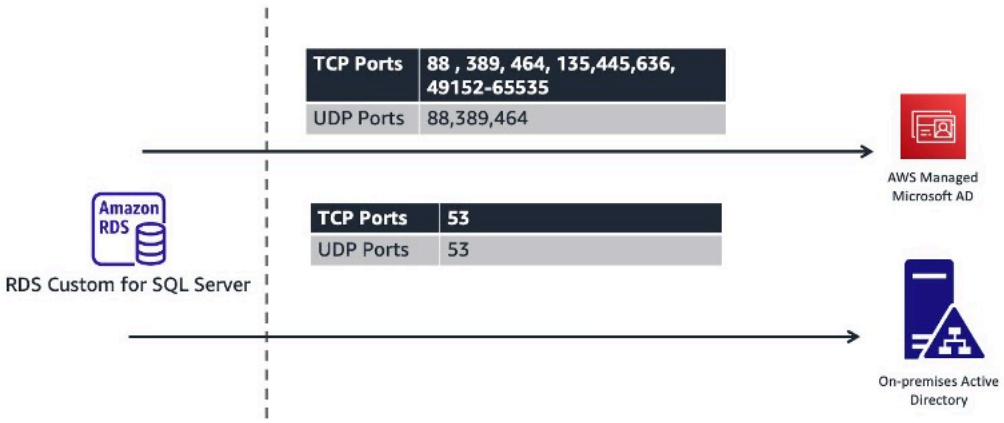
Topics

- Region and version availability
- Configure Self-Managed or On-premise AD
- Configure Microsoft Active Directory using Directory Service
- Network configuration port rules
- Network Validation
- Setting up Windows Authentication for RDS Custom for SQL Server instances
- Managing a DB instance in a Domain
- Understanding Domain membership
- Troubleshooting Active Directory

Region and version availability

RDS Custom for SQL Server supports both Self Managed AD and AWS Managed Microsoft AD using NTLM or Kerberos in all Regions where RDS Custom for SQL Server is supported. For more information, see Supported Regions and DB engines for RDS Custom.

Configure Self-Managed or On-premise AD



To join your on-premise or self-managed Microsoft AD to your RDS Custom for SQL Server DB instance, your Active Domain must be configured as follows:

- Define the subnets in the VPC associated with your RDS Custom for SQL Server DB instance in your self-managed or on-premises AD. Confirm there are no conflicts between the subnets in your VPC and the subnets in your AD sites.
- Your AD domain controller has a domain functional level of Windows Server 2008 R2 or higher.
- Your AD domain name can't be in Single Lable Domain (SLD) format. RDS Custom for SQL Server does not support SLD domains.
- The fully qualified domain name (FQDN) for your AD can't exceed 47 characters.

Configure your network connectivity

Configure your self-managed or on-premise AD network connectivity in the following manner:

- Set up connectivity between Amazon VPC where your RDS Custom for SQL Server instance is running, and your AD. Use Direct Connect, Site-to-Site VPN, AWS Transit Gateway, and VPC Peering.
- Allow traffic on the ports your RDS Custom for SQL Server security groups and network ACLs to your self-managed or on-premise AD. For more information, see Network configuration port rules.

Configure DNS resolution

Set up the following requirements to configure DNS resolution with self-managed or on-premises AD's:

- Configure DNS resolution within your VPC to resolve your self-hosted Active Directory's fully qualified domain name (FQDN). An example of an FQDN is `corp.example.local`. To configure DNS resolution, configure the VPC DNS resolver to forward queries for certain domains with an Amazon Route 53 outbound endpoint and resolver rule. For more information, see Configure a Route 53 Resolver outbound endpoint to resolve DNS records.
- For workloads that leverage both VPCs and on-premises resources, you must resolve DNS records hosted on-premises. On-premise resources might need to resolve names hosted on AWS.

  To create a hybrid cloud setup, use resolver endpoints and conditional forwarding riles to resolve DNS queries between your on-premise resources and custom VPC. For more information, see Resolving DNS queries between VPCs and your network in the *Amazon Route 53 Developer Guide*.

> **Important**
>
> Modifying the DNS resolver settings of the network interface on the RDS Custom for SQL Server causes DNS-enabled VPC endpoints to no longer work correctly. DNS-enabled VPC endpoints are required for instances within private subnets without internet access.

Configure Microsoft Active Directory using Directory Service

AWS Managed Microsoft AD creates a fully managed Microsoft Active Directory in AWS that is powered by Windows Server 2019 and operates at the 2012 R2 Forest and Domain functional levels. Directory Service creates the domain controllers in different subnets in an Amazon VPC, making your directory highly available even in the event of failure.

To create a directory with AWS Managed Microsoft AD, see Getting started with AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.

Configure your network connectivity

Enable cross-VPC traffic between the directory and the DB instance

To locate the directory and the DB instance in the same VPC, skip this step and move on to next step in Network configuration port rules.

To locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. For more information about using VPC peering, see What is VPC peering? in the *Amazon VPC Peering Guide* and What is AWS Transit Gateway? in the *Amazon VPC Transit Gateways*.

Enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Allow the DB instance's security group to recieve inbound traffic from the directory's security group. For more information, see Network configuration port rules.
3. Network access control list (ACL) must not block traffic.

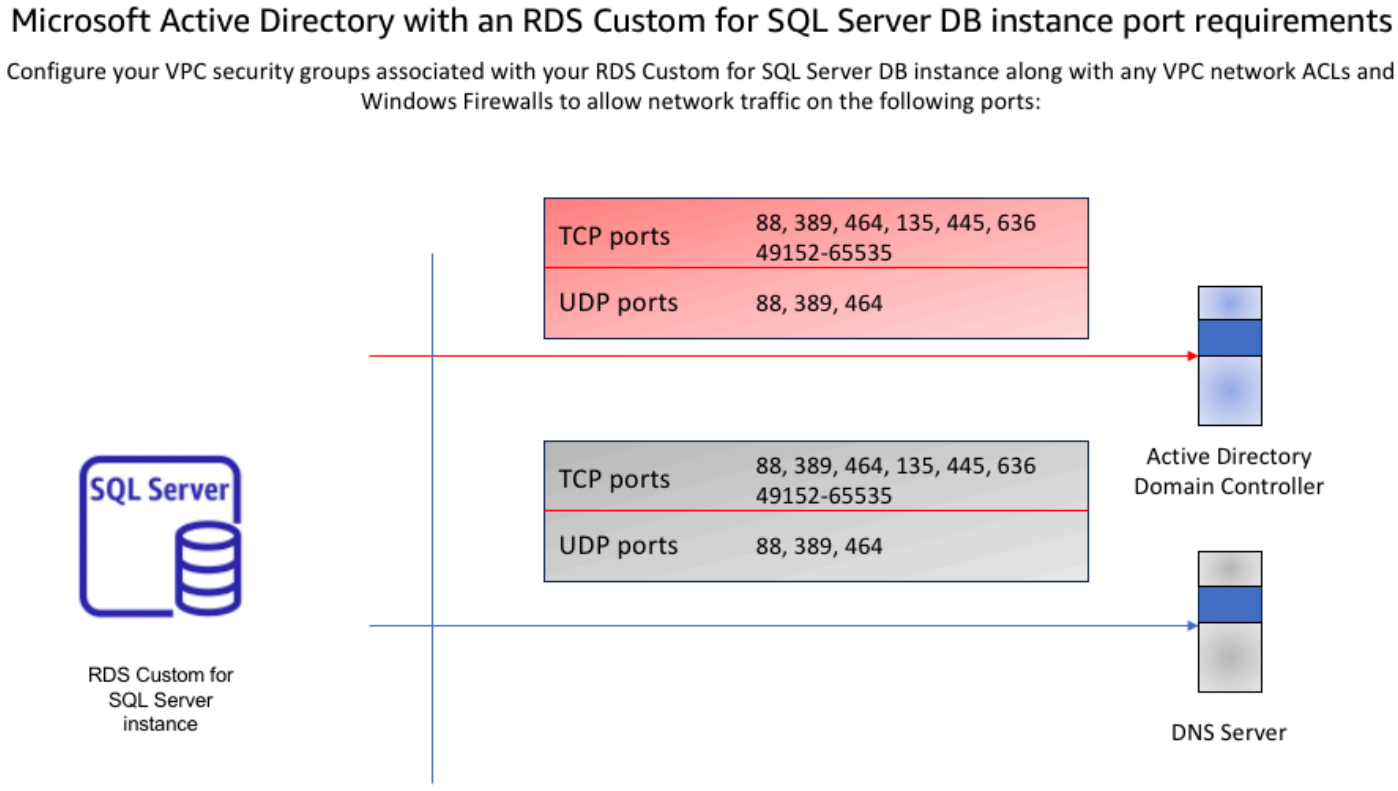
If a different AWS account owns the directory, you must share the directory. To share the directory with AWS account within which the RDS Custom for SQL Server instance is by following the Tutorial: Sharing your AWS Managed Microsoft AD for seamless EC2 domain-join in the *AWS Directory Service Administration Guide*.

Sharing a directory betweens AWS accounts

1. Sign in to the Directory Service console using the account for the DB instance and check if the domain has the SHARED status before proceeding.
2. After signing in to the Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this ID to join the DB instance to the domain.

Configure DNS resolution

When you create a directory with AWS Managed Microsoft AD, Directory Service creates two domain controllers and adds the DNS service on your behalf.



If you have an existing AWS Managed Microsoft AD or plan on launching one in a VPC other than your RDS Custom for SQL Server DB instance, configure the VPC DNS resolver to forward

queries for certain domains with a Route 53 outbound and resolver rule, see Configure a Route 53 Resolver outbound endpoint to resolve DNS records.

Network configuration port rules

Make sure that you have met the following network configurations:

- Connectivity configured between the Amazon VPC where you want to create the RDS Custom for SQL Server DB instance to either your self-managed Active Directory or AWS Managed Microsoft AD. For self-managed Active Directory, set up connectivity using AWS Direct Connect, AWS VPN, VPC peering, or AWS Transit Gateway. For AWS Managed Microsoft AD, set up connectivity using VPC peering.
- Make sure that the security group and the VPC network ACLs for the subnet(s) where you're creating your RDS Custom for SQL Server DB instance allow traffic on the ports and in the directions shown in the following diagram.

The following table identifies the role of each port.

Protocol	Ports	Role
TCP/UDP	53	Domain Name System (DNS)
TCP/UDP	88	Kerberos authentication
TCP/UDP	464	Change/Set password
TCP/UDP	389	Lightweight Directory Access Protocol (LDAP)
TCP	135	Distributed Computing Environment / End Point Mapper (DCE / EPMAP)
TCP	445	Directory Services SMB file sharing
TCP	636	Lightweight Directory Access Protocol over TLS/SSL (LDAPS)
TCP	49152 - 65535	Ephemeral ports for RPC

- Generally, the domain DNS servers are located in the AD domain controllers. You do not need to configure the VPC DHCP option set to use this feature. For more information, see DHCP option sets in the *Amazon VPC User Guide*.

Important

If you're using VPC network ACLs, you must also allow outbound traffic on dynamic ports (49152-65535) from your RDS Custom for SQL Server DB instance. Ensure that these traffic rules are also mirrored on the firewalls that apply to each of the AD domain controllers, DNS servers, and RDS Custom for SQL Server DB instances.
While VPC security groups require ports to be opened only in the direction that network traffic is initiated, most Windows firewalls and VPC network ACLs require ports to be open in both directions.

Network Validation

Before joining your RDS Custom instance to either self-managed or AWS Managed Microsoft AD, check the following from a EC2 instance in the same VPC as where you plan to launch the RDS Custom for SQL Server instance.

- Check if you are able to resolve the fully qualified domain name (FQDN) to domain controller IPs.

```
nslookup corp.example.com
```

  The command must return a similar output:

```
Server:  ip-10-0-0-2.us-west-2.compute.internal
Address:  25.0.0.2

Non-authoritative answer:
Name:    corp.example.com
Addresses:  40.0.9.25 (DC1 IP)
            40.0.50.123 (DC2 IP)
```

- Resolve AWS services from an EC2 instance in the VPC where you are launching your RDS Custom instance:

```
$region='input-your-aws-region'
$domainFQDN='input-your-domainFQDN'

function Test-DomainPorts {
    param (
        [string]$Domain,
        [array]$Ports
    )

    foreach ($portInfo in $Ports) {
        try {
            $conn = New-Object System.Net.Sockets.TcpClient
            $connectionResult = $conn.BeginConnect($Domain, $portInfo.Port, $null,
 $null)
            $success = $connectionResult.AsyncWaitHandle.WaitOne(1000) # 1 second
 timeout
            if ($success) {
                $conn.EndConnect($connectionResult)
                $result = $true
```

```
            } else {
                $result = $false
            }
        }
        catch {
            $result = $false
        }
        finally {
            if ($null -ne $conn) {
                $conn.Close()
            }
        }
        Write-Host "$($portInfo.Description) port open: $result"
    }
}

# Check if ports can be reached
$ports = @(
    @{Port = 53;   Description = "DNS"},
    @{Port = 88;   Description = "Kerberos"},

    @{Port = 3269; Description = "Global Catalog over SSL"},
    @{Port = 9389; Description = "AD DS"}
)

function Test-DomainReachability {
    param (
        [string]$DomainName
    )

    try {
        $dnsResults = Resolve-DnsName -Name $DomainName -ErrorAction Stop
        Write-Host "Domain $DomainName is successfully resolving to following IP
 addresses: $($dnsResults.IpAddress)"
        Write-Host ""
        return $true
    }
    catch {
        Write-Host ""
        Write-Host "Error Message: $($_.Exception.Message)"
```

```
        Write-Host "Domain $DomainName reachability check failed, please Configure
 DNS resolution"
        return $false
    }
}

$domain = (Get-WmiObject Win32_ComputerSystem).Domain
if ($domain -eq 'WORKGROUP') {
    Write-Host ""
    Write-Host "Host $env:computername is still part of WORKGROUP and not part of any
 domain"
    }
else {
    Write-Host ""
    Write-Host "Host $env:computername is joined to $domain domain"
    Write-Host ""
    }

$isReachable = Test-DomainReachability -DomainName $domainFQDN
if ($isReachable) {
    write-Host "Checking if domain $domainFQDN is reachable on required ports  "
    Test-DomainPorts -Domain $domainFQDN -Ports $ports
}
else {
    Write-Host "Port check skipped. Domain not reachable"
}

# Get network adapter configuration
$networkConfig = Get-WmiObject Win32_NetworkAdapterConfiguration |
                 Where-Object { $_.IPEnabled -eq $true } |
                 Select-Object -First 1

# Check DNS server settings
$dnsServers = $networkConfig.DNSServerSearchOrder

if ($dnsServers) {
    Write-Host "`nDNS Server settings:"
    foreach ($server in $dnsServers) {
        Write-Host "  - $server"
    }
} else {
```

```
    Write-Host "`nNo DNS servers configured or unable to retrieve DNS server
 information."
}

write-host ""

# Checks reachability to dependent services
$services = "s3", "ec2", "secretsmanager", "logs", "events", "monitoring", "ssm",
 "ec2messages", "ssmmessages"

function Get-TcpConnectionAsync {
    param (
        $ServicePrefix,
        $region
    )
    $endpoint = "${ServicePrefix}.${region}.amazonaws.com"
    $tcp = New-Object Net.Sockets.TcpClient
    $result = $false

    try {
        $connectTask = $tcp.ConnectAsync($endpoint, 443)
        $timedOut = $connectTask.Wait(3000)
        $result = $tcp.Connected
    }
    catch {
        $result = $false
    }
    return $result
}

foreach ($service in $services) {
    $validationResult = Get-TcpConnectionAsync -ServicePrefix $service -Region
 $region
    Write-Host "Reachability to $service is $validationResult"
}
```

The `TcpTestSucceeded` value must return `True` for `s3`, `ec2`, `secretsmanager`, `logs`, `events`, `monitoring`, `ssm`, `ec2messages`, and `ssmmessages`.

Setting up Windows Authentication for RDS Custom for SQL Server instances

We recommend creating a dedicated OU and service credentials scoped to that OU for any AWS account that owns an RDS Custom for SQL Server DB instance joined to your AD domain. By dedicating an OU and service credentials, you avoid conflicting permissions and follow the principle of least privilege.

Active directory level group policies might conflict with AWS automations and permissions. We recommend selecting GPO's that apply only to the OU that you create for RDS Custom for SQL Server.

- To create OU and AD domain user in your self-managed or on-premise AD, you can connect the domain controller as a domain administrator.
- To create users and groups in an Directory Service directory, you must be connected to a management instance and you must also be logged in as a user with privileges to create users and groups. For more information, see User and group management in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.
- To manage your Active Directory from Amazon EC2 Windows Server instance, you need to install the Active Directory domain services and Active Directory Lightweight Directory services tools on the EC2 instance. For more information, see Installing Active Directory Administration Tools for AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.
- We recommend that you install these tools on a separate EC2 instance for administration, and not on your RDS Custom for SQL Server DB instance for ease of administration.

The following are the requirements for an AD domain service account:

- You must have a service account in your AD domain with delegated permissions to join computers to the domain. A domain service account is a user account in your AD that has delegated permission to perform certain tasks.
- Delegate the following permissions to your domain service account in the Organizational Unit that you're joining your RDS Custom for SQL Server instance to:
  - Validated ability to write to the DNS host name
  - Validated ability to write to the service principal name
  - Create and delete computer objects
- For self-managed and on-premises AD, the domain service account must be a member of the "AWS Delegated Domain Name System Administrators" group.

- For AWS Managed Microsoft AD, the domain service account should be member of "DnsAdmins" group.

These are the minimum set of permissions required to join computer objects to your self-managed AD and AWS Managed Microsoft AD. For more information, see Error: Access is denied when non-administrator users who have been delegated control try to join computers to a domain controller in the Microsoft Windows Server documentation.

> **Important**
>
> Do not move computer objects that RDS Custom for SQL Server creates in the Organizational Unit (OU) after your DB instance is created. Moving associated objects might cause your RDS Custom for SQL Server DB instance to become misconfigured. If you need to move the computer objects created by Amazon RDS, use the ModifyDBInstance action to modify the domain parameters with the desired location of the computer objects.

Topics

- Step 1: Create an organizational unit (OU) in your AD
- Step 2: Create an AD domain user
- Step 3: Delegate control to the AD user in self-managed or AWS Managed Microsoft AD
- Step 4: Create a secret
- Step 5: Create or modify a RDS Custom for SQL Server DB instance
- Step 6: Create Windows Authentication SQL Server Login
- Step 7: Using Kerberos or NTLM Authentication

Step 1: Create an organizational unit (OU) in your AD

Use the following steps to create an organization unit in your AD:

Create an OU in your AD

1. Connect to your domain AD as a domain administrator.
2. Open **Active Directory Users and Computers** and select the domain where you want to create your OU.
3. Right-click the domain and choose **New**, then **Organization Unit**.

4. Enter a name for the OU.

   Enable **Protect container from accidental deletion**.
5. Choose **OK**. Your new OU appears under your domain.

For AWS Managed Microsoft AD, the name of this OU is based off the NetBIOS name you typed when you created your directory. This OU is owned by AWS and contains all of your AWS-related directory objects, which you are granted full control over. By default, two child OUs exist under this OU, namely **Computers and Users**. New OUs that RDS Custom creates are a child of the OU that is based off of the NetBIOS.

Step 2: Create an AD domain user

The domain user credentials are used for the secret in Secrets Manager.

Create an AD domain user in your AD

1. Open **Active Directory Users and Computers** and select the domain and OU where you want to create the user.
2. Right-click the **Users** object and choose **New**, then **User**.
3. Enter a first name, last name, and login name for the user. Click **Next**.
4. Enter a password for the user. Don't select **User must change password at next login** or **Account is disabled.**. Click **Next**.
5. Click **OK**. You new user appears under your domain.

Step 3: Delegate control to the AD user in self-managed or AWS Managed Microsoft AD

To delegate control to the AD domain user in your domain

1. Open **Active Directory Users and Computers** MMC snap-in and select your domain.
2. Right-click on the OU you created earlier and choose **Delegate Control**.
3. In the **Delegation Control Wizard**, click **Next**.
4. In **Users or Groups** section, click **Add**.
5. In **Select Users, Computers, or Groups**, enter the AD user you created and click **Check Names**. If your AD user check is successful, click **OK**.
6. In the **Users or Groups** section, confirm your AD user was added and click **Next**.

7. In the **Tasks to Delegate** section, choose **Create a custom task to delegate** and click **Next**.
8. In the **Active Directory Object Type** section:

   Choose **ONly the following objects in the folder**.

   Select **Computer Objects**

   Select **Create selected objects in this folder**

   Select **Delete selected objects in this folder** and click **Next**.
9. In the **Permissions** section:

   Keep **General** selected.

   Select **Validated write to DNS host name**.

   Select **Validated write to service principal name** and click **Next**.
10. In **Completing the Delegation of Control Wizard**, confirm your settings and click **Finish**.

Step 4: Create a secret

Create the secret in the same AWS account and Region that contains the RDS Custom for SQL Server DB instance that you want to include in your active directory. Store credentials of the AD domain user created in Step 2: Create an AD domain user.

Console

- In AWS Secrets Manager, choose **Store a new secret**.
- For **Secret type**, choose **Other type of secret**.
- For **Key/value pairs**, add two keys:
  - The first key, `SELF_MANAGED_ACTIVE_DIRECTORY_USERNAME` and enter the name of your AD user (without the domain prefix) for the value.
  - For the second key, enter `SELF_MANAGED_ACTIVE_DIRECTORY_PASSWORD` and enter the password for your AD user on your domain.
- For **Encryption key**, enter the same AWS KMS key you used to create RDS Custom for SQL Server instance.

- For **Secret name**, choose the secret name starting with `do-not-delete-rds-custom-` to allow your instance profile to access this secret. IF you want to choose a different name for the secret, update `RDSCustomInstanceProfile` to access **Secret name**.
- (Optional) For **Description**, enter a description for the secret name.
- Add the tags `Key="AWSRDSCustom",Value="custom-sqlserver"`
- Click **Save**, then **Next**.
- For **Configure rotation settings**, keep the default values and choose **Next**.
- Review the settings for the secret and click **Store**.
- Choose the new secret and copy the value for **Secret ARN**. We use this in the next step to set up you Active Directory.

CLI

Run the following command in your CLI to create a secret:

```
# Linux based
aws secretsmanager create-secret \
--name do-not-delete-rds-custom-DomainUserCredentails \
--description "Active directory user credentials for managing RDS Custom" \
--secret-string "{\"SELF_MANAGED_ACTIVE_DIRECTORY_USERNAME\":\"tester\",
\"SELF_MANAGED_ACTIVE_DIRECTORY_PASSWORD\":\"xxxxxxxx\"}" \
--kms-key-id <RDSCustomKMSKey> \
--tags Key="AWSRDSCustom",Value="custom-sqlserver"

# Windows based
aws secretsmanager create-secret ^
--name do-not-delete-rds-custom-DomainUserCredentails ^
--description "Active directory user credentials for managing RDS Custom" ^
--secret-string "{\"SELF_MANAGED_ACTIVE_DIRECTORY_USERNAME\":\"tester\",
\"SELF_MANAGED_ACTIVE_DIRECTORY_PASSWORD\":\"xxxxxxxx\"}" ^
--kms-key-id <RDSCustomKMSKey> ^
--tags Key="AWSRDSCustom",Value="custom-sqlserver"
```

Step 5: Create or modify a RDS Custom for SQL Server DB instance

Create or modify a RDS Custom for SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.

- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.

- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.

- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

> **Note**
>
> If your RDS Custom for SQL Server instance is already joined to an AD manually, check the settings for Network configuration port rules, Network Validation, and complete steps 1 though Step 4. Update the `--domain-fqdn`, `--domain-ou`, and `--domain-auth-secret-arn` to your AD, so that domain join credentials and configurations are registered with RDS Custom to monitor, register CNAME, and take recovery actions.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain-fqdn` parameter, use the fully qualified domain name of your self-managed AD.
- For the `--domain-ou` parameter, use the OU that you created in your self-managed AD.
- For the `--domain-auth-secret-arn` parameter, use the value of the **Secret ARN** that you created.

Important

If you modify a DB instance to join or remove from a self-managed AD domain or AWS Managed Microsoft AD, a reboot of the DB instance is required for the modification to take effect. You can choose to apply the changes immediately or wait until the next maintenance window. Choosing the **Apply Immediately** option causes downtime for a single-AZ DB instance. A Multi-AZ DB cluster performs a failover before completing a reboot. For more information, see Modifying an Amazon RDS DB instance.

The following CLI command creates a new RDS Custom for SQL Server DB instance and joins it to self-managed or AWS Managed Microsoft AD domain.

For Linux, macOS, or Unix:

```
aws rds create-db-instance  \
--engine custom-sqlserver-se \
--engine-version 15.00.4312.2.v1 \
--db-instance-identifier my-custom-instance \
--db-instance-class db.m5.large \
--allocated-storage 100 --storage-type io1 --iops 1000 \
--master-username my-master-username \
--master-user-password my-master-password \
--kms-key-id  my-RDSCustom-key-id \
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance  \
--domain-fqdn "corp.example.com" \
--domain-ou "OU=RDSCustomOU,DC=corp,DC=example,DC=com" \
--domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:do-not-delete-rds-custom-my-AD-test-secret-123456" \
--db-subnet-group-name my-DB-subnet-grp \
--vpc-security-group-ids  my-securitygroup-id \
--no-publicly-accessible \
--backup-retention-period 3 \
--port 8200 \
--region us-west-2 \
--no-multi-az
```

For Windows:

```
aws rds create-db-instance  ^
```

```
--engine custom-sqlserver-se ^
--engine-version 15.00.4312.2.v1 ^
--db-instance-identifier my-custom-instance ^
--db-instance-class db.m5.large ^
--allocated-storage 100 --storage-type io1 --iops 1000 ^
--master-usernamemy-master-username ^
--master-user-password my-master-password ^
--kms-key-id  my-RDSCustom-key-id ^
--custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance  ^
--domain-fqdn "corp.example.com" ^
--domain-ou "OU=RDSCustomOU,DC=corp,DC=example,DC=com" ^
--domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:do-not-
delete-rds-custom-my-AD-test-secret-123456" ^
--db-subnet-group-name my-DB-subnet-grp ^
--vpc-security-group-ids  my-securitygroup-id ^
--no-publicly-accessible ^
--backup-retention-period 3 ^
--port 8200 ^
--region us-west-2 ^
--no-multi-az
```

Important

If your NetBIOS for AWS Managed Microsoft AD is **corpexample**, then it appears as an OU itself. Any new OU created earlier will appear as a nested OU. For AWS Managed Microsoft AD, set `--domain-ou` to `"OU=RDSCustomOU,OU=corpexample,DC=corp,DC=example,DC=com"`.

The following command modifies an existing RDS Custom for SQL Server DB instance to use an Active Directory domain.

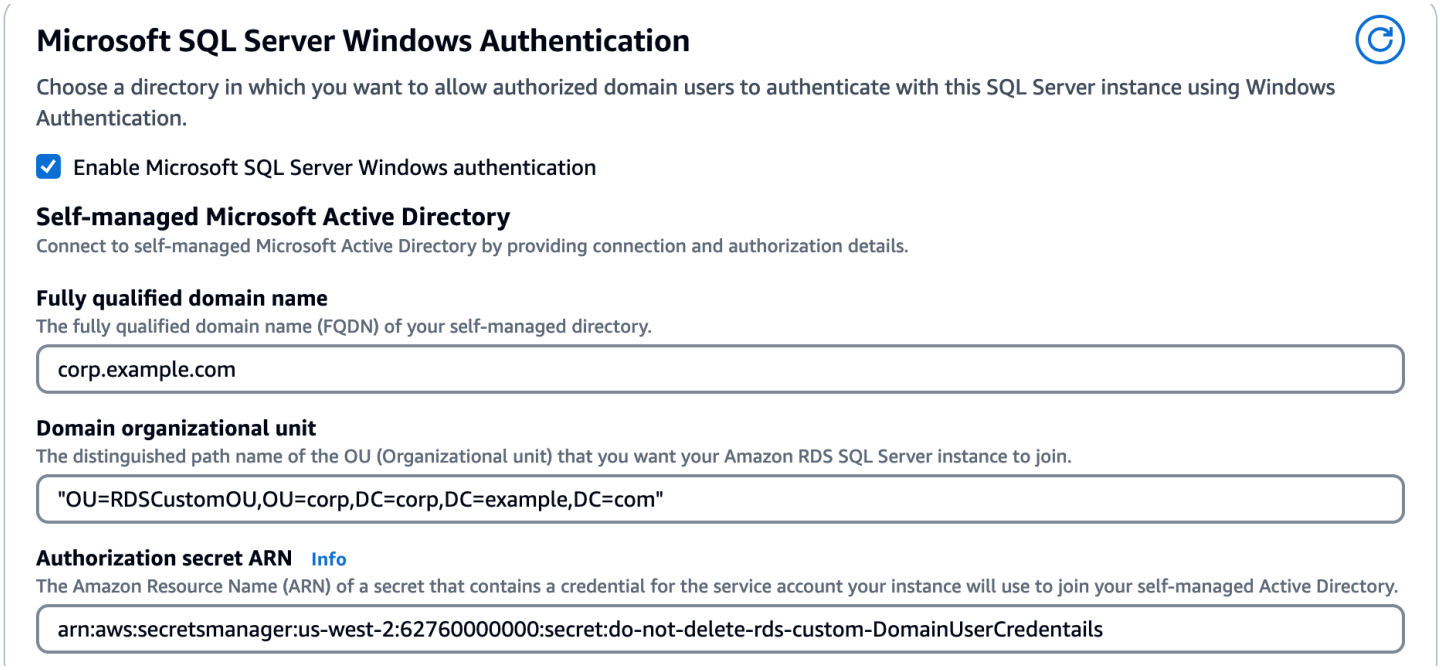
For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --domain-fqdn "corp.example.com" \
    --domain-ou "OU=RDSCustomOU,DC=corp,DC=example,DC=com" \
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:do-
not-delete-rds-custom-my-AD-test-secret-123456" \
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --domain-fqdn "corp.example.com" ^
    --domain-ou "OU=RDSCustomOU,DC=corp,DC=example,DC=com" ^
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:do-
not-delete-rds-custom-my-AD-test-secret-123456" ^
```

The following CLI command removes and RDS Custom for SQL Server DB instance from a Active Directory domain.



For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-custom-instance \
    --disable-domain
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-custom-instance ^
    --disable-domain
```

When using the console to create or modify your instance, click on **Enable Microsoft SQL Server Windows Authentication** to see the following options.

You are responsible to make sure your domain FQDN is resolving to the domain controller IP addresses. If domain controller IPs are not resolving, domain join operations fail but RDS Custom for SQL Server instance creation succeeds. For troubleshooting information, see Troubleshooting Active Directory.

Step 6: Create Windows Authentication SQL Server Login

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do for any other DB instance. Because the DB instance is joined to the AD domain, you can provision SQL Server logins and users. You do this from the AD users and groups utility in your AD domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

For an AD user to authenticate with SQL Server, a SQL Server Windows login must exist for the AD user or an Active Directory group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. An AD user that doesn't have a SQL Server login or belong to an AD group with such a login can't access the SQL Server DB instance.

The `ALTER ANY LOGIN` permission is required to create an AD SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication and create your AD SQL Server logins under the context of the master user.

You can run a data definition language (DDL) command such as the following to create a SQL Server login for an AD user or group.

```
USE [master]
GO
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
 DEFAULT_LANGUAGE = [us_english];
GO
```

Users (both humans and applications) from your domain can now connect to the RDS Custom for SQL Server instance from a domain-joined client machine using Windows authentication.

Step 7: Using Kerberos or NTLM Authentication

NTLM authentication using RDS endpoint

Each Amazon RDS DB instance has an endpoint and each endpoint has a DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance. To authenticate using NTLM authentication, you must connect to the RDS endpoint.

During planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary database so operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the secondary as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Kerberos authentication

Kerberos-based authentication for RDS Custom for SQL Server requires connections be made to a specific Service Principal Name (SPN). However, after a failover event, the application might not be aware of the new SPN. To address this, RDS Custom for SQL Server offers a Kerberos-based endpoint.

The Kerberos-based endpoint follows a specific format. If your RDS endpoint is *rds-instance-name*.*account-region-hash*.*aws-region*.rds.amazonaws.com, the corresponding Kerberos-based endpoint would be *rds-instance-name*.*account-region-hash*.*aws-region*.awsrds.*fully qualified domain name (FQDN)*.

For example, if the RDS endpoint is `ad-test.cocv6zwtircu.us-east-1.rds.amazonaws.com` and the domain name is `corp-ad.company.com`, the Kerberos-based endpoint would be `ad-test.cocv6zwtircu.us-east-1.awsrds.corp-ad.company.com`.

This Kerberos-based endpoint can be used to authenticate with the SQL Server instance using Kerberos, even after a failover event, as the endpoint is automatically updated to point to the new SPN of the primary SQL Server instance.

Finding your CNAME

To find your CNAME, connect to your domain controller and open **DNS Manager**. Navigate to **Forward Lookup Zones** and your FQDN.

Navigate through **awsrds**, **aws-region**, and **account and region specific hash**.

If you are connecting the RDS Custom EC2 instance and trying to connect to the database locally using CNAME, your connection will use NTLM authentication instead of Kerberos.

If after connecting CNAME from remote client, an NTLM connection is returned, check if required ports are allowlisted.

To check if your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
    FROM sys.dm_exec_connections
    WHERE session_id = @@SSPID;
```

Managing a DB instance in a Domain

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the `ModifyDBInstance` API operation and specify none as the domain parameter.

- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the DescribeDBInstances API operation.

Restoring a RDS Custom for SQL Server DB instance and adding it to an Active Directory domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to an Active Directory domain. Once the DB instance is restored, modify the instance using the process explained in Step 5: Create or modify a RDS Custom for SQL Server DB instance to add the DB instance to an AD domain.

Understanding Domain membership

After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the domain.
- **joining** – The instance is in the process of becoming a member of the domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

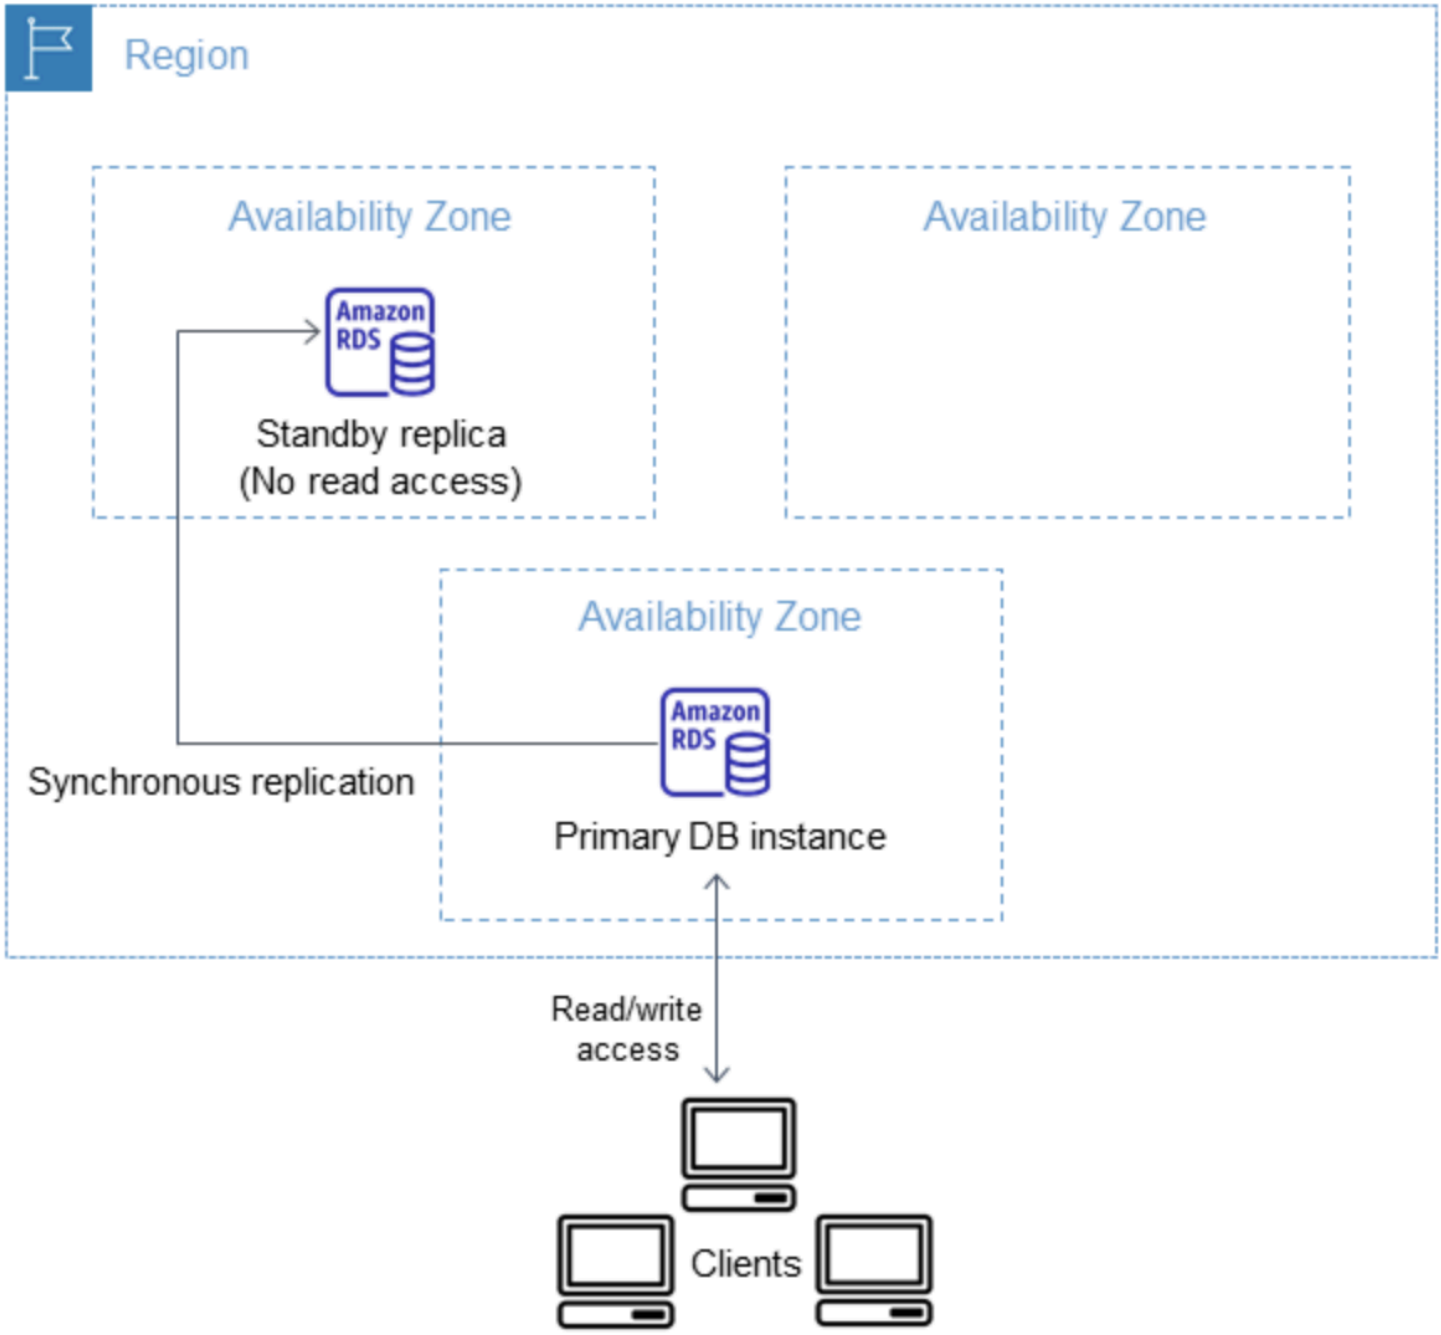
Troubleshooting Active Directory

The following are issues you might encounter when you set up or modify an AD.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 2 / 0x2	The system cannot find the file specified.	The format or location for the Organizational Unit (OU) specified with the `–domain-ou` parameter is invalid. The domain service account specified via AWS Secrets Manager lack the permissions required to join the OU.	Review the `–domain-ou` parameter. Ensure the domain service account has the correct permissions to the OU.
Error 5 / 0x5	Access is denied.	Misconfigured permissions for the domain service account, or the computer account already exists in the domain.	Review the domain service account permissions in the domain, and verify that the RDS computer account is not duplicated in the domain. You can verify the name of the RDS computer account by running `SELECT @@SERVERNAME` on your RDS Custom for SQL Server DB instance. If you are using Multi-AZ, try rebooting with failover and then verify that the RDS computer account again. For more information, see Rebooting a DB instance.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 87 / 0x57	The parameter is incorrect.	The domain service account specified via AWS Secrets Manager doesn't have the correct permissions. The user profile may also be corrupted.	Review the requirements for the domain service account.
Error 234 / 0xEA	Specified Organizational Unit (OU) does not exist.	The OU specified with the `–domain-ou` parameter doesn't exist in your AD.	Review the `–domain-ou` parameter and ensure the specified OU exists in your AD.
Error 1326 / 0x52E	The user name or password is incorrect.	The domain service account credentials provided in AWS Secrets Manager contains an unknown username or bad password. The domain account may also be disabled in your AD.	Ensure the credentials provided in AWS Secrets Manager are correct and the domain account is enabled in your Active Directory.
Error 1355 / 0x54B	The specified domain either does not exist or could not be contacted.	The domain is down, the specified set of DNS IPs are unreachable, or the specified FQDN is unreachable.	Review the `–domain-dns-ips` and `–domain-fqdn` parameters to ensure they're correct. Review the networking configuration of your RDS Custom for SQL Server DB instance and ensure your AD is reachable.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 1722 / 0x6BA	The RPC server is unavailable.	There was an issue reaching the RPC service of your AD domain. This might be a service or network issue.	Validate that the RPC service is running on your domain controllers and that the TCP ports 135 and 49152-65535 are reachable on your domain from your RDS Custom for SQL Server DB instance.
Error 2224 / 0x8B0	The user account already exists.	The computer account that's attempting to be added to your AD already exists.	Identify the computer account by running `SELECT @@SERVERNAME` on your RDS Custom for SQL Server DB instance and then carefully remove it from your AD.
Error 2242 / 0x8c2	The password of this user has expired.	The password for the domain service account specified via AWS Secrets Manager has expired.	Update the password for the domain service account used to join your RDS Custom for SQL Server DB instance to your AD.



Managing a Multi-AZ deployment for RDS Custom for SQL Server

In a Multi-AZ DB instance deployment for RDS Custom for SQL Server, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone (AZ). The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy.

Important

A Multi-AZ deployment for RDS Custom for SQL Server is different than Multi-AZ for RDS for SQL Server. Unlike Multi-AZ for RDS for SQL Server, you must set up prerequisites for RDS Custom for SQL Server before creating your Multi-AZ DB instance because RDS Custom runs inside your own account, which requires permissions.
If you don't complete the prerequisites, your Multi-AZ DB instance might fail to run, or automatically revert to a Single-AZ DB instance. For more information about prerequisites, see Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server.

Running a DB instance with high availability can enhance availability during planned system maintenance. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

You can create an RDS Custom for SQL Server Multi-AZ deployment by specifying Multi-AZ when creating an RDS Custom DB instance. You can use the console to convert existing RDS Custom for SQL Server DB instances to Multi-AZ deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ DB instance deployment with the AWS CLI or Amazon RDS API.

The RDS console shows the Availability Zone of the standby replica (the secondary AZ). You can also use the `describe-db-instances` CLI command or the `DescribeDBInstances` API operation to find the secondary AZ.

RDS Custom for SQL Server DB instances with Multi-AZ deployment can have increased write and commit latency compared to a Single-AZ deployment. This increase can happen because of the synchronous data replication between DB instances. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones.

> **Note**
>
> For production workloads, we recommend that you use a DB instance class with Provisioned IOPS (input/output operations per second) for fast, consistent performance. For more information about DB instance classes, see Requirements and limitations for Amazon RDS Custom for SQL Server.

- Region and version availability
- Limitations for a Multi-AZ deployment with RDS Custom for SQL Server
- Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server
- Creating an RDS Custom for SQL Server Multi-AZ deployment
- Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment
- Modifying an RDS Custom for SQL Server Multi-AZ deployment to a Single-AZ deployment
- Failover process for an RDS Custom for SQL Server Multi-AZ deployment

Region and version availability

Multi-AZ deployments for RDS Custom for SQL Server are supported for the following SQL Server editions:

- SQL Server 2022 and 2019: Enterprise, Standard, Web, and Developer Edition

Note

Multi-AZ deployments for RDS Custom for SQL Server aren't supported on SQL Server 2019 CU8 (15.00.4073.23) or lower versions.

Multi-AZ deployments for RDS Custom for SQL Server are available in all Regions where RDS Custom for SQL Server is available. For more information on Region availability of Multi-AZ deployments for RDS Custom for SQL Server, see Supported Regions and DB engines for RDS Custom for SQL Server.

Limitations for a Multi-AZ deployment with RDS Custom for SQL Server

Multi-AZ deployments with RDS Custom for SQL Server have the following limitations:

- Cross-Region Multi-AZ deployments aren't supported.
- You can’t configure the secondary DB instance to accept database read activity.
- When you use a Custom Engine Version (CEV) with a Multi-AZ deployment, your secondary DB instance will also use the same CEV. The secondary DB instance can't use a different CEV.

Prerequisites for a Multi-AZ deployment with RDS Custom for SQL Server

If you have an existing RDS Custom for SQL Server Single-AZ deployment, the following additional prerequisites are required before modifying it to a Multi-AZ deployment. You can choose to complete the prerequisites manually or with the provided CloudFormation template. The latest CloudFormation template contains the prerequisites for both Single-AZ and Multi-AZ deployments.

Important

To simplify setup, we recommend that you use the latest CloudFormation template file provided in the network setup instructions to create the prerequisites. For more information, see Configuring with CloudFormation.

Note

When you modify an existing RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment, you must complete these prerequisites. If you don't complete the

prerequisites, the Multi-AZ setup will fail. To complete the prerequisites, follow the steps in Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment.

- Update the RDS security group inbound and outbound rules to allow port 1120.
- Add a rule in your private network Access Control List (ACL) that allows TCP ports `0-65535` for the DB instance VPC.
- Create new Amazon SQS VPC endpoints that allow the RDS Custom for SQL Server DB instance to communicate with SQS.
- Update the SQS permissions in the instance profile role.

Creating an RDS Custom for SQL Server Multi-AZ deployment

To create an RDS Custom for SQL Server Multi-AZ deployment, follow the steps in Creating and connecting to a DB instance for Amazon RDS Custom for SQL Server.

Important

To simplify setup, we recommend that you use the latest CloudFormation template file provided in the network setup instructions. For more information, see Configuring with CloudFormation.

Creating a Multi-AZ deployment takes a few minutes to complete.

Modifying an RDS Custom for SQL Server Single-AZ deployment to a Multi-AZ deployment

You can modify an existing RDS Custom for SQL Server DB instance from a Single-AZ deployment to a Multi-AZ deployment. When you modify the DB instance,Amazon RDS performs several actions:

- Takes a snapshot of the primary DB instance.
- Creates new volumes for the standby replica from the snapshot. These volumes initialize in the background, and maximum volume performance is achieved after the data is fully initialized.
- Turns on synchronous block-level replication between the primary and secondary DB instances.

Important

We recommend that you avoid modifying your RDS Custom for SQL Server DB instance from a Single-AZ to a Multi-AZ deployment on a production DB instance during periods of peak activity.

AWS uses a snapshot to create the standby instance to avoid downtime when you convert from Single-AZ to Multi-AZ, but performance might be impacted during and after converting to Multi-AZ. This impact can be significant for workloads that are sensitive to write latency. While this capability allows large volumes to quickly be restored from snapshots, it can cause increase in the latency of I/O operations because of the synchronous replication. This latency can impact your database performance.

Note

If you created your RDS Custom for SQL Server DB instance before 29 August, 2024, patch to the latest minor version before modifying.

- For SQL Server 2019 instances, upgrade the DB engine version to `15.00.4410.1.v1` or higher.
- For SQL Server 2022 instances, upgrade the DB engine version to `16.00.4150.1.v1` or higher.

- Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually
- Modify using the RDS console, AWS CLI, or RDS API.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation

To use a Multi-AZ deployment, you must ensure you've applied the latest CloudFormation template with prerequisites, or manually configure the latest prerequisites. If you've already applied the latest CloudFormation prerequisite template, you can skip these steps.

To configure the RDS Custom for SQL Server Multi-AZ deployment prerequisites using CloudFormation

1. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
2. To start the Create Stack wizard, select the existing stack you used to create a Single-AZ deployment and choose **Update**.

   The **Update stack** page appears.
3. For **Prerequisite - Prepare template**, choose **Replace current template**.
4. For **Specify template**, do the following:

   a. Download the latest CloudFormation template file. Open the context (right-click) menu for the link custom-sqlserver-onboard.zip and choose **Save Link As**.

   b. Save and extract the `custom-sqlserver-onboard.json` file to your computer.

   c. For **Template source**, choose **Upload a template file**.

   d. For **Choose file**, navigate to and then choose `custom-sqlserver-onboard.json`.
5. Choose **Next**.

   The **Specify stack details** page appears.
6. To keep the default options, choose **Next**.

   The **Advanced Options** page appears.
7. To keep the default options, choose **Next**.
8. To keep the default options, choose **Next**.
9. On the **Review Changes** page, do the following:

   a. For **Capabilities**, select the **I acknowledge that CloudFormation might create IAM resources with custom names** check box.

   b. Choose **Submit**.
10. Verify the update is successful. The status of a successful operation shows `UPDATE_COMPLETE`.

If the update fails, any new configuration specified in the update process will be rolled back. The existing resource will still be usable. For example, if you add network ACL rules numbered 18 and 19, but there were existing rules with same numbers, the update would return the following error: `Resource handler returned message: "The network acl entry identified by 18`

`already exists.` In this scenario you can modify the existing ACL rules to use a number lower than 18, then retry the update.

Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment manually

> **Important**
>
> To simplify setup, we recommend that you use the latest CloudFormation template file provided in the network setup instructions. For more information, see Configuring prerequisites to modify a Single-AZ to a Multi-AZ deployment using CloudFormation.

If you choose to configure the prerequisites manually, perform the following tasks.

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Endpoint**. The **Create Endpoint** page appears.
3. For **Service Category**, choose **AWS services**.
4. In **Services**, search for *SQS*
5. In **VPC**, choose the VPC where your RDS Custom for SQL Server DB instance is deployed.
6. In **Subnets**, choose the subnets where your RDS Custom for SQL Server DB instance is deployed.
7. In **Security Groups**, choose the *-vpc-endpoint-sg* group.
8. For **Policy**, choose **Custom**
9. In your custom policy, replace the *AWS partition*, *Region*, *accountId*,and *IAM-Instance-role* with your own values.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/AWSRDSCustom": "custom-sqlserver"
                }
            },
            "Action": [
```

```
                "SQS:SendMessage",
                "SQS:ReceiveMessage",
                "SQS:DeleteMessage",
                "SQS:GetQueueUrl"
            ],
            "Resource": "arn:aws:sqs:us-east-1:111122223333:do-not-delete-
rds-custom-*",

            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/{IAM-Instance-role}"
            }
        }
    ]
}
```

10. Update the **Instance profile** with permission to access Amazon SQS. Replace the *AWS partition*, *Region*, and *accountId* with your own values.

```
                    {
    "Sid": "SendMessageToSQSQueue",
    "Effect": "Allow",
    "Action": [
      "SQS:SendMessage",
      "SQS:ReceiveMessage",
      "SQS:DeleteMessage",
      "SQS:GetQueueUrl"

    ],
    "Resource": [
      {
        "Fn::Sub": "arn:${AWS::Partition}:sqs:${AWS::Region}:${AWS::AccountId}:do-
not-delete-rds-custom-*"
      }
    ],
    "Condition": {
      "StringLike": {
        "aws:ResourceTag/AWSRDSCustom": "custom-sqlserver"
      }
    }
  }
                    >
```

11. Update the Amazon RDS security group inbound and outbound rules to allow port 1120.

    a. In **Security Groups**, choose the *-rds-custom-instance-sg* group.

    b. For **Inbound Rules**, create a **Custom TCP** rule to allow port *1120* from the source *-rds-custom-instance-sg* group.

    c. For **Outbound Rules**, create a **Custom TCP** rule to allow port *1120* to the destination *-rds-custom-instance-sg* group.

12. Add a rule in your private network Access Control List (ACL) that allows TCP ports `0-65535` for the source subnet of the DB instance.

    > **Note**
    >
    > When creating an **Inbound Rule** and **Outbound Rule**, take note of the highest existing **Rule number**. The new rules you create must have a **Rule number** lower than 100 and not match any existing **Rule number**.

    a. In **Network ACLs**, choose the *-private-network-acl* group.

    b. For **Inbound Rules**, create an **All TCP** rule to allow TCP ports `0-65535` with a source from *privatesubnet1* and *privatesubnet2*.

    c. For **Outbound Rules**, create an **All TCP** rule to allow TCP ports `0-65535` to destination *privatesubnet1* and *privatesubnet2*.

Modify using the RDS console, AWS CLI, or RDS API.

After you've completed the prerequisites, you can modify an RDS Custom for SQL Server DB instance from a Single-AZ to Multi-AZ deployment using the RDS console, AWS CLI, or RDS API.

Console

To modify an existing RDS Custom for SQL Server Single-AZ to Multi-AZ deployment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears.

3. Choose the RDS Custom for SQL Server DB instance that you want to modify.
4. For **Actions**, choose **Convert to Multi-AZ deployment**.
5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see Using the schedule modifications setting.
6. On the **Confirmation** page, choose **Convert to Multi-AZ**.

AWS CLI

To convert to a Multi-AZ DB instance deployment by using the AWS CLI, call the modify-db-instance command and set the `--multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see Settings for DB instances.

Example

The following code modifies `mycustomdbinstance` by including the `--multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Using the schedule modifications setting.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mycustomdbinstance \
    --multi-az \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mycustomdbinstance ^
    --multi-az  \ ^
    --no-apply-immediately
```

RDS API

To convert to a Multi-AZ DB instance deployment with the RDS API, call the ModifyDBInstance operation and set the `MultiAZ` parameter to true.

Modifying an RDS Custom for SQL Server Multi-AZ deployment to a Single-AZ deployment

You can modify an existing RDS Custom for SQL Server DB instance from a Multi-AZ to a Single-AZ deployment.

Console

To modify an RDS Custom for SQL Server DB instance from a Multi-AZ to Single-AZ deployment.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears.
3. Choose the RDS Custom for SQL Server DB instance that you want to modify.
4. For **Multi-AZ deployment**, choose **No**.
5. On the **Confirmation** page, choose **Apply immediately** to apply the changes immediately. Choosing this option doesn't cause downtime, but there is a possible performance impact. Alternatively, you can choose to apply the update during the next maintenance window. For more information, see Using the schedule modifications setting.
6. On the **Confirmation** page, choose **Modify DB Instance**.

AWS CLI

To modify a Multi-AZ deployment to a Single-AZ deployment by using the AWS CLI, call the modify-db-instance command and include the `--no-multi-az` option. Specify the DB instance identifier and the values for other options that you want to modify. For information about each option, see Settings for DB instances.

Example

The following code modifies `mycustomdbinstance` by including the `--no-multi-az` option. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see Using the schedule modifications setting.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mycustomdbinstance \
    --no-multi-az  \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mycustomdbinstance ^
    --no-multi-az \ ^
    --no-apply-immediately
```

RDS API

To modify a Multi-AZ deployment to a Single-AZ deployment by using the RDS API, call the ModifyDBInstance operation and set the `MultiAZ` parameter to `false`.

Failover process for an RDS Custom for SQL Server Multi-AZ deployment

If a planned or unplanned outage of your DB instance results from an infrastructure defect, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have turned on Multi-AZ. The time that it takes for the failover to complete depends on the database activity and other conditions at the time that the primary DB instance became unavailable. Failover times are typically 60 – 120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to show the new Availability Zone.

> **Note**
>
> You can force a failover manually when you reboot a DB instance with failover. For more information on rebooting a DB instance, see Rebooting a DB instance

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the RDS event log.

Failover reason	Description
`The operating system for the RDS Custom for SQL Server Multi-AZ DB instance is being patched in an offline operation`	A failover was triggered during the maintenance window for an OS patch or a security update. For more information, see Maintaining a DB instance.
`The primary host of the RDS Custom for SQL Server Multi-AZ DB instance is unhealthy.`	The Multi-AZ DB instance deployment detected an impaired primary DB instance and failed over.
`The primary host of the RDS Custom for SQL Server Multi-AZ DB instance is unreachable due to loss of network connectivity.`	RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.
`The RDS Custom for SQL Server Multi-AZ DB instance was modified by the customer.`	A DB instance modification triggered a failover. For more information, see Modifying an RDS Custom for SQL Server DB instance.
`The storage volume of the primary host of the RDS Custom`	The Multi-AZ DB instance deployment detected a storage issue on the primary DB instance and failed over.

Failover reason	Description
`for SQL Server Multi-AZ DB instance experienced a failure.`	
`The user requested a failover of the RDS Custom for SQL Server Multi-AZ DB instance.`	The RDS Custom for SQL Server Multi-AZ DB instance was rebooted with failover. For more information, see Rebooting a DB instance.
`The RDS Custom for SQL Server Multi-AZ primary DB instance is busy or unresponsive.`	The primary DB instance is unresponsive. We recommend that you try the following steps: • Examine the event logs and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Working with Amazon RDS event notification. • Create a rule that triggers on an Amazon RDS event. For more information, see Creating a rule that triggers on an Amazon RDS event. • Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes.

To determine if your Multi-AZ DB instance has failed over, you can do the following:

- Set up DB event subscriptions to notify you by email or SMS that a failover has been initiated. For more information about events, see Working with Amazon RDS event notification.
- View your DB events by using the RDS console or API operations.
- View the current state of your RDS Custom for SQL Server Multi-AZ DB instance deployment by using the RDS console, CLI, or API operations.

Time to live (TTL) settings with applications using an RDS Custom for SQL Server Multi-AZ deployment

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. Ensure that any DNS cache time-to-live (TTL) configuration value is low, and validate that your application will not cache DNS for an extended time. A high TTL value might prevent your application from quickly reconnecting to the DB instance after failover.

Backing up and restoring an Amazon RDS Custom for SQL Server DB instance

Like Amazon RDS, RDS Custom creates and saves automated backups of your RDS Custom for SQL Server DB instance when backup retention is enabled. You can also back up your DB instance manually. The automated backups are comprised of snapshot backups and transaction log backups. Snapshot backups are taken for the entire storage volume of DB instance during your specified backup window. Transaction log backups are taken for the PITR-eligible databases on a regular interval period. RDS Custom saves the automated backups of your DB instance according to your specified backup retention period. You can use automated backups to recover your DB instance to a point in time within the backup retention period.

You can also take snapshot backups manually. You can create a new DB instance from these snapshot backups at any time. For more information about manually creating a DB snapshot, see Creating an RDS Custom for SQL Server snapshot.

Although snapshot backups serve operationally as full backups, you are billed only for incremental storage use. The first snapshot of an RDS Custom DB instance contains the data for the full DB instance. Subsequent snapshots of the same database are incremental, which means that only the data that has changed after your most recent snapshot is saved.

Topics

- Creating an RDS Custom for SQL Server snapshot
- Restoring from an RDS Custom for SQL Server DB snapshot
- Restoring an RDS Custom for SQL Server instance to a point in time
- Deleting an RDS Custom for SQL Server snapshot
- Deleting RDS Custom for SQL Server automated backups

Creating an RDS Custom for SQL Server snapshot

RDS Custom for SQL Server creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create a snapshot, specify which RDS Custom for SQL Server DB instance to back up. Give your snapshot a name so you can restore from it later.

When you create a snapshot, RDS Custom for SQL Server creates an Amazon EBS snapshot for volume (`D:`), which is the database volume attached to the DB instance. To make snapshots

easy to associate with a specific DB instance, they're tagged with `DBSnapshotIdentifier`, `DbiResourceId`, and `VolumeType`.

Creating a DB snapshot results in a brief I/O suspension. This suspension can last from a few seconds to a few minutes, depending on the size and class of your DB instance. The snapshot creation time varies with the total count and size of your databases. To learn more about the number of databases eligible for a point in time restore (PITR) operation, see Number of databases eligible for PITR per instance class type.

Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects snapshot creation time. To learn more about creating snapshots, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

Create an RDS Custom for SQL Server snapshot using the console or the AWS CLI.

Console

To create an RDS Custom snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. In the list of RDS Custom DB instances, choose the instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

   The **Take DB snapshot** window appears.
5. For **Snapshot name**, enter the name of the snapshot.
6. Choose **Take snapshot**.

AWS CLI

You create a snapshot of an RDS Custom DB instance by using the create-db-snapshot AWS CLI command.

Specify the following options:

- `--db-instance-identifier` – Identifies which RDS Custom DB instance you are going to back up

- `--db-snapshot-identifier` – Names your RDS Custom snapshot so you can restore from it later

In this example, you create a DB snapshot called *my-custom-snapshot* for an RDS Custom DB instance called *my-custom-instance*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier my-custom-instance \
    --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier my-custom-instance ^
    --db-snapshot-identifier my-custom-snapshot
```

Restoring from an RDS Custom for SQL Server DB snapshot

When you restore an RDS Custom for SQL Server DB instance, you provide the name of the DB snapshot and a name for the new instance. You can't restore from a snapshot to an existing RDS Custom DB instance. A new RDS Custom for SQL Server DB instance is created when you restore.

Restoring from a snapshot will restore the storage volume to the point in time at which the snapshot was taken. This will include all the databases and any other files that were present on the `(D:)` volume.

Console

To restore an RDS Custom DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.

5. On the **Restore DB instance** page, for **DB instance identifier**, enter the name for your restored RDS Custom DB instance.
6. Choose **Restore DB instance**.

AWS CLI

You restore an RDS Custom DB snapshot by using the restore-db-instance-from-db-snapshot AWS CLI command.

If the snapshot you are restoring from is for a private DB instance, make sure to specify both the correct `db-subnet-group-name` and `no-publicly-accessible`. Otherwise, the DB instance defaults to publicly accessible. The following options are required:

- `db-snapshot-identifier` – Identifies the snapshot from which to restore
- `db-instance-identifier` – Specifies the name of the RDS Custom DB instance to create from the DB snapshot
- `custom-iam-instance-profile` – Specifies the instance profile associated with the underlying Amazon EC2 instance of an RDS Custom DB instance.

The following code restores the snapshot named `my-custom-snapshot` for `my-custom-instance`.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot \
  --db-instance-identifier my-custom-instance \
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
  --no-publicly-accessible
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot ^
  --db-instance-identifier my-custom-instance ^
  --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
  --no-publicly-accessible
```

Restoring an RDS Custom for SQL Server instance to a point in time

You can restore a DB instance to a specific point in time (PITR), creating a new DB instance. To support PITR, your DB instances must have backup retention enabled.

The latest restorable time for an RDS Custom for SQL Server DB instance depends on several factors, but is typically within 5 minutes of the current time. To see the latest restorable time for a DB instance, use the AWS CLI describe-db-instances command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

For general information about PITR, see Restoring a DB instance to a specified time for Amazon RDS.

Topics

- PITR considerations for RDS Custom for SQL Server
- Number of databases eligible for PITR per instance class type
- Making databases ineligible for PITR
- Transaction logs in Amazon S3
- PITR Restore using the AWS Management Console, the AWS CLI, or the RDS API.

PITR considerations for RDS Custom for SQL Server

In RDS Custom for SQL Server, PITR differs in the following important ways from PITR in Amazon RDS:

- PITR only restores the databases in the DB instance. It doesn't restore the operating system or files on the C: drive.
- For an RDS Custom for SQL Server DB instance, a database is backed up automatically and is eligible for PITR only under the following conditions:
  - The database is online.
  - Its recovery model is set to `FULL`.
  - It's writable.

  - It has its physical files on the D: drive.
  - It's not listed in the `rds_pitr_blocked_databases` table. For more information, see Making databases ineligible for PITR.
- The databases eligible for PITR are determined by the order of their database ID. RDS Custom for SQL Server allows up to 5,000 databases per DB instance. However, the maximum number of databases restored by a PITR operation for an RDS Custom for SQL Server DB instance is dependent on the instance class type. For more information, see Number of databases eligible for PITR per instance class type.

  Other databases that aren't part of PITR can be restored from DB snapshots, including the automated snapshot backups used for PITR.
- Adding a new database, renaming a database, or restoring a database that is eligible for PITR initiates a snapshot of the DB instance.
- The maximum number of databases eligible for PITR changes when the database instance goes through a scale compute operation, depending on the target instance class type. If the instance is scaled up, allowing more databases on the instance to be eligible for PITR, a new snapshot is taken.
- Restored databases have the same name as in the source DB instance. You can't specify a different name.
- `AWSRDSCustomSQLServerIamRolePolicy` requires access to other AWS services. For more information, see Add an access policy to AWSRDSCustomSQLServerInstanceRole.
- Time zone changes aren't supported for RDS Custom for SQL Server. If you change the operating system or DB instance time zone, PITR (and other automation) doesn't work.

Number of databases eligible for PITR per instance class type

The following table shows the maximum number of databases eligible for PITR based on instance class type.

Instance class type	Maximum number of PITR eligible databases				
db.*.large	100				

Instance class type	Maximum number of PITR eligible databases
db.*.xlarge to db.*.2xlarge	150
db.*.4xlarge to db.*.8xlarge	300
db.*.12xlarge to db.*.16xlarge	600
db.*.24xlarge, db.*32xlarge	1000

* *Represents different instance class types.*

The maximum number of databases eligible for PITR on a DB instance depends on the instance class type. The number ranges from 100 on the smallest to 1000 on the largest instance class types supported by RDS Custom for SQL Server. SQL server system databases (`master, model, msdb, tempdb`), aren't included in this limit. When a DB instance is scaled up or down, depending on the target instance class type, RDS Custom will automatically update the number of database eligible for PITR. RDS Custom for SQL Server will send `RDS-EVENT-0352` when the maximum number of databases eligible for PITR changes on a DB instance. For more information, see Custom engine version events.

Note

PITR support for greater than 100 databases is only available on DB instances created after August 26, 2023. For instances created before August 26, 2023, the maximum number of databases eligible for PITR is 100, regardless of the instance class. To enable PITR support for more than 100 databases on DB instances created before August 26, 2023, you can perform the following action:

- Upgrade the DB engine version to 15.00.4322.2.v1 or higher

During a PITR operation, RDS Custom will restore all of the databases that were part of PITR on source DB instance at restore time. Once the target DB instance has completed restore operations, if backup retention is enabled, the DB instance will start backing up based on the maximum number of databases eligible for PITR on target DB instance.

For example, if your DB instance runs on a `db.*.xlarge` that has 200 databases:

1. RDS Custom for SQL Server will choose the first 150 databases, ordered by their database ID, for PITR backup.
2. You modify the instance to scale up to db.*.4xlarge.
3. Once the scale compute operation is completed, RDS Custom for SQL Server will choose the first 300 databases, ordered by their database ID, for PITR backup. Each one of the 200 databases that satisfy the PITR requirement conditions will now be eligible for PITR.
4. You now modify the instance to scale down back to db.*.xlarge.
5. Once the scale compute operation is completed, RDS Custom for SQL Server will again select the first 150 databases, ordered by their database ID, for PITR backup.

Making databases ineligible for PITR

You can choose to exclude individual databases from PITR. To do this, put their `database_id` values into a `rds_pitr_blocked_databases` table. Use the following SQL script to create the table.

To create the rds_pitr_blocked_databases table

- Run the following SQL script.

```
create table msdb..rds_pitr_blocked_databases
(
database_id INT NOT NULL,
database_name SYSNAME NOT NULL,
db_entry_updated_date datetime NOT NULL DEFAULT GETDATE(),
db_entry_updated_by SYSNAME NOT NULL DEFAULT CURRENT_USER,
PRIMARY KEY (database_id)
```

```
);
```

For the list of eligible and ineligible databases, see the `RI.End` file in the `RDSCustomForSQLServer/Instances/`*`DB_instance_resource_ID`*`/TransactionLogMetadata` directory in the Amazon S3 bucket `do-not-delete-rds-custom-`*`$ACCOUNT_ID`*`-`*`$REGION`*`-`*`unique_identifier`*. For more information about the `RI.End` file, see Transaction logs in Amazon S3.

You can also determine the list of eligible databases for PITR using the following SQL script. Set the `@limit` variable to the maximum number of databases on eligible for PITR for the instance class. For more information, see Number of databases eligible for PITR per instance class type.

To determine the list of eligible databases for PITR on a DB instance class

- Run the following SQL script.

```
DECLARE @Limit INT;
SET @Limit = (insert-database-instance-limit-here);

USE msdb;
IF (EXISTS (SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA = 'dbo' AND
 TABLE_NAME = 'rds_pitr_blocked_databases'))
    WITH TABLE0 AS (
        SELECT hdrs.database_id as DatabaseId, sdb.name as DatabaseName,
 'ALWAYS_ON_NOT_WRITABLE_REPLICA' as Reason, NULL as DatabaseNameOnPitrTable
        FROM sys.dm_hadr_database_replica_states hdrs
        INNER JOIN sys.databases sdb ON sdb.database_id = hdrs.database_id
        WHERE (hdrs.is_local = 1 AND hdrs.is_primary_replica = 0)
        OR (sys.fn_hadr_is_primary_replica (sdb.name) = 1 AND DATABASEPROPERTYEX
 (sdb.name, 'Updateability') = 'READ_ONLY')
    ),
    TABLE1 as (
            SELECT dbs.database_id as DatabaseId, sysdbs.name as DatabaseName,
 'OPTOUT' as Reason,
            CASE WHEN dbs.database_name = sysdbs.name THEN NULL ELSE
 dbs.database_name END AS DatabaseNameOnPitrTable
            FROM msdb.dbo.rds_pitr_blocked_databases dbs
            INNER JOIN sys.databases sysdbs ON dbs.database_id = sysdbs.database_id
            WHERE sysdbs.database_id > 4
            ),
    TABLE2 as (
```

```
            SELECT
            db.name AS DatabaseName,
            db.create_date AS CreateDate,
            db.state_desc AS DatabaseState,
            db.database_id AS DatabaseId,
            rs.database_guid AS DatabaseGuid,
            rs.last_log_backup_lsn AS LastLogBackupLSN,
            rs.recovery_fork_guid RecoveryForkGuid,
            rs.first_recovery_fork_guid AS FirstRecoveryForkGuid,
            db.recovery_model_desc AS RecoveryModel,
            db.is_auto_close_on AS IsAutoClose,
            db.is_read_only as IsReadOnly,
            NEWID() as FileName,
            CASE WHEN(db.state_desc = 'ONLINE'
                    AND db.recovery_model_desc != 'SIMPLE'
                    AND((db.is_auto_close_on = 0 and db.collation_name IS NOT NULL)
 OR db.is_auto_close_on = 1))
                    AND db.is_read_only != 1
                    AND db.user_access = 0
                    AND db.source_database_id IS NULL
                    AND db.is_in_standby != 1
                    THEN 1 ELSE 0 END AS IsPartOfSnapshot,
            CASE WHEN db.source_database_id IS NULL THEN 0 ELSE 1 END AS
 IsDatabaseSnapshot
            FROM sys.databases db
            INNER JOIN sys.database_recovery_status rs
            ON db.database_id = rs.database_id
            WHERE DB_NAME(db.database_id) NOT IN('tempdb') AND
            db.database_id NOT IN (SELECT DISTINCT DatabaseId FROM TABLE1) AND
            db.database_id NOT IN (SELECT DISTINCT DatabaseId FROM TABLE0)
        ),
        TABLE3 as(
            Select @Limit+count(DatabaseName) as TotalNumberOfDatabases from TABLE2
 where TABLE2.IsPartOfSnapshot=1 and DatabaseName in ('master','model','msdb')
        )
        SELECT TOP(SELECT TotalNumberOfDatabases from TABLE3)
 DatabaseName,CreateDate,DatabaseState,DatabaseId from TABLE2 where
 TABLE2.IsPartOfSnapshot=1
        ORDER BY TABLE2.DatabaseID ASC
ELSE
    WITH TABLE0 AS (
        SELECT hdrs.database_id as DatabaseId, sdb.name as DatabaseName,
 'ALWAYS_ON_NOT_WRITABLE_REPLICA' as Reason, NULL as DatabaseNameOnPitrTable
        FROM sys.dm_hadr_database_replica_states hdrs
```

```
       INNER JOIN sys.databases sdb ON sdb.database_id = hdrs.database_id
       WHERE (hdrs.is_local = 1 AND hdrs.is_primary_replica = 0)
       OR (sys.fn_hadr_is_primary_replica (sdb.name) = 1 AND DATABASEPROPERTYEX
(sdb.name, 'Updateability') = 'READ_ONLY')
   ),
   TABLE1 as (
           SELECT
           db.name AS DatabaseName,
           db.create_date AS CreateDate,
           db.state_desc AS DatabaseState,
           db.database_id AS DatabaseId,
           rs.database_guid AS DatabaseGuid,
           rs.last_log_backup_lsn AS LastLogBackupLSN,
           rs.recovery_fork_guid RecoveryForkGuid,
           rs.first_recovery_fork_guid AS FirstRecoveryForkGuid,
           db.recovery_model_desc AS RecoveryModel,
           db.is_auto_close_on AS IsAutoClose,
           db.is_read_only as IsReadOnly,
           NEWID() as FileName,
           CASE WHEN(db.state_desc = 'ONLINE'
                   AND db.recovery_model_desc != 'SIMPLE'
                   AND((db.is_auto_close_on = 0 and db.collation_name IS NOT NULL)
OR db.is_auto_close_on = 1))
                   AND db.is_read_only != 1
                   AND db.user_access = 0
                   AND db.source_database_id IS NULL
                   AND db.is_in_standby != 1
                   THEN 1 ELSE 0 END AS IsPartOfSnapshot,
           CASE WHEN db.source_database_id IS NULL THEN 0 ELSE 1 END AS
IsDatabaseSnapshot
           FROM sys.databases db
           INNER JOIN sys.database_recovery_status rs
           ON db.database_id = rs.database_id
           WHERE DB_NAME(db.database_id) NOT IN('tempdb') AND
           db.database_id NOT IN (SELECT DISTINCT DatabaseId FROM TABLE0)
       ),
       TABLE2 as(
           SELECT @Limit+count(DatabaseName) as TotalNumberOfDatabases from TABLE1
where TABLE1.IsPartOfSnapshot=1 and DatabaseName in ('master','model','msdb')
       )
       select top(select TotalNumberOfDatabases from TABLE2)
DatabaseName,CreateDate,DatabaseState,DatabaseId from TABLE1 where
TABLE1.IsPartOfSnapshot=1
```

```
        ORDER BY TABLE1.DatabaseID ASC
```

> **Note**
>
> The databases that are only symbolic links are also excluded from databases eligible for PITR operations. The above query doesn't filter based on this criteria.

Transaction logs in Amazon S3

The backup retention period determines whether transaction logs for RDS Custom for SQL Server DB instances are automatically extracted and uploaded to Amazon S3. A nonzero value means that automatic backups are created, and that the RDS Custom agent uploads the transaction logs to S3 every 5 minutes.

Transaction log files on S3 are encrypted at rest using the AWS KMS key that you provided when you created your DB instance. For more information, see Protecting data using server-side encryption in the *Amazon Simple Storage Service User Guide*.

The transaction logs for each database are uploaded to an S3 bucket named `do-not-delete-rds-custom-`*`$ACCOUNT_ID`*`-`*`$REGION`*`-`*`unique_identifier`*. The `RDSCustomForSQLServer/Instances/`*`DB_instance_resource_ID`* directory in the S3 bucket contains two subdirectories:

- `TransactionLogs` – Contains the transaction logs for each database and their respective metadata.

  The transaction log file name follows the pattern *`yyyyMMddHHmm`*`.`*`database_id`*`.`*`timestamp`*, for example:

  ```
  202110202230.11.1634769287
  ```

  The same file name with the suffix `_metadata` contains information about the transaction log such as log sequence numbers, database name, and `RdsChunkCount`. `RdsChunkCount` determines how many physical files represent a single transaction log file. You might see files with suffixes `_0001`, `_0002`, and so on, which mean the physical chunks of a transaction log file. If you want to use a chunked transaction log file, make sure to merge the chunks after downloading them.

Consider a scenario where you have the following files:

- `202110202230.11.1634769287`
- `202110202230.11.1634769287_0001`
- `202110202230.11.1634769287_0002`
- `202110202230.11.1634769287_metadata`

The `RdsChunkCount` is 3. The order for merging the files is the following: `202110202230.11.1634769287`, `202110202230.11.1634769287_0001`, `202110202230.11.1634769287_0002`.

- `TransactionLogMetadata` – Contains metadata information about each iteration of transaction log extraction.

  The `RI.End` file contains information for all databases that had their transaction logs extracted, and all databases that exist but didn't have their transaction logs extracted. The `RI.End` file name follows the pattern *`yyyyMMddHHmm`*`.RI.End.`*`timestamp`*, for example:

  ```
  202110202230.RI.End.1634769281
  ```

PITR Restore using the AWS Management Console, the AWS CLI, or the RDS API.

You can restore an RDS Custom for SQL Server DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore an RDS Custom DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose the RDS Custom DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the instance.

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored RDS Custom DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. Choose **Restore to point in time**.

AWS CLI

You restore a DB instance to a specified time by using the restore-db-instance-to-point-in-time AWS CLI command to create a new RDS Custom DB instance.

Use one of the following options to specify the backup to restore from:

- `--source-db-instance-identifier` *`mysourcedbinstance`*
- `--source-dbi-resource-id` *`dbinstanceresourceID`*
- `--source-db-instance-automated-backups-arn` *`backupARN`*

The `custom-iam-instance-profile` option is required.

The following example restores `my-custom-db-instance` to a new DB instance named `my-restored-custom-db-instance`, as of the specified time.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my-custom-db-instance\
    --target-db-instance-identifier my-restored-custom-db-instance \
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance \
    --restore-time 2022-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
```

```
    --source-db-instance-identifier my-custom-db-instance ^
    --target-db-instance-identifier my-restored-custom-db-instance ^
    --custom-iam-instance-profile AWSRDSCustomInstanceProfileForRdsCustomInstance ^
    --restore-time 2022-10-14T23:45:00.000Z
```

Deleting an RDS Custom for SQL Server snapshot

You can delete DB snapshots managed by RDS Custom for SQL Server when you no longer need them. The deletion procedure is the same for both Amazon RDS and RDS Custom DB instances.

The Amazon EBS snapshots for the binary and root volumes remain in your account for a longer time because they might be linked to some instances running in your account or to other RDS Custom for SQL Server snapshots. These EBS snapshots are automatically deleted after they're no longer related to any existing RDS Custom for SQL Server resources (DB instances or backups).

Console

To delete a snapshot of an RDS Custom DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

To delete an RDS Custom snapshot, use the AWS CLI command delete-db-snapshot.

The following option is required:

- `--db-snapshot-identifier` – The snapshot to be deleted

The following example deletes the `my-custom-snapshot` DB snapshot.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
  --db-snapshot-identifier my-custom-snapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
  --db-snapshot-identifier my-custom-snapshot
```

Deleting RDS Custom for SQL Server automated backups

You can delete retained automated backups for RDS Custom for SQL Server when they are no longer needed. The procedure is the same as the procedure for deleting Amazon RDS backups.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Automated backups**.
3. Choose **Retained**.
4. Choose the retained automated backup that you want to delete.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **`delete me`** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command delete-db-instance-automated-backup.

The following option is used to delete a retained automated backup:

- `--dbi-resource-id` – The resource identifier for the source RDS Custom DB instance.

  You can find the resource identifier for the source DB instance of a retained automated backup by using the AWS CLI command describe-db-instance-automated-backups.

The following example deletes the retained automated backup with source DB instance resource identifier `custom-db-123ABCEXAMPLE`.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
    --dbi-resource-id custom-db-123ABCEXAMPLE
```

Copying an Amazon RDS Custom for SQL Server DB snapshot

With RDS Custom for SQL Server, you can copy automated backups and manual DB snapshots. After copying a snapshot, the copy you create is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot but each copy must have a unique identifier.

You can only copy a snapshot within the same AWS account across different AWS Regions where RDS Custom for SQL Server is available. The following operations are currently not supported:

- Copying DB snapshots within the same AWS Region.
- Copying DB snapshots across AWS accounts.

RDS Custom for SQL Server supports incremental snapshot copying. For more information, see Considerations for incremental snapshot copying.

Topics

- Limitations
- Handling encryption
- Cross-Region copying
- Snapshots of DB instances created with Custom Engine Versions (CEV)
- Grant required permissions to your IAM principal
- Copying a DB snapshot

Limitations

The following limitations apply to copying a DB snapshot for RDS Custom for SQL Server:

- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of `AVAILABLE` before you delete the source snapshot.
- You cannot specify an option group name or copy an options group in your DB snapshot copy request.
- If you delete any dependent AWS resources of the source DB snapshot before or during the copy process, your copy snapshot request could fail asynchronously.
  - If you delete the Service Master Key (SMK) backup file for your source DB instance stored in the RDS Custom managed S3 bucket in your account, the DB snapshot copy succeeds

asynchronously. However, SQL Server features dependent on SMK such as TDE enabled databases run into issues. For more information, see Troubleshooting PENDING_RECOVERY state for TDE enabled databases in RDS Custom for SQL Server.

- Copying DB snapshots within the same AWS Region is currently not supported.
- Copying DB snapshots across AWS accounts is currently not supported.

The limitations of copying a DB snapshot for Amazon RDS also apply to RDS Custom for SQL Server. For more information, see Limitations.

Handling encryption

All RDS Custom for SQL Server DB instances and DB snapshots are encrypted with KMS keys. You can only copy an encrypted snapshot to an encrypted snapshot, therefore you must specify a KMS key valid in the destination AWS Region for your DB snapshot copy request.

The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy operation with the specified destination AWS Region KMS key. For more information, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

Cross-Region copying

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Authorizing RDS to communicate across AWS Regions for snapshot copying

After a cross-Region DB snapshot copy request is processed successfully, RDS starts the copy. An authorization request for RDS to access the source snapshot is created. This authorization request links the source DB snapshot to the target DB snapshot. This allows RDS to copy only to the specified target snapshot.

RDS verifies the authorization by using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the copy is authorized, RDS can communicate with the source Region and complete the copy operation.

RDS doesn't have access to DB snapshots that weren't authorized previously by a CopyDBSnapshot request. The authorization is revoked after the copy completes.

RDS uses the service-linked role to verify the authorization in the source Region. The copy fails if you delete the service-linked role during the copy process.

For more information, see Using service-linked roles in the *AWS Identity and Access Management User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. Your credentials must be valid in both Regions, which is true for opt-in Regions only when you use the regional AWS STS endpoint.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid` in all AWS Regions in the AWS STS account settings.

For more information, see Managing AWS STS in an AWS Region in the *AWS Identity and Access Management User Guide*.

Snapshots of DB instances created with Custom Engine Versions (CEV)

For a DB snapshot of a DB instance using a Custom Engine Version (CEV), RDS associates the CEV with the DB snapshot. To copy a source DB snapshot associated with a CEV across AWS Regions, RDS copies the CEV along with the source DB snapshot to the destination region.

If you are copying multiple DB snapshots associated with the same CEV to the same destination region, the first copy request copies the associated CEV. The copy process of the following requests finds the initially copied CEV and associates it with the following DB snapshot copies. The existing CEV copy must be in `AVAILABLE` state to be associated with the DB snapshot copies.

To copy a DB snapshot associated with a CEV, the requester's IAM policy must have the permissions to authorize both the DB snapshot copying and the associated CEV copying. The following permissions are needed in your requester's IAM policy to allow the associated CEV copying:

- `rds:CopyCustomDBEngineVersion` - Your requester IAM principal needs to have the permission to copy the source CEV to the target region along with the source DB snapshot. The snapshot copy request fails due to authorization errors if your requester IAM principal is not authorized to copy the source CEV.
- `ec2:CreateTags` - The underlying EC2 AMI of the source CEV is copied to the target region as a part of the CEV copy. RDS Custom attempts to tag the AMI with the `AWSRDSCustom` tag before

copying the AMI. Make sure your requester IAM principal has the permission to create the tag against the AMI underlying the source CEV in the source region.

For more information about CEV copying permissions, see Grant required permissions to your IAM principal.

Grant required permissions to your IAM principal

Make sure that you have sufficient access to copy a RDS Custom for SQL Server DB snapshot. The IAM role or user (referred to as the IAM principal) for copying a DB snapshot using the console or CLI must have either of the following policies for successful DB instance creation:

- The `AdministratorAccess` policy or,
- The `AmazonRDSFullAccess` policy with the following additional permissions:

```
s3:CreateBucket
s3:GetBucketPolicy
s3:PutBucketPolicy
kms:CreateGrant
kms:DescribeKey
ec2:CreateTags
```

RDS Custom uses these permissions during snapshot copying across AWS Regions. These permissions configure resources in your account that are required for RDS Custom operations. For more information about the `kms:CreateGrant` permission, see AWS KMS key management.

The following sample JSON policy grants the required permissions in addition to `AmazonRDSFullAccess` policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3BucketAndReadWriteBucketPolicy",

        },
        {
            "Sid": "CreateEc2Tags",
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "*"
        }
    ]
}
```

Note

Make sure that the listed permissions aren't restricted by service control policies (SCPs), permission boundaries, or session policies associated with the IAM principal.

If you use conditions with context keys in the requester's IAM policy, certain conditions can cause the request to fail. For more information about common pitfalls due to IAM policy conditions, see Requesting a cross-Region DB snapshot copy.

Copying a DB snapshot

Use the following procedures to copy a DB snapshot. For each AWS account, you can copy up to 20 DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a

DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges. For more information about data transfer pricing, see Amazon RDS pricing.

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, AWS CLI, or the Amazon RDS API.

Console

The following procedure copies a RDS Custom for SQL Server DB snapshot by using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Select the RDS Custom for SQL Server DB snapshot that you want to copy.
4. In the **Actions** dropwdown , choose **Copy snapshot**.

RDS > Snapshots > Copy snapshot

Copy snapshot

Settings

Source DB snapshot
DB snapshot identifier for the snapshot being copied.
db1-snapshot

New DB snapshot identifier
DB snapshot identifier for the new snapshot.
copied-db1-snapshot
Must start with a letter and only contain letters, digits, or hyphens.

Destination Region Info
Choose a Region

Resource tags Info
Copy tags from the source DB snapshot

Depending on the amount of data to be copied and the Region you choose, this operation can take several hours to complete. The display on the progress bar might be delayed until setup is complete.

Encryption

Encryption Info
Enable Encryption
Choose to encrypt the copy of the source DB snapshot. Master key IDs and aliases appear in the list after they have been created using KMS. You cannot remove encryption from an encrypted DB snapshot.

AWS KMS key Info
Enter a key ARN

Amazon Resource Name (ARN)
[redacted]
Example: arn:aws:kms:<region>:<accountID>:key/<key-id>

Account
[redacted]

KMS key ID
[redacted]

5. To copy the DB snapshot to a different AWS Region, set **Destination Region** to the required value.

   > **Note**
   >
   > The destination AWS Region must have the same database engine version available as the source AWS Region.

6. For **New DB snapshot identifier**, enter a unique name for the DB snapshot. You can make multiple copies of an automated backup or manual snapshot but each copy must have a unique identifier.
7. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.
8. For **Encryption**, specify the KMS key identifier to use to encrypt the DB snapshot copy.

   > **Note**
   >
   > RDS Custom for SQL Server encrypts all DB snapshots. You can't create an unencrypted DB snapshot.

9. Choose **Copy snapshot**.

RDS Custom for SQL Server creates a DB snapshot copy of your DB instance in the AWS Region of your selection.

AWS CLI

You can copy a RDS Custom for SQL Server DB snapshot by using the AWS CLI command copy-db-snapshot. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region. The following options are used to copy a DB snapshot. Not all options are required for all scenarios.

- `--source-db-snapshot-identifier` - The identifier for the source DB snapshot.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:instance1-snapshot-12345678`.
- `--target-db-snapshot-identifier` - The identifier for the new copy of the DB snapshot.

- `--kms-key-id` -The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in and you cannot use encryption keys from one AWS Region in another AWS Region unless a multi-Region key is used. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.
- `--copy-tags` - Include the tags and values from the source snapshot to the copy of the snapshot.

The following options are not supported for copying an RDS Custom for SQL Server DB snapshot:

- `--copy-option-group`
- `--option-group-name`
- `--pre-signed-url`
- `--target-custom-availability-zone`

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
     --region us-east-1 \
    --source-db-snapshot-identifier arn:aws:rds:us-
west-2:123456789012:snapshot:instance1-snapshot-12345678 \
    --target-db-snapshot-identifier mydbsnapshotcopy \
    --kms-key-id a1b2c3d4-1234-5678-wxyz-a1b2c3d4d5e6
```

For Windows:

```
aws rds copy-db-snapshot ^
     --region us-east-1 ^
    --source-db-snapshot-identifier arn:aws:rds:us-
west-2:123456789012:snapshot:instance1-snapshot-12345678 ^
```

```
    --target-db-snapshot-identifier mydbsnapshotcopy ^
    --kms-key-id a1b2c3d4-1234-5678-wxyz-a1b2c3d4d5e6
```

RDS API

You can copy a RDS Custom for SQL Server DB snapshot by using the Amazon RDS API operation CopyDBSnapshot. If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region. The following parameters are used to copy a DB snapshot. Not all parameters are required:

- `SourceDBSnapshotIdentifier` - The identifier for the source DB snapshot.
  - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:instance1-snapshot-12345678`.
- `TargetDBSnapshotIdentifier` - The identifier for the new copy of the DB snapshot.
- `KmsKeyId` - The KMS key identifier for an encrypted DB snapshot. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key.
  - If you copy an encrypted snapshot to a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS keys are specific to the AWS Region that they are created in and you cannot use encryption keys from one AWS Region in another AWS Region unless a multi-Region key is used. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.
- `CopyTags` - Set this parameter to `true` to copy tags and values from the source snapshot to the copy of the snapshot. The default is `false`.

The following options are not supported copying a RDS Custom for SQL Server DB snapshot:

- `CopyOptionGroup`
- `OptionGroupName`
- `PreSignedUrl`
- `TargetCustomAvailabilityZone`

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the US East (N. Virginia) Region.

```
https://rds.us-east-1.amazonaws.com/
```

```
    ?Action=CopyDBSnapshot
    &KmsKeyId=a1b2c3d4-1234-5678-wxyz-a1b2c3d4d5e6
    &SourceDBSnapshotIdentifier=arn%3Aaws%3Ards%3Aus-
west-2%3A123456789012%3Asnapshot%3Ainstance1-snapshot-12345678
    &TargetDBSnapshotIdentifier=mydbsnapshotcopy
    &Version=2014-10-31
    &X-Amz-Algorithm=AWS4-HMAC-SHA256
    &X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
    &X-Amz-Date=20161117T221704Z
    &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-
date
    &X-Amz-
Signature=da4f2da66739d2e722c85fcfd225dc27bba7e2b8dbea8d8612434378e52adccf
```

Migrating an on-premises database to Amazon RDS Custom for SQL Server

You can use the following process to migrate an on-premises Microsoft SQL Server database to Amazon RDS Custom for SQL Server using native backup and restore:

1. Take a full backup of the database on the on-premises DB instance.
2. Upload the backup file to Amazon S3.
3. Download the backup file from S3 to your RDS Custom for SQL Server DB instance.
4. Restore a database using the downloaded backup file on the RDS Custom for SQL Server DB instance.

This process explains the migration of a database from on-premises to RDS Custom for SQL Server, using native full backup and restore. To reduce the cutover time during the migration process, you might also consider using differential or log backups.

For general information about native backup and restore for RDS for SQL Server, see Importing and exporting SQL Server databases using native backup and restore.

Topics

- Prerequisites
- Backing up the on-premises database
- Uploading the backup file to Amazon S3
- Downloading the backup file from Amazon S3
- Restoring the backup file to the RDS Custom for SQL Server DB instance

Prerequisites

Perform the following tasks before migrating the database:

1. Configure Remote Desktop Connection (RDP) for your RDS Custom for SQL Server DB instance. For more information, see Connecting to your RDS Custom DB instance using RDP.
2. Configure access to Amazon S3 so you can upload and download the database backup file.

Backing up the on-premises database

You use SQL Server native backup to take a full backup of the database on the on-premises DB instance.

The following example shows a backup of a database called `mydatabase`, with the `COMPRESSION` option specified to reduce the backup file size.

To back up the on-premises database

1. Using SQL Server Management Studio (SSMS), connect to the on-premises SQL Server instance.
2. Run the following T-SQL command.

```
backup database mydatabase to
disk ='C:\Program Files\Microsoft SQL Server\MSSQL13.MSSQLSERVER\MSSQL\Backup\mydb-full-compressed.bak'
with compression;
```

Uploading the backup file to Amazon S3

You use the AWS Management Console to upload the backup file `mydb-full-compressed.bak` to Amazon S3.

To upload the backup file to S3

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. For **Buckets**, choose the name of the bucket to which you want to upload your backup file.
3. Choose **Upload**.
4. In the **Upload** window, do one of the following:

   - Drag and drop `mydb-full-compressed.bak` to the **Upload** window.
   - Choose **Add file**, choose `mydb-full-compressed.bak`, and then choose **Open**.

   Amazon S3 uploads your backup file as an S3 object. When the upload completes, you can see a success message on the **Upload: status** page.

Downloading the backup file from Amazon S3

You use the console to download the backup file from S3 to the RDS Custom for SQL Server DB instance.

To download the backup file from S3

1. Using RDP, connect to your RDS Custom for SQL Server DB instance.
2. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the **Buckets** list, choose the name of the bucket that contains your backup file.
4. Choose the backup file `mydb-full-compressed.bak`.
5. For **Actions**, choose **Download as**.
6. Open the context (right-click) menu for the link provided, then choose **Save As**.
7. Save `mydb-full-compressed.bak` to the `D:\rdsdbdata\BACKUP` directory.

Restoring the backup file to the RDS Custom for SQL Server DB instance

You use SQL Server native restore to restore the backup file to your RDS Custom for SQL Server DB instance.

In this example, the `MOVE` option is specified because the data and log file directories are different from the on-premises DB instance.

To restore the backup file

1. Using SSMS, connect to your RDS Custom for SQL Server DB instance.
2. Run the following T-SQL command.

```
restore database mydatabase from disk='D:\rdsdbdata\BACKUP\mydb-full-
compressed.bak'
with move 'mydatabase' to 'D:\rdsdbdata\DATA\mydatabase.mdf',
move 'mydatabase_log' to 'D:\rdsdbdata\DATA\mydatabase_log.ldf';
```

RDS Custom for SQL Server Operating system updates

RDS Custom for SQL Server provides the following methods to apply operating system updates to your RDS Provided Engine Version (RPEV) instances:

- *system-update maintenance actions*
- *database minor version upgrades*
  - DB minor engine version upgrades using RPEV include up to date Operating System updates. This approach is particularly useful if you want to combine OS updates with SQL Server minor version upgrades. For more information, see Upgrading an Amazon RDS Custom for SQL Server DB instance.

Scenarios for Operating system update

There are two ways to ways to manage Operating system updates for your RDS Custom for SQL Server instances:

- For Single-AZ instances, the instance is unavailable during the Operating system update.
- For Multi-AZ deployments, RDS applies operating system updates in the following manner:
  - First, RDS performs an Operating system update on the standby instance.
  - RDS fails over to the upgraded standby DB instance, making it the new primary DB instance.
  - Lastly, RDS performs an Operating system update on the new standby DB instance.

The downtime for Multi-AZ deployments is the time it takes for the failover.

Applying Operating system updates using system-update maintenance actions

To apply Operating system updates to your Amazon RDS RPEV instances, you can use the AWS Management Console, AWS CLI, or RDS API. For more information, see Operating system updates for RDS DB instances.

Example

For Linux, macOS, or Unix:

Step 1: Check for available updates

Use the `describe-pending-maintenance-actions` command to see if OS updates are available for your instances:

```
aws rds describe-pending-maintenance-actions
```

Example response:

```
{
    "PendingMaintenanceActions": [
        {
            "ResourceIdentifier": "arn:aws:rds:us-east-1:111122223333:db:my-sqlserver-
instance",
            "PendingMaintenanceActionDetails": [
                {
                    "Action": "system-update",
                    "Description": "New Operating System update is available"
                }
            ]
        }
    ]
}
```

An action type of `system-update` indicates that an OS update is available for your instance.

Step 2: Apply the OS update

Use the `apply-pending-maintenance-action` command to schedule the update:

```
aws rds apply-pending-maintenance-action \
                --resource-identifier arn:aws:rds:us-east-1:111122223333:db:my-
sqlserver-instance \
                --apply-action system-update \
                --opt-in-type immediate
```

The `opt-in-type` input has the following options:

- `immediate`: Apply the update right away
- `next-maintenance`: Apply the update during the next scheduled maintenance window
- `undo-opt-in`: Cancel a previously scheduled update

Example response:

```
{
    "ResourcePendingMaintenanceActions": {
        "ResourceIdentifier": "arn:aws:rds:us-east-1:111122223333:db:my-sqlserver-
instance",
        "PendingMaintenanceActionDetails": [
            {
                "Action": "system-update",
                "AutoAppliedAfterDate": "2024-04-10T20:41:01.695000+00:00",
                "ForcedApplyDate": "2024-04-10T20:41:01.694000+00:00",
                "CurrentApplyDate": "2024-04-10T20:41:01.695000+00:00",
                "Description": "New Operating System update is available"
            }
        ]
    }
}
```

OS update notifications

To be notified when a new, optional operating system patch becomes available, you can subscribe to RDS-EVENT-0230 in the security patching event category. For information about subscribing to RDS events, see Subscribing to Amazon RDS event notification.

Considerations

The following consideations and limitations apply to OS updates:

- Any operating system customizations made to the C:\ drive are not preserved during Operating system updates.
- We recommend taking a manual snapshot before applying updates.

Upgrading an Amazon RDS Custom for SQL Server DB instance

You can upgrade an Amazon RDS Custom for SQL Server DB instance by modifying it to use a new DB engine version. For general information about upgrading DB instances, see Upgrading a DB instance engine version.

Topics

- Overview of upgrades in RDS Custom for SQL Server
- Upgrading major and minor engine version
- Database compatibility level

Overview of upgrades in RDS Custom for SQL Server

Amazon RDS Custom for SQL Server supports major and minor version upgrades. Minor version upgrades can include security patches, bug fixes, and engine improvements. Microsoft releases these updates as cumulative updates (CUs). Major version upgrades introduce new features and engine changes between versions, like upgrading from SQL Server 2019 to 2022. You can apply both upgrades immediately or during scheduled maintenance windows. To prevent potential backward compatibility issues, we recommend testing your applications in a non-production environment before upgrading.

RDS Custom for SQL Server allows you to upgrade an RDS Provided Engine Version (RPEV) or a Custom Engine Version (CEV).

- RDS-provided engine versions (RPEV) contain up-to-date operating system (OS) patches and SQL Server cumulative updates (CU).
- For a custom engine version (CEV), you must follow a two-step process. First, create a new CEV with your target SQL Server version, see Preparing to create a CEV for RDS Custom for SQL Server. This target version must be equal to or newer than your current version. Once the new CEV is created, modify your database instance to use this new version. For more information, see Performing a minor version upgrade for Amazon RDS Custom for SQL Server CEV with Multi-AZ.

  Do not apply SQL Server cumulative updates in-place to your running RDS Custom instance. Once you create a CEV with a specific SQL Server version (for example, SQL Server 2022 CU16), applying a newer cumulative update directly to the instance takes it out of the support perimeter and reports error `SP-S3006`. To patch an existing SQL Server instance using a CEV, create a new

CEV that includes the desired cumulative update, then modify your existing instance to switch to the new CEV.

If you upgrade an RDS Custom for SQL Server DB instance in a Multi-AZ deployment, RDS Custom for SQL Server performs rolling upgrades for your instance. This approach minimizes downtime by upgrading one instance at a time. RDS performs the following actions to perform rolling upgrades:

1. Upgrade the standby DB instance.
2. Failover to the upgraded standby DB instance, making it the new primary DB instance.
3. Upgrade the new standby DB instance.

The DB instance downtime for Multi-AZ deployments is the time it takes for the failover.

The following limitations apply when upgrading an RDS Custom for SQL Server DB instance:

- Custom DB option and parameter groups aren't supported.
- Any additional storage volumes that you attach to your RDS Custom for SQL Server DB instance are not attached after the upgrade.
- For CEVs, in-place application of SQL Server cumulative updates is not supported and results in the instance being taken out of the support perimeter.

Upgrading major and minor engine version

Both major and minor engine version upgrades are irreversible and must always be done to a newer version. To identify available target versions, use the AWS Management Console and choose from the available versions when modifying your DB instance. Alternatively, use the `describe-db-engine-versions` CLI command or DescribeDBEngineVersions RDS API command.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --engine custom-sqlserver-se \
    --engine-version 15.00.4322.2.v1 \
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
    --output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --engine custom-sqlserver-se ^
    --engine-version 15.00.4322.2.v1 ^
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
    --output table
```

The output shows the available target engine versions:

```
-------------------------
|DescribeDBEngineVersions|
+------------------------+
|      EngineVersion     |
+------------------------+
|  15.00.4410.1.v1       |
|  15.00.4415.2.v1       |
|  15.00.4430.1.v1       |
|  16.00.4165.4.v1       |
|  16.00.4175.1.v1       |
|  16.00.4185.3.v1       |
+------------------------+
```

After identifying your target version, use the AWS Management Console and follow the instructions in Modifying an RDS Custom for SQL Server DB instance. Alternatively, use `modify-db-instance` CLI command or ModifyDBInstance RDS API command.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier DB_INSTANCE_IDENTIFIER \
    --engine-version ENGINE_VERSION \
    --allow-major-version-upgrade \
    --region Region \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier DB_INSTANCE_IDENTIFIER ^
    --engine-version ENGINE_VERSION ^
    --allow-major-version-upgrade ^
    --region Region ^
```

```
    --no-apply-immediately
```

> **Note**
>
> You must include the `--allow-major-version-upgrade` parameter to perform major version upgrades.

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see Compatibility level in the Microsoft documentation.

When you upgrade your DB instance, all existing databases remain at their original compatibility level. For example, if you upgrade from SQL Server 2019 to SQL Server 2022, all existing databases have a compatibility level of 150. Any new database created after the upgrade have compatibility level 160.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named `customeracct` to be compatible with SQL Server 2022, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 160
```

Troubleshooting DB issues for Amazon RDS Custom for SQL Server

The shared responsibility model of RDS Custom provides OS shell–level access and database administrator access. RDS Custom runs resources in your account, unlike Amazon RDS, which runs resources in a system account. With greater access comes greater responsibility. In the following sections, you can learn how to troubleshoot issues with Amazon RDS Custom for SQL Server DB instances.

> **Note**
>
> This section explains how to troubleshoot RDS Custom for SQL Server. For troubleshooting RDS Custom for Oracle, see Troubleshooting DB issues for Amazon RDS Custom for Oracle.

Topics

- Viewing RDS Custom events
- Subscribing to RDS Custom events
- Troubleshooting CEV errors for RDS Custom for SQL Server
- Fixing unsupported configurations in RDS Custom for SQL Server
- Troubleshooting Storage-Full in RDS Custom for SQL Server
- Troubleshooting PENDING_RECOVERY state for TDE enabled databases in RDS Custom for SQL Server

Viewing RDS Custom events

The procedure for viewing events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Viewing Amazon RDS events.

To view RDS Custom event notification using the AWS CLI, use the `describe-events` command. RDS Custom introduces several new events. The event categories are the same as for Amazon RDS. For the list of events, see Amazon RDS event categories and event messages.

The following example retrieves details for the events that have occurred for the specified RDS Custom DB instance.

```
aws rds describe-events \
    --source-identifier my-custom-instance \
```

```
    --source-type db-instance
```

Subscribing to RDS Custom events

The procedure for subscribing to events is the same for RDS Custom and Amazon RDS DB instances. For more information, see Subscribing to Amazon RDS event notification.

To subscribe to RDS Custom event notification using the CLI, use the `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

The following example creates a subscription for backup and recovery events for an RDS Custom DB instance in the current AWS account. Notifications are sent to an Amazon Simple Notification Service (Amazon SNS) topic, specified by `--sns-topic-arn`.

```
aws rds create-event-subscription \
    --subscription-name my-instance-events \
    --source-type db-instance \
    --event-categories '["backup","recovery"]' \
    --sns-topic-arn arn:aws:sns:us-east-1:123456789012:interesting-events
```

Troubleshooting CEV errors for RDS Custom for SQL Server

When you try to create a CEV, it might fail. In this case, RDS Custom issues the `RDS-EVENT-0198` event message. For more information on viewing RDS events, see Amazon RDS event categories and event messages.

Use the following information to help you address possible causes.

Message	Troubleshooting suggestions		
`Custom Engine Version creation expected a Sysprep'd AMI. Retry creation using a Sysprep'd AMI.`	Run Sysprep on the EC2 instance that you created from the AMI. For more information about prepping an AMI using Sysprep, see Create a standardized Amazon Machine Image (AMI) using Sysprep.		

Message	Troubleshooting suggestions
`EC2 Image permissio ns for image (AMI_ID) weren't found for customer (Customer_ID). Verify customer (Customer_ID) has valid permissions on the EC2 Image.`	Verify that your account and profile used for creation has the required permissions on `create EC2 Instance` and `Describe Images` for the selected AMI.
`Failed to rebuild databases with server collation (collation name) due to missing setup.exe file for SQL Server.`	Verify that the `setup` file is available at `C:\Program Files \Microsoft SQL Server\nnn \Setup Bootstrap\SQLnnnn\ setup.exe` .
`Image (AMI_ID) doesn't exist in your account (ACCOUNT_ID). Verify (ACCOUNT_ID) is the owner of the EC2 image.`	Ensure the AMI exists in the same customer account.
`Image id (AMI_ID) isn't valid. Specify a valid image id, and try again.`	The name of the AMI is incorrect . Ensure the correct AMI ID is provided.

Message	Troubleshooting suggestions
`Image (AMI_ID) operating system platform isn't supported. Specify a valid image, and try again.`	Choose a supported AMI that has Windows Server with SQL Server Enterprise, Standard, or Web edition. Choose an AMI with one of the following usage operation codes from the EC2 Marketplace: • RunInstances:0102 - Windows with SQL Server Enterprise • RunInstances:0006 - Windows with SQL Server Standard • RunInstances:0202 - Windows with SQL Server Web
`SQL Server Web Edition isn't supported for creating a Custom Engine Version using Bring Your Own Media. Specify a valid image, and try again.`	Use an AMI that contains a supported edition of SQL Server. For more information, see Version support for RDS Custom for SQL Server CEVs.
`The custom engine version can't be the same as the OEV engine version. Specify a valid CEV, and try again.`	Classic RDS Custom for SQL Server engine versions aren't supported . For example, version **15.00.4073.23.v1**. Use a supported version number.
`The custom engine version isn't in an active state. Specify a valid CEV, and try again.`	The CEV must be in an `AVAILABLE` state to complete the operation. Modify the CEV from `INACTIVE` to `AVAILABLE` .

Message	Troubleshooting suggestions
`The custom engine version isn't valid for an upgrade. Specify a valid CEV with an engine version greater or equal to (X), and try again.`	The target CEV is not valid. Check the requirements for a valid upgrade path.
`The custom engine version isn't valid. Names can include only lowercase letters (a-z), dashes (-), underscores (_), and periods (.). Specify a valid CEV, and try again.`	Follow the required CEV naming convention. For more information, see Requirements for RDS Custom for SQL Server CEVs.
`The custom engine version isn't valid. Specify valid database engine version, and try again. Example: 15.00.4073.23-cev123.`	An unsupported DB engine version was provided. Use a supported DB engine version.
`The expected architecture is (X) for image (AMI_ID), but architecture (Y) was found.`	Use an AMI built on the **x86_64** architecture.
`The expected owner of image (AMI_ID) is customer account ID (ACCOUNT_ID), but owner (ACCOUNT_ID) was found.`	Create the EC2 instance from the AMI that you have permission for. Run Sysprep on the EC2 instance to create and save a base image.
`The expected platform is (X) for image (AMI_ID), but platform (Y) was found.`	Use an AMI built with the Windows platform.

Message	Troubleshooting suggestions
`The expected root device type is (X) for image %s, but root device type (Y) was found.`	Create the AMI with the EBS device type.
`The expected SQL Server edition is (X), but (Y) was found.`	Choose a supported AMI that has Windows Server with SQL Server Enterprise, Standard, or Web edition. Choose an AMI with one of the following usage operation codes from the EC2 Marketplace: • RunInstances:0102 - Windows with SQL Server Enterprise • RunInstances:0006 - Windows with SQL Server Standard • RunInstances:0202 - Windows with SQL Server Web
`The expected state is (X) for image (AMI_ID), but the following state was found: (Y).`	Ensure the AMI is in a state of `AVAILABLE` .
`The provided Windows OS name (X) isn't valid. Make sure the OS is one of the following: (Y).`	Use a supported Windows OS.
`Unable to find bootstrap log file in path.`	Verify that the log file is available at `C:\Program Files\Microsoft SQL Server\nnn\Setup Bootstrap\Log\Summary.txt` .

Message	Troubleshooting suggestions
`RDS expected a Windows build version greater than or equal to (X), but found version (Y)..`	Use an AMI with a minimum OS build version of **14393**.
`RDS expected a Windows major version greater than or equal to (X), but found version (Y)..`	Use an AMI with a minimum OS major version of **10.0** or higher.

Fixing unsupported configurations in RDS Custom for SQL Server

Because of the shared responsibility model, it's your responsibility to fix configuration issues that put your RDS Custom for SQL Server DB instance into the `unsupported-configuration` state. If the issue is with the AWS infrastructure, you can use the console or the AWS CLI to fix it. If the issue is with the operating system or the database configuration, you can log in to the host to fix it.

> **Note**
>
> This section explains how to fix unsupported configurations in RDS Custom for SQL Server. For information about RDS Custom for Oracle, see Fixing unsupported configurations in RDS Custom for Oracle.

In the following tables, you can find descriptions of the notifications and events that the support perimeter sends and how to fix them. These notifications and the support perimeter are subject to change. For background on the support perimeter, see RDS Custom support perimeter. For event descriptions, see Amazon RDS event categories and event messages.

Event Code	Configuration area	RDS event message	Validation process
`SP-S0000`	Manual Unsupported Configuration	The RDS Custom DB instance status is set to [Unsuppor	To resolve this issue, create a support case.

Event Code	Configuration area	RDS event message	Validation process
		ted configuration] because of: X.	

AWS resource (infrastructure)

Event Code	Configuration area	RDS event message	Validation process
SP-S1001	EC2 Instance State	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The underlying EC2 instance %s has been stopped without stopping the RDS instance. You can resolve this by starting the underlying EC2 instance and ensuring that the binary and data volumes are attached. If your intention is to stop the RDS instance, make sure that underlying EC2 instance is in the AVAILABLE state first and then use	To check the status of a DB instance, use the console or run the following AWS CLI command: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep DBInstanceStatus`

Event Code	Configuration area	RDS event message	Validation process
		the RDS console or CLI to stop the RDS instance.	

SP-S1002	EC2 Instance State	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The RDS DB instance status is set to STOPPED but the underlying EC2 instance %s has been started. You can resolve this by stopping the underlying EC2 instance. If your intention is to start the RDS instance, use the console or CLI.	Use the following AWS CLI command to check the status of a DB instance:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep DBInstanceStatus`
			You can also check the status of the EC2 instance using the EC2 console.
			To start a DB instance, use the console or run the following AWS CLI command:
			`aws rds start-db-instance \ --db-instance-identifier db-instance-name`

Event Code	Configuration area	RDS event message	Validation process
SP-S1003	EC2 Instance Class	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured DB instance class of the EC2 host. You can resolve this by modifying the DB instance class to its original class type.	Use the following CLI command to check the expected DB instance class: `aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep DBInstanceClass`
SP-S1004	EBS Storage Volume Not Accessible	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The original EBS storage volume %s that was associated with the EC2 instance is currently not accessible.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1005	EBS Storage Volume Detached	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The original EBS storage volume "volume-id" isn't attached. You can resolve this by attaching the EBS volume associated to the EC2 instance.	After re-attaching the EBS volume, use the following CLI commands to check if the EBS volume 'volume-id' is properly attached to the RDS instance: `aws ec2 describe-volumes \ --volume-ids volume-id | grep InstanceId`

SP-S1006	EBS Storage Volume Size	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured settings of EBS storage volume "volume-id". The volume size has been changed manually at EC2 level from its original value(s) of [%s]. To resolve this issue, create a support case.	Use the following CLI command to compare the volume size of the EBS volume 'volume-id' details and the RDS instance details:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep AllocatedStorage`
			Use the following CLI command to view the actual allocated volume size:
			`aws ec2 describe-volumes \ --volume-ids |grep Size`

Event Code	Configuration area	RDS event message	Validation process

SP-S1007	EBS Storage Volume Configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured settings of EBS storage volume "volume-id". You can resolve this by modifying the EBS storage volume configuration [IOPS, Throughput, Volume type] to its original value(s) of [IOPS: %s, Throughput: %s, Volume type: %s] at the EC2 level. For future storage modifications, use the RDS console or CLI. The volume size has also been changed manually at EC2 level from its original value(s) of [%s]. To resolve this issue, create a support case.	Use the following CLI command to compare the volume type of the EBS volume 'volume-id' details and the RDS instance details. Make sure that the values at the EBS level matches the values at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageType`
			To get the expected value for Storage Throughput at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageThroughput`
			To get the expected value for Volume IOPS at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep Iops`
			To get the current Storage Type at the EC2 Level:

Event Code	Configuration area	RDS event message	Validation process

			`aws ec2 describe-volumes \ --volume-ids |grep VolumeType`
			
			To get the current value for Storage Throughput at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Throughput`
			
			To get the current value for Volume IOPS at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Iops`

Event Code	Configuration area	RDS event message	Validation process

SP-S1008	EBS Storage Volume Size and Configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and configured settings of EBS storage volume "volume-id". You can resolve this by modifying the EBS storage volume configuration [IOPS, Throughput, Volume type] to its original value(s) of [IOPS: %s, Throughput: %s, Volume type: %s] at the EC2 level. For future storage modifications, use the RDS console or CLI. The volume size has also been changed manually at EC2 level from its original value(s) of [%s]. To resolve this issue, create a support case.	Use the following CLI command to compare the volume type of the EBS volume 'volume-id' details and the RDS instance details. Make sure that the values at the EBS level matches the values at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageType`
			To get the expected value for Storage Throughput at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep StorageThroughput`
			To get the expected value for Volume IOPS at the RDS level:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep Iops`
			To get the current Storage Type at the EC2 Level:

Event Code	Configuration area	RDS event message	Validation process

			`aws ec2 describe-volumes \ --volume-ids |grep VolumeType`
			
			To get the current value for Storage Throughput at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Throughput`
			
			To get the current value for Volume IOPS at the EC2 Level:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Iops`
			
			To get the expected Allocated Volume Size:
			
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name | grep AllocatedStorage`
			
			To get the actual Allocated Volume Size:
			
			`aws ec2 describe-volumes \ --volume-ids |grep Size`

Event Code	Configuration area	RDS event message	Validation process
SP-S1009	SQS Permissions	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Amazon Simple Queue Service (SQS) permissions are missing for the IAM instance profile. You can resolve this by making sure the IAM profile associated with the host has the following permissions: ["SQS:SendMessage","SQS:ReceiveMessage","SQS:DeleteMessage","SQS:GetQueueUrl"].	

Event Code	Configuration area	RDS event message	Validation process
SP-S1010	SQS VPC Endpoint	The RDS Custom DB instance status is set to [Unsupported configuration] because of: A VPC endpoint policy is blocking the Amazon Simple Queue Service (SQS) operations. You can resolve this by modifying your VPC endpoint policy to allow the required SQS actions.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1011	Event bus policy	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The resource-based policy for your event bus arn:aws:events:region-1:123456789012:event-bus/default denies Amazon CloudWatch events:PutEvents actions. Resolve this by modifying your resource-based policy to allow events:PutEvents actions for EventBus %s.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1012	CloudWatch VPC permissions	The RDS Custom DB instance status is set to [Unsupported configuration] because of: A VPC endpoint policy is missing permissions to access Amazon CloudWatch events. Resolve this by modifying your VPC endpoint policy to allow events:PutEvents on EventBus arn:aws:events:region-1:123456789012:event-bus/default.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1013	Service control policy	The RDS Custom DB instance status is set to [Unsupported configuration] because of: A service control policy in your AWS Organizations is missing permissions to access Amazon CloudWatch events. Resolve this by modifying your service control policy to allow events:PutEvents on EventBus arn:aws:events:region-1:123456789012:event-bus/default.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1014	IAM instance profile	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Your IAM instance profile %s permissions deny Amazon CloudWatch events. Resolve this by setting ["events:PutEvents"] to 'Allow' and allowing events:PutEvents on EventBus arn:aws:events:region-1:123456789012:event-bus/default in your IAM profile associated with the instance.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1015	IAM instance profile	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Your IAM instance profile %s is missing Amazon CloudWatch event permissions. Resolve this by including the ["events:PutEvents"] permissions and allowing events:PutEvents on EventBus arn:aws:events:region-1:123456789012:event-bus/default in your IAM profile associated with the instance.	

Event Code	Configuration area	RDS event message	Validation process
SP-S1016	IAM permissions boundary	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Your IAM instance profile %s has permissions boundary that deny Amazon CloudWatch events. Resolve this by setting ["events:PutEvents"] to 'Allow' for the EventBus arn:aws:events:region-1:123456789012:event-bus/default in your IAM instance profile permissions boundary.	

Operating system

Event Code	Configuration area	RDS event message	Validation process
SP-S2001	SQL Service Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The SQL Server service isn't started. You	

Event Code	Configuration area	RDS event message	Validation process
		can resolve this by restarting the SQL Server service on the host. If this DB instance is a Multi-AZ DB instance and restart fails, then stop and start the host to initiate a failover.	

Event Code	Configuration area	RDS event message	Validation process

SP-S2002	RDS Custom Agent Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The RDS Custom Agent service isn't installed or couldn't be started. You can resolve this by reviewing the Windows Event Log to determine why the service won't start, and take appropriate steps to fix the issue. For additional assistance, create a support case.	Log in to the host and make sure that the RDS Custom agent is running.
			
			You can use the following commands to view the agent status.
			
			`$name = "RDSCustomAgent"`
			`$service = Get-Service $name`
			`Write-Host $service.Status`
			
			If the status isn't Running, you can start the service with the following command:
			
			`Start-Service $name`
			
			If the agent can't start, check the Windows Events to see why it can't start. The agent requires a Windows user to start the service. Ensure a Windows user exists and has privileges to run the service.

Event Code	Configuration area	RDS event message	Validation process
SP-S2003	SSM Agent Status	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The Amazon SSM Agent service is unreachable. You can troubleshoot this by checking the service status with the `Get-Service AmazonSSMAgent` PowerShell command, or starting the service with `Start-Service AmazonSSMAgent`. Ensure that HTTPS (port 443) outbound traffic to the **ssm**, **ssmmessages**, and **ec2messages** regional endpoints is allowed.	For more information, see Troubleshooting SSM Agent. To troubleshoot SSM endpoints, see Unable to connect to SSM endpoints and Use ssm-cli to troubleshoot managed node availability.

Event Code	Configuration area	RDS event message	Validation process
SP-S2004	RDS Custom Agent Login	The RDS Custom DB instance status is set to [Unsupported configuration] because of: An unexpected issue occurred with the SQL login "$HOSTNAME/RDSAgent" . To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S2005	Timezone	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The timezone on the Amazon EC2 Instance [%s] was changed. You can resolve this by modifying the time zone back to the setting specified during instance creation. If you would like to create an instance with a specific timezone, see the RDS Custom documentation.	Run the `Get-Timezone` PowerShell command to confirm the timezone. For more information, see Local time zone for RDS Custom for SQL Server DB instances.

Event Code	Configuration area	RDS event message	Validation process
SP-S2006	High Availability Software Solution Version	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The high availability software solution of the current instance is different from the expected version. To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S2007	High Availability Software Solution Configuration	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The configuration settings of the high availability software solution have been modified to unexpected values on the instance %s. To fix this issue, reboot the EC2 instance. When you reboot the EC2 instance, it automatically updates the settings to the required configuration for the high availability software solution.	

Event Code	Configuration area	RDS event message	Validation process

SP-S2008	SQL Server Service	The RDS Custom DB instance is set to [Unsupported configuration]: SQLServer (MSSQLServer) service doesn't exist on the host. To resolve this, create a support case.	You can use the following commands to view the agent status.
			`$name = "MSSQLServer"`
			`$service = Get-Service $name`
			`Write-Host $service.Status`

SP-S2009	SSL Certificate	The RDS Custom DB instance is set to [Unsupported configuration] because of: Non self-signed SSL certificate(s) causing disruption in RDS. To resolve this issue, remove the non self-signed certificate(s) from the trusted root certificate store.	Run the following PowerShell command to review non self-signed certificate(s). `Get-ChildItem cert:\LocalMachine\root -Recurse | Where-Object {$_.Issuer -ne $_.Subject -and $_.Issuer -notlike "*RDSCustomAgentCA*"}` For more information, see HTTP Error 403.16 when you try to access a website that's hosted on IIS.

Event Code	Configuration area	RDS event message	Validation process
SP-S2010	Root Volume Storage Status	The RDS Custom DB instance is set to [Unsupported configuration] because of: Root volume storage is full. To resolve this issue, free up at least 500 MiB of storage space in the root EBS volume "volume-id" or increase the volume size and resize the C drive on the EC2 instance "instance-id". The root volume size changes do not persist when you replace the EC2 instance.	Use the following command to view available storage on the root (C:) volume. `(Get-PSDrive -Name C).Free / 1MB` For more information on modifying the EBS root volume, see How

Database

Event Code	Configuration area	RDS event message	Validation process
SP-S3001	SQL Server Shared Memory Protocol	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The SQL Server shared	You can validate this by checking: **SQL Server Configuration Manager > SQL Server Network Configuration > Protocols for MSSQLSERVER> Shared Memory** as Enabled. After you enable the

Event Code	Configuration area	RDS event message	Validation process
		memory protocol is disabled. You can resolve this by enabling the shared memory protocol in SQL Server Configuration Manager.	protocol, restart the SQL Server process.
SP-S3002	Service Master Key	The RDS Custom DB instance status is set to [Unsupported configuration] because of: RDS Automation is unable to take the backup of Service Master Key (SMK) as part of the new SMK generation. To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process
SP-S3003	Service Master Key	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The metadata related to the Service Master Key (SMK) is missing or incomplete. To resolve this issue, create a support case.	

Event Code	Configuration area	RDS event message	Validation process

SP-S3004	DB Engine Version and Edition	The RDS Custom DB instance status is set to [Unsupported configuration] because of: There is a mismatch between the expected and installed SQL Server version and edition: Modifying the SQL Server edition is not supported on RDS Custom for SQL Server. Also, manually changing the SQL Server version on the RDS Custom EC2 instance is not supported. To resolve this issue, create a support case.	Run the following query to get the SQL version:
			`select @@version`
			Run the following AWS CLI command to get the RDS SQL engine version and edition:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep EngineVersion`
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep Engine`
			For more information, see Modifying an RDS Custom for SQL Server DB instance and Upgrading a DB instance engine version.

Event Code	Configuration area	RDS event message	Validation process

SP-S3005	DB Engine Edition	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The current SQL Server edition doesn't match the expected SQL Server edition [%s]: Modifying the SQL Server edition is not supported on RDS Custom for SQL Server. To resolve this issue, create a support case.	Run the following query to get the SQL edition:
			Example
			`select @@version`
			Run the following AWS CLI command to get the RDS SQL engine edition:
			`aws rds describe-db-instances \ --db-instance-identifier db-instance-name |grep Engine`

Event Code	Configuration area	RDS event message	Validation process

SP-S3006	DB Engine Version	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The current SQL Server version doesn't match the expected SQL Server version [%s]: You can't manually change the SQL Server version on the RDS Custom EC2 instance. To resolve this issue, create a support case. For any future modifications to SQL Server version, you can modify the instance from the AWS RDS console or through the modify-db-instance CLI command.	Run the following query to get the SQL version:
			Example
			`select @@version`
			Run the following AWS CLI command to get the RDS SQL engine version:
			`aws rds describe-db-instances \ --db-instance-identifier *db-instance-name* |grep EngineVersion`
			For more information, see Modifying an RDS Custom for SQL Server DB instance and Upgrading a DB instance engine version.

Event Code	Configuration area	RDS event message	Validation process

SP-S3007	Database file location	The RDS Custom DB instance status is set to [Unsupported configuration] because of: Database files are configured outside of the D:\ drive. You can resolve this by making sure that all database files, including ROW, LOG, FILESTREAM, etc... are stored on the D:\ drive.	Run the following query to list the location of database files that aren't in the default path:
			`USE master;`
			`SELECT physical_name as files_not_in_default_path`
			`FROM sys.master_files`
			`WHERE SUBSTRING(physical_name,1,3)!='D:\';`

SP-S3008	Database Count Limit Exceeded	The RDS Custom DB instance status is set to [Unsupported configuration] because of: The total number of databases on the DB instance exceeds the maximum limit of 5000. To resolve this, reduce the number of databases below the maximum supported limit.	Use the following command to view total database count:
			`SELECT COUNT(name) as databaseCount`
			`FROM sys.databases`
			`WHERE name not in ('tempdb','master','model','msdb','DWDiagnostics','DWConfiguration','DWQueue');`

Troubleshooting `Storage-Full` in RDS Custom for SQL Server

RDS Custom also monitors the root (C:) volume. The RDS Custom for SQL Server DB instance moves to the `unsupported-configuration` state when the root volume has less than 500 MiB disk space available. See `Event SP-S2010` in Fixing unsupported configurations in RDS Custom for SQL Server.

Troubleshooting PENDING_RECOVERY state for TDE enabled databases in RDS Custom for SQL Server

SQL Server databases with transparent data encryption (TDE) enabled might remain in `PENDING_RECOVERY` state if the automatic decryption runs into issues. This typically occurs after a DB instance restore if the source DB instance Service Master Key (SMK) backup file stored in the RDS Custom managed S3 bucket in your account has been deleted prior to the restore completion.

To enable the automatic decryption and bring the TDE enabled databases online, you need to open the Database Master Key (DMK) with its password and ecrypt the DMK using the SMK.

Use the following SQL Server commands for reference:

```
-- Identify PENDING_RECOVERY TDE databases
USE MASTER;
GO
SELECT name, is_encrypted, state_desc FROM sys.databases;
GO

-- Open DMK using password
OPEN MASTER KEY DECRYPTION BY PASSWORD = '<password>';
GO

-- Encrypt DMK using SMK
ALTER MASTER KEY ADD ENCRYPTION BY SERVICE MASTER KEY;
GO

-- Close SMK
CLOSE MASTER KEY;
GO

-- Bring the TDE databases online
ALTER DATABASE <database_name> SET ONLINE;
GO
```

```
-- Verify TDE databases are now in ONLINE state
SELECT name, is_encrypted, state_desc FROM sys.databases;
GO
```

Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL databases to AWS Outposts Rack Gen1 and Gen2 environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information about AWS Outposts, see the AWS Outposts documentation and the AWS Outposts product page.

You use the same AWS Management Console, AWS CLI, and RDS API to provision and manage on-premises RDS on Outposts DB instances as you do for RDS DB instances running in the AWS Cloud. RDS on Outposts automates tasks, such as database provisioning, operating system and database patching, backup, and long-term archival in Amazon S3.

RDS on Outposts supports automated backups of DB instances. Network connectivity between your Outpost and your AWS Region is required to back up and restore DB instances. All DB snapshots and transaction logs from an Outpost are stored in your AWS Region. From your AWS Region, you can restore a DB instance from a DB snapshot to a different Outpost. For more information, see Introduction to backups.

RDS on Outposts supports automated maintenance and upgrades of DB instances. For more information, see Maintaining a DB instance.

RDS on Outposts uses encryption at rest for DB instances and DB snapshots using your AWS KMS key. For more information about encryption at rest, see Encrypting Amazon RDS resources.

By default, EC2 instances in Outposts subnets can use the Amazon Route 53 DNS Service to resolve domain names to IP addresses. You might encounter longer DNS resolution times with Route 53, depending on the path latency between your Outpost and the AWS Region. In such cases, you can use the DNS servers installed locally in your on-premises environment. For more information, see DNS in the *AWS Outposts User Guide*.

When network connectivity to the AWS Region isn't available, your DB instance continues to run locally. You can continue to access DB instances using DNS name resolution by configuring a local DNS server as a secondary server. However, you can't create new DB instances or modify existing DB instances. Automatic backups don't occur when there is no connectivity. If there is a DB instance failure, the DB instance isn't automatically replaced until connectivity is restored. We recommend restoring network connectivity as soon as possible.

Topics

- Prerequisites for Amazon RDS on AWS Outposts
- Amazon RDS on AWS Outposts support for Amazon RDS features
- Supported DB instance classes for Amazon RDS on AWS Outposts
- Customer-owned IP addresses for Amazon RDS on AWS Outposts
- Working with Multi-AZ deployments for Amazon RDS on AWS Outposts
- Creating DB instances for Amazon RDS on AWS Outposts

Prerequisites for Amazon RDS on AWS Outposts

The following are prerequisites for using Amazon RDS on AWS Outposts:

- Install AWS Outposts in your on-premises data center. For more information, see Installing an AWS Outposts server in the *AWS Outposts Server installation guide*.
- Make sure that you have at least one subnet available for RDS on Outposts. You can use the same subnet for other workloads.
- Make sure that you have a reliable network connection between your Outpost and an AWS Region.

Amazon RDS on AWS Outposts support for Amazon RDS features

The following table describes the Amazon RDS features supported by Amazon RDS on AWS Outposts.

Feature	Supported	Notes	More information

DB instance provisioning	Yes	You can only create DB instances for RDS for SQL Server, RDS for MySQL, and RDS for PostgreSQL DB engines. The following versions are supported:
		• Microsoft SQL Server:
		  • 16.00.4085.2.v1 and higher 2022 versions
		  • 15.00.4043.16.v1 and higher 2019 versions
		  • 14.00.3294.2.v1 and higher 2017 versions
		  • 13.00.5820.21.v1 and higher 2016 versions
		• MySQL 8.0 and 8.4 versions
		• All PostgreSQL 16 & 15 & 14 & 13 versions, and PostgreSQL version 12.5 and higher PostgreSQL 12 versions
			Creating DB instances for Amazon RDS on AWS Outposts

Connect to a Microsoft SQL Server DB instance	Yes	Some TLS versions and encryption ciphers might not be secure. To turn them off, follow the	Connecting to your Microsoft SQL Server DB instance

Feature	Supported	Notes	More information
with Microsoft SQL Server Management Studio		instructions in Configuring SQL Server security protocols and ciphers.	
Modifying the master user password	Yes	None	Modifying an Amazon RDS DB instance
Renaming a DB instance	Yes	None	Modifying an Amazon RDS DB instance
Rebooting a DB instance	Yes	None	Rebooting a DB instance
Stopping a DB instance	Yes	None	Stopping an Amazon RDS DB instance temporarily
Starting a DB instance	Yes	None	Starting an Amazon RDS DB instance that was previously stopped
Multi-AZ deployments	Yes	Multi-AZ deployments are supported on MySQL and PostgreSQL DB instances. Multi-AZ deployments do not support Direct VPC Routing (DVR).	Creating DB instances for Amazon RDS on AWS Outposts Configuring and managing a Multi-AZ deployment for Amazon RDS
DB parameter groups	Yes	None	Parameter groups for Amazon RDS

Feature	Supported	Notes	More information
Read replicas	Yes	Read replicas are supported for MySQL and PostgreSQL DB instances. Read replicas do not support Direct VPC Routing (DVR).	Creating read replicas for Amazon RDS on AWS Outposts
Encryption at rest	Yes	RDS on Outposts doesn't support unencrypted DB instances.	Encrypting Amazon RDS resources
AWS Identity and Access Management (IAM) database authentication	No	None	IAM database authentic ationfor MariaDB, MySQL, and PostgreSQL
Associating an IAM role with a DB instance	No	None	add-role-to-db-instance AWS CLI command AddRoleToDBInstance RDS API operation
Kerberos authentication	No	None	Kerberos authentication
Tagging Amazon RDS resources	Yes	None	Tagging Amazon RDS resources
Option groups	Yes	None	Working with option groups
Modifying the maintenance window	Yes	None	Maintaining a DB instance

Feature	Supported	Notes	More information
Automatic minor version upgrade	Yes	None	Automatically upgrading the minor engine version
Modifying the backup window	Yes	None	Introduction to backups Modifying an Amazon RDS DB instance
Changing the DB instance class	Yes	None	Modifying an Amazon RDS DB instance
Changing the allocated storage	Yes	None	Modifying an Amazon RDS DB instance
Storage autoscaling	Yes	None	Managing capacity automatically with Amazon RDS storage autoscaling

Feature	Supported	Notes	More information
Manual and automatic DB instance snapshots	Yes	You can store automated backups and manual snapshots in your AWS Region. Or you can store them locally on your Outpost. Local backups are supported on MySQL and PostgreSQL DB instances. To store backups on your Outpost, make sure that you have Amazon S3 on Outposts configured. Local backups are not supported for Multi-AZ instance deployments.	Creating DB instances for Amazon RDS on AWS Outposts Amazon S3 on Outposts Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS
Restoring from a DB snapshot	Yes	You can store automated backups and manual snapshots for the restored DB instance in the parent AWS Region or locally on your Outpost.	Considerations for restoring DB instances on Amazon RDS on AWS Outposts Restoring to a DB instance
Restoring a DB instance from Amazon S3	No	None	Restoring a backup into an Amazon RDS for MySQL DB instance
Exporting snapshot data to Amazon S3	No	None	Exporting DB snapshot data to Amazon S3 for Amazon RDS

Feature	Supported	Notes	More information
Point-in-time recovery	Yes	You can store automated backups and manual snapshots for the restored DB instance in the parent AWS Region or locally on your Outpost, with one exception.	Considerations for restoring DB instances on Amazon RDS on AWS Outposts Restoring a DB instance to a specified time for Amazon RDS
Enhanced monitoring	No	None	Monitoring OS metrics with Enhanced Monitoring
Amazon CloudWatch monitoring	Yes	You can view the same set of metrics that are available for your databases in the AWS Region.	Monitoring Amazon RDS metrics with Amazon CloudWatch
Publishing database engine logs to CloudWatch Logs	Yes	None	Publishing database logs to Amazon CloudWatch Logs
Event notification	Yes	None	Working with Amazon RDS event notification
Amazon RDS Performance Insights	No	None	Monitoring DB load with Performance Insights on Amazon RDS

Feature	Supported	Notes	More information
Viewing or downloading database logs	No	RDS on Outposts doesn't support viewing database logs using the console or describing database logs using the AWS CLI or RDS API. RDS on Outposts doesn't support downloading database logs using the console or downloading database logs using the AWS CLI or RDS API.	Monitoring Amazon RDS log files
Amazon RDS Proxy	No	None	Amazon RDS Proxy
Stored procedures for Amazon RDS for MySQL	Yes	None	RDS for MySQL stored procedure reference
Replication with external databases for RDS for MySQL	No	None	Configuring binary log file position replication with an external source instance
Native backup and restore for Amazon RDS for Microsoft SQL Server	Yes	None	Importing and exporting SQL Server databases using native backup and restore

Supported DB instance classes for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts supports the following DB instance classes:

- General purpose DB instance classes
  - db.m7i.48xlarge
  - db.m7i.24xlarge
  - db.m7i.16xlarge
  - db.m7i.12xlarge
  - db.m7i.8xlarge
  - db.m7i.4xlarge
  - db.m7i.2xlarge
  - db.m7i.xlarge
  - db.m7i.large
  - db.m5.24xlarge
  - db.m5.16xlarge
  - db.m5.12xlarge
  - db.m5.8xlarge
  - db.m5.4xlarge
  - db.m5.2xlarge
  - db.m5.xlarge
  - db.m5.large
- Memory optimized DB instance classes
  - db.r7i.48xlarge
  - db.r7i.24xlarge
  - db.r7i.16xlarge
  - db.r7i.12xlarge
  - db.r7i.8xlarge
  - db.r7i.4xlarge
  - db.r7i.2xlarge

- db.r7i.xlarge
- db.r7i.large
- db.r5.24xlarge
- db.r5.16xlarge
- db.r5.12xlarge
- db.r5.8xlarge
- db.r5.4xlarge
- db.r5.2xlarge
- db.r5.xlarge
- db.r5.large

Depending on how you've configured your Outpost, you might not have all of these classes available. For example, if you haven't purchased the db.r5 classes for your Outpost, you can't use them with RDS on Outposts.

Only general purpose SSD storage is supported for RDS on Outposts DB instances. For more information about DB instance classes, see DB instance classes.

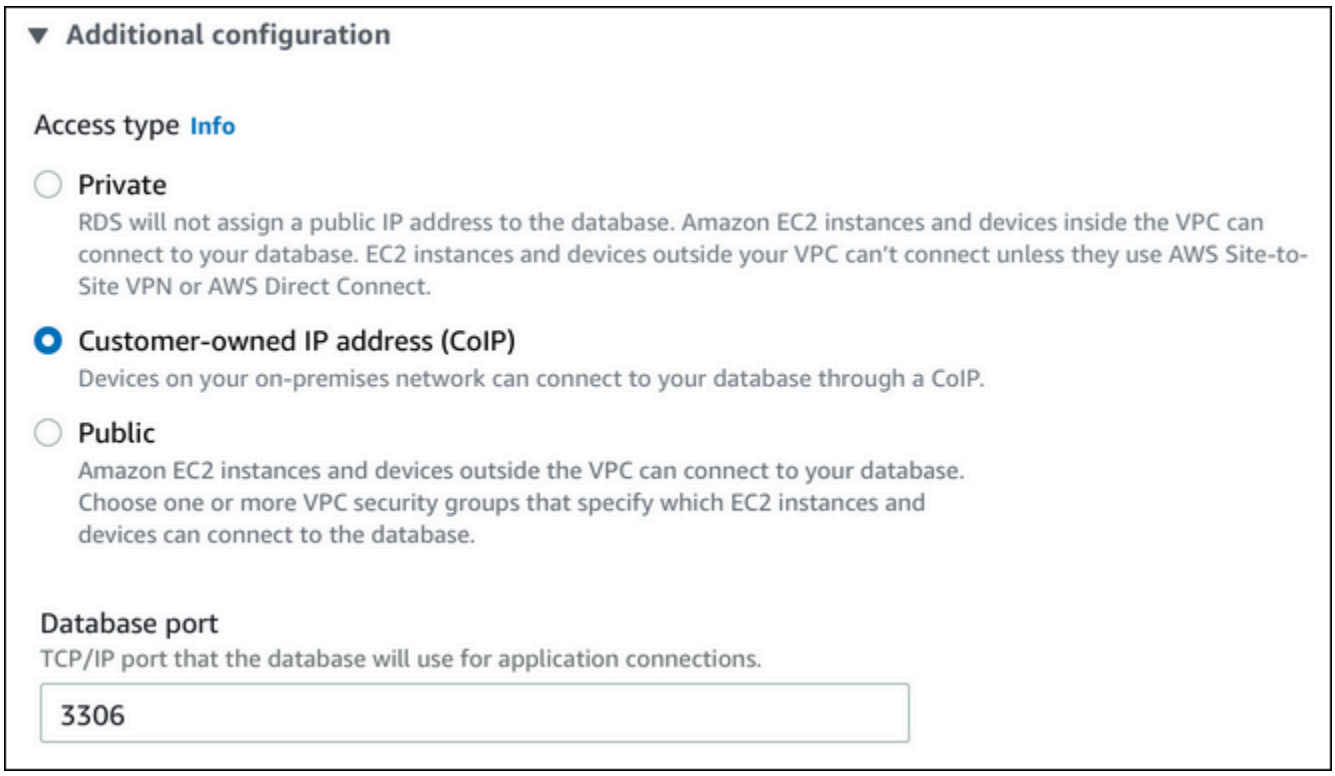
Amazon RDS manages maintenance and recovery for your DB instances and requires active capacity on the Outpost to do so. We recommend that you configure N+1 EC2 instances for each DB instance class in your production environments. RDS on Outposts can use the extra capacity of these EC2 instances for maintenance and repair operations. For example, if your production environments have 3 db.m5.large and 5 db.r5.xlarge DB instance classes, then we recommend that they have at least 4 m5.large EC2 instances and 6 r5.xlarge EC2 instances. For more information, see Resilience in AWS Outposts in the *AWS Outposts User Guide*.

Customer-owned IP addresses for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses information that you provide about your on-premises network to create an address pool. This pool is known as a *customer-owned IP address pool* (CoIP pool). *Customer-owned IP addresses* (CoIPs) provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information about CoIPs, see Customer-owned IP addresses in the *AWS Outposts User Guide*.

Each RDS on Outposts DB instance has a private IP address for traffic inside its virtual private cloud (VPC). This private IP address isn't publicly accessible. You can use the **Public** option to set whether the DB instance also has a public IP address in addition to the private IP address. Using the public IP address for connections routes them through the internet and can result in high latencies in some cases.

Instead of using these private and public IP addresses, RDS on Outposts supports using CoIPs for DB instances through their subnets. When you use a CoIP for an RDS on Outposts DB instance, you connect to the DB instance with the DB instance endpoint. RDS on Outposts then automatically uses the CoIP for all connections from both inside and outside of the VPC.



CoIPs can provide the following benefits for RDS on Outposts DB instances:

- Lower connection latency
- Enhanced security

Using CoIPs

You can turn CoIPs on or off for an RDS on Outposts DB instance using the AWS Management Console, the AWS CLI, or the RDS API:

- With the AWS Management Console, choose the **Customer-owned IP address (CoIP)** setting in **Access type** to use CoIPs. Choose one of the other settings to turn them off.

- With the AWS CLI, use the `--enable-customer-owned-ip | --no-enable-customer-owned-ip` option.
- With the RDS API, use the `EnableCustomerOwnedIp` parameter.

You can turn CoIPs on or off when you perform any of the following actions:

- Create a DB instance

  For more information, see Creating DB instances for Amazon RDS on AWS Outposts.
- Modify a DB instance

  For more information, see Modifying an Amazon RDS DB instance.
- Create a read replica

  For more information, see Creating read replicas for Amazon RDS on AWS Outposts.
- Restore a DB instance from a snapshot

  For more information, see Restoring to a DB instance.
- Restore a DB instance to a specified time

For more information, see Restoring a DB instance to a specified time for Amazon RDS.

> **Note**
>
> In some cases, you might turn on CoIPs for a DB instance but Amazon RDS isn't able to allocate a CoIP for the DB instance. In such cases, the DB instance status is changed to **incompatible-network**. For more information about the DB instance status, see Viewing Amazon RDSDB instance status.

Limitations

The following limitations apply to CoIP support for RDS on Outposts DB instances:

- When using a CoIP for a DB instance, make sure that public accessibility is turned off for that DB instance.
- Make sure that the inbound rules for your VPC security groups include the CoIP address range (CIDR block). For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.
- You can't assign a CoIP from a CoIP pool to a DB instance. When you use a CoIP for a DB instance, Amazon RDS automatically assigns a CoIP from a CoIP pool to the DB instance.
- You must use the AWS account that owns the Outpost resources (owner) or share the following resources with other AWS accounts (consumers) in the same organization:
  - The Outpost
  - The local gateway (LGW) route table for the DB instance's VPC
  - The CoIP pool or pools for the LGW route table

  For more information, see Working with shared AWS Outposts resources in the *AWS Outposts User Guide*.

Working with Multi-AZ deployments for Amazon RDS on AWS Outposts

For Multi-AZ deployments, Amazon RDS creates a primary DB instance on one AWS Outpost. RDS synchronously replicates the data to a standby DB instance on a different Outpost.

Multi-AZ deployments on AWS Outposts operate like Multi-AZ deployments in AWS Regions, but with the following differences:

- They require a local connection between two or more Outposts.
- They require customer-owned IP (CoIP) pools. For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts.
- Replication runs on your local network.

Multi-AZ on AWS Outposts is available for all supported versions of MySQL and PostgreSQL on RDS on Outposts. Local backups aren't supported for Multi-AZ deployments. For more information, see Creating DB instances for Amazon RDS on AWS Outposts.

Working with the shared responsibility model

Although AWS uses commercially reasonable efforts to provide DB instances configured for high availability, the availability uses a shared responsibility model. The ability of RDS on Outposts to fail over and repair DB instances requires each of your Outposts to be connected to its AWS Region.

RDS on Outposts also requires connectivity between the Outpost that is hosting the primary DB instance and the Outpost that is hosting the standby DB instance for synchronous replication. Any impact to this connection can prevent RDS on Outposts from performing a failover.

You might see elevated latencies for a standard DB instance deployment as a result of the synchronous data replication. The bandwidth and latency of the connection between the Outpost hosting the primary DB instance and the Outpost hosting the standby DB instance directly affect latencies. For more information, see Prerequisites.

Improving availability

We recommend the following actions to improve availability:

- Allocate enough additional capacity for your mission-critical applications to allow recovery and failover if there is an underlying host issue. This applies to all Outposts that contain subnets in your DB subnet group. For more information, see Resilience in AWS Outposts.
- Provide redundant network connectivity for your Outposts.
- Use more than two Outposts. Having more than two Outposts allows Amazon RDS to recover a DB instance. RDS does this recovery by moving the DB instance to another Outpost if the current Outpost experiences a failure.
- Provide dual power sources and redundant network connectivity for your Outpost.

We recommend the following for your local networks:

- The round trip time (RTT) latency between the Outpost hosting your primary DB instance and the Outpost hosting your standby DB instance directly affects write latency. Keep the RTT latency between the AWS Outposts in the low single-digit milliseconds. We recommend not more than 5 milliseconds, but your requirements might vary.

  You can find the net impact to network latency in the Amazon CloudWatch metrics for `WriteLatency`. For more information, see Amazon CloudWatch metrics for Amazon RDS.
- The availability of the connection between the Outposts affects the overall availability of your DB instances. Have redundant network connectivity between the Outposts.

Prerequisites

Multi-AZ deployments on RDS on Outposts have the following prerequisites:

- Have at least two Outposts, connected over local connections and attached to different Availability Zones in an AWS Region.
- Make sure that your DB subnet groups contain the following:
  - At least two subnets in at least two Availability Zones in a given AWS Region.
  - Subnets only in Outposts.
  - At least two subnets in at least two Outposts within the same virtual private cloud (VPC).
- Associate your DB instance's VPC with all of your local gateway route tables. This association is necessary because replication runs over your local network using your Outposts' local gateways.

For example, suppose that your VPC contains subnet-A in Outpost-A and subnet-B in Outpost-B. Outpost-A uses LocalGateway-A (LGW-A), and Outpost-B uses LocalGateway-B (LGW-B). LGW-A has RouteTable-A, and LGW-B has RouteTable-B. You want to use both RouteTable-A and RouteTable-B for replication traffic. To do this, associate your VPC with both RouteTable-A and RouteTable-B.

For more information about how to create an association, see the Amazon EC2 create-local-gateway-route-table-vpc-association AWS CLI command.

- Make sure that your Outposts use customer-owned IP (CoIP) routing. Each route table must also each have at least one address pool. Amazon RDS allocates an additional IP address each for the primary and standby DB instances for data synchronization.
- Make sure that the AWS account that owns the RDS DB instances owns the local gateway route tables and CoIP pools. Or make sure it's part of a Resource Access Manager share with access to the local gateway route tables and CoIP pools.
- Make sure that the IP addresses in your CoIP pools can be routed from one Outpost local gateway to the others.
- Make sure that the VPC's CIDR blocks (for example, 10.0.0.0/4) and your CoIP pool CIDR blocks don't contain IP addresses from Class E (240.0.0.0/4). RDS uses these IP addresses internally.
- Make sure that you correctly set up outbound and related inbound traffic.

  RDS on Outposts establishes a virtual private network (VPN) connection between the primary and standby DB instances. For this to work correctly, your local network must allow outbound and related inbound traffic for Internet Security Association and Key Management Protocol (ISAKMP). It does so using User Datagram Protocol (UDP) port 500 and IP Security (IPsec) Network Address Translation Traversal (NAT-T) using UDP port 4500.

For more information on CoIPs, see Customer-owned IP addresses for Amazon RDS on AWS Outposts in this guide, and Customer-owned IP addresses in the *AWS Outposts User Guide*.

Working with API operations for Amazon EC2 permissions

Regardless of whether you use CoIPs for your DB instance on AWS Outposts, RDS requires access to your CoIP pool resources. RDS can call the following EC2 permissions API operations for CoIPs on your behalf for Multi-AZ deployments:

- `CreateCoipPoolPermission` – When you create a Multi-AZ DB instance on RDS on Outposts

- `DeleteCoipPoolPermission` – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to allocate elastic IP addresses from the CoIP pool specified by the permission. You can view these IP addresses using the `DescribeCoipPoolUsage` API operation. For more information on CoIPs, see Customer-owned IP addresses for Amazon RDS on AWS Outposts and Customer-owned IP addresses in the *AWS Outposts User Guide*.

RDS can also call the following EC2 permission API operations for local gateway route tables on your behalf for Multi-AZ deployments:

- `CreateLocalGatewayRouteTablePermission` – When you create a Multi-AZ DB instance on RDS on Outposts
- `DeleteLocalGatewayRouteTablePermission` – When you delete a Multi-AZ DB instance on RDS on Outposts

These API operations grant to, or remove from, internal RDS accounts the permission to associate internal RDS VPCs with your local gateway route tables. You can view these route table–VPC associations using the `DescribeLocalGatewayRouteTableVpcAssociations` API operations.

Creating DB instances for Amazon RDS on AWS Outposts

Creating an Amazon RDS on AWS Outposts DB instance is similar to creating an Amazon RDS DB instance in the AWS Cloud. However, make sure that you specify a DB subnet group that is associated with your Outpost.

A virtual private cloud (VPC) based on the Amazon VPC service can span all of the Availability Zones in an AWS Region. You can extend any VPC in the AWS Region to your Outpost by adding an Outpost subnet. To add an Outpost subnet to a VPC, specify the Amazon Resource Name (ARN) of the Outpost when you create the subnet.

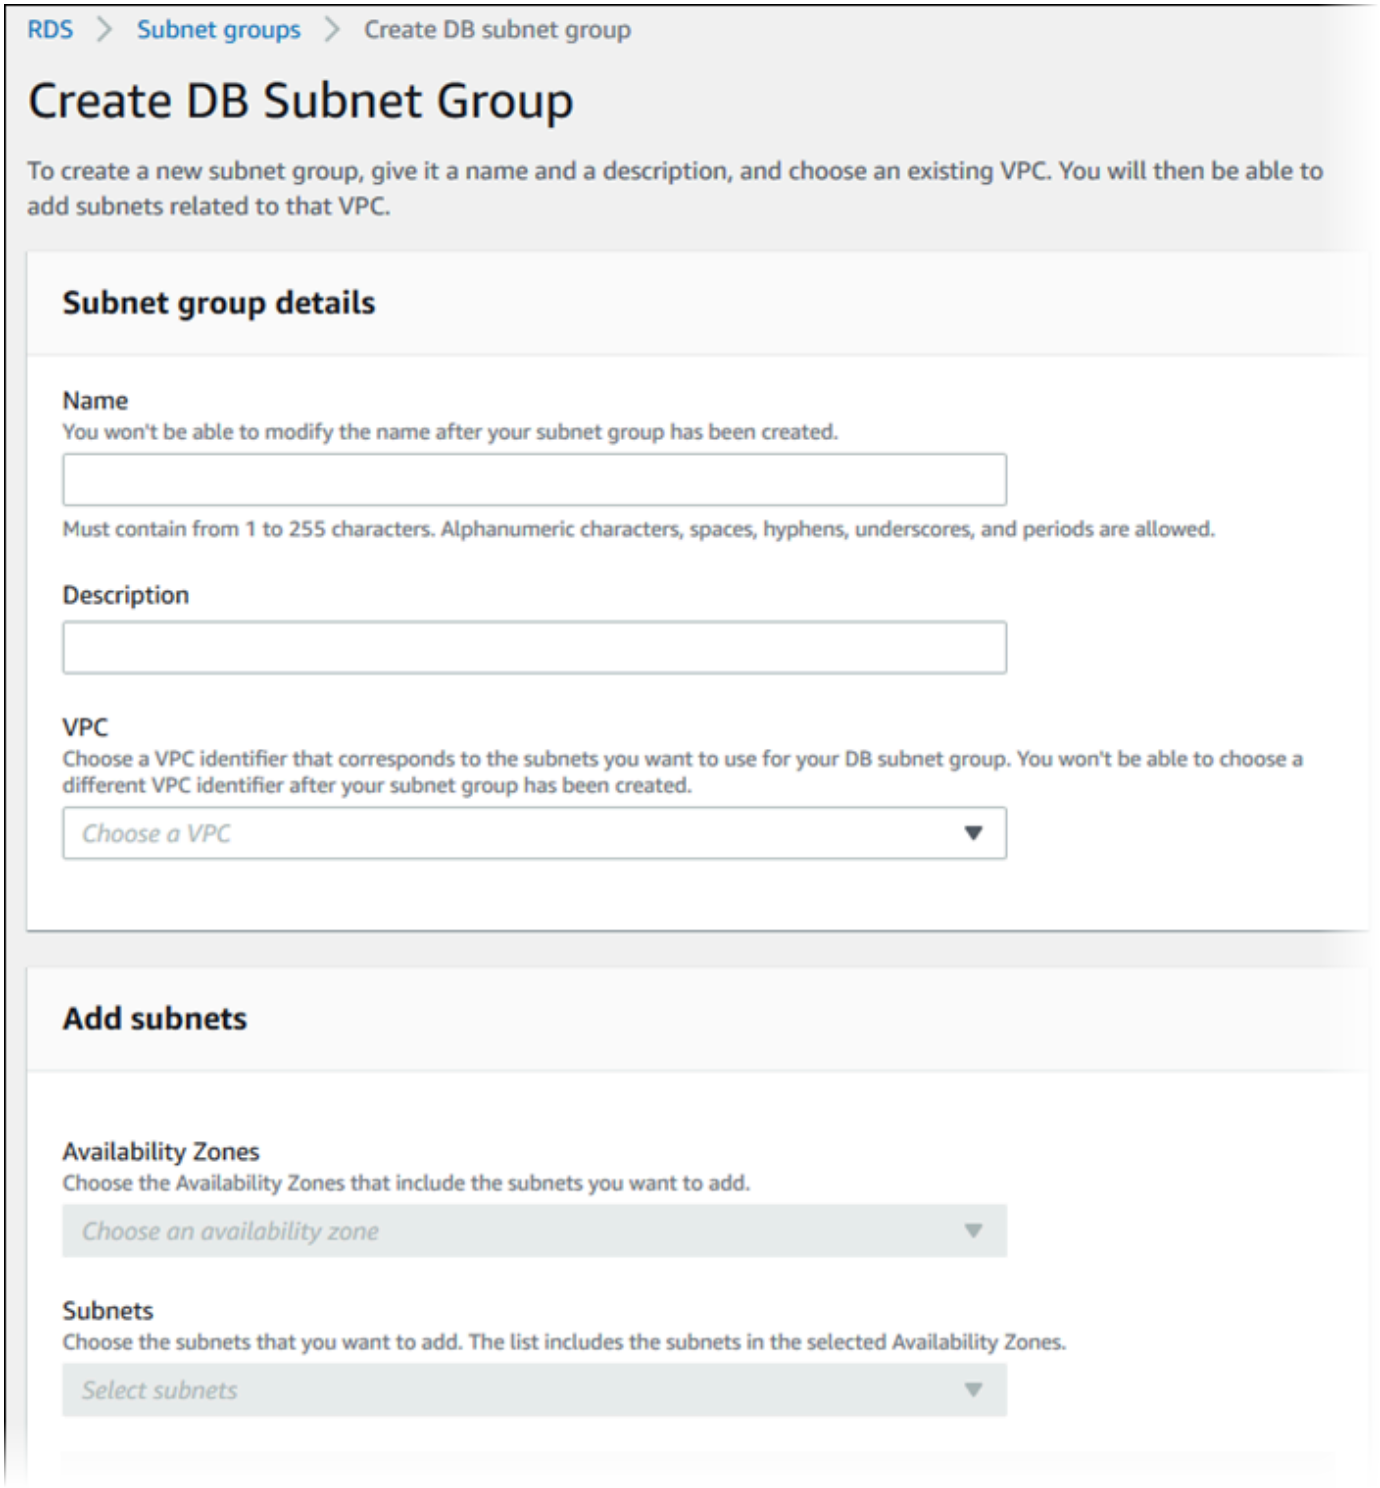
Before you create an RDS on Outposts DB instance, you can create a DB subnet group that includes one subnet that is associated with your Outpost. When you create an RDS on Outposts DB instance, specify this DB subnet group. You can also choose to create a new DB subnet group when you create your DB instance.

For information about configuring AWS Outposts, see the AWS Outposts User Guide.

Console

Creating a DB subnet group

Create a DB subnet group with one subnet that is associated with your Outpost.



You can also create a new DB subnet group for the Outpost when you create your DB instance. If you want to do so, then skip this procedure.

> **Note**
>
> To create a DB subnet group for the AWS Cloud, specify at least two subnets.

To create a DB subnet group for your Outpost

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB subnet group.
3. Choose **Subnet groups**, and then choose **Create DB Subnet Group**.

The **Create DB subnet group** page appears.

4. For **Name**, choose the name of the DB subnet group.
5. For **Description**, choose a description for the DB subnet group.
6. For **VPC**, choose the VPC that you're creating the DB subnet group for.

7. For **Availability Zones**, choose the Availability Zone for your Outpost.
8. For **Subnets**, choose the subnet for use by RDS on Outposts.
9. Choose **Create** to create the DB subnet group.

Creating the RDS on Outposts DB instance

Create the DB instance, and choose the Outpost for your DB instance.

To create an RDS on Outposts DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where the Outpost on which you want to create the DB instance is attached.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.

   The AWS Management Console detects available Outposts that you have configured and presents the **On-premises** option in the **Database location** section.

   > **Note**
   >
   > If you haven't configured any Outposts, either the **Database location** section doesn't appear or the **RDS on Outposts** option isn't available in the **Choose an on-premises creation method** section.

5. For **Database location**, choose **On-premises**.
6. For **On-premises creation method**, choose **RDS on Outposts**.
7. Specify your settings for **Outposts Connectivity**. These settings are for the Outpost that uses the VPC that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.

   a. For **Virtual Private Cloud (VPC)**, choose the VPC that contains the DB subnet group for your DB instance.

   b. For **VPC security group**, choose the Amazon VPC security group for your DB instance.

   c. For **DB subnet group**, choose the DB subnet group for your DB instance.

You can choose an existing DB subnet group that's associated with the Outpost—for example, if you performed the procedure in Creating a DB subnet group.

You can also create a new DB subnet group for the Outpost.

8. For **Multi-AZ deployment**, choose **Create a standby instance (recommended for production usage)** to create a standby DB instance in another Outpost.

> **Note**
>
> This option isn't available for Microsoft SQL Server.
> If you choose to create a Multi-AZ deployment, you can't store backups on your Outpost.

9. Under **Backup**, do the following:

   a. For **Backup target**, choose one of the following:

   - **AWS Cloud** to store automated backups and manual snapshots in the parent AWS Region.
   - **Outposts (on-premises)** to create local backups.

   > **Note**
   >
   > To store backups on your Outpost, your Outpost must have Amazon S3 capability. For more information, see Amazon S3 on Outposts.
   > Local backups aren't supported for Multi-AZ deployments or read replicas.

   b. Choose **Enable automated backups** to create point-in-time snapshots of your DB instance.

   If you turn on automated backups, then you can choose values for **Backup retention period** and **Backup window**, or leave the default values.

10. Specify other DB instance settings as needed.

    For information about each setting when creating a DB instance, see Settings for DB instances.

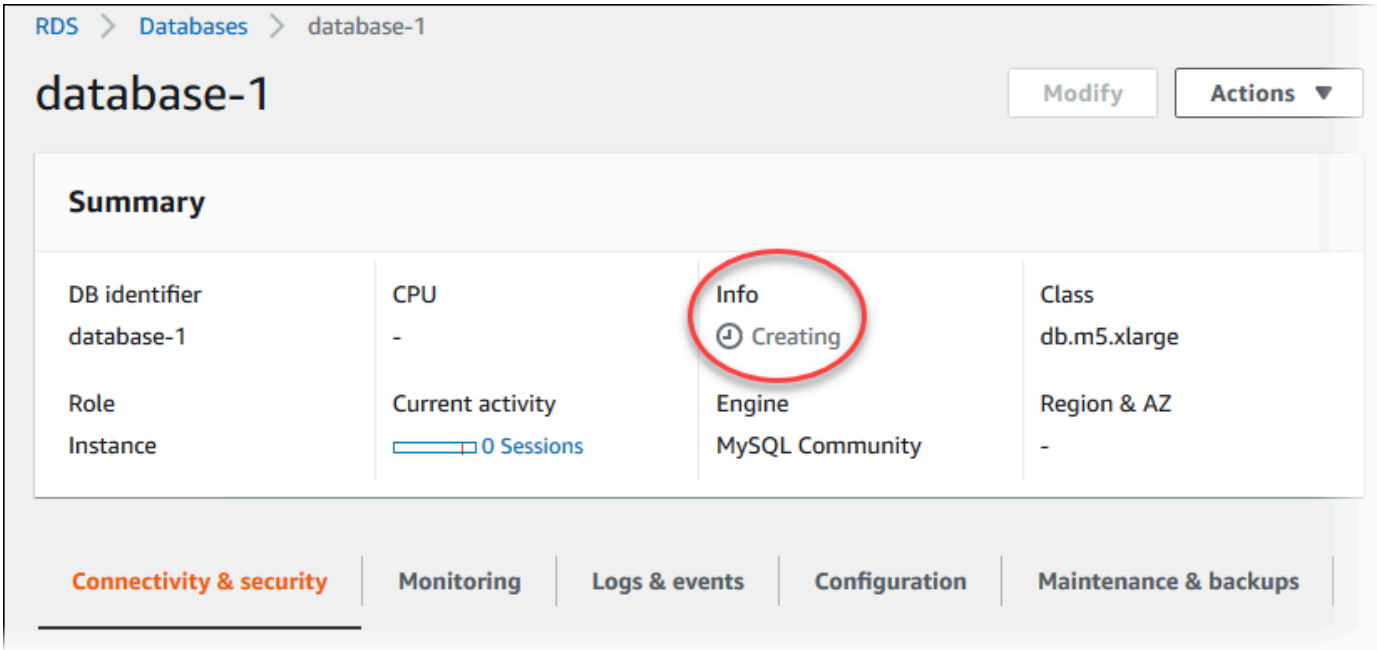
11. Choose **Create database**.

The **Databases** page appears. A banner tells you that your DB instance is being created, and displays the **View credential details** button.

Viewing DB instance details

After you create your DB instance, you can view credentials and other details for it.

To view DB instance details



1. To view the master user name and password for the DB instance, choose **View credential details** on the **Databases** page.

   You can connect to the DB instance as the master user by using these credentials.

   > **Important**
   >
   > You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the DB instance is available, modify the DB instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

2. Choose the name of the new DB instance on the **Databases** page.

   On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new DB instance to be available.

After the DB instance is available, you can manage it the same way that you manage RDS DB instances in the AWS Cloud.

AWS CLI

Before you create a new DB instance in an Outpost with the AWS CLI, first create a DB subnet group for use by RDS on Outposts.

To create a DB subnet group for your Outpost

- Use the create-db-subnet-group command. For `--subnet-ids`, specify the subnet group in the Outpost for use by RDS on Outposts.

  For Linux, macOS, or Unix:

```
aws rds create-db-subnet-group \
    --db-subnet-group-name myoutpostdbsubnetgr \
    --db-subnet-group-description "DB subnet group for RDS on Outposts" \
    --subnet-ids subnet-abc123
```

  For Windows:

```
aws rds create-db-subnet-group ^
    --db-subnet-group-name myoutpostdbsubnetgr ^
```

```
    --db-subnet-group-description "DB subnet group for RDS on Outposts" ^
    --subnet-ids subnet-abc123
```

To create an RDS on Outposts DB instance using the AWS CLI

- Use the create-db-instance command. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost. You can include the following options:
  - `--db-instance-identifier`
  - `--db-instance-class`
  - `--engine` – The database engine. Use one of the following values:
    - MySQL – Specify `mysql`.
    - PostgreSQL – Specify `postgres`.
    - Microsoft SQL Server – Specify `sqlserver-ee`, `sqlserver-se`, or `sqlserver-web`.
  - `--availability-zone`
  - `--vpc-security-group-ids`
  - `--db-subnet-group-name`
  - `--allocated-storage`
  - `--max-allocated-storage`
  - `--master-username`
  - `--master-user-password`
  - `--multi-az | --no-multi-az` – (Optional) Whether to create a standby DB instance in a different Availability Zone. The default is `--no-multi-az`.

    The `--multi-az` option isn't available for SQL Server.
  - `--backup-retention-period`
  - `--backup-target` – (Optional) Where to store automated backups and manual snapshots. Use one of the following values:
    - `outposts` – Store them locally on your Outpost.
    - `region` – Store them in the parent AWS Region. This is the default value.

If you use the `--multi-az` option, you can't use `outposts` for `--backup-target`. In addition, the DB instance can't have read replicas if you use `outposts` for `--backup-target`.

- `--storage-encrypted`
- `--kms-key-id`

Example

The following example creates a MySQL DB instance named `myoutpostdbinstance` with backups stored on your Outpost.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myoutpostdbinstance \
    --engine-version 8.0.17 \
    --db-instance-class db.m5.large \
    --engine mysql \
    --availability-zone us-east-1d \
    --vpc-security-group-ids outpost-sg \
    --db-subnet-group-name myoutpostdbsubnetgr \
    --allocated-storage 100 \
    --max-allocated-storage 1000 \
    --master-username masterawsuser \
    --manage-master-user-password \
    --backup-retention-period 3 \
    --backup-target outposts \
    --storage-encrypted \
    --kms-key-id mykey
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myoutpostdbinstance ^
    --engine-version 8.0.17 ^
    --db-instance-class db.m5.large ^
    --engine mysql ^
    --availability-zone us-east-1d ^
    --vpc-security-group-ids outpost-sg ^
    --db-subnet-group-name myoutpostdbsubnetgr ^
```

```
    --allocated-storage 100 ^
    --max-allocated-storage 1000 ^
    --master-username masterawsuser ^
    --manage-master-user-password ^
    --backup-retention-period 3 ^
    --backup-target outposts ^
    --storage-encrypted ^
    --kms-key-id mykey
```

For information about each setting when creating a DB instance, see Settings for DB instances.

RDS API

To create a new DB instance in an Outpost with the RDS API, first create a DB subnet group for use by RDS on Outposts by calling the CreateDBSubnetGroup operation. For `SubnetIds`, specify the subnet group in the Outpost for use by RDS on Outposts.

Next, call the CreateDBInstance operation with the following parameters. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost.

- `AllocatedStorage`
- `AvailabilityZone`
- `BackupRetentionPeriod`
- `BackupTarget`

  If you are creating a Multi-AZ DB instance deployment, you can't use `outposts` for `BackupTarget`. In addition, the DB instance can't have read replicas if you use `outposts` for `BackupTarget`.
- `DBInstanceClass`
- `DBInstanceIdentifier`
- `VpcSecurityGroupIds`
- `DBSubnetGroupName`
- `Engine`
- `EngineVersion`
- `MasterUsername`
- `MasterUserPassword`

- `MaxAllocatedStorage` (optional)
- `MultiAZ` (optional)
- `StorageEncrypted`
- `KmsKeyID`

For information about each setting when creating a DB instance, see Settings for DB instances.

Creating read replicas for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts uses the MySQL and PostgreSQL DB engines' built-in replication functionality to create a read replica from a source DB instance. The source DB instance becomes the primary DB instance. Updates made to the primary DB instance are asynchronously copied to the read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

When you create a read replica from an RDS on Outposts DB instance, the read replica uses a customer-owned IP address (CoIP). For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts.

Read replicas on RDS on Outposts have the following limitations:

- You can't create read replicas for RDS for SQL Server on RDS on Outposts DB instances.
- Cross-Region read replicas aren't supported on RDS on Outposts.
- Cascading read replicas aren't supported on RDS on Outposts.
- The source RDS on Outposts DB instance can't have local backups. The backup target for the source DB instance must be your AWS Region.
- Read replicas require customer-owned IP (CoIP) pools. For more information, see Customer-owned IP addresses for Amazon RDS on AWS Outposts.
- Read replicas on RDS on Outposts can only be created in the same virtual private cloud (VPC) as the source DB instance.
- Read replicas on RDS on Outposts can be located on the same Outpost or another Outpost in the same VPC as the source DB instance.
- You can't create read replicas for DB instances encrypted with AWS KMS External Key Store (XKS).

You can create a read replica from an RDS on Outposts DB instance using the AWS Management Console, AWS CLI, or RDS API. For more information on read replicas, see Working with DB instance read replicas.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Specify your settings for **Outposts Connectivity**. These settings are for the Outpost that uses the virtual private cloud (VPC) that has the DB subnet group for your DB instance. Your VPC must be based on the Amazon VPC service.
7. Choose your **DB instance class**. We recommend that you use the same or larger DB instance class and storage type as the source DB instance for the read replica.
8. For **Multi-AZ deployment**, choose **Create a standby instance (recommended for production usage)** to create a standby DB instance in a different Availability Zone.

   Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
9. (Optional) Under **Connectivity**, set values for **Subnet Group** and **Availability Zone**.

   If you specify values for both **Subnet Group** and **Availability Zone**, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.

   If you specify a value for **Subnet Group** and **No preference** for **Availability Zone**, the read replica is created on a random Outpost in the DB subnet group.
10. For **AWS KMS key**, choose the AWS KMS key identifier of the KMS key.

    The read replica must be encrypted.
11. Choose other options as needed.
12. Choose **Create read replica**.

After the read replica is created, you can see it on the **Databases** page in the RDS console. It shows **Replica** in the **Role** column.

AWS CLI

To create a read replica from a source MySQL or PostgreSQL DB instance, use the AWS CLI command create-db-instance-read-replica.

You can control where the read replica is created by specifying the `--db-subnet-group-name` and `--availability-zone` options:

- If you specify both the `--db-subnet-group-name` and `--availability-zone` options, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
- If you specify the `--db-subnet-group-name` option and don't specify the `--availability-zone` option, the read replica is created on a random Outpost in the DB subnet group.
- If you don't specify either option, the read replica is created on the same Outpost as the source RDS on Outposts DB instance.

The following example creates a replica and specifies the location of the read replica by including `--db-subnet-group-name` and `--availability-zone` options.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --availability-zone us-west-2a
```

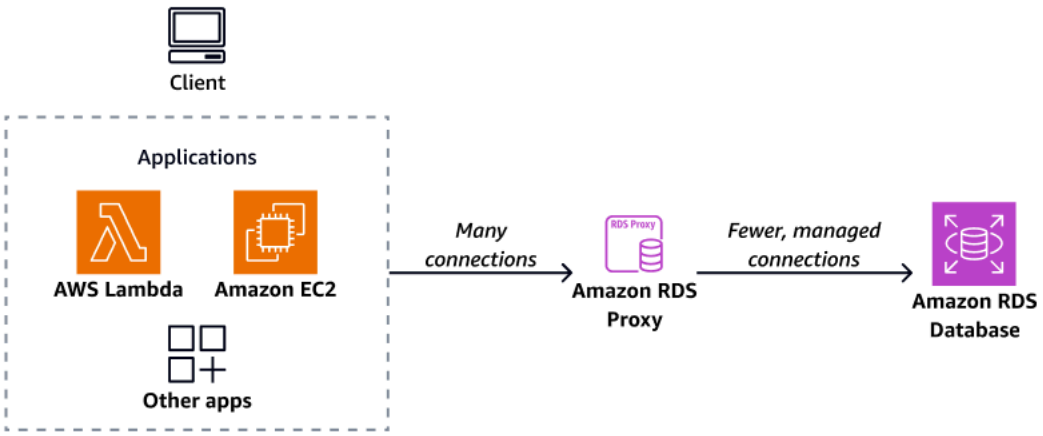
RDS API

To create a read replica from a source MySQL or PostgreSQL DB instance, call the Amazon RDS API CreateDBInstanceReadReplica operation with the following required parameters:

- `DBInstanceIdentifier`
- `SourceDBInstanceIdentifier`

You can control where the read replica is created by specifying the `DBSubnetGroupName` and `AvailabilityZone` parameters:

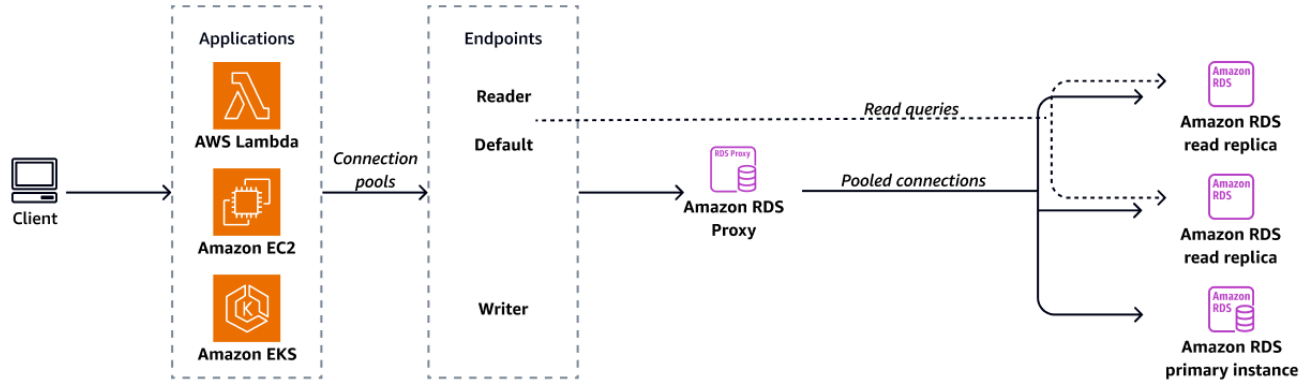
- If you specify both the `DBSubnetGroupName` and `AvailabilityZone` parameters, the read replica is created on an Outpost that is associated with the Availability Zone in the DB subnet group.
- If you specify the `DBSubnetGroupName` parameter and don't specify the `AvailabilityZone` parameter, the read replica is created on a random Outpost in the DB subnet group.
- If you don't specify either parameter, the read replica is created on the same Outpost as the source RDS on Outposts DB instance.



Considerations for restoring DB instances on Amazon RDS on AWS Outposts

When you restore a DB instance in Amazon RDS on AWS Outposts, you can generally choose the storage location for automated backups and manual snapshots of the restored DB instance.

- When restoring from a manual DB snapshot, you can store backups either in the parent AWS Region or locally on your Outpost.
- When restoring from an automated backup (point-in-time recovery), you have fewer choices:
  - If restoring from the parent AWS Region, you can store backups either in the AWS Region or on your Outpost.
  - If restoring from your Outpost, you can store backups only on your Outpost.



Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can enforce AWS Identity and Access Management (IAM) authentication for clients connecting to the proxy, and the proxy can connect to databases using either IAM database authentication or credentials stored in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or new connections being created at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect a database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the connection pool. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that RDS can serve with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with RDS Proxy, see Supported Regions and DB engines for Amazon RDS Proxy.

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- Each AWS account ID is limited to 20 proxies. If your application requires more proxies, request an increase via the **Service Quotas** page within the AWS Management Console. In the **Service Quotas** page, select **Amazon Relational Database Service (Amazon RDS)** and locate **Proxies** to request a quota increase. AWS can automatically increase your quota or pending review of your request by Support.
- Each proxy can have up to 200 associated Secrets Manager secrets, thus limiting connections to up to 200 different user accounts when using secrets.
- Each proxy has a default endpoint. You can also add up to 20 proxy endpoints for each proxy. You can create, view, modify, and delete these endpoints.
- For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping your database on a local host, you can't connect to your proxy unless you set up the necessary network requirements to allow connection to the proxy. This is because your local host is outside of the proxy's VPC.
- You can't use RDS Proxy with a VPC that has its tenancy set to `dedicated`.
- You can't use RDS Proxy in a VPC that has encryption controls with `Enforce Mode` enabled.
- For IPv6 endpoint network types, configure your VPC and subnets to support only IPv6. For both IPv4 and IPv6 target connection network types, configure your VPC and subnets to support dual-stack mode.
- If you use RDS Proxy with an RDS DB instance that has IAM authentication enabled, the proxy can connect to the database using either IAM authentication or credentials stored in Secrets Manager. Clients connecting to the proxy must authenticate using IAM credentials. For detailed configuration instructions, see Setting up database credentials for RDS Proxy and Configuring IAM authentication for RDS Proxy
- You can't use RDS Proxy with custom DNS when using SSL hostname validation.
- Each proxy can be associated with a single target DB instance . However, you can associate multiple proxies with the same DB instance .
- Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.

- Certain Regions have Availability-Zone (AZ) restrictions to consider while creating your proxy. US East (N. Virginia) Region does not support RDS Proxy in the `use1-az3` Availability Zone. US West (N. California) Region does not support RDS Proxy in the `usw1-az2` Availability Zone. When selecting subnets while creating your proxy, make sure that you don't select subnets in the Availability Zones mentioned above.
- Currently, RDS Proxy doesn't support any global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the *IAM User Guide*.
- You can't use RDS Proxy with RDS Custom for SQL Server.
- To reflect any database parameter group modification to your proxy, an instance reboot is required even if your chose to apply your changes immediately. For cluster-level parameters, a cluster-wide reboot is required.
- Your proxy automatically creates the `rdsproxyadmin` DB user when you register a proxy target. This is a protected user that is essential for proxy functionality. You should avoid tampering with the `rdsproxyadmin` user in any capacity. Deleting or modifying the `rdsproxyadmin` user or its permissions can result in complete unavailability of the proxy to your application.

For additional limitations for each DB engine, see the following sections:

- Additional limitations for RDS for MariaDB
- Additional limitations for RDS for Microsoft SQL Server
- Additional limitations for RDS for MySQL
- Additional limitations for RDS for PostgreSQL

Additional limitations for RDS for MariaDB

The following additional limitations apply to RDS Proxy with RDS for MariaDB databases:

- Currently, all proxies listen on port 3306 for MariaDB. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MariaDB databases in Amazon EC2 instances.
- You can't use RDS Proxy with an RDS for MariaDB DB instance that has the `read_only` parameter in its DB parameter group set to 1.

- RDS Proxy doesn't support MariaDB compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning an RDS Proxy.
- RDS Proxy doesn't support the MariaDB `auth_ed25519` plugin.
- RDS Proxy doesn't support Transport Layer Security (TLS) version 1.3 for MariaDB databases.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections. For more information, see Overview of RDS Proxy concepts.
- RDS Proxy currently doesn't support the `caching_sha2_password` option for `ClientPasswordAuthType` for MariaDB.

> **Important**
>
> For proxies associated with MariaDB databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for Microsoft SQL Server

The following additional limitations apply to RDS Proxy with RDS for Microsoft SQL Server databases:

- The number of Secrets Manager secrets that you need to create for a proxy depends on the collation that your DB instance uses. For example, suppose that your DB instance uses case-sensitive collation. If your application accepts both "Admin" and "admin," then your proxy needs two separate secrets. For more information about collation in SQL Server, see the Microsoft SQL Server documentation.
- RDS Proxy doesn't support connections that use Active Directory.
- You can't use IAM authentication with clients that don't support token properties. For more information, see Considerations for connecting to Microsoft SQL Server.

- The results of `@@IDENTITY`, `@@ROWCOUNT`, and `SCOPE_IDENTITY` aren't always accurate. As a work-around, retrieve their values in the same session statement to ensure that they return the correct information.
- If the connection uses multiple active result sets (MARS), RDS Proxy doesn't run the initialization queries. For information about MARS, see the Microsoft SQL Server documentation.
- Currently, RDS Proxy does not support RDS for SQL Server DB instances that run on major version *SQL Server 2022*.
- RDS Proxy does not support RDS for SQL Server DB instances that run on major version *SQL Server 2014*.
- RDS Proxy does not support client applications that can't handle multiple response messages in one TLS record.
- RDS Proxy does not support end-to-end IAM authentication for RDS for SQL Server.

Additional limitations for RDS for MySQL

The following additional limitations apply to RDS Proxy with RDS for MySQL databases:

- RDS Proxy support for `caching_sha2_password` authentication requires a secure (TLS) connection.
- RDS Proxy support for `caching_sha2_password` is known to have compatibility issues with certain go-sql driver versions.
- When using the MySQL 8.4 C driver, the `mysql_stmt_bind_named_param` API might form malformed packets if parameter count exceeds placeholder count in a prepared statements. This results in incorrect responses. For more information, see MySQL bug report.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.

- Some SQL statements and functions such as `SET LOCAL` can change the connection state without causing pinning. For the most current pinning behavior, see Avoiding pinning an RDS Proxy.
- Using the `ROW_COUNT()` function in a multi-statement query is not supported.
- RDS Proxy does not support client applications that can't handle multiple response messages in one TLS record.
- RDS Proxy does not support the MySQL dual passwords.
- RDS Proxy might not work as expected when you configure the `init_connect` parameter in your RDS DB parameter group to set session state variables. Instead, set the initialization query for your proxy to run session initialization statements when using proxy to connect to your database.

> **Important**
>
> For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

Additional limitations for RDS for PostgreSQL

The following additional limitations apply to RDS Proxy with RDS for PostgreSQL databases:

- RDS Proxy doesn't support session pinning filters for PostgreSQL.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case, for example, when you cancel a long-running query in an interactive psql session by using Ctrl+C.
- The results of the PostgreSQL function lastval aren't always accurate. As a work-around, use the INSERT statement with the `RETURNING` clause.
- RDS Proxy currently doesn't support streaming replication mode.
- With RDS for PostgreSQL 16, modifications to the `scram_iterations` value exclusively impact the authentication process between the proxy and the database. Specifically, if you configure `ClientPasswordAuthType` to `scram-sha-256`, any customizations made to the

`scram_iterations` value doesn't influence client-to-proxy password authentication. Instead, the iteration value for client-to-proxy password authentication is fixed at 4096.

- The default `postgres` database must exist on the RDS for PostgreSQL instance for RDS Proxy to function. Don't delete this database even if your application uses different databases.
- If you use `ALTER ROLE` to change the user role with `SET ROLE`, subsequent connections as that user to the proxy might not use this role setting, if those connections encounter pinning. To prevent this, when using proxy, use `SET ROLE` in the initialization query of the proxy. For more information, see **Initialization query** in Creating a proxy for Amazon RDS.

> **Important**
>
> For existing proxies with PostgreSQL databases, if you modify the database authentication to use `SCRAM` only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:
>
> - Ensure that the database allows both `SCRAM` and `MD5` authentication.
> - To use only `SCRAM` authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB instance that encounters "too many connections" errors is a good candidate for associating with a proxy. This is often characterized by a high value of the `ConnectionAttempts` CloudWatch metric. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance .
- For DB instances that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch

metrics to determine whether a DB instance is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances . The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Amazon RDS Multi-AZ DB instances. RDS Proxy also automatically routes traffic to a new database instance while preserving application connections. This makes failovers more transparent for applications.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous

connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instance. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

- Transactions

Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the **Proxies** page.

Each proxy handles connections to a single RDS DB instance. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instance or cluster.

The connections that a proxy keeps open and available for your database applications to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an Amazon RDS DB instance. You do so instead of connecting to the read/write endpoint that connects directly to the instance . For RDS DB clusters, you can also create additional read/write and read-only endpoints. For more information, see Overview of proxy endpoints.

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within a cluster. If you use other AWS services such as AWS Lambda to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance that the proxy can connect to. The RDS DB instance associated with a proxy are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling separately for the writer and reader instance of its associated RDS database . *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see Security in Amazon RDS . Also, make sure to familiarize yourself with how RDS work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.3, even if the underlying DB instance supports an older version of TLS. You can connect to the proxy using an IAM role even if the proxy connects to the database using the database user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You can use the following methods of authentication with RDS Proxy:

- **Database credentials**
- **Standard IAM authentication**
- **End-to-end IAM authentication**

Using IAM with RDS Proxy

RDS Proxy offers two methods of IAM authentication:

- **Standard IAM authentication**: Enforce IAM authentication for connections to your proxy while the proxy connects to the database using credentials stored in Secrets Manager. This enforces IAM authentication for database access even if the databases use native password authentication. The proxy retrieves the database credentials from Secrets Manager and handles the authentication to the database on behalf of your application.
- **End-to-end IAM authentication**: Enforces IAM authentication for connections directly from your applications to your database through the proxy. End-to-end IAM authentication simplifies your security configuration and avoids database credential management in Secrets Manager. This additional layer of security enforces IAM-based access control from the client application to the database.

To use standard IAM authentication, configure your proxy to use Secrets Manager secrets for authentication and enable IAM authentication for client connections. Your applications

authenticate to the proxy using IAM, while the proxy authenticates to the database using the credentials retrieved from Secrets Manager.

To use end-to-end IAM authentication, configure your proxy to use IAM authentication when setting the default authentication scheme when creating or modifying your proxy.

For end-to-end IAM authentication, you must update the IAM role associated with the proxy to grant the `rds-db:connect` permission. With end-to-end IAM authentication, this eliminates the need to register individual database users with the proxy through Secrets Manager secrets.

Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

> **Note**
>
> RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy in the AWS Management Console.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, 1.2, and 1.3. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

PREFERRED

SSL is the first choice, but it isn't required.

DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For the `.pem` file to use, download all root CA PEMs from Amazon Trust Services and place them into a single `.pem` file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration.

Connecting through a proxy makes your applications more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. This helps speed up and simplify the failover process. This is less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on the database in failover. Any existing database connections are disrupted, and your

application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL `autocommit` setting is turned on.
- Conversely, when the `autocommit` setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.

- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see Avoiding pinning an RDS Proxy.

Getting started with RDS Proxy

Use the information in the following pages to set up and manage Amazon RDS Proxy and set related security options. The security options control who can access each proxy and how each proxy connects to DB instances.

If you're new to RDS Proxy, we recommend following the pages in the order that we present them.

Topics

- Setting up network prerequisites for RDS Proxy
- Setting up database credentials for RDS Proxy
- Configuring IAM authentication for RDS Proxy
- Creating a proxy for Amazon RDS
- Viewing a proxy
- Connecting to a database through RDS Proxy

Setting up network prerequisites for RDS Proxy

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see Work with shared VPCs.

For IPv6 support, additional network configuration is required:

- **IPv6 endpoint network types** – Your VPC and subnets must be configured to support IPv6. This includes having IPv6 CIDR blocks assigned to your VPC and subnets.
- **Dual-stack endpoint network types** – Your VPC and subnets must support both IPv4 and IPv6 addressing.
- **IPv6 target connection network types** – Your database must be configured for dual-stack mode to support IPv6 connections from the proxy.

Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any RDS DB instances , you already have the required network resources.

Topics

- Getting information about your subnets
- Planning for IP address capacity

Getting information about your subnets

To create a proxy, you must provide the subnets and the VPC that the proxy operates within. The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific RDS DB instance. Find the VPC ID for the DB instance. Examine the VPC to find its subnets. The following Linux example shows how.

```
$ #From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet
 IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].
[DBSubnetGroup]||[0]||[0]||[Subnets]||[0]||[*].SubnetIdentifier' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
...
```

```
$ #From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].
[DBSubnetGroup]||[0]||[0].VpcId' --output text
```

```
my_vpc_id
```

```
$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].
[SubnetId]' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

Planning for IP address capacity

An RDS Proxy automatically adjusts its capacity as needed based on the size and number of DB instances registered with it. Certain operations might also require additional proxy capacity such as increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event `RDS-EVENT-0243` when there aren't enough free IP addresses in your subnets. For information about this event, see Working with RDS Proxy events.

> **Note**
>
> RDS Proxy doesn't consume more than 215 IP addresses for each proxy in a VPC.

Reserve the following minimum numbers of free IP addresses in your subnets for your proxy, based on DB instance class sizes.

DB instance class	Minimum free IP addresses
db.*.xlarge or smaller	10
db.*.2xlarge	15
db.*.4xlarge	25
db.*.8xlarge	45
db.*.12xlarge	60
db.*.16xlarge	75
db.*.24xlarge	110

These recommended numbers of IP addresses are estimates for a proxy with only the default endpoint. A proxy with additional endpoints or read replicas might need more free IP addresses. For each additional endpoint, we recommend that you reserve three more IP addresses. For each read replica, we recommend that you reserve additional IP addresses as specified in the table based on that read replica's size.

Setting up database credentials for RDS Proxy

RDS Proxy in Amazon RDS uses AWS Secrets Manager to store and manage database credentials securely. Instead of embedding credentials in your application, you associate a proxy with a Secrets Manager secret that contains the necessary authentication details. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance.

Alternatively, you can configure RDS Proxy to use end-to-end IAM authentication, which eliminates the need to store database credentials in Secrets Manager. RDS Proxy uses IAM authentication for both client-to-proxy and proxy-to-database connections. This provides a fully integrated IAM-based authentication solution that doesn't require managing secrets or passwords. For information about adding a new IAM DB user, see Creating a database account using IAM authentication.

Topics

- Creating secrets to use with RDS Proxy

Creating secrets to use with RDS Proxy

Before you create a proxy, you must first create at least one secret that stores your database credentials.

Console

To create a secret

1. Open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.
2. Choose **Store a new secret**.
3. Choose **Credentials for Amazon RDS database**.
4. Enter a user name and password. The credentials that you enter must match the credentials of a database user that exists in the associated RDS database. RDS Proxy uses these credentials to authenticate and establish connections to the database on behalf of applications.

   If there's a mismatch, you can update the secret to match the database password. Until you update the secret, attempts to connect through the proxy using that secret fail, but connections using other valid secrets still work.

   > **Note**
   >
   > For RDS for SQL Server, RDS Proxy requires a case-sensitive secret in Secrets Manager, regardless of the DB instance collation settings. If your application allows usernames with different capitalizations, such as "Admin" and "admin," you must create separate secrets for each. RDS Proxy doesn't support case-insensitive username authentication between the client and proxy.
   > For more information about collation in SQL Server, see the Microsoft SQL Server documentation.

5. For **Database**, select the Amazon RDS database that the secret will access.
6. Fill in other settings for the secret, then choose **Store**. For comprehensive instructions, see Creating an AWS Secrets Manager secret in the *AWS Secrets Manager User Guide*.

AWS CLI

When you create a proxy through the AWS CLI, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

- To create a Secrets Manager secret for use with RDS Proxy, use the create-secret command:

```
aws secretsmanager create-secret \
  --name "secret_name" \
  --description "secret_description" \
  --region region_name \
  --secret-string '{"username":"db_user","password":"db_user_password"}'
```

- You can also create a custom key to encrypt your Secrets Manager secret. The following command creates an example key.

```
aws kms create-key --description "test-key" --policy '{
  "Id":"kms-policy",
  "Version": "2012-10-17",
  "Statement":
    [
      {
        "Sid":"Enable IAM User Permissions",
        "Effect":"Allow",
        "Principal":{"AWS":"arn:aws:iam::account_id:root"},
        "Action":"kms:*","Resource":"*"
      },
      {
        "Sid":"Allow access for Key Administrators",
        "Effect":"Allow",
        "Principal":
          {
            "AWS":
              ["$USER_ARN","arn:aws:iam:account_id::role/Admin"]
          },
        "Action":
          [
            "kms:Create*",
            "kms:Describe*",
            "kms:Enable*",
            "kms:List*",
            "kms:Put*",
```

```
            "kms:Update*",
            "kms:Revoke*",
            "kms:Disable*",
            "kms:Get*",
            "kms:Delete*",
            "kms:TagResource",
            "kms:UntagResource",
            "kms:ScheduleKeyDeletion",
            "kms:CancelKeyDeletion"
          ],
        "Resource":"*"
      },
      {
        "Sid":"Allow use of the key",
        "Effect":"Allow",
        "Principal":{"AWS":"$ROLE_ARN"},
        "Action":["kms:Decrypt","kms:DescribeKey"],
        "Resource":"*"
      }
    ]
}'
```

For example, the following commands create Secrets Manager secrets for two database users:

```
aws secretsmanager create-secret \
  --name secret_name_1 --description "db admin user" \
  --secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
  --name secret_name_2 --description "application user" \
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To create these secrets encrypted with your custom AWS KMS key, use the following commands:

```
aws secretsmanager create-secret \
  --name secret_name_1 --description "db admin user" \
  --secret-string '{"username":"admin","password":"choose_your_own_password"}' \
  --kms-key-id arn:aws:kms:us-east-2:account_id:key/key_id

aws secretsmanager create-secret \
  --name secret_name_2 --description "application user" \
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}' \
```

```
  --kms-key-id arn:aws:kms:us-east-2:account_id:key/key_id
```

To see the secrets owned by your AWS account, use the list-secrets command:

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To confirm that the secret contains the correct credentials in the proper format, use the get-secret-value command. Replace *your_secret_name* with the secret's short name or ARN.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output contains a line with a JSON-encoded value similar to the following:

```
...
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
...
```

Configuring IAM authentication for RDS Proxy

To set up AWS Identity and Access Management (IAM) authentication for RDS Proxy in Amazon RDS, create and configure an IAM policy that grants the necessary permissions.

This topic provides the steps to configure IAM authentication for RDS Proxy, including creating the required IAM policy and attaching it to an IAM role.

> **Tip**
>
> This procedure is only necessary if you want to create your own IAM role. Otherwise, RDS can automatically create the required role when you set up the proxy, so you can skip these steps.

Prerequisites

Before you set up IAM authentication for RDS Proxy, make sure that you have the following:

- **AWS Secrets Manager** – At least one stored secret that contains database credentials. For instructions to create secrets, see the section called "Setting up database credentials".

  This is not required if you are using end-to-end IAM authentication.
- **IAM permissions** – An IAM role or user with permissions to create and manage IAM policies, roles, and secrets in AWS Secrets Manager.

Creating an IAM policy for end-to-end IAM authentication

When using end-to-end IAM authentication, RDS Proxy connects to your database using IAM authentication instead of retrieving credentials from Secrets Manager. This requires configuring your IAM role with `rds-db:connect` permissions for the database accounts you want to use with the proxy.

To authenticate your RDS Proxy to the database using IAM, create an IAM role with a policy that grants the necessary database connection permissions.

Console

To create a role for end-to-end IAM authentication with your proxy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Create a permissions policy for the role. For general steps, see Create IAM policies (console).

   Paste this policy into the JSON editor and make the following changes:

   - Substitute your own account ID.
   - Substitute `us-east-2` with the where the proxy must reside.
   - Substitute the database resource IDs and user names with the ones you want to use. The resource ID format differs between RDS instances and Aurora clusters.

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": "rds-db:connect",
            "Resource": [
                "arn:aws:rds-db:us-
east-2:account_id:dbuser:db_instance_resource_id/db_user_name_1",
                "arn:aws:rds-db:us-
east-2:account_id:dbuser:db_instance_resource_id/db_user_name_2"
            ]
        }
    ]
}
```

3. Create the role and attach the permissions policy to it. For general steps, see Create a role to delegate permissions to an AWS service.

   For the **Trusted entity type**, choose **AWS service**. Under **Use case**, select **RDS** and choose **RDS - Add Role to Database** for the use case.

4. For **Permissions policies**, choose the policy that you created.
5. For **Select trusted entities**, enter the following trust policy for the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

AWS CLI

To create the role using the AWS CLI, send the following request:

```
aws iam create-role \
  --role-name my_e2e_iam_role_name \
```

```
  --assume-role-policy-document '{"Version":"2012-10-17",
     "Statement":[{"Effect":"Allow","Principal":{"Service":
["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'
```

Then, attach the policy to the role:

```
aws iam put-role-policy \
  --role-name my_e2e_iam_role_name \
  --policy-name e2e_iam_db_connect_policy \
  --policy-document '{

    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "rds-db:connect",
            "Resource": [
                "arn:aws:rds-db:us-
east-2:account_id:dbuser:db_instance_resource_id/db_user_name_1",
                "arn:aws:rds-db:us-
east-2:account_id:dbuser:db_instance_resource_id/db_user_name_2"
            ]
        }
    ]
}'
```

With the IAM role and permissions configured for end-to-end IAM authentication, you can now create a proxy with `DefaultAuthScheme` set to `IAM_AUTH`. This proxy directly authenticates to the database using IAM without requiring Secrets Manager secrets. For instructions, see the section called “Creating a proxy”.

When using end-to-end IAM authentication, ensure that your database users are configured for IAM authentication as described in Creating a database account using IAM authentication.

Creating an IAM policy for Secrets Manager access

To allow RDS Proxy to retrieve database credentials from Secrets Manager, create an IAM role with a policy that grants the necessary permissions.

Console

To create a role to access your secrets for use with your proxy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Create a permissions policy for the role. For general steps, see Create IAM policies (console).

   Paste this policy into the JSON editor and make the following changes:

   - Substitute your own account ID.
   - Substitute `us-east-2` with the Region where the proxy will reside.
   - Substitute the secret names with the ones you created. For more information, see Specifying KMS keys in IAM policy statements.
   - Substitue the KMS key ID with the one you used to encrypt the Secrets Manager secrets, either the default key or your own key.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-
east-2:111122223333:secret:secret_name_1",
                "arn:aws:secretsmanager:us-
east-2:111122223333:secret:secret_name_2"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:111122223333:key/key_id",
            "Condition": {
                "StringEquals": {
```

```
                    "kms:ViaService": "secretsmanager.us-
east-2.amazonaws.com"
                }
            }
        }
    ]
}
```

3. Create the role and attach the permissions policy to it. For general steps, see Create a role to delegate permissions to an AWS service.

   For the **Trusted entity type**, choose **AWS service**. Under **Use case**, select **RDS** and choose **RDS - Add Role to Database** for the use case.

4. For **Permissions policies**, choose the policy that you created.

5. For **Select trusted entities**, enter the following trust policy for the role:

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

AWS CLI

To create the role using the AWS CLI, send the following request:

```
aws iam create-role \
  --role-name my_role_name \
```

```
  --assume-role-policy-document '{"Version": "2012-10-17",
      "Statement":[{"Effect":"Allow","Principal":{"Service":
["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'
```

Then, attach the policy to the role:

```
aws iam put-role-policy \
  --role-name my_role_name \
  --policy-name secret_reader_policy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
                }
            }
        }
    ]
}'
```

With the IAM role and permissions configured, you can now create a proxy and associate it with this role. This allows the proxy to retrieve database credentials securely from AWS Secrets Manager and enable IAM authentication for your applications. For instructions, see the section called “Creating a proxy”.

Creating a proxy for Amazon RDS

You can associate a proxy with an RDS for MariaDB, RDS for Microsoft SQL Server, RDS for MySQL, or RDS for PostgreSQL DB instance.

Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Configure the following settings for your proxy.

Setting	Description
Engine family	The database network protocol the proxy recognizes when it interprets network traffic to and from the database. **Note** To use RDS for PostgreSQL, make sure to retain the `postgres` database in your instance. See Troubleshooting deleted `postgres` database.
Proxy identifier	A name that is unique within your AWS account ID and current AWS Region.
Idle client connection timeout	The proxy closes a client connection if it remains idle for a set period. By default, this is 1,800 seconds (30 minutes). A connection is idle when the application doesn't submit a new request within the specified time after completing the previous request. The proxy keeps the underlying database connection open and returns it to the connection pool, making it available for new client connections.

Setting	Description
	To proactively remove stale connections, reduce the idle client connection timeout. To minimize connection costs during workload spikes, increase the timeout.
Database	The RDS DB instance to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in Creating an Amazon RDS DB instance. Then, try creating the proxy again.
Connection pool maximum connections	A value between 1 and 100 to define the percentage of the `max_connections` limit that RDS Proxy can use. If you only intend to use one proxy with this DB instance or cluster, set this value to 100. For more information about how RDS Proxy uses this setting, see the section called “MaxConnectionsPercent”.

Setting	Description
Session pinning filters	Prevents RDS Proxy from pinning certain detected session states, which bypasses default safety measures for multiplexing connections. Currently, PostgreSQL doesn't support this setting, and the only available option is `EXCLUDE_VARIABLE_SETS`. Enabling it might cause session variables from one connection to affect others, leading to errors or correctness issues if queries rely on session variables set outside the current transaction. Use this option only after confirming that your applications can safely share database connections. The following patterns are considered safe: • `SET` statements where there is no change to the effective session variable value. In other words, there is no change to the session variable. • You change the session variable value and execute a statement in the same transaction. For more information, see Avoiding pinning an RDS Proxy.
Connection borrow timeout	If you expect the proxy to use all available database connections, set the wait time before it returns a timeout error. You can specify up to five minutes. This setting applies only when the proxy has reached the maximum number of connections and all are in use.

Setting	Description
Initialization query	(Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings. Make sure that the query you add is valid. To include multiple variables in a single SET statement, use comma separators. For example: `SET variable1 =value1, variable2 =value2` For multiple statements, use semicolons as the separator. **Important** Since you can access initialization query as part of target group configuration, it is not protected by authentication or cryptographic methods. Anyone with access to view or manage your proxy target group configuration can view the initialization query. You should not add sensitive data, such as passwords or long-lived encryption keys, to this option.
AWS Identity and Access Management (IAM) role	An IAM role with permission to access the Secrets Manager secrets, which represent the credentials for database user accounts that the proxy can use. Alternatively, you can create a new IAM role from the AWS Management Console.

Setting	Description
Secrets Manager secrets	Create or choose Secrets Manager secrets representing the credentials for database users accounts that can use the proxy. When **Default authentication scheme** is set to **None**, this field is required. When **Default authentication scheme** is set to **IAM authentication**, this field becomes optional and is marked as such in the console. You can choose one or more secrets from the dropdown or create a new secret using the **Create a new secret** link.
Client authentication type	The type of authentication the proxy uses for connections from clients. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different client authentication type for each secret, create your proxy by using the AWS CLI or the API instead. Specify this option only when your client connection uses database credentials for authentication.
IAM authentication	Specify **Required**, **Allowed**, or **Not Allowed** for IAM authentic ation for connections to your proxy. The **Allowed** option is only valid for proxies for RDS for SQL Server. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different IAM authentication for each secret, create your proxy by using the AWS CLI or the API instead.

Setting	Description
Default authentication scheme	Choose the default type of authentication that the proxy uses for client connections to the proxy and the connections from the proxy to the underlying database. You have the following options: • **None** (default) - The proxy retrieves database credentials from Secrets Manager secrets. • **IAM authentication** - The proxy uses IAM authentication to connect to the database, enabling end-to-end IAM authentic ation. When you select **IAM authentication**, an information alert appears reminding you to enable IAM database authentication for the databases in the target group configuration. **Note** This option is supported for MySQL, PostgreSQL, and MariaDB engine families only.

Setting	Description
Database accounts for IAM authentication	This field appears only when **Default authentication scheme** is set to **IAM authentication** and **Identity and access management (IAM) role** is set to **Create IAM role**. Name the database user accounts for the proxy to use with IAM authentication. This is a required field. Specify multiple accounts by: • Typing a database user name to add it as a tag • Using specific database user names (e.g., `db_user`, `jane_doe`) • Using wildcard patterns for multiple users (e.g., `db_test_*`) Each account appears as a removable tag that you can delete by clicking the X icon. The console uses these values to create the appropriate `rds-db:connect` permissions in the IAM role policy.
Require Transport Layer Security	Enforces TLS/SSL for all client connections. The proxy uses the same encryption setting for its connection to the underlyin g database, whether the client connection is encrypted or unencrypted.

Setting	Description
Target connection network type	The IP version that the proxy uses to connect to the target database. Choose from the following options: • **IPv4** – The proxy connects to the database using IPv4 addresses. • **IPv6** – The proxy connects to the database using IPv6 addresses. The default is IPv4. To use IPv6, your database must support dual-stack mode. Dual-stack mode is not available for target connections.
Endpoint network type	The IP version for the proxy endpoint that clients use to connect to the proxy. Choose from the following options: • **IPv4** – The proxy endpoint uses IPv4 addresses only. • **IPv6** – The proxy endpoint uses IPv6 addresses only. • **Dual-stack** – The proxy endpoint supports both IPv4 and IPv6 addresses. The default is IPv4. To use IPv6 or dual-stack, your VPC and subnets must be configured to support the selected network type.
Subnets	This field is prepopulated with all subnets associated with your VPC. You can remove any subnets not needed for the proxy, but you must leave at least two subnets. For IPv6 or dual-stac k endpoint network types, ensure that the selected subnets support the chosen network type.

Setting	Description
VPC security group	Choose an existing VPC security group or create a new one from the AWS Management Console. Configure the inbound rules to allow your applications to access the proxy and the outbound rules to permit traffic from your database targets. **Note** The security group must allow connections from the proxy to the database. It serves both for ingress from your applications to the proxy and egress from the proxy to the database. For example, if you use the same security group for both the database and the proxy, make sure that resources within that security group can communicate with each other. When you use a shared VPC, avoid using the default security group for the VPC or one associated with another account. Instead, select a security group that belongs to your account. If none exists, create one. For more information, see Work with shared VPCs. RDS deploys a proxy across multiple Availability Zones to ensure high availability. To enable cross-AZ communication, the network access control list (ACL) for your proxy subnet must allow egress on the engine port and ingress on all ports. For more information about network ACLs, see Control traffic to subnets using network ACLs. If the network ACL for your proxy and target are identical, you must add a **TCP** protocol ingress rule where the **Source** is set to the VPC CIDR. You must also add an engine port specific **TCP** protocol egress rule where the **Destination** is set to the VPC CIDR.

Setting	Description
Activate enhanced logging	Enable this setting to troubleshoot proxy compatibility or performance issues. When enabled, RDS Proxy logs detailed performance information to help you debug SQL behavior or proxy connection performance and scalability. Only enable this setting for debugging and ensure proper security measures are in place to protect sensitive informati on in the logs. To minimize overhead, RDS Proxy automatically disables this setting 24 hours after activation. Use it temporari ly to troubleshoot specific issues.

5. Choose **Create proxy**.

AWS CLI

To create a proxy by using the AWS CLI, call the create-db-proxy command with the following required parameters:

- `--db-proxy-name`
- `--engine-family`
- `--role-arn`
- `--vpc-subnet-ids`

The `--engine-family` value is case-sensitive.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
    --db-proxy-name proxy_name \
    --engine-family { MYSQL | POSTGRESQL | SQLSERVER } \
    --role-arn iam_role \
    --vpc-subnet-ids space_separated_list \
    [--default-auth-scheme { NONE | IAM_AUTH }] \
    [--auth ProxyAuthenticationConfig_JSON_string] \
```

```
    [--vpc-security-group-ids space_separated_list] \
    [--require-tls | --no-require-tls] \
    [--idle-client-timeout value] \
    [--debug-logging | --no-debug-logging] \
    [--endpoint-network-type { IPV4 | IPV6 | DUAL }] \
    [--target-connection-network-type { IPV4 | IPV6 }] \
    [--tags comma_separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
    --db-proxy-name proxy_name ^
    --engine-family { MYSQL | POSTGRESQL | SQLSERVER } ^
    --role-arn iam_role ^
    --vpc-subnet-ids space_separated_list ^
    [--default-auth-scheme { NONE | IAM_AUTH }] ^
    [--auth ProxyAuthenticationConfig_JSON_string] ^
    [--vpc-security-group-ids space_separated_list] ^
    [--require-tls | --no-require-tls] ^
    [--idle-client-timeout value] ^
    [--debug-logging | --no-debug-logging] ^
    [--endpoint-network-type { IPV4 | IPV6 | DUAL }] ^
    [--target-connection-network-type { IPV4 | IPV6 }] ^
    [--tags comma_separated_list]
```

The following is an example of the JSON value for the `--auth` option. This example applies a different client authentication type to each secret.

```
[
  {
    "Description": "proxy description 1",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:123456789123:secret/1234abcd-12ab-34cd-56ef-1234567890ab",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_SCRAM_SHA_256"
  },

  {
    "Description": "proxy description 2",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122223333:secret/1234abcd-12ab-34cd-56ef-1234567890cd",
```

```
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_MD5"

  },

  {
    "Description": "proxy description 3",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122221111:secret/1234abcd-12ab-34cd-56ef-1234567890ef",
    "IAMAuth": "REQUIRED"
  }

]
```

The `--endpoint-network-type` parameter specifies the IP version for the proxy endpoint that clients use to connect to the proxy. Valid values are:

- `IPV4` – The proxy endpoint uses IPv4 addresses only (default).
- `IPV6` – The proxy endpoint uses IPv6 addresses only.
- `DUAL` – The proxy endpoint supports both IPv4 and IPv6 addresses.

The `--target-connection-network-type` parameter specifies the IP version that the proxy uses to connect to the target database. Valid values are:

- `IPV4` – The proxy connects to the database using IPv4 addresses (default).
- `IPV6` – The proxy connects to the database using IPv6 addresses.

To use IPv6 or dual-stack endpoint network types, your VPC and subnets must be configured to support the selected network type. To use IPv6 target connection network type, your database must support dual-stack mode.

Tip

If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see Setting up network prerequisites for RDS Proxy for examples of how to find them.

Note

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.
When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see Work with shared VPCs.

To create the right associations for the proxy, you also use the register-db-proxy-targets command. Specify the target group name `default`. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
    --db-proxy-name value
    [--target-group-name target_group_name]
    [--db-instance-identifiers space_separated_list]  # rds db instances, or
    [--db-cluster-identifiers cluster_id]        # rds db cluster (all instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation CreateDBProxy. You pass a parameter with the AuthConfig data structure.

RDS Proxy automatically creates a target group named `default` when you create each proxy. You associate an RDS DB instance with the target group by calling the function RegisterDBProxyTargets.

Important

When you select **IAM authentication** for the default authentication scheme:

- You must enable IAM database authentication on your target database instances or clusters before the proxy can successfully connect.

- If you choose **Create IAM role**, the **Database accounts for IAM authentication** field is required.
- If you select an existing IAM role, the console does not automatically update the role with database connection permissions. Check that the role has the necessary `rds-db:connect` permissions.

Viewing a proxy

After you create one or more RDS proxies, you can view and manage them in the AWS Management Console, the AWS CLI, or the RDS API. You can review their configuration details, monitor performance, and determine which proxies to modify or delete as needed.

To enable database applications to route traffic through a proxy, you must specify the proxy endpoint in the connection string.

Console

To view a proxy in the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Select the proxy name to view its details.
4. On the details page, the **Target groups** section shows how the proxy is linked to a specific RDS DB instance. You can navigate to the default target group page for a deeper view of this association, including configuration settings defined during proxy creation. These settings include the maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

CLI

To view your proxy using the CLI, use the describe-db-proxies command. By default, the request returns all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups  --db-proxy-name proxy_name

aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run describe-db-proxies.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run describe-db-proxy-target-groups `--db-proxy-name`. Use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance associated with the returned target group, run describe-db-proxy-targets.

RDS API

To view your proxies using the RDS API, use the DescribeDBProxies operation. It returns values of the DBProxy data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the DescribeDBProxyTargetGroups operation. It returns values of the DBProxyTargetGroup data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the DescribeDBProxyTargets operation. It returns values of the DBProxyTarget data type.

Connecting to a database through RDS Proxy

The way to connect to an RDS DB instance through a proxy or by connecting to the database is generally the same. For more information, see Overview of proxy endpoints.

Topics

- Connecting to a database using database credentials
- Connecting to a database using IAM authentication
- Considerations for connecting to Microsoft SQL Server

- Considerations for connecting to PostgreSQL

Connecting to a database using database credentials

Use the following steps to connect to a proxy using database credentials:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the describe-db-proxies command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].
{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
    [
        {
            "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy"
        },
        {
            "Endpoint": "the-proxy-other-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-other-secret"
        },
        {
            "Endpoint": "the-proxy-rds-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-rds-secret"
        },
        {
            "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-t3"
        }
    ]
]
```

2. Specify the endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

Connecting to a database using IAM authentication

When you use IAM authentication with RDS Proxy, you have two options for authentication between your client and proxy:

- Set up your database users to authenticate with regular user names and passwords. RDS Proxy retrieves the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.
- You can also use end-to-end IAM authentication, which connects to your database through the proxy using IAM without requiring database credentials.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an RDS DB instance. For general information about using IAM, see Security in Amazon RDS . If you are using end-to-end IAM authentication, provide the IAM authentication plugin to your DB user. See Creating a database account using IAM authentication.

The major differences in IAM usage for RDS Proxy include the following:

- With standard IAM authentication, database users have regular credentials within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager. The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.
- With end-to-end IAM authentication, you don't need to configure Secrets Manager secrets for database credentials. The IAM authentication applies to the connection between the client to the proxy and proxy to the database.
- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see Connecting to your DB instance using IAM authentication.
- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKL01234/db_user"
```

Tip

When configuring IAM authentication for RDS Proxy connections, follow these important guidelines to avoid connection issues:

- Do not grant the `rds_iam` role while maintaining general password authentication for the same database user or role.
- Remember that while clients connect to RDS Proxy using IAM authentication, RDS Proxy always connects to the database using password authentication through Secrets Manager.
- If you experience frequent connection terminations and reconnections, remove any existing `rds_iam` grants from the user or role and use only password authentication.
- Ensure your password policy satisfies SCRAM-SHA-256 safe character requirements.

Mixing IAM and password authentication methods for the same database user can cause connection instability.

Considerations for connecting to Microsoft SQL Server

For connecting to a proxy using IAM authentication, you don't use the password field. Instead, you provide the appropriate token property for each type of database driver in the token field. For example, use the `accessToken` property for JDBC, or the `sql_copt_ss_access_token` property for ODBC. Or use the `AccessToken` property for the .NET SqlClient driver. You can't use IAM authentication with clients that don't support token properties.

Under some conditions, a proxy can't share a database connection and instead pins the connection from your client application to the proxy to a dedicated database connection. For more information about these conditions, see Avoiding pinning an RDS Proxy.

Considerations for connecting to PostgreSQL

If you create a new PostgreSQL database user for connecting to RDS Proxy, make sure that you grant the user `CONNECT` privilege on the database. Without this, the user can't establish a connection. For more information, see the section called “Adding a new database user to a PostgreSQL database when using RDS Proxy”.

When a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the `StartupMessage` in PostgreSQL message formats in the PostgreSQL documentation.

When you connect through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`

The startup message can also include the following additional runtime parameters:

- `application_name`
- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`
- `search_path`

For more information about PostgreSQL messaging, see the Frontend/Backend protocol in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC, we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least `9.0` to avoid pinning. This prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to *`any/your-application-name`* to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.

For more information, see Avoiding pinning an RDS Proxy. For more information about connecting using JDBC, see Connecting to the database in the PostgreSQL documentation.

Managing an RDS Proxy

This section provides information on how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

- Avoiding pinning an RDS Proxy
- Deleting an RDS Proxy

Modifying an RDS Proxy

You can change specific settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

Important

The values in the **Client authentication type** and **IAM authentication** fields apply to all Secrets Manager secrets that are associated with this proxy. To specify different values for each secret, modify your proxy by using the AWS CLI or the API instead.

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.

3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:

   - **Proxy identifier** – Rename the proxy by entering a new identifier.
   - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
   - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.

     > **Note**
     >
     > You can't create a new IAM role if you set **Default authentication scheme** to **IAM authentication**.

   - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
   - **Client authentication type** – Change the type of authentication for client connections to the proxy.
   - **IAM authentication** – Require or disallow IAM authentication for connections to the proxy.
   - **Default authentication scheme** – Change the default authentication scheme the proxy uses for client connections to the proxy and connections from the proxy to the underlying database.
   - **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
   - **VPC security group** – Add or remove VPC security groups for the proxy to use.
   - **Enable enhanced logging** – Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy. You can't rename the default target group.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the **default** target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:

   - **Database** – Choose a different RDS DB instance or cluster.
   - **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
   - **Session pinning filters** – (Optional) Choose a session pinning filter. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL. The only choice is `EXCLUDE_VARIABLE_SETS`.

     Enabling this setting can cause session variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

     The following patterns can be considered safe:

     - `SET` statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
     - You change the session variable value and execute a statement in the same transaction.

     For more information, see Avoiding pinning an RDS Proxy.
   - **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
   - **Initialization query**. (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new

database connection. The setting is typically used with SET statements to make sure that each connection has identical settings. Make sure that the query you add is valid. To include multiple variables in a single SET statement, use comma separators. For example:

```
SET variable1=value1, variable2=value2
```

For multiple statements, use semicolons as the separator.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

AWS CLI

To modify a proxy using the AWS CLI, use the commands modify-db-proxy, modify-db-proxy-target-group, deregister-db-proxy-targets, and register-db-proxy-targets.

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.
- The default authentication scheme associated with the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When you work with this target group, you specify the name of the proxy and `default` for the name of the target group. You can't rename the default target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy

{
    "TargetGroups": [
        {
            "Status": "available",
            "UpdatedDate": "2019-11-30T16:49:30.342Z",
            "ConnectionPoolConfig": {
                "MaxIdleConnectionsPercent": 50,
                "ConnectionBorrowTimeout": 120,
                "MaxConnectionsPercent": 100,
                "SessionPinningFilters": []
            },
            "TargetGroupName": "default",
            "CreatedDate": "2019-11-30T16:49:27.940Z",
            "DBProxyName": "the-proxy",
            "IsDefault": true
        }
    ]
}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name
 default --connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
```

```
}
```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instances the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {
            "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-8898"
        },
        {
            "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-1018"
        },
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "cluster-56-2020-02-25-1399"
        },
```

```
        {
            "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-4330"
        }
    ]
}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
 cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
 provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "gkldje"
        },
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}
```

RDS API

To modify a proxy using the RDS API, you use the operations ModifyDBProxy, ModifyDBProxyTargetGroup, DeregisterDBProxyTargets, and RegisterDBProxyTargets operations.

With `ModifyDBProxy`, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings. Currently, all proxies have a single target group named `default`. When you work with this target group, you specify the name of the proxy and `default` for the name of the target group. You can't rename the default target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which RDS DB instance the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance . The target group tracks the connection details for the RDS DB instances in a Multi-AZ configuration .

Adding a new database user when using RDS Proxy

In some cases, you might add a new database user to an RDS DB instance or cluster that's associated with a proxy. Proceed depending on whether you're using standard authentication with Secrets Manager secrets or end-to-end IAM authentication.

If you are using the standard IAM authentication, follow these instructions:

1. Create a new Secrets Manager secret, using the procedure described in Setting up database credentials for RDS Proxy.
2. Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
3. Modify the RDS Proxy to add the new Secrets Manager secret under **Secrets Manager secrets**.

4. If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

If you're using end-to-end IAM authentication, you need to create the database user and configure IAM permissions. To do this, run through the following steps:

1. Create a new database user in your database that matches the IAM user or role name you want to use for authentication.
2. Ensure the database user is configured with IAM authentication plugin at the database. See Creating a database account using IAM authentication.
3. Update the IAM policy to grant the `rds-db:connect` permission to the IAM user or role, as described in Creating an IAM policy for end-to-end IAM authentication.
4. Ensure your proxy is configured to use IAM authentication as the default authentication scheme.

With end-to-end IAM authentication, you don't need to manage database credentials in Secrets Manager secrets, as IAM credentials are used for authentication from the client to the proxy and from the proxy to the database.

Adding a new database user to a PostgreSQL database when using RDS Proxy

When adding a new user to your PostgreSQL database, if you have run the following command:

```
REVOKE CONNECT ON DATABASE postgres FROM PUBLIC;
```

Grant the `rdsproxyadmin` user the `CONNECT` privilege so the user can monitor connections on the target database.

```
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

You can also allow other target database users to perform health checks by changing `rdsproxyadmin` to the database user in the command above.

Changing the password for a database user when using RDS Proxy

In some cases, you might change the password for a database user in an RDS DB instance that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

If you're using end-to-end IAM authentication, you don't need to update any passwords in Secrets Manager secrets.

Moving from standard IAM authentication to end-to-end IAM authentication for RDS Proxy

If you currently use standard IAM authentication for RDS Proxy, where clients authenticate to the proxy using IAM but the proxy connects to the database using secrets, you can migrate to end-to-end IAM authentication where both client-to-proxy and proxy-to-database connections use IAM authentication.

To move to end-to-end IAM authentication

1. **Update RDS Proxy IAM role permissions**

   Create an updated proxy permission policy that includes both Secrets Manager and `rds:db-connect` permissions:

```
# Create updated proxy permission policy
cat > updated-proxy-policy.json # EOF
```

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetSecretsValue",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:secretsmanager:us-east-1:123456789012:secret:secretName-1234f"
      ]
    },
    {
      "Sid": "RdsDBConnect",
      "Action": [
        "rds-db:connect"
      ],
      "Effect": "Allow",
      "Resource": [
```

```
        "arn:aws:rds-db:us-east-1:123456789012:dbuser:cluster-ABCDEFGHIJKL01234/
jane_doe"
      ]
    }
  ]
}
```

Update proxy your role policy:

```
aws iam put-role-policy \
            --role-name RDSProxyRole \
            --policy-name UpdatedProxyPermissions \
            --policy-document file://updated-proxy-policy.json
```

2. Modify your RDS Proxy to enable end-to-end IAM authentication

```
aws rds modify-db-proxy \
  --db-proxy-name my-database-proxy \
  --default-auth-scheme IAM_AUTH \
  --region us-east-1
```

Verify that RDS Proxy status is **Available** and `DefaultAuthScheme` is `IAM_AUTH` before proceeding to ensure zero downtime during migration.

```
aws rds describe-db-proxies --db-proxy-name my-database-proxy --region us-east-1
```

Expected output:

```
{
  "DBProxies": [
    {
      "DBProxyName": "my-database-proxy",
      "DBProxyArn": "arn:aws:rds:us-east-1:123456789012:db-
proxy:prx-0123456789abcdef",
      "Status": "available",
      ...
      "DefaultAuthScheme": "IAM_AUTH"
    }
  ]
}
```

3. Enable IAM authentication on database

```
aws rds modify-db-cluster \
  --db-cluster-identifier my-database-cluster \
  --enable-iam-database-authentication \
  --region us-east-1
```

4. Configure database user for IAM authentication

   For RDS for PostgreSQL:

```
GRANT rds_iam TO jane_doe;
```

   For RDS for MySQL and RDS for MariaDB:

```
ALTER USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

5. Your client application code doesn't need to change. The connection process remains the same:

   For RDS for PostgreSQL:

```
# Generate authentication token
export PGPASSWORD=$(aws rds generate-db-auth-token \
  --hostname my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com
 \
  --port 5432 \
  --username jane_doe \
  --region us-east-1)

# Connect to database through proxy
psql "host=my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com
 port=5432 user=jane_doe dbname=postgres password=$PGPASSWORD sslmode=require
 sslrootcert=us-east-1-bundle.pem"
```

   For RDS for MySQL and RDS for MariaDB:

```
# Generate authentication token
export MYSQL_PWD=$(aws rds generate-db-auth-token \
  --hostname my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com
 \
```

```
  --port 3306 \
  --username jane_doe \
  --region us-east-1)

# Connect to database through proxy
mysql -h my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com \
  -P 3306 \
  -u jane_doe \
  --ssl-ca=us-east-1-bundle.pem \
  --enable-cleartext-plugin
```

RDS Proxy connection considerations

Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- IdleClientTimeout
- MaxConnectionsPercent
- MaxIdleConnectionsPercent
- ConnectionBorrowTimeout

IdleClientTimeout

You can specify how long a client connection can be idle before the proxy closes it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, then lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, then raise the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see AWS Management Console. To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command modify-db-proxy or the API operation ModifyDBProxy.

MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the target database. You specify the limit as a percentage of the maximum connections available for your database. This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API.

The `MaxConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the RDS DB instance used by the target group. The proxy doesn't create all of these connections in advance. This setting allows the proxy to establish these connections as the workload needs them.

For example, for a registered database target with `max_connections` set to 1000, and `MaxConnectionsPercent` set to 95, RDS Proxy sets 950 connections as the upper limit for concurrent connections to that database target.

A common side-effect of your workload reaching the maximum number of allowed database connections is an increase in overall query latency, along with an increase in the `DatabaseConnectionsBorrowLatency` metric. You can monitor currently used and total allowed database connections by comparing the `DatabaseConnections` and `MaxDatabaseConnectionsAllowed` metrics.

When setting this parameter, note the following best practices:

- Allow sufficient connection headroom for changes in workload pattern. It is recommended to set the parameter at least 30% above your maximum recent monitored usage. As RDS Proxy redistributes database connection quotas across multiple nodes, internal capacity changes might require at least 30% headroom for additional connections to avoid increased borrow latencies.
- RDS Proxy reserves a certain number of connections for active monitoring to support fast failover, traffic routing and internal operations. The `MaxDatabaseConnectionsAllowed` metric does not include these reserved connections. It represents the number of connections available to serve the workload, and can be lower than the value derived from the `MaxConnectionsPercent` setting.

  Minimal recommended `MaxConnectionsPercent` values

  - db.t3.small: 30
  - db.t3.medium or above: 20

To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see AWS Management Console. To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum number of database connections.

MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. By default, RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

The `MaxIdleConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the RDS DB instance target group. The default value is 50 percent of `MaxConnectionsPercent`, and the upper limit is the value of `MaxConnectionsPercent`. For example, if `MaxConnectionsPercent`, is 80, then the default value of `MaxIdleConnectionsPercent` is 40. If the value of `MaxConnectionsPercent` isn't specified, then for RDS for SQL Server, `MaxIdleConnectionsPercent` is 5, and for all other engines, the default is 50.

With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent`. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the AWS CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

For information on database connection limits, see Maximum number of database connections.

ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in

the connection pool. It also applies when no appropriate database instance is available to handle the request, such as when a failover operation is in process. Using this setting, you can set the best wait period for your application without changing the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see AWS Management Console. To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command modify-db-proxy-target-group or the API operation ModifyDBProxyTargetGroup.

Client and database connections

Connections from your application to RDS Proxy are known as client connections. Connections from a proxy to the database are database connections. When using RDS Proxy, client connections terminate at the proxy while database connections are managed within RDS Proxy.

Application-side connection pooling can provide the benefit of reducing recurring connection establishment between your application and RDS Proxy.

Consider the following configuration aspects before implementing an application-side connection pool:

- Client connection max life: RDS Proxy enforces a maximum life of client connections of 24 hours. This value is not configurable. Configure your pool with a maximum connection life less than 24 hours to avoid unexpected client connection drops.
- Client connection idle timeout: RDS Proxy enforces a maximum idle time for client connections. Configure your pool with an idle connection timeout of a value lower than your client connection idle timeout setting for RDS Proxy to avoid unexpected connection drops.

The maximum number of client connections configured in your application-side connection pool does not have to be limited to the **max_connections** setting for RDS Proxy.

Client connection pooling results in a longer client connection life. If your connections experience pinning, then pooling client connections might reduce multiplexing efficiency. Client connections that are pinned but idle in the application-side connection pool continue to hold on to a database connection and prevent the database connection to be reused by other client connections. Review your proxy logs to check whether your connections experience pinning.

> **Note**
>
> RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

Avoiding pinning an RDS Proxy

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through SET or SELECT statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus, RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For details about what RDS Proxy tracks for a database engine, see the following:

- What RDS Proxy tracks for RDS for SQL Server databases
- What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases

What RDS Proxy tracks for RDS for SQL Server databases

RDS Proxy tracks the following SQL Server statements:

- USE
- SET ANSI_NULLS
- SET ANSI_PADDING
- SET ANSI_WARNINGS
- SET ARITHABORT
- SET CONCAT_NULL_YIELDS_NULL
- SET CURSOR_CLOSE_ON_COMMIT
- SET DATEFIRST
- SET DATEFORMAT
- SET LANGUAGE
- SET LOCK_TIMEOUT
- SET NUMERIC_ROUNDABORT
- SET QUOTED_IDENTIFIER
- SET TEXTSIZE
- SET TRANSACTION ISOLATION LEVEL

What RDS Proxy tracks for RDS for MariaDB and RDS for MySQL databases

RDS Proxy tracks the following MariaDB and MySQL statements:

- DROP DATABASE
- DROP SCHEMA
- USE

RDS Proxy tracks the following MySQL and MariaDB variables:

- AUTOCOMMIT
- AUTO_INCREMENT_INCREMENT
- CHARACTER SET (or CHAR SET)

- CHARACTER_SET_CLIENT
- CHARACTER_SET_DATABASE
- CHARACTER_SET_FILESYSTEM
- CHARACTER_SET_CONNECTION
- CHARACTER_SET_RESULTS
- CHARACTER_SET_SERVER
- COLLATION_CONNECTION
- COLLATION_DATABASE
- COLLATION_SERVER
- INTERACTIVE_TIMEOUT
- NAMES
- NET_WRITE_TIMEOUT
- QUERY_CACHE_TYPE
- SESSION_TRACK_SCHEMA
- SQL_MODE
- TIME_ZONE
- TRANSACTION_ISOLATION (or TX_ISOLATION)
- TRANSACTION_READ_ONLY (or TX_READ_ONLY)
- WAIT_TIMEOUT

Note

RDS Proxy tracks changes to the TRANSACTION_ISOLATION and TRANSACTION_READ_ONLY variables when you set them at the session scope. However, if you set them at the next transaction scope, RDS Proxy pins connections. This behavior applies whether you use a SET statement or a SET TRANSACTION statement to configure these values.

Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

  However, for PostgreSQL setting a variable leads to session pinning.
- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see Monitoring RDS Proxy metrics with Amazon CloudWatch.
- If you use SET statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

  For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding SET statements from your application code, so that they don't interfere with transaction-level multiplexing.

  For metrics about how often pinning occurs for a proxy, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.

Conditions that cause pinning for RDS for Microsoft SQL Server

For RDS for SQL Server, the following interactions also cause pinning:

- Using multiple active result sets (MARS). For information about MARS, see the SQL Server documentation.
- Using distributed transaction coordinator (DTC) communication.
- Creating temporary tables, transactions, cursors, or prepared statements.
- Using the following SET statements:
  - SET ANSI_DEFAULTS
  - SET ANSI_NULL_DFLT
  - SET ARITHIGNORE
  - SET DEADLOCK_PRIORITY
  - SET FIPS_FLAGGER
  - SET FMTONLY
  - SET FORCEPLAN
  - SET IDENTITY_INSERT
  - SET NOCOUNT
  - SET NOEXEC
  - SET OFFSETS
  - SET PARSEONLY
  - SET QUERY_GOVERNOR_COST_LIMIT
  - SET REMOTE_PROC_TRANSACTIONS
  - SET ROWCOUNT
  - SET SHOWPLAN_ALL, SHOWPLAN_TEXT, and SHOWPLAN_XML
  - SET STATISTICS
  - SET XACT_ABORT

Conditions that cause pinning for RDS for MariaDB and RDS for MySQL

For MariaDB and MySQL, the following interactions also cause pinning:

- Explicit table lock statements LOCK TABLE, LOCK TABLES, or FLUSH TABLES WITH READ LOCK cause the proxy to pin the session.
- Creating named locks by using GET_LOCK causes the proxy to pin the session.

- Setting a user or system variable (with some exceptions) pins the session to the proxy. If this significantly limits connection reuse, you can configure SET operations to avoid pinning. To do this, adjust the session pinning filters property. For more information, see Creating a proxy for Amazon RDS and Modifying an RDS Proxy.
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the ROW_COUNT and FOUND_ROWS functions sometimes causes pinning.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- RDS Proxy does not pin connections when you use SET LOCAL.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.
- Queries with executable comments for MySQL (syntax /*! ... */) or MariaDB (syntax /*M! ... */) cause pinning. RDS Proxy cannot parse SQL embedded in these comments to track session state changes.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

Conditions that cause pinning for RDS for PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using SET commands.
- Using PREPARE, DISCARD, DEALLOCATE, or EXECUTE commands to manage prepared statements.
- Creating temporary sequences, tables, or views.
- Declaring cursors.
- Discarding the session state.
- Listening on a notification channel.

- Loading a library module such as `auto_explain`.
- Manipulating sequences using functions such as `nextval` and `setval`.
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`.

> **Note**
>
> RDS Proxy does not pin on transaction level advisory locks, specifically `pg_advisory_xact_lock`, `pg_advisory_xact_lock_shared`, `pg_try_advisory_xact_lock`, and `pg_try_advisory_xact_lock_shared`.

- Setting a parameter, or resetting a parameter to its default. Specifically, using `SET` and `set_config` commands to assign default values to session variables.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.
- Discarding session state. If you use connection pooling libraries with `DISCARD ALL` query configured as a reset query, RDS Proxy pins your client connection on release. This reduces the proxy's multiplexing efficiency and might lead to unexpected results because the `DISCARD ALL` command can interfere with session state management.

Deleting an RDS Proxy

You can delete a proxy when you no longer need it. Or, you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.

4. Choose **Delete Proxy**.

AWS CLI

To delete a DB proxy, use the AWS CLI command delete-db-proxy. To remove related associations, also use the deregister-db-proxy-targets command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
    --db-proxy-name proxy_name
    [--target-group-name target_group_name]
    [--target-ids comma_separated_list]       # or
    [--db-instance-identifiers instance_id]       # or
    [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function DeleteDBProxy. To delete related items and associations, you also call the functions DeleteDBProxyTargetGroup and DeregisterDBProxyTargets.

Working with Amazon RDS Proxy endpoints

RDS Proxy endpoints provide flexible and efficient ways to manage database connections, which improves scalability, availability, and security. With proxy endpoints, you can:

- **Simplify monitoring and troubleshooting** – Use multiple endpoints to track and manage connections from different applications independently.

Topics

- Overview of proxy endpoints
- Limitations for proxy endpoints
- Proxy endpoints for Multi-AZ DB clusters
- Accessing RDS databases across VPCs
- Creating a proxy endpoint
- Viewing proxy endpoints

- Modifying a proxy endpoint
- Deleting a proxy endpoint

Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with RDS instance endpoints. If you aren't familiar with RDS endpoints, find more information in Connecting to a DB instance running the MySQL database engine and Connecting to a DB instance running the PostgreSQL database engine.

When you create a proxy endpoint, you can associate it with a different virtual private cloud (VPC) than the proxy's VPC. This allows you to connect to the proxy from another VPC, such as one used by a different application within your organization.

For information about limits associated with proxy endpoints, see Limitations for proxy endpoints.

RDS Proxy logs prefix each entry with the name of the associated proxy endpoint. This can be either the name that you specified for a user-defined endpoint, or the special name `default` for the proxy's default read/write endpoint.

Each proxy endpoint has its own set of CloudWatch metrics. Monitor metrics for all proxy endpoints, a specific endpoint, or all read/write or read-only endpoints of a proxy. For more information, see Monitoring RDS Proxy metrics with Amazon CloudWatch.

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Limitations for proxy endpoints

RDS Proxy endpoints have the following limitations:

- The RDS proxy default endpoint cannot be modified.
- The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.
- When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint.
- For IPv6 or dual-stack endpoint network types, your VPC and subnets must be configured to support the selected network type.

When you create a proxy, RDS automatically creates a VPC endpoint for secure communication between applications and the database. The VPC endpoint is visible and can be accessed from the Amazon VPC Console.

Adding a new proxy endpoint provisions an AWS PrivateLink interface endpoint. If you add one or more endpoints to your proxy, you incure additional charges. For more information, see RDS Proxy Pricing.

Proxy endpoints for Multi-AZ DB clusters

By default, the endpoint that you connect to when you use RDS Proxy with a Multi-AZ DB cluster has read/write capability. As a result, this endpoint sends all requests to the writer instance of the cluster. All of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with a Multi-AZ DB cluster, then you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries. You do this the same way that you use the reader endpoint for a Multi-AZ DB cluster. Doing so helps you to take advantage of the read scalability of a Multi-AZ DB cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Multi-AZ DB cluster as needed. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

Reader endpoints for Multi-AZ DB clusters

With RDS Proxy, you can create and use reader endpoints. However, these endpoints only work for proxies associated with Multi-AZ DB clusters. If you use the RDS CLI or API, you might see the `TargetRole` attribute with a value of `READ_ONLY`. You can take advantage of such proxies by changing the target of a proxy from an RDS DB instance to a Multi-AZ DB cluster.

You can create and connect to read-only endpoints called *reader endpoints* when you use RDS Proxy with Multi-AZ DB clusters.

How reader endpoints help application availability

In some cases, a reader instance in your cluster might become unavailable. If that occurs, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Multi-AZ DB cluster reader endpoint. RDS Proxy routes connections to only the available

reader instance in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader instance without any interruption to your application. If a reader instance is in an unavailable state, all client connections to that instance endpoint are closed.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same proxy endpoint. RDS Proxy routes the connection to a different reader DB instance that's in `available` state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instance.

If your Multi-AZ DB cluster doesn't have any available reader instances, RDS Proxy attempts to connect to a reader endpoint when it becomes available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.

How reader endpoints help query scalability

Reader endpoints for a proxy help with Multi-AZ DB cluster query scalability in the following ways:

- Where practical, RDS Proxy uses the same reader DB instance for all the queries issue using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.
- If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see Overview of RDS Proxy concepts.

Accessing RDS databases across VPCs

By default, the components of your RDS technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Amazon RDS DB instance in one VPC from resources in another VPC, such as EC2 instances. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. The proxy itself resides in the same VPC as the Amazon RDS DB instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for RDS work. Each VPC should have its own associated network resources such as an internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult Getting started with Amazon RDS for the steps to set up another VPC to use RDS successfully. You can also examine your existing VPC in the Amazon EC2 console to see the kinds of resources to connect together.
2. Create a DB proxy associated with the Amazon RDS DB instance that you want to connect to. Follow the procedure in Creating a proxy for Amazon RDS.
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in Creating a proxy endpoint.
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Amazon RDS DB instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Amazon RDS DB instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.
7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in. Similarly, when using IAM authentication, your IAM configuration and permissions work consistently across all proxy endpoints, even when endpoints are in different VPCs. No additional IAM configuration is required per endpoint.
8. Wait for the new endpoint to reach the **Available** state.

9. Make a note of the full endpoint name. This is the value ending in *`Region_name`*`.rds.amazonaws.com` that you supply as part of the connection string for your database application.
10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then, log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

To create a proxy endpoint, follow these instructions:

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

   The details page for that proxy appears.
4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

   The **Create proxy endpoint** window appears.
5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

   Connections that use read/write endpoints can perform any kind of operations, such as data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the RDS DB cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

   Connections that use a read-only endpoint can only perform queries. RDS Proxy can use one of the reader instances for each connection to the endpoint. That way, a query-intensive

application can take advantage of a Multi-AZ DB cluster's clustering capability. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources that normally use to access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see Accessing RDS databases across VPCs.
8. For **Endpoint network type**, choose the IP version for the proxy endpoint. The available options are:

   - **IPv4** – The proxy endpoint uses IPv4 addresses only (default).
   - **IPv6** – The proxy endpoint uses IPv6 addresses only.
   - **Dual-stack** – The proxy endpoint supports both IPv4 and IPv6 addresses.

   To use IPv6 or dual-stack, your VPC and subnets must be configured to support the selected network type.
9. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint to only a portion of the VPC's address range being able to connect to it, remove one or more subnets.
10. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, then keep the default choice.

    If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console later.
11. Choose **Create proxy endpoint**.

AWS CLI

To create a proxy endpoint, use the AWS CLI create-db-proxy-endpoint command.

Include the following required parameters:

- `--db-proxy-name` *value*
- `--db-proxy-endpoint-name` *value*

- `--vpc-subnet-ids` *`list_of_ids`*. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to `READ_WRITE`. When the proxy is associated with a Multi-AZ DB cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. For more information about the intended use of read-only endpoints with Multi-AZ DB clusters, see Reader endpoints for Multi-AZ DB clusters.
- `--vpc-security-group-ids` *`value`*. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.
- `--endpoint-network-type { IPV4 | IPV6 | DUAL }`. This parameter specifies the IP version for the proxy endpoint. The default is `IPV4`. To use `IPV6` or `DUAL`, your VPC and subnets must be configured to support the selected network type.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
  --db-proxy-name my-proxy \
  --db-proxy-endpoint-name my-endpoint \
  --vpc-subnet-ids subnet_id subnet_id subnet_id ... \
  --target-role READ_ONLY \
  --vpc-security-group-ids security_group_id \
  --endpoint-network-type DUAL
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
  --db-proxy-name my-proxy ^
  --db-proxy-endpoint-name my-endpoint ^
  --vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
  --target-role READ_ONLY ^
  --vpc-security-group-ids security_group_id ^
  --endpoint-network-type DUAL
```

RDS API

To create a proxy endpoint, use the RDS API CreateDBProxyEndpoint action.

Viewing proxy endpoints

To view existing proxy endpoints, follow these instructions:

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
   - Whether the endpoint is read/write or read-only.
   - The endpoint address that you use in a database connection string.
   - The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more proxy endpoints, use the AWS CLI describe-db-proxy-endpoints command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
  --db-proxy-endpoint-name my-endpoint
```

RDS API

To describe one or more proxy endpoints, use the RDS API DescribeDBProxyEndpoints operation.

Modifying a proxy endpoint

To modify your proxy endpoints, follow these instructions:

Console

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or, on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

AWS CLI

To modify a proxy endpoint, use the AWS CLI modify-db-proxy-endpoint command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint \
  --new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint ^
  --new-db-proxy-endpoint-name new-endpoint-name
```

RDS API

To modify a proxy endpoint, use the RDS API ModifyDBProxyEndpoint operation.

Deleting a proxy endpoint

To delete an endpoint for your proxy, follow these instructions:

> **Note**
>
> You can't delete the default proxy endpoint that RDS Proxy automatically creates for each proxy.

When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

Console

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or, on the proxy endpoint details page, for **Actions**, choose **Delete**.

AWS CLI

To delete a proxy endpoint, run the delete-db-proxy-endpoint command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
  --db-proxy-endpoint-name my-endpoint
```

RDS API

To delete a proxy endpoint with the RDS API, run the DeleteDBProxyEndpoint operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see Using Amazon CloudWatch metrics in the Amazon CloudWatch User Guide.

> **Note**
>
> RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.
> Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for the default endpoint of a proxy that performs read/write requests.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints.

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName`, `EndpointName`
- Dimension set 3: `ProxyName`, `TargetGroup`, `Target`
- Dimension set 4: `ProxyName`, `TargetGroup`, `TargetRole`

Metric	Description	Valid period	CloudWatch dimension set
AvailabilityPercentage	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 4
ClientConnections	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 2
ClientConnectionsClosed	The number of client connections closed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsInSetup	The current number of client connections open but have not completed setup. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsNoTLS	The current number of client connections without Transport Layer Security (TLS). This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 2
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsSetupFailedAuth	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
ClientConnectionsSetupSucceeded	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 2
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionRequestsWithTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsBorrowLatency	The time in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
DatabaseConnectionsCurrentlyBorrowed	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsCurrentlyInTransaction	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsCurrentlySessionPinned	The current number of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsSetupFailed	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4
DatabaseConnectionsSetupSucceeded	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 3, Dimension set 4

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsWithTLS	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
MaxDatabaseConnectionsAllowed	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1, Dimension set 3, Dimension set 4
QueryDatabaseResponseLatency	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1, Dimension set 2, Dimension set 3, Dimension set 4
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2

Metric	Description	Valid period	CloudWatch dimension set
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1, Dimension set 2
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1, Dimension set 2

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

Important

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change.
In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

Working with RDS Proxy events

An *event* indicates a change in an environment such as an AWS environment or a service or application from a software as a service (SaaS) partner. Or, it can be one of your own custom applications or services. For example, Amazon RDS generates an event when you create or modify an RDS Proxy. Amazon RDS delivers events to Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see Viewing Amazon RDS events.
- To learn how to configure Amazon RDS to send events to EventBridge, see Creating a rule that triggers on an Amazon RDS event.

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0204	RDS modified DB proxy *name*.	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0207	RDS modified the end point of the DB proxy *name*.	None
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy *name*.	None
configuration change	RDS-EVENT-0214	RDS detected deletion of DB instance *name* and automatically removed it from target group *name* of DB proxy *name*.	None
configuration change	RDS-EVENT-0215	RDS detected deletion of DB cluster *name* and automatically removed it from target group *name* of DB proxy *name*.	None
creation	RDS-EVENT-0203	RDS created DB proxy *name*.	None
creation	RDS-EVENT-0206	RDS created endpoint *name* for DB proxy *name*.	None
deletion	RDS-EVENT-0205	RDS deleted DB proxy *name*.	None
deletion	RDS-EVENT-0208	RDS deleted endpoint *name* for DB proxy *name*.	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0243	RDS failed to provision capacity for proxy *name* because there aren't enough IP addresses available in your subnets: *name*. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses as recommend ed in the RDS Proxy documentation.	To determine the recommended number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.	None

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or, it can be the special name `default` for the default endpoint of a proxy that performs read/write requests. For more information about proxy endpoints, see Working with Amazon RDS Proxy endpoints.

Topics

- Verifying connectivity for a proxy
- Common issues and solutions
- Troubleshooting RDS Proxy issues with RDS for MySQL
- Troubleshooting RDS Proxy issues with RDS for PostgreSQL

Verifying connectivity for a proxy

You can use the following commands to verify that all components such as the proxy, database, and compute instances in the connection can communicate with the each other.

Examine the proxy itself using the describe-db-proxies command. Also examine the associated target group using the describe-db-proxy-target-groups command. Check that the details of the targets match the RDS DB instance that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the describe-db-proxy-targets command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the describe-db-proxy-targets command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (`nc`) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306

nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes the `username` and `password` fields. The following example shows the format of the `SecretString` field.

```
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": '{"username":"some_username","password":"some_password"}',
  "VersionStages": [ "some_stage" ],
  "CreatedDate": some_timestamp
}
```

When troubleshooting IAM authentication issues, verify the following:

- The database has IAM authentication enabled.
- The proxy is configured with the correct authentication scheme.
- The IAM policies in the IAM role provided to the proxy grant the necessary `rds-db:connect` permission to the appropriate database and its username.
- For end-to-end IAM authentication, database users exist that match the IAM user or role names.
- SSL/TLS is enabled for the connection.

Common issues and solutions

This section describes some common issues and potential solutions when using RDS Proxy.

After running the `aws rds describe-db-proxy-targets` CLI command, if the `TargetHealth` description states `Proxy does not have any registered credentials`, verify the following:

- There are credentials registered for the user to access the proxy.
- The IAM role to access the Secrets Manager secret used by the proxy is valid.

You might encounter the following RDS events while creating or connecting to a DB proxy.

Category	RDS event ID	Description
failure	RDS-EVENT-0243	RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommend ed number for your instance class, see Planning for IP address capacity.
failure	RDS-EVENT-0275	RDS throttled some connectio ns to DB proxy *name*. The number of simultaneous connection requests from the client to the proxy has exceeded the limit.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
`403: The security token included in the request is invalid`	Select an existing IAM role instead of choosing to create a new one.

Troubleshooting RDS Proxy issues with RDS for MySQL

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
`ERROR 1040 (HY000): Connections rate limit exceeded (limit_value )`	The rate of connection requests from the client to the proxy has exceeded the limit.
`ERROR 1040 (HY000): IAM authentication rate limit exceeded`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
`ERROR 1040 (HY000): Number simultane ous connectio ns exceeded (limit_value )`	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
`ERROR 1045 (28000): Access denied for user 'DB_USER'@'%' (usi password: YES)`	The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
`ERROR 1105 (HY000): Unknown error`	An unknown error occurred.

Error	Causes or workarounds
`ERROR 1231 (42000): Variable ''character_set_client'' can't be set to the value of value`	The value set for the `character_set_client` parameter is not valid. For example, the value `ucs2` is not valid because it can crash the MySQL server.
`ERROR 3159 (HY000): This RDS Proxy requires TLS connections.`	You enabled the setting **Require Transport Layer Security** in the proxy but your connection included the parameter `ssl-mode=DISABLED` in the MySQL client. Do either of the following: • Disable the setting **Require Transport Layer Security** for the proxy. • Connect to the database using the minimum setting of `ssl-mode=REQUIRED` in the MySQL client.
`ERROR 2026 (HY000): SSL connection error: Internal Server Error`	The TLS handshake to the proxy failed. Some possible reasons include the following: • SSL is required but the server doesn't support it. • An internal server error occurred. • A bad handshake occurred.
`ERROR 9501 (HY000): Timed-out waiting to acquire database connection`	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: • The proxy is unable to establish a database connection because the maximum connections have been reached • The proxy is unable to establish a database connection because the database is unavailable.

Troubleshooting RDS Proxy issues with RDS for PostgreSQL

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
`ERROR 28000: IAM authentication is allowed only with SSL connections.`	The user tried to connect to the database using IAM authentication with the setting `sslmode=disable` in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of `sslmode=require` in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.
`ERROR 28000: This RDS proxy has no credentials for the role` *`role_name`* `. Check the credentials for this role and try again.`	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role. For more information, see Configuring IAM authentication for RDS Proxy.
`ERROR 28000: RDS supports only IAM, MD5, or SCRAM authentication.`	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy.	If you're not using IAM authentication, use the MD5 or SCRAM password authentication.
`ERROR 28000: A user name is missing from the connection startup packet. Provide a user name for this connection.`	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
`ERROR 28000: IAM is allowed only with SSL connections.`	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.

Error	Cause	Solution
`ERROR 28000: This RDS Proxy requires TLS connections.`	The user enabled the option **Require Transport Layer Security** but tried to connect with `sslmode=disable` in the PostgreSQL client.	To fix this error, do one of the following: • Disable the proxy's **Require Transport Layer Security** option. • Connect to the database using the minimum setting of `sslmode=allow` in the PostgreSQL client.
`ERROR 28P01: IAM authentication failed for user` *`user_name`* `. Check the IAM token for this user and try again.`	This error might be due to the following reasons: • The client supplied the incorrect IAM user name. • The client supplied an incorrect IAM authorization token for the user. • The client is using an IAM policy that does not have the necessary permissions. • The client supplied an expired IAM authorization token for the user.	To fix this error, do the following: 1. Confirm that the provided IAM user exists. 2. Confirm that the IAM authorization token belongs to the provided IAM user. 3. Confirm that the IAM policy has adequate permissions for RDS. 4. Check the validity of the IAM authorization token used.
`ERROR 28P01: The password that was provided for the role` *`role_name`* `is wrong.`	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.

Error	Cause	Solution
`ERROR 28P01: The IAM authentication failed for the role` *`role_name`* `. Check the IAM token for this role and try again.`	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.
`ERROR 0A000: Feature not supported: RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.`	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL `psql` CLI, use a version greater than or equal to 7.4.
`ERROR 0A000: Feature not supported: RDS Proxy currently doesn't support streaming replication mode.`	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.
`ERROR 0A000: Feature not supported: RDS Proxy currently doesn't support the option` *`option_name`* `.`	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
`ERROR 53300: The IAM authentication failed because of too many competing requests.`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.

Error	Cause	Solution
`ERROR 53300: The maximum number of client connections to the proxy exceeded number_value .`	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
`ERROR 53300: Rate of connection to proxy exceeded number_value .`	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate in which connections from a PostgreSQL client are established.
`ERROR XX000: Unknown error.`	An unknown error occurred.	Reach out to AWS Support to investigate the issue.

Error	Cause	Solution
`ERROR 08000: Timed-out waiting to acquire database connection.`	The proxy timed-out waiting to acquire a database connection within the duration specified by the `ConnectionBorrowTimeout` setting. Some possible reasons include the following: • The proxy can't establish a database connection because the maximum connections have been reached. • The proxy can't establish a database connection because the database is unavailable or if connection establishment to the database takes longer than the configured `ConnectionBorrowTimeout` .	Possible solutions are the following: • Avoid pinning proxy connections. See Avoiding pinning an RDS Proxy. • Review `ConnectionBorrowTimeout` and `MaxConnectionsPercent` settings. See RDS Proxy connection considerations. • Review target availability. See `AvailabilityPercentage` in Monitoring RDS Proxy metrics with Amazon CloudWatch.

Error	Cause	Solution
`ERROR XX000: Request returned an error: database_error .`	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: `Request returned an error: database "your-database-name" does not exist`. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.
`ERROR 53300: The IAM authentication failed because of too many competing requests.`	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.
`ERROR 28000: Enable IAM authentication for the client connection to the proxy and try again.`	RDS Proxy can't connect to the database because IAM authentication isn't enabled for the client connection to the proxy. This occurs when the proxy's `DefaultAuthScheme` parameter is set to `IAM_AUTH` with a registered user, but the client is using password authentication instead of IAM authentication.	Enable IAM authentication for the client connection to the proxy and try again.

Error	Cause	Solution
`ERROR 28000: Configure IAM authentication as the DefaultAuthScheme in your proxy and try again.`	RDS Proxy can't connect to the database because the `DefaultAuthScheme` isn't set to `IAM_AUTH`. The proxy's `DefaultAuthScheme` parameter is set to `NONE`, but the client is attempting to use IAM authentication.	Set `DefaultAuthScheme` to `IAM_AUTH` for your proxy and try again.

Troubleshooting deleted `postgres` database

If you mistakenly delete the `postgres` database from your instance, you need to restore the database to restore connectivity to your instance. Run the following commands within your DB instance:

```
CREATE DATABASE postgres;
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. This helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Amazon RDS DB instance. RDS Proxy support in CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample CloudFormation template for RDS Proxy.

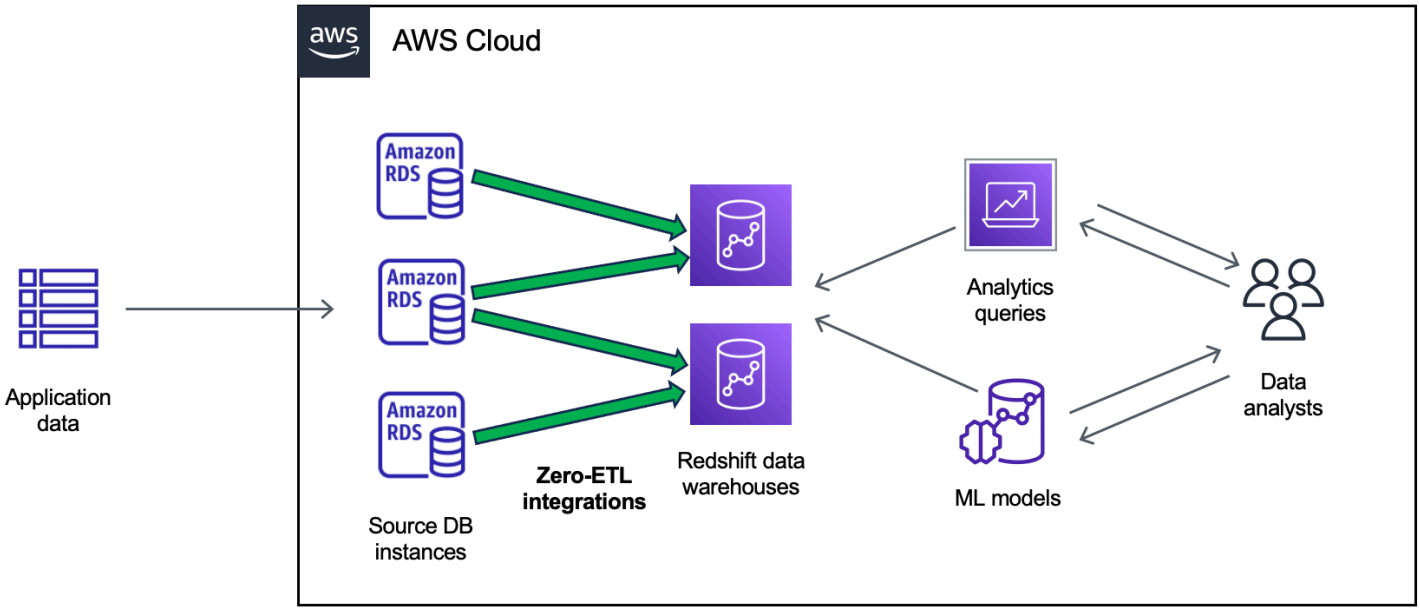
```
Resources:
 DBProxy:
   Type: AWS::RDS::DBProxy
   Properties:
     DBProxyName: CanaryProxy
     EngineFamily: MYSQL
     RoleArn:
      Fn::ImportValue: SecretReaderRoleArn
     Auth:
```

```
      - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
    VpcSubnetIds:
      Fn::Split: [",", "Fn::ImportValue": SubnetIds]

ProxyTargetGroup:
  Type: AWS::RDS::DBProxyTargetGroup
  Properties:
    DBProxyName: CanaryProxy
    TargetGroupName: default
    DBInstanceIdentifiers:
      - Fn::ImportValue: DBInstanceName
  DependsOn: DBProxy
```

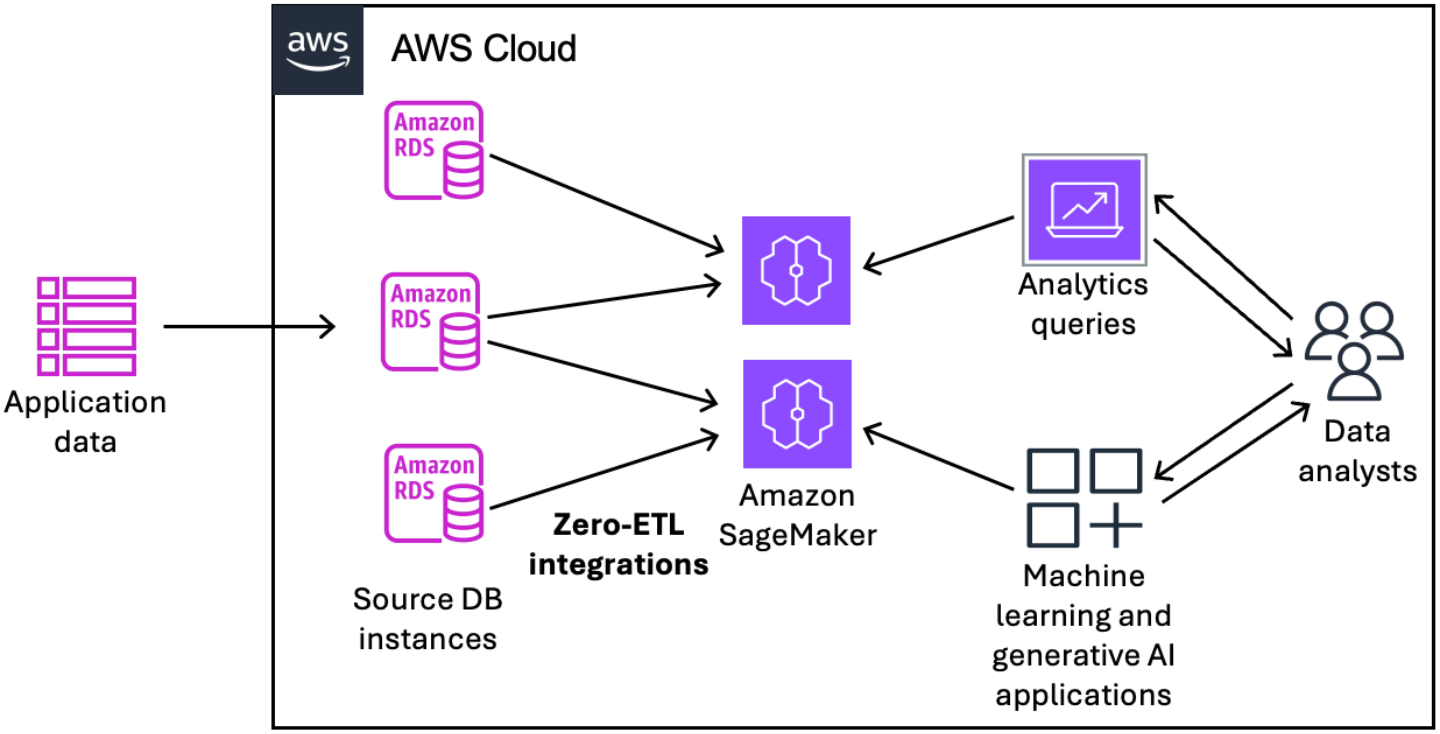
For more information about the resources in this sample, see DBProxy and DBProxyTargetGroup.

For more information about resources that you can create using CloudFormation, see RDS resource type reference.



Amazon RDS zero-ETL integrations

An Amazon RDS zero-ETL integration with Amazon Redshift and Amazon SageMaker AI enables near real-time analytics and machine learning (ML) using data from RDS. It's a fully managed solution for making transactional data available in your analytics destination after it is written to an RDS database. *Extract, transform,* and *load* (ETL) is the process of combining data from multiple sources into a large, central data warehouse.



A zero-ETL integration makes the data in your RDS database available in Amazon Redshift or an Amazon SageMaker AI lakehouse in near real-time. Once that data is in the target data warehouse or data lake, you can power your analytics, ML, and AI workloads using the built-in capabilities, such as machine learning, materialized views, data sharing, federated access to multiple data stores and data lakes, and integrations with Amazon SageMaker AI, Quick, and other AWS services.

To create a zero-ETL integration, you specify an RDS database as the *source*, and a supported data warehouse or lakehouse as the *target*. The integration replicates data from the source database into the target data warehouse or lakehouse.

The following diagram illustrates this functionality for zero-ETL integration with Amazon Redshift:

The following diagram illustrates this functionality for zero-ETL integration with an Amazon SageMaker AI lakehouse:

The integration monitors the health of the data pipeline and recovers from issues when possible. You can create integrations from multiple RDS databases into a single target data warehouse or lakehouse enabling you to derive insights across multiple applications.

- Adding data to a source RDS database and querying it
- Viewing and monitoring Amazon RDS zero-ETL integrations
- Modifying Amazon RDS zero-ETL integrations

- Deleting Amazon RDS zero-ETL integrations
- Troubleshooting Amazon RDS zero-ETL integrations

Benefits

RDS zero-ETL integrations have the following benefits:

- Help you derive holistic insights from multiple data sources.
- Eliminate the need to build and maintain complex data pipelines that perform extract, transform, and load (ETL) operations. Zero-ETL integrations remove the challenges that come with building and managing pipelines by provisioning and managing them for you.
- Reduce operational burden and cost, and let you focus on improving your applications.
- Let you leverage the target destination's analytics and ML capabilities to derive insights from transactional and other data, to respond effectively to critical, time-sensitive events.

Key concepts

As you get started with zero-ETL integrations, consider the following concepts:

Integration

A fully managed data pipeline that automatically replicates transactional data and schemas from an RDS database to a data warehouse or catalog.

Source database

The RDS database where data is replicated from. You can specify a Single-AZ or Multi-AZ DB instance, or a Multi-AZ DB cluster (for RDS for MySQL only).

Target

The data warehouse or lakehouse where the data is replicated to. There are two types of data warehouse: a provisioned cluster data warehouse and a serverless data warehouse. A provisioned cluster data warehouse is a collection of computing resources called nodes, which are organized into a group called a *cluster*. A serverless data warehouse is comprised of a workgroup that stores compute resources, and a namespace that houses the database objects and users. Both data warehouses run an analytics engine and contain one or more databases.

A target lakehouse consists of catalogs, databases, tables, and views. For more information about lakehouse architecture, see SageMaker Lakehouse components in the *Amazon SageMaker AI Unified Studio User Guide*.

Multiple source databases can write to the same target.

For more information, see Data warehouse system architecture in the *Amazon Redshift Developer Guide*.

Limitations

The following limitations apply to RDS zero-ETL integrations.

Topics

- General limitations
- RDS for MySQL limitations
- RDS for PostgreSQL limitations
- RDS for Oracle limitations
- Amazon Redshift limitations
- Amazon SageMaker AI lakehouse limitations

General limitations

- The source database must be in the same Region as the target.
- You can't rename a database if it has existing integrations.
- You can't create multiple integrations between the same source and target databases.
- You can't delete a database that has existing integrations. You must delete all associated integrations first.
- If you stop the source database, the last few transactions might not be replicated to the target until you resume the database.
- You can’t delete an integration if the source database is stopped.
- If your database is the source of a blue/green deployment, the blue and green environments can't have existing zero-ETL integrations during switchover. You must delete the integration first and switch over, then recreate it.

- You can't create an integration for a source database that has another integration being actively created.
- When you initially create an integration, or when a table is being resynchronized, data seeding from the source to the target can take 20-25 minutes or more depending on the size of the source database. This delay can lead to increased replica lag.
- Some data types aren't supported. For more information, see the section called “Data type differences”.
- System tables, temporary tables, and views aren't replicated to target warehouses.
- Performing DDL commands (for example `ALTER TABLE`) on a source table can trigger a table resynchronization, making the table unavailable for querying while it's resynchronizing. For more information, see the section called “One or more of my Amazon Redshift tables requires a resync”.

RDS for MySQL limitations

- Your source database must be running a supported version of RDS for MySQL. For a list of supported versions, see the section called “Zero-ETL integrations ”.
- Zero-ETL integrations are not supported on both the primary instance and a read replica instance in the same AWS Region.
- Zero-ETL integrations rely on MySQL binary logging (binlog) to capture ongoing data changes. Don't use binlog-based data filtering, as it can cause data inconsistencies between the source and target databases.
- Zero-ETL integrations are supported only for databases configured to use the InnoDB storage engine.
- Foreign key references with predefined table updates aren't supported. Specifically, `ON DELETE` and `ON UPDATE` rules aren't supported with `CASCADE`, `SET NULL`, and `SET DEFAULT` actions. Attempting to create or update a table with such references to another table will put the table into a failed state.
- You can't create an integration for a source database that uses magnetic storage.

RDS for PostgreSQL limitations

- The source database must be an RDS for PostgreSQL instance running version 15.7+, 16.3+, or 17.1+. Earlier versions are not supported.

- RDS for PostgreSQL zero-ETL integrations don't support Multi-AZ DB clusters as source databases.
- You can't create a zero-ETL integration from an RDS for PostgreSQL read replica instance.
- PostgreSQL unlogged tables and materialized views are not replicated to Amazon Redshift.
- Replication of certain PostgreSQL data types, such as geometry data types and data greater than 64KB, is not supported due to limitations in Amazon Redshift. For more information about data type differences between RDS for PostgreSQL and Amazon Redshift, see the section called "RDS for PostgreSQL" in the **Data type differences** section.
- You can't perform a major version upgrade on the source RDS for PostgreSQL instance while it has an active zero-ETL integration. To upgrade the source instance, you must first delete all existing zero-ETL integrations. After the major version upgrade is complete, you can recreate the zero-ETL integrations.
- If you perform declarative partitioning transactions on the source DB instance, all affected tables enter a failed state and are no longer accessible.

RDS for Oracle limitations

- The source database must be an RDS for Oracle instance running version 19c Enterprise Edition or Standard Edition 2, July 2019 Release Update or later. Earlier versions are not supported.
- You can't create a zero-ETL integration from an RDS for Oracle read replica instance.
- You can't rename a tenant database when there is a zero-ETL integration on that tenant database.
- A tenant database can have only one zero-ETL integration.
- RDS for Oracle and Amazon Redshift have some data type differences. For more information, see the section called "RDS for Oracle" in the **Data type differences** section.

Amazon Redshift limitations

For a list of Amazon Redshift limitations related to zero-ETL integrations, see Considerations when using zero-ETL integrations with Amazon Redshift in the *Amazon Redshift Management Guide*.

Amazon SageMaker AI lakehouse limitations

Following is a limitation for Amazon SageMaker AI lakehouse zero-ETL integrations.

- Catalog names are limited to 19 characters in length.

Quotas

Your account has the following quotas related to RDS zero-ETL integrations. Each quota is per-Region unless otherwise specified.

Name	Default	Description
Integrations	100	The total number of integrations within an AWS account.
Integrations per target	50	The number of integrations sending data to a single target data warehouse or lakehouse.
Integrations per source instance	5	The number of integrations sending data from a single source DB instance.

In addition, the target warehouse places certain limits on the number of tables allowed in each DB instance or cluster node. For more information about Amazon Redshift quotas and limits, see Quotas and limits in Amazon Redshift in the *Amazon Redshift Management Guide*.

Supported Regions

RDS zero-ETL integrations are available in a subset of AWS Regions. For a list of supported Regions, see the section called “Zero-ETL integrations ”.

Getting started with Amazon RDS zero-ETL integrations

Before you create a zero-ETL integration, configure your RDS database and your data warehouse with the required parameters and permissions. During setup, you'll complete the following steps:

1. Create a custom DB parameter group.
2. Create a source database.
3. Create a target data warehouse for Amazon Redshift or Create a target Amazon SageMaker Lakehouse.

After you complete these tasks, continue to the section called "Creating zero-ETL integrations with Amazon Redshift" or the section called "Creating zero-ETL integrations with an Amazon SageMaker lakehouse".

> **Tip**
>
> You can have RDS complete these setup steps for you while you're creating the integration, rather than performing them manually. To immediately start creating an integration, see the section called "Creating zero-ETL integrations with Amazon Redshift".

For Step 3, you can choose to create either a target data warehouse (Step 3a) or a target lakehouse (Step 3b) depending on your needs:

- Choose a data warehouse if you need traditional data warehousing capabilities with SQL-based analytics.
- Choose an Amazon SageMaker Lakehouse if you need machine learning capabilities and want to use lakehouse features for data science and ML workflows.

Step 1: Create a custom DB parameter group

Amazon RDS zero-ETL integrations require specific values for the DB parameters that control data replication. The specific parameters depend on your source DB engine. To configure these parameters, you must first create a custom DB parameter group, and then associate it with the source database. Configure the following parameter values depending on your source DB engine. For instructions to create a parameter group, see the section called "DB parameter groups". We recommend that you configure all parameter values within the same request to avoid dependency issues.

RDS for MySQL:

- `binlog_format=ROW`
- `binlog_row_image=full`

In addition, make sure that the `binlog_row_value_options` parameter is *not* set to `PARTIAL_JSON`. If the source database is a Multi-AZ DB cluster, make sure that the `binlog_transaction_compression` parameter is *not* set to `ON`.

Some of these parameters (such as `binlog_format`) are dynamic, meaning you can apply changes to the parameter without triggering a reboot. This means that some existing sessions might continue using the old value of the parameter. To prevent this from causing problems when creating a zero-ETL integration, enable Performance Schema. Performance Schema ensures that zero-ETL pre-checks run, which help detect missing parameters early in the process.

RDS for PostgreSQL:

- `rds.logical_replication = 1`
- `rds.replica_identity_full = 1`
- `session_replication_role = origin`
- `wal_sender_timeout ≥ 20000 or = 0`
- `max_wal_senders ≥ 20`
- `max_replication_slots ≥ 20`

For multiple PostgreSQL integrations, one logical replication slot will be used per integration. Review the `max_replication_slots` and `max_wal_senders` parameters based on your usage.

For efficient data synchronization in zero-ETL integrations, set `rds.replica_identity_full` in your source DB instance. This instructs the database to log complete row data in the write-ahead log (WAL) during `UPDATE` and `DELETE` operations, rather than just primary key information. Zero-ETL requires complete row data even when all replicated tables are required to have primary keys. To determine which data is visible during queries, Amazon Redshift uses a specialized anti-join strategy to compare your data against an internal delete tracking table. Logging full-row images helps Amazon Redshift perform these anti-joins efficiently. Without full row data, Amazon Redshift would need to perform additional lookups, which could slow performance during high-throughput operations in the columnar engine that Amazon Redshift uses.

> **Important**
>
> Setting replica identity to log full rows increases your WAL volume, which can lead to higher write amplification and I/O usage, especially for wide tables or frequent updates. To prepare for these impacts, plan your storage capacity and I/O requirements, monitor your WAL growth, and track replication lag in write-heavy workloads.

RDS for Oracle:

No parameter changes are required for RDS for Oracle.

Step 2: Select or create a source database

After you create a custom DB parameter group, choose or create an RDS DB instance . This database will be the source of data replication to the target data warehouse. For instructions to create a Single-AZ or Multi-AZ DB instance, see the section called “Creating a DB instance”. For instructions to create a Multi-AZ DB cluster (RDS for MySQL only), see the section called “Creating a Multi-AZ DB cluster”.

The database must be running a supported DB engine version. For a list of supported versions, see the section called “Zero-ETL integrations ”.

When you create the database, under **Additional configuration**, change the default **DB parameter group** to the custom parameter group that you created in the previous step.

> **Note**
>
> If you associate the parameter group with the database *after* the database is already created, you must reboot the database to apply the changes before you can create a zero-ETL integration. For instructions, see the section called “Rebooting a DB instance” or the section called “Rebooting a Multi-AZ DB cluster”.

In addition, make sure that automated backups are enabled on the database. For more information, see the section called “Enabling automated backups”.

Step 3a: Create a target data warehouse

After you create your source database, you must create and configure a target data warehouse. The data warehouse must meet the following requirements:

- Using an RA3 node type with at least two nodes, or Redshift Serverless.
- Encrypted (if using a provisioned cluster). For more information, see Amazon Redshift database encryption.

For instructions to create a data warehouse, see Creating a cluster for provisioned clusters, or Creating a workgroup with a namespace for Redshift Serverless.

Enable case sensitivity on the data warehouse

For the integration to be successful, the case sensitivity parameter (`enable_case_sensitive_identifier`) must be enabled for the data warehouse. By default, case sensitivity is disabled on all provisioned clusters and Redshift Serverless workgroups.

To enable case sensitivity, perform the following steps depending on your data warehouse type:

- **Provisioned cluster** – To enable case sensitivity on a provisioned cluster, create a custom parameter group with the `enable_case_sensitive_identifier` parameter enabled. Then, associate the parameter group with the cluster. For instructions, see Managing parameter groups using the console or Configuring parameter values using the AWS CLI.

  > **Note**
  >
  > Remember to reboot the cluster after you associate the custom parameter group with it.

- **Serverless workgroup** – To enable case sensitivity on a Redshift Serverless workgroup, you must use the AWS CLI. The Amazon Redshift console doesn't currently support modifying Redshift Serverless parameter values. Send the following update-workgroup request:

  ```
  aws redshift-serverless update-workgroup \
    --workgroup-name target-workgroup \
    --config-parameters
   parameterKey=enable_case_sensitive_identifier,parameterValue=true
  ```

  You don't need to reboot a workgroup after you modify its parameter values.

Configure authorization for the data warehouse

After you create a data warehouse, you must configure the source RDS database as an authorized integration source. For instructions, see Configure authorization for your Amazon Redshift data warehouse.

Set up an integration using the AWS SDKs

Rather than setting up each resource manually, you can run the following Python script to automatically set up the required resources for you. The code example uses the AWS SDK for Python (Boto3) to create a source RDS for MySQL DB instance and target data warehouse, each

with the required parameter values. It then waits for the databases to be available before creating a zero-ETL integration between them. You can comment out different functions depending on which resources you need to set up.

To install the required dependencies, run the following commands:

```
pip install boto3
pip install time
```

Within the script, optionally modify the names of the source, target, and parameter groups. The final function creates an integration named `my-integration` after the resources are set up.

Python code example

```
import boto3
import time

# Build the client using the default credential configuration.
# You can use the CLI and run 'aws configure' to set access key, secret
# key, and default Region.

rds = boto3.client('rds')
redshift = boto3.client('redshift')
sts = boto3.client('sts')

source_db_name = 'my-source-db' # A name for the source database
source_param_group_name = 'my-source-param-group' # A name for the source parameter
 group
target_cluster_name = 'my-target-cluster' # A name for the target cluster
target_param_group_name = 'my-target-param-group' # A name for the target parameter
 group

def create_source_db(*args):
    """Creates a source RDS for MySQL DB instance"""

    response = rds.create_db_parameter_group(
        DBParameterGroupName=source_param_group_name,
        DBParameterGroupFamily='mysql8.0',
        Description='RDS for MySQL zero-ETL integrations'
    )
    print('Created source parameter group: ' + response['DBParameterGroup']
['DBParameterGroupName'])
```

```
    response = rds.modify_db_parameter_group(
        DBParameterGroupName=source_param_group_name,
        Parameters=[
            {
                'ParameterName': 'binlog_format',
                'ParameterValue': 'ROW',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_image',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            }
        ]
    )
    print('Modified source parameter group: ' + response['DBParameterGroupName'])

    response = rds.create_db_instance(
        DBInstanceIdentifier=source_db_name,
        DBParameterGroupName=source_param_group_name,
        Engine='mysql',
        EngineVersion='8.0.32',
        DBName='mydb',
        DBInstanceClass='db.m5.large',
        AllocatedStorage=15,
        MasterUsername='username',
        MasterUserPassword='Password01**'
    )
    print('Creating source database: ' + response['DBInstance']
['DBInstanceIdentifier'])
    source_arn = (response['DBInstance']['DBInstanceArn'])
    create_target_cluster(target_cluster_name, source_arn, target_param_group_name)
    return(response)

def create_target_cluster(target_cluster_name, source_arn, target_param_group_name):
    """Creates a target Redshift cluster"""

    response = redshift.create_cluster_parameter_group(
        ParameterGroupName=target_param_group_name,
        ParameterGroupFamily='redshift-1.0',
        Description='RDS for MySQL zero-ETL integrations'
    )
    print('Created target parameter group: ' + response['ClusterParameterGroup']
['ParameterGroupName'])
```

```
response = redshift.modify_cluster_parameter_group(
    ParameterGroupName=target_param_group_name,
    Parameters=[
        {
            'ParameterName': 'enable_case_sensitive_identifier',
            'ParameterValue': 'true'
        }
    ]
)
print('Modified target parameter group: ' + response['ParameterGroupName'])

response = redshift.create_cluster(
    ClusterIdentifier=target_cluster_name,
    NodeType='ra3.4xlarge',
    NumberOfNodes=2,
    Encrypted=True,
    MasterUsername='username',
    MasterUserPassword='Password01**',
    ClusterParameterGroupName=target_param_group_name
)
print('Creating target cluster: ' + response['Cluster']['ClusterIdentifier'])

# Retrieve the target cluster ARN
response = redshift.describe_clusters(
    ClusterIdentifier=target_cluster_name
)
target_arn = response['Clusters'][0]['ClusterNamespaceArn']

# Retrieve the current user's account ID
response = sts.get_caller_identity()
account_id = response['Account']

# Create a resource policy granting access to source database and account ID
response = redshift.put_resource_policy(
    ResourceArn=target_arn,
    Policy='''
    {
        \"Version\":\"2012-10-17\",
        \"Statement\":[
            {\"Effect\":\"Allow\",
            \"Principal\":{
                \"Service\":\"redshift.amazonaws.com\"
            },
```

```
                \"Action\":[\"redshift:AuthorizeInboundIntegration\"],
                \"Condition\":{
                    \"StringEquals\":{
                        \"aws:SourceArn\":\"%s\"}
                    }
                },
                {\"Effect\":\"Allow\",
                \"Principal\":{
                    \"AWS\":\"arn:aws:iam::%s:root\"},
                \"Action\":\"redshift:CreateInboundIntegration\"}
            ]
        }
        ''' % (source_arn, account_id)
    )
    return(response)

def wait_for_db_availability(*args):
    """Waits for both databases to be available"""

    print('Waiting for source and target to be available...')

    response = rds.describe_db_instances(
        DBInstanceIdentifier=source_db_name
    )
    source_status = response['DBInstances'][0]['DBInstanceStatus']
    source_arn = response['DBInstances'][0]['DBInstanceArn']

    response = redshift.describe_clusters(
        ClusterIdentifier=target_cluster_name
    )
    target_status = response['Clusters'][0]['ClusterStatus']
    target_arn = response['Clusters'][0]['ClusterNamespaceArn']

    # Every 60 seconds, check whether the databases are available
    if source_status != 'available' or target_status != 'available':
        time.sleep(60)
        response = wait_for_db_availability(
            source_db_name, target_cluster_name)
    else:
        print('Databases available. Ready to create zero-ETL integration.')
        create_integration(source_arn, target_arn)
        return

def create_integration(source_arn, target_arn):
```

```
    """Creates a zero-ETL integration using the source and target databases"""

    response = rds.create_integration(
        SourceArn=source_arn,
        TargetArn=target_arn,
        IntegrationName='my-integration'
    )
    print('Creating integration: ' + response['IntegrationName'])

def main():
    """main function"""
    create_source_db(source_db_name, source_param_group_name)
    wait_for_db_availability(source_db_name, target_cluster_name)

if __name__ == "__main__":
    main()
```

Step 3b: Create an AWS Glue catalog for Amazon SageMaker Lakehouse zero-ETL integration

When creating a zero-ETL integration with an Amazon SageMaker Lakehouse, you must create an AWS Glue managed catalog in AWS Lake Formation. The target catalog must be an Amazon Redshift managed catalog. To create an Amazon Redshift managed catalog, first create the `AWSServiceRoleForRedshift` service-linked role. In the Lake Formation console, add the `AWSServiceRoleForRedshift` as a read-only administrator.

For more information about the previous tasks, see the following topics.

- For information about creating an Amazon Redshift managed catalog, see Creating an Amazon Redshift managed catalog in the AWS Glue Data Catalog in the *AWS Lake Formation Developer Guide*.
- For information about the service-linked role for Amazon Redshift, see Using service-linked roles for Amazon Redshift in the *Amazon Redshift Management Guide*.
- For information about read-only administrator permissions for Lake Formation, see Lake Formation personas and IAM permissions reference in the *AWS Lake Formation Developer Guide*.

Configure permissions for the target AWS Glue catalog

Before creating a target catalog for zero-ETL integration, you must create the Lake Formation target creation role and the AWS Glue data transfer role. Use the Lake Formation target creation role to create the target catalog. When creating the target catalog, enter the Glue data transfer role in the **IAM role** field in the **Access from engines section**.

Lake Formation target creation role

The target creation role must be a Lake Formation administrator and requires the following permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "lakeformation:RegisterResource",
            "Resource": "*"
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": [
                "s3:PutEncryptionConfiguration",
                "iam:PassRole",
                "glue:CreateCatalog",
                "glue:GetCatalog",
                "s3:PutBucketTagging",
                "s3:PutLifecycleConfiguration",
                "s3:PutBucketPolicy",
                "s3:CreateBucket",
                "redshift-serverless:CreateNamespace",
                "s3:DeleteBucket",
                "s3:PutBucketVersioning",
                "redshift-serverless:CreateWorkgroup"
            ],
            "Resource": [
                "arn:aws:glue:*:111122223333:catalog",
```

```
                "arn:aws:glue:*:111122223333:catalog/*",
                "arn:aws:s3:::*",
                "arn:aws:redshift-serverless:*:111122223333:workgroup/*",
                "arn:aws:redshift-serverless:*:111122223333:namespace/*",
                "arn:aws:iam::111122223333:role/GlueDataCatalogDataTransferRole"
            ]
        }
    ]
}
```

The target creation role must have the following trust relationship.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "glue.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        },
        {
          "Effect": "Allow",
          "Principal": {
            "AWS": "arn:aws:iam::111122223333:user/Username"
          },
          "Action": "sts:AssumeRole"
        }
    ]
}
```

Glue data transfer role

The Glue data transfer role is required for MySQL catalog operations and must have the following permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DataTransferRolePolicy",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt",
                "glue:GetCatalog",
                "glue:GetDatabase"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

The Glue data transfer role must have the following trust relationship.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "glue.amazonaws.com",
                    "redshift.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Next steps

With a source RDS database and either an Amazon Redshift target data warehouse or Amazon SageMaker Lakehouse, you can create a zero-ETL integration and replicate data. For instructions, see the section called "Creating zero-ETL integrations with Amazon Redshift".

Creating Amazon RDS zero-ETL integrations with Amazon Redshift

When you create an Amazon RDS zero-ETL integration, you specify the source RDS database and the target Amazon Redshift data warehouse. You can also customize encryption settings and add tags. Amazon RDS creates an integration between the source database and its target. Once the integration is active, any data that you insert into the source database will be replicated into the configured Amazon Redshift target.

Prerequisites

Before you create a zero-ETL integration, you must create a source database and a target Amazon Redshift data warehouse. You also must allow replication into the data warehouse by adding the database as an authorized integration source.

For instructions to complete each of these steps, see the section called "Getting started with zero-ETL integrations".

Required permissions

Certain IAM permissions are required to create a zero-ETL integration. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source RDS database.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target data warehouse.

The following sample policies demonstrate the least privilege permissions required to create and manage integrations. You might not need these exact permissions if your user or role has broader permissions, such as an `AdministratorAccess` managed policy.

Note

Redshift Amazon Resource Names (ARNs) have the following format. Note the use of a forward slash (`/`) rather than a colon (`:`) before the serverless namespace UUID.

- Provisioned cluster – `arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid`
- Serverless – `arn:aws:redshift-serverless:{region}:{account-id}:namespace/namespace-uuid`

Sample policy for Redshift target

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "CreateIntegration",
      "Effect": "Allow",
      "Action": [
        "rds:CreateIntegration"
      ],
      "Resource": [
        "arn:aws:rds:us-east-1:123456789012:db:source-db",
        "arn:aws:rds:us-east-1:123456789012:integration:*"
      ]
    },
    {
      "Sid": "DescribeIntegrationDetails",
      "Effect": "Allow",
      "Action": [
        "rds:DescribeIntegrations"
      ],
      "Resource": [
      "arn:aws:rds:us-east-1:123456789012:integration:*"
  ]
    },
    {
```

```
      "Sid": "ChangeIntegrationDetails",
      "Effect": "Allow",
      "Action": [
        "rds:DeleteIntegration",
        "rds:ModifyIntegration"
      ],
      "Resource": [
        "arn:aws:rds:us-east-1:123456789012:integration:*"
      ]
    },
    {
      "Sid": "AllowRedShiftIntegration",
      "Effect": "Allow",
      "Action": [
        "redshift:CreateInboundIntegration"
      ],
      "Resource": [
        "arn:aws:redshift:us-east-1:123456789012:namespace:namespace-uuid"
      ]
    }
  ]
}
```

Choosing a target data warehouse in a different account

If you plan to specify a target Amazon Redshift data warehouse that's in another AWS account, you must create a role that allows users in the current account to access resources in the target account. For more information, see Providing access to an IAM user in another AWS account that you own.

The role must have the following permissions, which allow the user to view available Amazon Redshift provisioned clusters and Redshift Serverless namespaces in the target account.

Required permissions and trust policy

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
```

```
         "Effect":"Allow",
         "Action":[
            "redshift:DescribeClusters",
            "redshift-serverless:ListNamespaces"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

The role must have the following trust policy, which specifies the target account ID.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

Creating zero-ETL integrations

You can create a zero-ETL integration using the AWS Management Console, the AWS CLI, or the RDS API.

> **Important**
>
> zero-ETL integrations do not support refresh or resync operations. If you encounter issues with an integration after creation, you must delete the integration and create a new one.

By default, RDS for MySQL immediately purges binary log files. Because zero-ETL integrations rely on binary logs to replicate data from the source to the target, the retention period for the source database must be at least one hour. As soon as you create an integration, Amazon RDS checks the binary log file retention period for the selected source database. If the current value is 0 hours, Amazon RDS automatically changes it to 1 hour. Otherwise, the value remains the same.

RDS console

To create a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.

   > **Important**
   >
   > Catalog names are limited to 19 characters in length. Ensure your integration identifier meets this requirement if it will be used as a catalog name.

5. Choose **Next**.
6. For **Source**, select the RDS database where the data will originate from.

   > **Note**
   >
   > RDS notifies you if the DB parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see the section called “Step 1: Create a custom DB parameter group”.

Modifying DB parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the database.

7. Once your source database is successfully configured, choose **Next**.
8. For **Target**, do the following:

   1. (Optional) To use a different AWS account for the Amazon Redshift target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your data warehouses. For instructions to create the IAM role, see the section called "Choosing a target data warehouse in a different account".
   2. For **Amazon Redshift data warehouse**, select the target for replicated data from the source database. You can choose a provisioned Amazon Redshift *cluster* or a Redshift Serverless *namespace* as the target.

   Note

   RDS notifies you if the resource policy or case sensitivity settings for the specified data warehouse aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see Turn on case sensitivity for your data warehouse and Configure authorization for your data warehouse in the *Amazon Redshift Management Guide*.
   Modifying case sensitivity for a *provisioned* Redshift cluster requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter value must be successfully applied to the cluster.
   If your selected source and target are in different AWS accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in Amazon Redshift.

9. Once your target data warehouse is configured correctly, choose **Next**.
10. (Optional) For **Tags**, add one or more tags to the integration. For more information, see the section called "Tagging RDS resources".
11. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an AWS owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see the section called "Encrypting Amazon RDS resources".

Optionally, add an encryption context. For more information, see Encryption context in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> Amazon RDS adds the following encryption context pairs in addition to any that you add:
>
> - `aws:redshift:integration:arn` - `IntegrationArn`
> - `aws:servicename:id` - `Redshift`
>
> This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see Using grant constraints in the *AWS Key Management Service Developer Guide*.

12. Choose **Next**.
13. Review your integration settings and choose **Create zero-ETL integration**.

    If creation fails, see the section called "I can't create a zero-ETL integration" for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon Redshift data warehouse has a status of `Modifying`. During this time, you can't query the data warehouse or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon Redshift data warehouse both change to `Active`.

AWS CLI

To create a zero-ETL integration using the AWS CLI, use the create-integration command with the following options:

> **Note**
>
> Remember that catalog names are limited to 19 characters. Choose your integration name accordingly if it will be used as a catalog name.

- `--integration-name` – Specify a name for the integration.
- `--source-arn` – Specify the ARN of the RDS database that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```
aws rds create-integration \
    --integration-name my-integration \
    --source-arn arn:aws:rds:{region}:{account-id}:my-db \
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

For Windows:

```
aws rds create-integration ^
    --integration-name my-integration ^
    --source-arn arn:aws:rds:{region}:{account-id}:my-db ^
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

RDS API

To create a zero-ETL integration by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

> **Note**
>
> Catalog names are limited to 19 characters. Ensure your IntegrationName parameter meets this requirement if it will be used as a catalog name.

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the RDS database that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an AWS owned key when you create an integration, the key policy must provide the Amazon Redshift service principal access to the `CreateGrant` action. In addition, it must allow the current user to perform to the `DescribeKey` and `CreateGrant` actions.

The following sample policy demonstrates how to provide the required permissions in the key policy. It includes context keys to further reduce the scope of permissions.

Sample key policy

JSON

```
{
    "Version":"2012-10-17",
    "Id": "Key policy",
    "Statement": [
        {
            "Sid": "Enables IAM user permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "Allows the Redshift service principal to add a grant to a KMS
 key",
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}": "{context-value}"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
```

```
                        "Decrypt",
                        "GenerateDataKey",
                        "CreateGrant"
                    ]
                }
            }
        },
        {
            "Sid": "Allows the current user or role to add a grant to a KMS key",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/{role-name}"
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}": "{context-value}",
                    "kms:ViaService": "rds.us-east-1.amazonaws.com"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
                        "Decrypt",
                        "GenerateDataKey",
                        "CreateGrant"
                    ]
                }
            }
        },
        {
            "Sid": "Allows the current uer or role to retrieve information about
 a KMS key",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/{role-name}"
            },
            "Action": "kms:DescribeKey",
            "Resource": "*"
        }
    ]
}
```

For more information, see Creating a key policy in the *AWS Key Management Service Developer Guide*.

Next steps

After you successfully create a zero-ETL integration, you must create a destination database within your target Amazon Redshift cluster or workgroup. Then, you can start adding data to the source RDS database and querying it in Amazon Redshift. For instructions, see Creating destination databases in Amazon Redshift.

Creating Amazon RDS zero-ETL integrations with an Amazon SageMaker lakehouse

When you create an Amazon RDS zero-ETL integration with an Amazon SageMaker lakehouse, you specify the source RDS database and the target AWS Glue managed catalog. You can also customize encryption settings and add tags. Amazon RDS creates an integration between the source database and its target. Once the integration is active, any data that you insert into the source database will be replicated into the configured target.

Prerequisites

Before you create a zero-ETL integration with an Amazon SageMaker lakehouse, you must create a source database and a target AWS Glue managed catalog. You also must allow replication into the catalog by adding the database as an authorized integration source.

For instructions to complete each of these steps, see the section called “Getting started with zero-ETL integrations”.

Required permissions

Certain IAM permissions are required to create a zero-ETL integration with an Amazon SageMaker lakehouse. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source RDS database.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target AWS Glue managed catalog.
- Access Amazon S3 buckets used by the AWS Glue managed catalog.

- Use AWS KMS keys for encryption if custom encryption is configured.
- Register resources with Lake Formation.
- Put resource policy on the AWS Glue managed catalog to authorize inbound integrations.

The following sample policy demonstrates the least privilege permissions required to create and manage integrations with an Amazon SageMaker lakehouse. You might not need these exact permissions if your user or role has broader permissions, such as an `AdministratorAccess` managed policy.

Additionally, you must configure a resource policy on the target AWS Glue managed catalog to authorize inbound integrations. Use the following AWS CLI command to apply the resource policy.

Sample AWS CLI command to authorize inbound integrations on the target catalog

```
aws glue put-resource-policy \
      --policy-in-json  '{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Principal": {
            "Service": "glue.amazonaws.com"
        },
        "Action": [
            "glue:AuthorizeInboundIntegration"
        ],
        "Resource": ["arn:aws:glue:region:account_id:catalog/catalog_name"],
        "Condition": {
            "StringEquals": {
                "aws:SourceArn": "arn:aws:rds:region:account_id:db:source_name"
            }
        }
    },
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "account_id"
        },
        "Action": ["glue:CreateInboundIntegration"],
        "Resource": ["arn:aws:glue:region:account_id:catalog/catalog_name"]
    }
    ]
```

```
}' \
      --region region
```

> **Note**
>
> Glue catalog Amazon Resource Names (ARNs) have the following format:
>
> - Glue catalog – `arn:aws:glue:{region}:{account-id}:catalog/catalog-name`

Choosing a target AWS Glue managed catalog in a different account

If you plan to specify a target AWS Glue managed catalog that's in another AWS account, you must create a role that allows users in the current account to access resources in the target account. For more information, see Providing access to an IAM user in another AWS account that you own.

The role must have the following permissions, which allow the user to view available AWS Glue catalogs in the target account.

Required permissions and trust policy

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "glue:GetCatalog"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

The role must have the following trust policy, which specifies the target account ID.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "AWS": "arn:aws:iam::111122223333:root"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

Creating zero-ETL integrations with an Amazon SageMaker lakehouse

You can create a zero-ETL integration with an Amazon SageMaker lakehouse using the AWS Management Console, the AWS CLI, or the RDS API.

> **Important**
>
> Zero-ETL integrations with an Amazon SageMaker lakehouse do not support refresh or resync operations. If you encounter issues with an integration after creation, you must delete the integration and create a new one.

By default, RDS for MySQL immediately purges binary log files. Because zero-ETL integrations rely on binary logs to replicate data from the source to the target, the retention period for the source database must be at least one hour. As soon as you create an integration, Amazon RDS checks the binary log file retention period for the selected source database. If the current value is 0 hours, Amazon RDS automatically changes it to 1 hour. Otherwise, the value remains the same.

RDS console

To create a zero-ETL integration with an Amazon SageMaker lakehouse

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.
5. Choose **Next**.
6. For **Source**, select the RDS database where the data will originate from.

> **Note**
>
> RDS notifies you if the DB parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see the section called "Step 1: Create a custom DB parameter group".
> Modifying DB parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the database.

7. Once your source database is successfully configured, choose **Next**.
8. For **Target**, do the following:

    1. (Optional) To use a different AWS account for the Amazon SageMaker lakehouse target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your AWS Glue catalogs. For instructions to create the IAM role, see the section called "Choosing a target AWS Glue managed catalog in a different account".
    2. For **AWS Glue catalog**, select the target for replicated data from the source database. You can choose an existing AWS Glue managed catalog as the target.
    3. The target IAM role needs describe permissions on the target catalog and must have the following permissions:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "glue:GetCatalog",
            "Resource": [
                "arn:aws:glue:us-east-1:111122223333:catalog/*",
                "arn:aws:glue:us-east-1:111122223333:catalog"
            ]
        }
    ]
}
```

The target IAM role must have the following trust relationship:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "glue.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

4. You must grant the target IAM role describe permissions for the target AWS Glue managed catalog with the Lake Formation administrator role created in Step 3b: Create an AWS Glue catalog for Amazon SageMaker Lakehouse zero-ETL integration.

> **Note**
>
> RDS notifies you if the resource policy or configuration settings for the specified AWS Glue managed catalog aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually.
> If your selected source and target are in different AWS accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in SageMaker Unified Studio.

9. Once your target AWS Glue managed catalog is configured correctly, choose **Next**.
10. (Optional) For **Tags**, add one or more tags to the integration. For more information, see the section called "Tagging RDS resources".
11. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an AWS owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see the section called "Encrypting Amazon RDS resources".

    Optionally, add an encryption context. For more information, see Encryption context in the *AWS Key Management Service Developer Guide*.

    > **Note**
    >
    > Amazon RDS adds the following encryption context pairs in addition to any that you add:
    >
    > - `aws:glue:integration:arn` - `IntegrationArn`
    > - `aws:servicename:id` - `glue`
    >
    > This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see Using grant constraints in the *AWS Key Management Service Developer Guide*.

12. Choose **Next**.
13. Review your integration settings and choose **Create zero-ETL integration**.

If creation fails, see the section called "Troubleshooting zero-ETL integrations" for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon SageMaker lakehouse has a status of `Modifying`. During this time, you can't query the catalog or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon SageMaker lakehouse both change to `Active`.

AWS CLI

To prepare a target AWS Glue managed catalog for zero-ETL integration using the AWS CLI, you must first use the create-integration-resource-property command with the following options:

- `--resource-arn` – Specify the ARN of the AWS Glue managed catalog that will be the target for the integration.
- `--target-processing-properties` – Specify the ARN of the IAM role to access the target AWS Glue managed catalog

```
aws glue create-integration-resource-property --region us-east-1
 --resource-arn arn:aws:glue:region:account_id:catalog/catalog_name \
 --target-processing-properties '{"RoleArn" : "arn:aws:iam::account_id:role/
TargetIamRole"}'
```

To create a zero-ETL integration with an Amazon SageMaker lakehouse using the AWS CLI, use the create-integration command with the following options:

- `--integration-name` – Specify a name for the integration.
- `--source-arn` – Specify the ARN of the RDS database that will be the source for the integration.
- `--target-arn` – Specify the ARN of the AWS Glue managed catalog that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```
aws rds create-integration \
    --integration-name my-sagemaker-integration \
    --source-arn arn:aws:rds:{region}:{account-id}:cluster:my-db \
    --target-arn arn:aws:glue:{region}:{account-id}:catalog/catalog-name
```

For Windows:

```
aws rds create-integration ^
    --integration-name my-sagemaker-integration ^
    --source-arn arn:aws:rds:{region}:{account-id}:cluster:my-db ^
    --target-arn arn:aws:glue:{region}:{account-id}:catalog/catalog-name
```

RDS API

To create a zero-ETL integration with Amazon SageMaker by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

> **Note**
>
> Catalog names are limited to 19 characters. Ensure your IntegrationName parameter meets this requirement if it will be used as a catalog name.

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the RDS database that will be the source for the integration.
- `TargetArn` – Specify the ARN of the AWS Glue managed catalog that will be the target for the integration.

Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an AWS owned key when you create an integration with Amazon SageMaker, the key policy must provide the SageMaker Unified Studio service principal access to the `CreateGrant` action. In addition, it must allow the current user to perform to the `DescribeKey` and `CreateGrant` actions.

The following sample policy demonstrates how to provide the required permissions in the key policy. It includes context keys to further reduce the scope of permissions.

Sample key policy

JSON

```
{
    "Version":"2012-10-17",
    "Id": "Key policy",
    "Statement": [
        {
            "Sid": "EnablesIAMUserPermissions",
            "Effect": "Allow",
            "Principal": {
            "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "GlueServicePrincipalAddGrant",
            "Effect": "Allow",
            "Principal": {
                "Service": "glue.amazonaws.com"
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}":"{context-value}"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
                        "Decrypt",
                        "GenerateDataKey",
                        "CreateGrant"
                    ]
                }
            }
        },
        {
            "Sid": "AllowsCurrentUserRoleAddGrantKMSKey",
            "Effect": "Allow",
            "Principal": {
            "AWS": "arn:aws:iam::111122223333:role/{role-name}"
```

```
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}":"{context-value}",
                    "kms:ViaService": "rds.us-east-1.amazonaws.com"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
                        "Decrypt",
                        "GenerateDataKey",
                        "CreateGrant"
                    ]
                }
            }
        },
        {
            "Sid": "AllowsCurrentUserRoleRetrieveKMSKeyInformation",
            "Effect": "Allow",
            "Principal": {
            "AWS": "arn:aws:iam::111122223333:role/{role-name}"
            },
            "Action": "kms:DescribeKey",
            "Resource": "*"
        }
    ]
}
```

For more information, see Creating a key policy in the *AWS Key Management Service Developer Guide*.

Next steps

After you successfully create a zero-ETL integration with Amazon SageMaker, you can start adding data to the source RDS database and querying it in your Amazon SageMaker lakehouse. The data will be automatically replicated and made available for analytics and machine learning workloads.

Data filtering for Amazon RDS zero-ETL integrations

Amazon RDS zero-ETL integrations support data filtering, which lets you control which data is replicated from your source Amazon RDS database to your target data warehouse. Instead of replicating the entire database, you can apply one or more filters to selectively include or exclude specific tables. This helps you optimize storage and query performance by ensuring that only relevant data is transferred. Currently, filtering is limited to the database and table levels. Column- and row-level filtering are not supported.

Data filtering can be useful when you want to:

- Join certain tables from two or more different source databases, and you don't need complete data from either database.
- Save costs by performing analytics using only a subset of tables rather than an entire fleet of databases.
- Filter out sensitive information—such as phone numbers, addresses, or credit card details—from certain tables.

You can add data filters to a zero-ETL integration using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API.

If the integration has a provisioned cluster as its target, the cluster must be on patch 180 or higher to use data filtering.

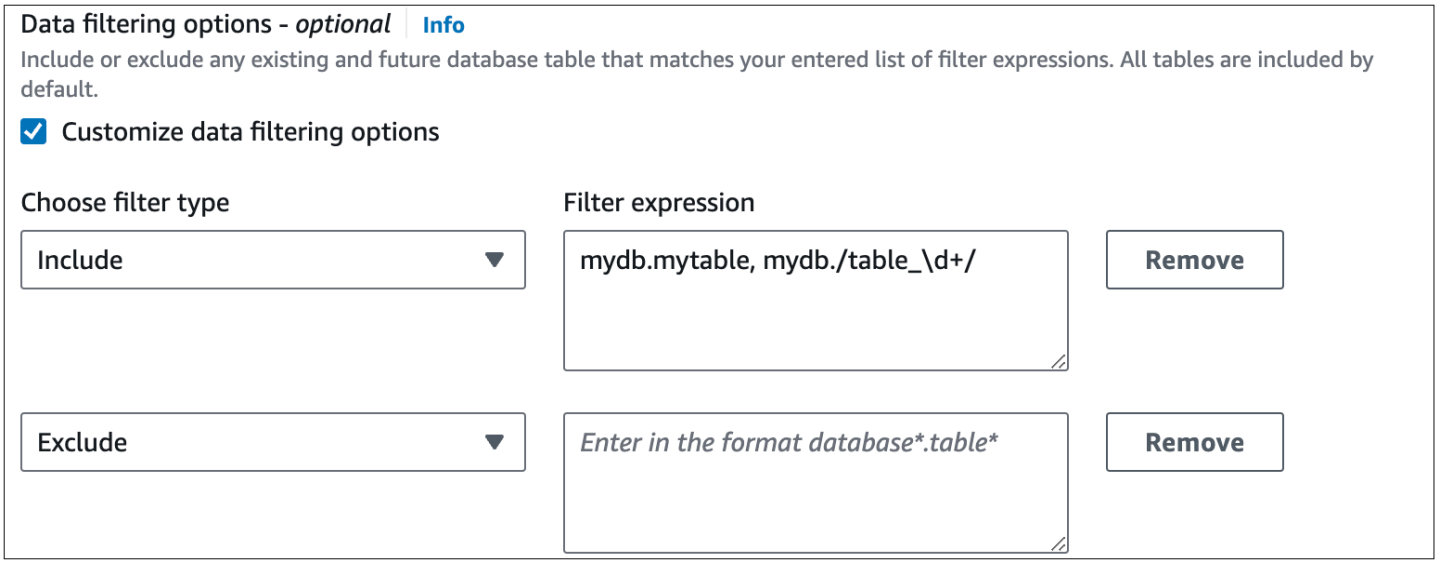
Topics

- Format of a data filter
- Filter logic
- Filter precedence
- RDS for MySQL examples
- RDS for PostgreSQL examples
- RDS for Oracle examples
- Adding data filters to an integration
- Removing data filters from an integration

Format of a data filter

You can define multiple filters for a single integration. Each filter either includes or excludes any existing and future database tables that match one of the patterns in the filter expression. Amazon RDS zero-ETL integrations use Maxwell filter syntax for data filtering.

Each filter has the following elements:



Element	Description
Filter type	An `Include` filter type *includes* all tables that match one of the patterns in the filter expression. An `Exclude` filter type *excludes* all tables that match one of the patterns.
Filter expression	A comma-separated list of patterns. Expressions must use Maxwell filter syntax.
Pattern	A filter pattern in the format *`database`*`.`*`table`* for RDS for MySQL, or *`database`*`.`*`schema`*`.`*`table`* for RDS for PostgreSQL. You can specify literal names, or define regular expressions. **Note** For RDS for MySQL, regular expressions are supported in both the database and table name. For RDS for PostgreSQL, regular expressions are supported only in the schema and table name, not in the database name. You can't include column-level filters or denylists.

Element	Description
	A single integration can have a maximum of 99 total patterns. In the console, you can enter patterns within a single filter expressio n, or spread them out among multiple expressions. A single pattern can't exceed 256 characters in length.

Important

If you select an RDS for PostgreSQL source database, you must specify at least one data filter pattern. At minimum, the pattern must include a single database (*`database-name`*`.*.*`) for replication to the target data warehouse.

The following image shows the structure of RDS for MySQL data filters in the console:

Important

Do not include personally identifying, confidential, or sensitive information in your filter patterns.

Data filters in the AWS CLI

When using the AWS CLI to add a data filter, the syntax differs slightly from the console. You must assign a filter type (`Include` or `Exclude`) to each pattern individually, so you can't group multiple patterns under one filter type.

For example, in the console you can group the following comma-separated patterns under a single `Include` statement:

RDS for MySQL

```
mydb.mytable, mydb./table_\d+/
```

RDS for PostgreSQL

```
mydb.myschema.mytable, mydb.myschema./table_\d+/
```

However, when using the AWS CLI, the same data filter must be in the following format:

RDS for MySQL

```
'include: mydb.mytable, include: mydb./table_\d+/'
```

RDS for PostgreSQL

```
'include: mydb.myschema.mytable, include: mydb.myschema./table_\d+/'
```

Filter logic

If you don't specify any data filters in your integration, Amazon RDS assumes a default filter of `include:*.*`, which replicates all tables to the target data warehouse. However, if you add at least one filter, the default logic switches to `exclude:*.*`, which excludes all tables by default. This lets you explicitly define which databases and tables to include in replication.

For example, if you define the following filter:

```
'include: db.table1, include: db.table2'
```

Amazon RDS evaluates the filter as follows:

```
'exclude:*.*, include: db.table1, include: db.table2'
```

Therefore, Amazon RDS only replicates `table1` and `table2` from the database named db to the target data warehouse.

Filter precedence

Amazon RDS evaluates data filters in the order you specify. In the AWS Management Console, it processes filter expressions from left to right and top to bottom. A second filter or an individual pattern that follows the first can override it.

For example, if the first filter is `Include books.stephenking`, it includes only the `stephenking` table from the `books` database. However, if you add a second filter, `Exclude books.*`, it overrides the first filter. This prevents any tables from the `books` index from being replicated to the target data warehouse.

When you specify at least one filter, the logic starts by assuming `exclude:*.*` by default, which automatically *excludes* all tables from replication. As a best practice, define filters from broadest to most specific. Start with one or more `Include` statements to specify the data to replicate, then add `Exclude` filters to selectively remove certain tables.

The same principle applies to filters that you define using the AWS CLI. Amazon RDS evaluates these filter patterns in the order that you specify them, so a pattern might override one that you specify before it.

RDS for MySQL examples

The following examples demonstrate how data filtering works for RDS for MySQL examples zero-ETL integrations:

- Include all databases and all tables:

  ```
  'include: *.*'
  ```

- Include all tables within the `books` database:

  ```
  'include: books.*'
  ```

- Exclude any tables named `mystery`:

```
'include: *.*, exclude: *.mystery'
```

- Include two specific tables within the `books` database:

```
'include: books.stephen_king, include: books.carolyn_keene'
```

- Include all tables in the `books` database, except for those containing the substring `mystery`:

```
'include: books.*, exclude: books./.*mystery.*/'
```

- Include all tables in the `books` database, except those starting with `mystery`:

```
'include: books.*, exclude: books./mystery.*/'
```

- Include all tables in the `books` database, except those ending with `mystery`:

```
'include: books.*, exclude: books./.*mystery/'
```

- Include all tables in the `books` database that start with `table_`, except for the one named `table_stephen_king`. For example, `table_movies` or `table_books` would be replicated, but not `table_stephen_king`.

```
'include: books./table_.*/, exclude: books.table_stephen_king'
```

RDS for PostgreSQL examples

The following examples demonstrate how data filtering works for RDS for PostgreSQL zero-ETL integrations:

- Include all tables within the `books` database:

```
'include: books.*.*'
```

- Exclude any tables named `mystery` in the `books` database:

```
'include: books.*.*, exclude: books.*.mystery'
```

- Include one table within the `books` database in the `mystery` schema, and one table within `employee` database in the `finance` schema:

```
'include: books.mystery.stephen_king, include: employee.finance.benefits'
```

- Include all tables in the books database and `science_fiction` schema, except for those containing the substring `king`:

```
'include: books.science_fiction.*, exclude: books.*./.*king.*/
```

- Include all tables in the books database, except those with a schema name starting with `sci`:

```
'include: books.*.*, exclude: books./sci.*/.*'
```

- Include all tables in the books database, except those in the `mystery` schema ending with `king`:

```
'include: books.*.*, exclude: books.mystery./.*king/'
```

- Include all tables in the books database that start with `table_`, except for the one named `table_stephen_king`. For example, `table_movies` in the `fiction` schema and `table_books` in the `mystery` schema are replicated, but not `table_stephen_king` in either schema:

```
'include: books.*./table_.*/, exclude: books.*.table_stephen_king'
```

RDS for Oracle examples

The following examples demonstrate how data filtering works for RDS for Oracle zero-ETL integrations:

- Include all tables within the books database:

```
'include: books.*.*'
```

- Exclude any tables named mystery in the books database:

```
'include: books.*.*, exclude: books.*.mystery'
```

- Include one table within the books database in the mystery schema, and one table within employee database in the finance schema:

```
'include: books.mystery.stephen_king, include: employee.finance.benefits'
```

- Include all tables in the mystery schema within the books database:

```
'include: books.mystery.*'
```

Case sensitivity considerations

Oracle Database and Amazon Redshift handle object name casing differently, which affects both data filter configuration and target queries. Note the following:

- Oracle Database stores database, schema, and object names in uppercase unless explicitly quoted in the `CREATE` statement. For example, if you create `mytable` (no quotes), the Oracle data dictionary stores the table name as `MYTABLE`. If you quote the object name, the data dictionary preserves the case.
- Zero-ETL data filters are case sensitive and must match the exact case of object names as they appear in the Oracle data dictionary.
- Amazon Redshift queries default to lowercase object names unless explicitly quoted. For example, a query of `MYTABLE` (no quotes) searches for `mytable`.

Be mindful of the case differences when you create the Amazon Redshift filter and query the data.

Creating an uppercase integration

When you create a table without specifying the name in double quotes, the Oracle database stores the name in uppercase in the data dictionary. For example, you can create `MYTABLE` using any of the following SQL statements.

```
CREATE TABLE REINVENT.MYTABLE (id NUMBER PRIMARY KEY, description VARCHAR2(100));
CREATE TABLE reinvent.mytable (id NUMBER PRIMARY KEY, description VARCHAR2(100));
CREATE TABLE REinvent.MyTable (id NUMBER PRIMARY KEY, description VARCHAR2(100));
CREATE TABLE reINVENT.MYtabLE (id NUMBER PRIMARY KEY, description VARCHAR2(100));
```

Because you didn't quote the table name in the preceding statements, the Oracle database stores the object name in uppercase as `MYTABLE`.

To replicate this table to Amazon Redshift, you must specify the uppercase name in your data filter of your `create-integration` command. The Zero-ETL filter name and Oracle data dictionary name must match.

```
aws rds create-integration \
  --integration-name upperIntegration \
  --data-filter "include: ORCL.REINVENT.MYTABLE" \
...
```

By default, Amazon Redshift stores data in lowercase. To query `MYTABLE` in the replicated database in Amazon Redshift, you must quote the uppercase name `MYTABLE` so that it matches the case in the Oracle data dictionary.

```
SELECT * FROM targetdb1."REINVENT"."MYTABLE";
```

The following queries don't use the quoting mechanism. They all return an error because they search for an Amazon Redshift table named `mytable`, which uses the default lowercase name, but the table is named `MYTABLE` in the Oracle data dictionary.

```
SELECT * FROM targetdb1."REINVENT".MYTABLE;
SELECT * FROM targetdb1."REINVENT".MyTable;
SELECT * FROM targetdb1."REINVENT".mytable;
```

The following queries uses the quoting mechanism to specify a mixed case name. The queries all return an error because they search for an Amazon Redshift table that isn't named `MYTABLE`.

```
SELECT * FROM targetdb1."REINVENT"."MYtablE";
SELECT * FROM targetdb1."REINVENT"."MyTable";
SELECT * FROM targetdb1."REINVENT"."mytable";
```

Creating a lowercase integration

In the following alternative example, you use double quotes to store the table name in lowercase in the Oracle data dictionary. You create `mytable` as follows.

```
CREATE TABLE REINVENT."mytable" (id NUMBER PRIMARY KEY, description VARCHAR2(100));
```

The Oracle database stores the table name as `mytable` in lowercase. To replicate this table to Amazon Redshift, you must specify the lowercase name `mytable` in your Zero-ETL data filter.

```
aws rds create-integration \
  --integration-name lowerIntegration \
  --data-filter "include: ORCL.REINVENT.mytable" \
...
```

When you query this table in the replicated database in Amazon Redshift, you can specify the lowercase name `mytable`. The query succeeds because it searches for a table named `mytable`, which is the table name in the Oracle data dictionary.

```
SELECT * FROM targetdb1."REINVENT".mytable;
```

Because Amazon Redshift defaults to lowercase object names, the following queries also succeed in finding `mytable`.

```
SELECT * FROM targetdb1."REINVENT".MYtablE;
SELECT * FROM targetdb1."REINVENT".MYTABLE;
SELECT * FROM targetdb1."REINVENT".MyTable;
```

The following queries use the quoting mechanism for the object name. They all return an error because they search for an Amazon Redshift table whose name is different from `mytable`.

```
SELECT * FROM targetdb1."REINVENT"."MYTABLE";
SELECT * FROM targetdb1."REINVENT"."MyTable";
SELECT * FROM targetdb1."REINVENT"."MYtablE";
```

Create a table with a mixed-case integration

In the following example, you use double quotes to store the table name in lowercase in the Oracle data dictionary. You create `MyTable` as follows.

```
CREATE TABLE REINVENT."MyTable" (id NUMBER PRIMARY KEY, description VARCHAR2(100));
```

The Oracle database stores this table name as `MyTable` with mixed case. To replicate this table to Amazon Redshift, you must specify the mixed case name in the data filter.

```
aws rds create-integration \
  --integration-name mixedIntegration \
  --data-filter "include: ORCL.REINVENT.MyTable" \
...
```

When you query this table in the replicated database in Amazon Redshift, you must specify the mixed case name `MyTable` by quoting the object name.

```
SELECT * FROM targetdb1."REINVENT"."MyTable";
```

Because Amazon Redshift defaults to lowercase object names, the following queries don't find the object because they are searching for the lowercase name `mytable`.

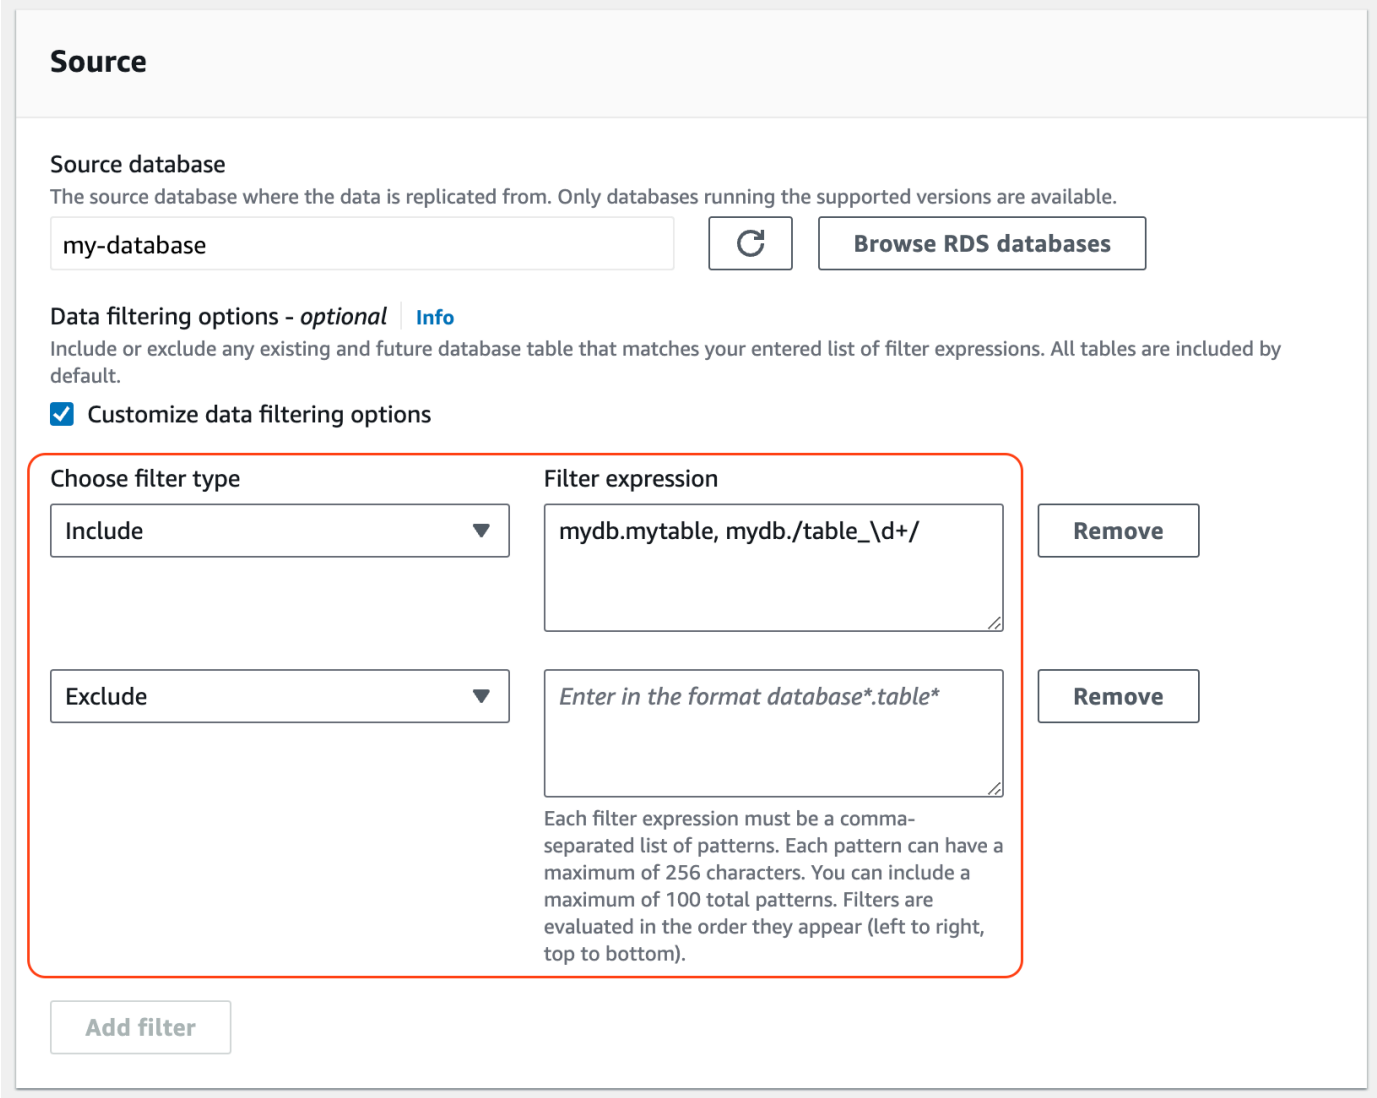
```
SELECT * FROM targetdb1."REINVENT".MYtablE;
SELECT * FROM targetdb1."REINVENT".MYTABLE;
SELECT * FROM targetdb1."REINVENT".mytable;
```

> **Note**
>
> You can't use regular expressions in the filter value for database name, schema, or table name in RDS for Oracle integrations.

Adding data filters to an integration

You can configure data filtering using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

> **Important**
>
> If you add a filter after you create an integration, Amazon RDS treats it as if it always existed. It removes any data in the target data warehouse that doesn't match the new filtering criteria and resynchronizes all affected tables.



RDS console

To add data filters to a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**. Select the integration that you want to add data filters to, and then choose **Modify**.

3. Under **Source**, add one or more `Include` and `Exclude` statements.

   The following image shows an example of data filters for a MySQL integration:

4. When you're satisfied with the changes, choose **Continue** and **Save changes**.

AWS CLI

To add data filters to a zero-ETL integration using the AWS CLI, call the [modify-integration] command. In addition to the integration identifier, specify the `--data-filter` parameter with a comma-separated list of `Include` and `Exclude` Maxwell filters.

Example

The following example adds filter patterns to `my-integration`.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier my-integration \
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier my-integration ^
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier and provide a comma-separated list of filter patterns.

Removing data filters from an integration

When you remove a data filter from an integration, Amazon RDS reevaluates the remaining filters as if the removed filter never existed. It then replicates any previously excluded data that now meets the criteria into the target data warehouse. This triggers a resynchronization of all affected tables.

Adding data to a source RDS database and querying it

To finish creating a zero-ETL integration that replicates data from Amazon RDS into Amazon Redshift, you must create a database in the target destination.

For connections with Amazon Redshift, connect to your Amazon Redshift cluster or workgroup and create a database with a reference to your integration identifier. Then, you can add data to your source RDS database and see it replicated in Amazon Redshift or Amazon SageMaker.

Topics

- Creating a target database
- Adding data to the source database
- Querying your Amazon RDS data in Amazon Redshift

- Data type differences between RDS and Amazon Redshift databases
- DDL operations for RDS for PostgreSQL

Creating a target database

Before you can start replicating data into Amazon Redshift, after you create an integration, you must create a database in your target data warehouse. This database must include a reference to the integration identifier. You can use the Amazon Redshift console or the Query editor v2 to create the database.

For instructions to create a destination database, see Create a destination database in Amazon Redshift.

Adding data to the source database

After you configure your integration, you can populate the source RDS database with data that you want to replicate into your data warehouse.

> **Note**
>
> There are differences between data types in Amazon RDS and the target analytics warehouse. For a table of data type mappings, see the section called "Data type differences".

First, connect to the source database using the MySQL client of your choice. For instructions, see the section called "Connecting to a DB instance running MySQL".

Then, create a table and insert a row of sample data.

> **Important**
>
> Make sure that the table has a primary key. Otherwise, it can't be replicated to the target data warehouse.

RDS for MySQL

The following example uses the MySQL Workbench utility.

```
CREATE DATABASE my_db;

USE my_db;

CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author
 VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977, 'Supernatural
 fiction');
```

RDS for PostgreSQL

The following example uses the psql PostgreSQL interactive terminal. When connecting to the database, include the database name that you want to replicate.

```
psql -h mydatabase.123456789012.us-east-2.rds.amazonaws.com -p 5432 -U username -
d named_db;

named_db=> CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL,
 Author VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

named_db=> INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977,
 'Supernatural fiction');
```

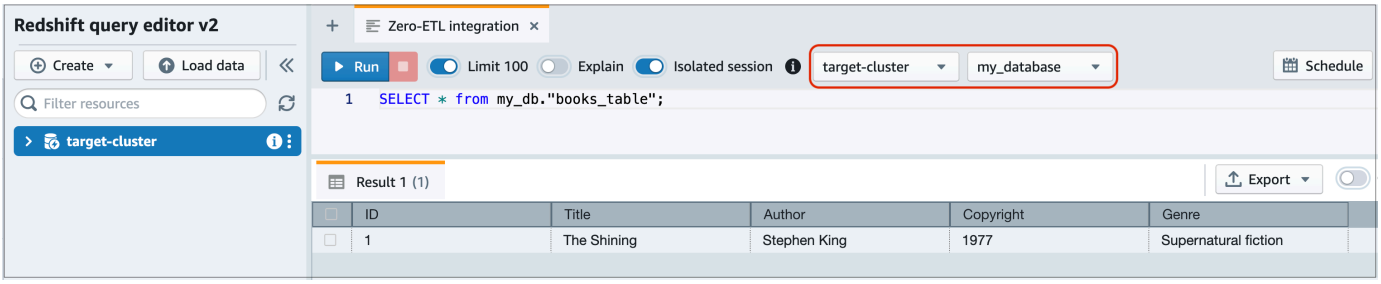
RDS for Oracle

The following example uses SQL*Plus to connect to your RDS for Oracle database.

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))'

SQL> CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author
 VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

SQL> INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977,
 'Supernatural fiction');
```



Querying your Amazon RDS data in Amazon Redshift

After you add data to the RDS database, it's replicated into the destination database and is ready to be queried.

To query the replicated data

1. Navigate to the Amazon Redshift console and choose **Query editor v2** from the left navigation pane.
2. Connect to your cluster or workgroup and choose your destination database (which you created from the integration) from the dropdown menu (**destination_database** in this example). For instructions to create a destination database, see Create a destination database in Amazon Redshift.
3. Use a SELECT statement to query your data. In this example, you can run the following command to select all data from the table that you created in the source RDS database:

```
SELECT * from my_db."books_table";
```

- *my_db* is the RDS database schema name.
- *books_table* is the RDS table name.

You can also query the data using the a command line client. For example:

```
destination_database=# select * from my_db."books_table";

 ID |       Title |        Author |   Copyright |                 Genre |  txn_seq |
 txn_id
----+-------------+---------------+-------------+-----------------------+----------
+--------+
```

```
 1 | The Shining |  Stephen King |        1977 |   Supernatural fiction |        2 |
12192
```

> **Note**
>
> For case-sensitivity, use double quotes (" ") for schema, table, and column names. For more information, see enable_case_sensitive_identifier.

Data type differences between RDS and Amazon Redshift databases

The following tables show the mappings of RDS for MySQL, RDS for PostgreSQL, and RDS for Oracle data types to corresponding destination data types. *Amazon RDS currently supports only these data types for zero-ETL integrations.*

If a table in your source database includes an unsupported data type, the table goes out of sync and isn't consumable by the destination target. Streaming from the source to the target continues, but the table with the unsupported data type isn't available. To fix the table and make it available in the target destination, you must manually revert the breaking change and then refresh the integration by running `ALTER DATABASE...INTEGRATION REFRESH`.

> **Note**
>
> You can't refresh zero-ETL integrations with an Amazon SageMaker lakehouse. Instead, delete and try to create the integration again.

RDS for MySQL

RDS for MySQL data type	Target data type	Description	Limitations
INT	INTEGER	Signed four-byte integer	None
SMALLINT	SMALLINT	Signed two-byte integer	None
TINYINT	SMALLINT	Signed two-byte integer	None
MEDIUMINT	INTEGER	Signed four-byte integer	None
BIGINT	BIGINT	Signed eight-byte integer	None
INT UNSIGNED	BIGINT	Signed eight-byte integer	None
TINYINT UNSIGNED	SMALLINT	Signed two-byte integer	None
MEDIUMINT UNSIGNED	INTEGER	Signed four-byte integer	None
BIGINT UNSIGNED	DECIMAL(20,0)	Exact numeric of selectable precision	None
DECIMAL(p,s) = NUMERIC(p,s)	DECIMAL(p,s)	Exact numeric of selectable precision	Precision greater than 38 and scale greater than 37 not supported

RDS for MySQL data type	Target data type	Description	Limitations
DECIMAL(p,s) UNSIGNED = NUMERIC(p,s) UNSIGNED	DECIMAL(p,s)	Exact numeric of selectable precision	Precision greater than 38 and scale greater than 37 not supported
FLOAT4/REAL	REAL	Single precision floating-point number	None
FLOAT4/REAL UNSIGNED	REAL	Single precision floating-point number	None
DOUBLE/REAL/FLOAT8	DOUBLE PRECISION	Double precision floating-point number	None
DOUBLE/REAL/FLOAT8 UNSIGNED	DOUBLE PRECISION	Double precision floating-point number	None
BIT(n)	VARBYTE(8)	Variable-length binary value	None
BINARY(n)	VARBYTE(n)	Variable-length binary value	None
VARBINARY(n)	VARBYTE(n)	Variable-length binary value	None
CHAR(n)	VARCHAR(n)	Variable-length string value	None
VARCHAR(n)	VARCHAR(n)	Variable-length string value	None

RDS for MySQL data type	Target data type	Description	Limitations
TEXT	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
TINYTEXT	VARCHAR(255)	Variable-length string value up to 255 characters	None
MEDIUMTEXT	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
LONGTEXT	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
ENUM	VARCHAR(1020)	Variable-length string value up to 1,020 characters	None
SET	VARCHAR(1020)	Variable-length string value up to 1,020 characters	None
DATE	DATE	Calendar date (year, month, day)	None

RDS for MySQL data type	Target data type	Description	Limitations
DATETIME	TIMESTAMP	Date and time (without time zone)	None
TIMESTAMP(p)	TIMESTAMP	Date and time (without time zone)	None
TIME	VARCHAR(18)	Variable-length string value up to 18 characters	None
YEAR	VARCHAR(4)	Variable-length string value up to 4 characters	None
JSON	SUPER	Semistructured data or documents as values	None

RDS for PostgreSQL

Zero-ETL integrations for RDS for PostgreSQL don't support custom data types or data types created by extensions.

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
array	SUPER	Semistructured data or documents as values	None

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
bigint	BIGINT	Signed eight-byte integer	None
bigserial	BIGINT	Signed eight-byte integer	None
bit varying(n)	VARBYTE(n)	Variable-length binary value up to 16,777,216 bytes	None
bit(n)	VARBYTE(n)	Variable-length binary value up to 16,777,216 bytes	None
bit, bit varying	VARBYTE(16777216)	Variable-length binary value up to 16,777,216 bytes	None
boolean	BOOLEAN	Logical boolean (true/false)	None
bytea	VARBYTE(16777216)	Variable-length binary value up to 16,777,216 bytes	None
char(n)	CHAR(n)	Fixed-length character string value up to 65,535 bytes	None

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
char varying(n)	VARCHAR(65535)	Variable-length character string value up to 65,535 characters	None
cid	BIGINT	Signed eight-byte integer	None
cidr	VARCHAR(19)	Variable-length string value up to 19 characters	None
date	DATE	Calendar date (year, month, day)	Values greater than 294,276 A.D. not supported
double precision	DOUBLE PRECISION	Double precision floating-point numbers	Subnormal values not fully supported
gtsvector	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
inet	VARCHAR(19)	Variable-length string value up to 19 characters	None
integer	INTEGER	Signed four-byte integer	None

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
int2vector	SUPER	Semistructured data or documents as values.	None
interval	INTERVAL	Duration of time	Only INTERVAL types that specify either a year to month or a day to second qualifier are supported.
json	SUPER	Semistructured data or documents as values	None
jsonb	SUPER	Semistructured data or documents as values	None
jsonpath	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
macaddr	VARCHAR(17)	Variable-length string value up to 17 characters	None
macaddr8	VARCHAR(23)	Variable-length string value up to 23 characters	None

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
money	DECIMAL(20,3)	Currency amount	None
name	VARCHAR(64)	Variable-length string value up to 64 characters	None
numeric(p,s)	DECIMAL(p,s)	User-defined fixed precision value	• NaN values not supported • Precision and scale must be explicitly defined and not greater than 38 (precision) and 37 (scale) • Negative scale not supported
oid	BIGINT	Signed eight-byte integer	None
oidvector	SUPER	Semistructured data or documents as values.	None
pg_brin_bloom_summary	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
pg_dependencies	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_lsn	VARCHAR(17)	Variable-length string value up to 17 characters	None
pg_mcv_list	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_ndistinct	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_node_tree	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_snapshot	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
real	REAL	Single precision floating-point number	Subnormal values not fully supported

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
refcursor	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
smallint	SMALLINT	Signed two-byte integer	None
smallserial	SMALLINT	Signed two-byte integer	None
serial	INTEGER	Signed four-byte integer	None
text	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
tid	VARCHAR(23)	Variable-length string value up to 23 characters	None
time [(p)] without time zone	VARCHAR(19)	Variable-length string value up to 19 characters	`Infinity` and `-Infinity` values not supported
time [(p)] with time zone	VARCHAR(22)	Variable-length string value up to 22 characters	`Infinity` and `-Infinity` values not supported

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
timestamp [(p)] without time zone	TIMESTAMP	Date and time (without time zone)	• `Infinity` and `-Infinity` values not supported • Values greater than `9999-12-31` not supported • B.C. values not supported
timestamp [(p)] with time zone	TIMESTAMPTZ	Date and time (with time zone)	• `Infinity` and `-Infinity` values not supported • Values greater than `9999-12-31` not supported • B.C. values not supported
tsquery	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
tsvector	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

RDS for PostgreSQL data type	Amazon Redshift data type	Description	Limitations
txid_snapshot	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
uuid	VARCHAR(36)	Variable-length 36 character string	None
xid	BIGINT	Signed eight-byte integer	None
xid8	DECIMAL(20, 0)	Fixed precision decimal	None
xml	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

RDS for Oracle

Unsupported data types

The following RDS for Oracle data types are not supported by Amazon Redshift:

- `ANYDATA`
- `BFILE`
- `REF`
- `ROWID`
- `UROWID`
- `VARRAY`
- `SDO_GEOMETRY`
- User-defined data types

Data type differences

The following table shows the data type differences that affect a zero-ETL integration when RDS for Oracle is the source and Amazon Redshift is the target.

RDS for Oracle data type	Amazon Redshift data type
BINARY_FLOAT	FLOAT4
BINARY_DOUBLE	FLOAT8
BINARY	VARCHAR (Length)
FLOAT (P)	If precision is =< 24, then FLOAT4. If precision is > 24, then FLOAT8.
NUMBER (P,S)	If scale is => 0 and =< 37, then NUMERIC (p,s). If scale is => 38 and =< 127, then VARCHAR (Length). If scale is 0: • And precision is less than or equal to 2, then INT2. • And precision is greater than 2 and less than or equal to 4, then INT2. • And precision is greater than 4 and less than or equal to 9, then INT4. • And precision is greater than 9, then NUMERIC (p,s). • And precision is greater than or equal to scale, then NUMERIC (p,s). If scale is less than 0, then INT8.

RDS for Oracle data type	Amazon Redshift data type
DATE	If the scale is => 0 and =< 6, depending on the Redshift target column type, then one of the following: • TIMESTAMP (s) • TIMESTAMPTZ (s) — If source timestamp contains a zone offset (such as in SQL Server or Oracle) it converts to UTC on insert/up date. If it does not contain an offset, then time is considered in UTC already. If the scale is => 7 and =< 9, then VARCHAR (37).
INTERVAL_YEAR TO MONTH	If the length is 1–65,535, then VARCHAR (length in bytes). If the length is 65,536–2,147,483,647, then VARCHAR (65535).
INTERVAL_DAY TO SECOND	If the length is 1–65,535, then VARCHAR (length in bytes). If the length is 65,536–2,147,483,647, then VARCHAR (65535).

RDS for Oracle data type	Amazon Redshift data type
TIMESTAMP	If the scale is => 0 and =< 6, depending on the Redshift target column type, then one of the following: • TIMESTAMP (s) • TIMESTAMPTZ (s) — If source timestamp contains a zone offset (such as in SQL Server or Oracle) it converts to UTC on insert/up date. If it does not contain an offset, then time is considered in UTC already. If the scale is => 7 and =< 9, then VARCHAR (37).
TIMESTAMP WITH TIME ZONE	If the length is 1–65,535, then VARCHAR (length in bytes). If the length is 65,536–2,147,483,647, then VARCHAR (65535).
TIMESTAMP WITH LOCAL TIME ZONE	If the length is 1–65,535, then VARCHAR (length in bytes). If the length is 65,536–2,147,483,647, then VARCHAR (65535).
CHAR	If the length is 1–65,535, then VARCHAR (length in bytes). If the length is 65,536–2,147,483,647, then VARCHAR (65535).

RDS for Oracle data type	Amazon Redshift data type
VARCHAR2	When the length is greater than 4,000 bytes, then VARCHAR (maximum LOB size). The maximum LOB size cannot exceed 63 KB. Amazon Redshift does not support VARCHARs larger than 64 KB. When the length is 4,000 bytes or less, then VARCHAR (length in bytes).
NCHAR	If the length is 1–65,535, then NVARCHAR (length in bytes). If the length is 65,536–2,147,483,647, then NVARCHAR (65535).
NVARCHAR2	When the length is greater than 4,000 bytes, then NVARCHAR (maximum LOB size). The maximum LOB size cannot exceed 63 KB. Amazon Redshift does not support VARCHARs larger than 64 KB. When the length is 4,000 bytes or less, then NVARCHAR (length in bytes).
RAW	VARCHAR (Length)
REAL	FLOAT8
BLOB	VARCHAR (maximum LOB size *2) The maximum LOB size cannot exceed 31 KB. Amazon Redshift does not support VARCHARs larger than 64 KB.

RDS for Oracle data type	Amazon Redshift data type
CLOB	VARCHAR (maximum LOB size) The maximum LOB size cannot exceed 63 KB. Amazon Redshift does not support VARCHARs larger than 64 KB.
NCLOB	NVARCHAR (maximum LOB size) The maximum LOB size cannot exceed 63 KB. Amazon Redshift does not support VARCHARs larger than 64 KB.
LONG	VARCHAR (maximum LOB size) The maximum LOB size cannot exceed 63 KB. Amazon Redshift does not support VARCHARs larger than 64 KB.
LONG RAW	VARCHAR (maximum LOB size *2) The maximum LOB size cannot exceed 31 KB. Amazon Redshift does not support VARCHARs larger than 64 KB.
XMLTYPE	VARCHAR (maximum LOB size) The maximum LOB size cannot exceed 63 KB. Amazon Redshift does not support VARCHARs larger than 64 KB.

DDL operations for RDS for PostgreSQL

Amazon Redshift is derived from PostgreSQL, so it shares several features with RDS for PostgreSQL due to their common PostgreSQL architecture. Zero-ETL integrations leverage these similarities to streamline data replication from RDS for PostgreSQL to Amazon Redshift, mapping databases by name and utilizing the shared database, schema, and table structure.

Consider the following points when managing RDS for PostgreSQL zero-ETL integrations:

- Isolation is managed at the database level.
- Replication occurs at the database level.
- RDS for PostgreSQL databases are mapped to Amazon Redshift databases by name, with data flowing to the corresponding renamed Redshift database if the original is renamed.

Despite their similarities, Amazon Redshift and RDS for PostgreSQL have important differences. The following sections outline Amazon Redshift system responses for common DDL operations.

Topics

- Database operations
- Schema operations
- Table operations

Database operations

The following table shows the system responses for database DDL operations.

DDL operation	Redshift system response
`CREATE DATABASE`	No operation
`DROP DATABASE`	Amazon Redshift drops all the data in the target Redshift database.
`RENAME DATABASE`	Amazon Redshift drops all the data in the original target database and resynchro nize the data in the new target database. If the new database doesn't exist, you must manually create it. For instructions, see Create a destination database in Amazon Redshift.

Schema operations

The following table shows the system responses for schema DDL operations.

DDL operation	Redshift system response
CREATE SCHEMA	No operation
DROP SCHEMA	Amazon Redshift drops the original schema.
RENAME SCHEMA	Amazon Redshift drops the original schema then resynchronizes the data in the new schema.

Table operations

The following table shows the system responses for table DDL operations.

DDL operation	Redshift system response
CREATE TABLE	Amazon Redshift creates the table. Some operations cause table creation to fail, such as creating a table without a primary key or performing declarative partitioning. For more information, see the section called "Limitations" and the section called "Troubles hooting zero-ETL integrations".
DROP TABLE	Amazon Redshift drops the table.
TRUNCATE TABLE	Amazon Redshift truncates the table.
ALTER TABLE (RENAME...)	Amazon Redshift renames the table or column.
ALTER TABLE (SET SCHEMA)	Amazon Redshift drops the table in the original schema and resynchronizes the table in the new schema.
ALTER TABLE (ADD PRIMARY KEY)	Amazon Redshift adds a primary key and resynchronizes the table.

DDL operation	Redshift system response
ALTER TABLE (ADD COLUMN)	Amazon Redshift adds a column to the table.
ALTER TABLE (DROP COLUMN)	Amazon Redshift drops the column if it's not a primary key column. Otherwise, it resynchronizes the table.
ALTER TABLE (SET LOGGED/UNLOGGED)	If you change the table to logged, Amazon Redshift resynchronizes the table. If you change the table to unlogged, Amazon Redshift drops the table.

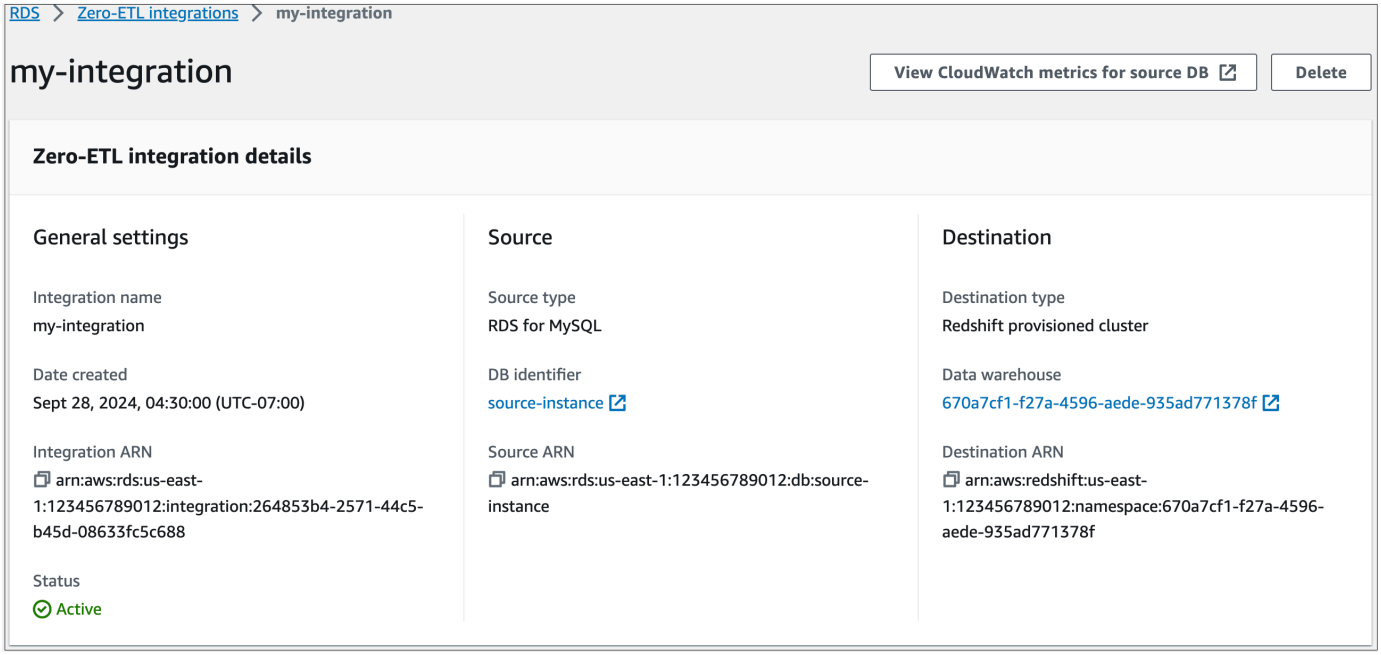
Viewing and monitoring Amazon RDS zero-ETL integrations

You can view the details of an Amazon RDS zero-ETL integration to see its configuration information and current status. You can also monitor the status of your integration by querying specific system views in Amazon Redshift. In addition, Amazon Redshift publishes certain integration-related metrics to Amazon CloudWatch, which you can view within the Amazon Redshift console.

Topics

- Viewing integrations
- Monitoring integrations using system tables for Amazon Redshift
- Monitoring integrations with Amazon EventBridge for Amazon Redshift

Viewing integrations



You can view Amazon RDS zero-ETL integrations using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To view the details of a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select an integration to view more details about it, such as its source database and target data warehouse.

An integration can have the following statuses:

- `Creating` – The integration is being created.
- `Active` – The integration is sending transactional data to the target data warehouse.
- `Syncing` – The integration has encountered a recoverable error and is reseeding data. Affected tables aren't available for querying until they finish resyncing.
- `Needs attention` – The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details page.
- `Failed` – The integration encountered an unrecoverable event or error that can't be fixed. You must delete and recreate the integration.
- `Deleting` – The integration is being deleted.

AWS CLI

To view all zero-ETL integrations in the current account using the AWS CLI, use the describe-integrations command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds describe-integrations \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds describe-integrations ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To view zero-ETL integration using the Amazon RDS API, use the `DescribeIntegrations` operation with the `IntegrationIdentifier` parameter.

Monitoring integrations using system tables for Amazon Redshift

Amazon Redshift has system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any other database table. For more information about system tables and views in Amazon Redshift, see System tables and views reference in the *Amazon Redshift Database Developer Guide*.

You can query the following system views and tables to get information about your zero-ETL integrations:

- SVV_INTEGRATION – Provides configuration details for your integrations.
- SVV_INTEGRATION_TABLE_STATE – Describes the state of each table within an integration.
- SYS_INTEGRATION_TABLE_STATE_CHANGE – Displays table state change logs for an integration.
- SYS_INTEGRATION_ACTIVITY – Provides information about completed integration runs.

All integration-related Amazon CloudWatch metrics originate from Amazon Redshift. For more information, see Metrics for zero-ETL integrations in the *Amazon Redshift Management Guide*. Currently, Amazon RDS doesn't publish any integration metrics to CloudWatch.

Monitoring integrations with Amazon EventBridge for Amazon Redshift

Amazon Redshift send integration-related events to Amazon EventBridge. For a list of events and their corresponding event IDs, see Zero-ETL integration event notifications with Amazon EventBridge in the *Amazon Redshift Management Guide*.

Modifying Amazon RDS zero-ETL integrations

You can modify only the name, description, and data filtering options for a zero-ETL integration in a supported data warehouse. You can't modify the AWS KMS key used to encrypt the integration, or the source or target databases.

If you add a data filter to an existing integration, Amazon RDS reevaluates the filter as if it always existed. It removes any data that is currently in the target data warehouse that doesn't match the new filtering criteria. If you *remove* a data filter from an integration, it replicates any data that previously didn't match the filtering criteria (but now does) into the target data warehouse. For more information, see the section called “Data filtering for zero-ETL integrations”.

You can modify a zero-ETL integration using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

RDS console

To modify a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**, and then choose the integration that you want to modify.
3. Choose **Modify** and make modifications to any available settings.
4. When all the changes are as you want them, choose **Modify**.

AWS CLI

To modify a zero-ETL integration using the AWS CLI, call the modify-integration command. Along with the `--integration-identifier`, specify any of the following options:

- `--integration-name` – Specify a new name for the integration.

- `--description` – Specify a new description for the integration.
- `--data-filter` – Specify data filtering options for the integration. For more information, see the section called "Data filtering for zero-ETL integrations".

Example

The following request modifies an existing integration.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 \
    --integration-name my-renamed-integration
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 ^
    --integration-name my-renamed-integration
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier, and the parameters that you want to modify.

Deleting Amazon RDS zero-ETL integrations

When you delete a zero-ETL integration, Amazon RDS removes it from the source database. Your transactional data isn't deleted from Amazon RDS or the analytics destination, but Amazon RDS doesn't send new data to Amazon Redshift or Amazon SageMaker.

You can only delete an integration when it has a status of `Active`, `Failed`, `Syncing`, or `Needs attention`.

You can delete zero-ETL integrations using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To delete a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select the zero-ETL integration that you want to delete.
4. Choose **Actions**, **Delete**, and confirm deletion.

AWS CLI

To delete a zero-ETL integration, use the delete-integration command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds delete-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds delete-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To delete a zero-ETL integration using the Amazon RDS API, use the `DeleteIntegration` operation with the `IntegrationIdentifier` parameter.

Troubleshooting Amazon RDS zero-ETL integrations

You can check the state of a zero-ETL integration by querying the SVV_INTEGRATION system table in the analytics destination. If the `state` column has a value of `ErrorState`, it means something's wrong. For more information, see the section called “Monitoring using system tables”.

Use the following information to troubleshoot common issues with Amazon RDS zero-ETL integrations.

> **Important**
>
> Resync and refresh operations are not available for zero-ETL integrations with an Amazon SageMaker AI lakehouse. If there are issues with an integration, you must delete the integration and create a new integration. You can't refresh or resync an existing integration.

Topics

- I can't create a zero-ETL integration
- My integration is stuck in a state of Syncing
- My tables aren't replicating to Amazon Redshift
- One or more of my Amazon Redshift tables requires a resync
- Integration failed issues for Amazon SageMaker AI lakehouse zero-ETL integrations

I can't create a zero-ETL integration

If you can't create a zero-ETL integration, make sure that the following are correct for your source database:

- Your source database must be running a supported DB engine version. For a list of supported versions, see the section called “Zero-ETL integrations ”.
- You correctly configured DB parameters. If the required parameters are set incorrectly or not associated with the database, creation fails. See the section called “Step 1: Create a custom DB parameter group”.

In addition, make sure the following are correct for your target data warehouse:

- Case sensitivity is enabled. See Turn on case sensitivity for your data warehouse.
- You added the correct authorized principal and integration source. See Configure authorization for your Amazon Redshift data warehouse.
- The data warehouse is encrypted (if it's a provisioned cluster). See Amazon Redshift database encryption.

My integration is stuck in a state of `Syncing`

Your integration might consistently show a status of `Syncing` if you change the value of one of the required DB parameters.

To fix this issue, check the values of the parameters in the parameter group associated with the source database, and make sure that they match the required values. For more information, see the section called “Step 1: Create a custom DB parameter group”.

If you modify any parameters, make sure to reboot the database to apply the changes.

My tables aren't replicating to Amazon Redshift

If you don't see one or more tables reflected in Amazon Redshift, you can run the following command to resynchronize them:

```
ALTER DATABASE dbname INTEGRATION REFRESH TABLES table1, table2;
```

For more information, see ALTER DATABASE in the Amazon Redshift SQL reference.

Your data might not be replicating because one or more of your source tables doesn't have a primary key. The monitoring dashboard in Amazon Redshift displays the status of these tables as `Failed`, and the status of the overall zero-ETL integration changes to `Needs attention`. To resolve this issue, you can identify an existing key in your table that can become a primary key, or you can add a synthetic primary key. For detailed solutions, see Handle tables without primary keys while creating Amazon Aurora MySQL or Amazon RDS for MySQL zero-ETL integrations with Amazon Redshift.

One or more of my Amazon Redshift tables requires a resync

Running certain commands on your source database might require your tables to be resynchronized. In these cases, the SVV_INTEGRATION_TABLE_STATE system view shows a `table_state` of `ResyncRequired`, which means that the integration must completely reload data for that specific table from MySQL to Amazon Redshift.

When the table starts to resynchronize, it enters a state of `Syncing`. You don't need to take any manual action to resynchronize a table. While table data is resynchronizing, you can't access it in Amazon Redshift.

The following are some example operations that can put a table into a `ResyncRequired` state, and possible alternatives to consider.

Operation	Example	Alternative
Adding a column into a specific position	`ALTER TABLE table_name ADD COLUMN column_name INTEGER NOT NULL first;`	Amazon Redshift doesn't support adding columns into specific positions using `first` or `after` keywords. If the order of columns in the target table isn't critical, add the column to the end of the table using a simpler command: `ALTER TABLE table_name ADD COLUMN column_name column_type ;`
Adding a timestamp	`ALTER TABLE table_name`	The CURRENT_T

Operation	Example	Alternative
column with the default CURRENT_TIMESTAMP	`ADD COLUMN column_name TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP;`	IMESTAMP value for existing table rows is calculated by RDS for MySQL and can't be simulated in Amazon Redshift without full table data resynchronization. If possible, switch the default value to a literal constant like 2023-01-01 00:00:15 to avoid latency in table availability.

Operation	Example	Alternative
Performing multiple column operations within a single command	`ALTER TABLE table_name ADD COLUMN column_1, RENAME COLUMN column_2 TO column_3;`	Consider splitting the command into two separate operations, ADD and RENAME, which won't require resynchronization.

Integration failed issues for Amazon SageMaker AI lakehouse zero-ETL integrations

If you encounter issues with an existing zero-ETL integration with an Amazon SageMaker AI lakehouse, the only resolution is to delete the integration and create a new one. Unlike other AWS services, zero-ETL integrations do not support refresh or resync operations.

To resolve integration issues:

1. Delete the problematic zero-ETL integration using the console, CLI, or API.
2. Verify that the source database and target data warehouse configurations are correct.
3. Create a new zero-ETL integration with the same or updated configuration.

This process will result in a complete re-initialization of the data pipeline, which may take time depending on the size of your source database.

Amazon RDS for Db2

Amazon RDS supports DB instances that run the following editions of IBM Db2:

- Db2 Standard Edition
- Db2 Advanced Edition

Amazon RDS supports DB instances that run the following versions of Db2:

- Db2 11.5

For more information about minor version support, see Db2 on Amazon RDS versions.

Before creating a DB instance, complete the steps in the Setting up your Amazon RDS environment section of this user guide. When you create a DB instance using your master user, the user gets `DBADM` authority, with some limitations. Use this user for administrative tasks such as creating additional database accounts. You can't use `SYSADM`, `SYSCTRL`, `SYSMAINT` instance-level authority, or `SECADM` database-level authority.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated storage backups
- Manual storage backups

You can use DB instances running Db2 inside a virtual private cloud (VPC). You can also add features to your Amazon RDS for Db2 DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for RDS for Db2 as a high availability, failover solution.

Important

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need elevated

privileges. You can access your database using standard SQL clients such as IBM Db2 CLP. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

Overview of Db2 on Amazon RDS

You can read the following sections to get an overview of Db2 on Amazon RDS.

Topics

- Amazon RDS for Db2 features
- Db2 on Amazon RDS versions
- Amazon RDS for Db2 licensing options
- Amazon RDS for Db2 instance classes

- Amazon RDS for Db2 default roles
- Amazon RDS for Db2 parameters
- EBCDIC collation for Db2 databases on Amazon RDS
- Local time zone for Amazon RDS for Db2 DB instances

Amazon RDS for Db2 features

Amazon RDS for Db2 supports most of the features and capabilities of the IBM Db2 database. Some features might have limited support or restricted privileges. For more information about the Db2 database features for specific Db2 versions, see the IBM Db2 documentation.

You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then, you can search by using keywords such as **`Db2 2023`**.

> **Note**
>
> The following lists aren't exhaustive.

Topics

- Supported features in RDS for Db2
- Unsupported features in RDS for Db2

Supported features in RDS for Db2

RDS for Db2 supports features that include features that are native to IBM Db2 and features that are core to Amazon RDS.

Features native to IBM Db2

RDS for Db2 supports the following Db2 database features:

- Creation of a standard database that uses a customer-defined code set, collation, page size, and territory. Use the Amazon RDS rdsadmin.create_database stored procedure.
- Addition, deletion, or modification of local users and groups. Use the Amazon RDS stored procedures for Stored procedures for granting and revoking privileges for RDS for Db2.

- Creation of roles with the Amazon RDS rdsadmin.create_role stored procedure.
- Support for standard row-organized tables.
- Support for analytic workload for column-organized tables.
- Ability to define Db2-compatibility features such as Oracle and MySQL.
- Support for Java-based external stored procedures.
- Support for data encryption in transit by using SSL/TLS.
- Monitoring the status of a database (`ALIVE`, `DOWN`, `STORAGE_FULL`, `UNKNOWN`, and `STANDBY_CONNECTABLE`).
- Restoration of a customer-provided offline or online Linux (LE) database. Use Amazon RDS stored procedures for Stored procedures for databases for RDS for Db2.
- Application of customer-provided Db2 archive logs to keep the database synchronized with self-managed Db2 databases. Use Amazon RDS stored procedures for Stored procedures for databases for RDS for Db2.
- Support for Db2 instance-level and database-level auditing.
- Support for homogeneous federation.
- Ability to load a table from data files in Amazon Simple Storage Service (Amazon S3).
- Authorizations granted to users, groups or roles, such as `CONNECT`, `SYSMON`, `ACCESSCTRL`, `DATAACCESS`, `SQLADM`, `WLMADM`, `EXPLAIN`, `LOAD`, or `IMPLICIT_SCHEMA`.
- Creation of multiple databases.

> **Note**
>
> An RDS for Db2 DB instance can contain up to 50 databases. For more information, see the section called “Multiple Db2 databases”.

Features core to Amazon RDS

RDS for Db2 supports the following core Amazon RDS features:

- Custom parameter groups to assign to DB instances
- Creation, modification, and deletion of DB instances
- Restoration of a self-managed Db2 offline or online Linux (LE) database backup

> **Note**
>
> To be able to restore your backup, don't provide a name for your database when you create a DB instance. For more information, see Creating an Amazon RDS DB instance.

- Support of gp3, io2, and io1 storage types
- Use of AWS Managed Microsoft AD for Kerberos authentication, and LDAP group authorization for RDS for Db2
- Modification of security groups, ports, instance types, storage, backup retention periods, and other settings for existing Db2 instances
- Deletion protection for DB instances
- Cross-Region point-in-time recovery (PITR), including for encrypted backups
- Use of AWS Key Management Service (AWS KMS) for storage encryption and encryption at rest
- Multi-AZ DB instances with one standby for high availability
- Reboots of DB instances
- Updates to master passwords
- Restoration of DB instances to a specific time
- Backup and restoration of DB instances by using storage-level backups
- Start and stop of DB instances
- Maintenance of DB instances
- Same-Region and cross-Region standby and read replicas

Unsupported features in RDS for Db2

RDS for Db2 doesn't support the following Db2 database features:

- `SYSADM`, `SECADM`, and `SYSMAINT` access for the master user.
- External stored procedures written in C, C++, or Cobol.
- Multiple Db2 DB instances on a single host.
- External GSS-API plugins for authentication.
- External third-party plugins to back up or restore Db2 databases.

- Multi-node massively parallel processing (MPP), such as IBM Db2 Warehouse.
- IBM Db2 pureScale.
- Manual setup of High Availability Disaster Recovery (HADR) for RDS for Db2.

> **Note**
>
> Amazon RDS supports and manages HADR for RDS for Db2 through replicas. For more information, see Working with replicas for Amazon RDS for Db2.
> RDS for Db2 supports Multi-AZ deployments, cross-Region automated backups, and replication. For more information, see Multi-AZ DB instance deployments for Amazon RDS and Replicating automated backups to another AWS Region.

- Native database encryption.
- Heterogeneous federation to Informix, Sybase, and Teradata. For more information, see the section called "Federation".
- Creation of non-fenced routines and migration of existing non-fenced routines by backing up and restoring data. For more information, see Non-fenced routines.
- Creation of new non-automatic storage tablespaces. For more information, see Non-automatic storage tablespaces during migration.
- External tables.

Db2 on Amazon RDS versions

For Db2, version numbers take the form of *major.minor.build.revision*, for example, 11.5.9.0.sb00000000.r1. Our version implementation matches that of Db2.

major

The major version number is both the integer and the first fractional part of the version number, for example, 11.5. A version change is considered major if the major version number changes—for example, going from version 11.5 to 12.1.

minor

The minor version number is both the third and fourth parts of the version number, for example, 9.0 in 11.5.9.0. The third part indicates the Db2 modpack, for example, 9 in 9.0. The fourth part indicates the Db2 fixpack, for example, 0 in 9.0. A version change is considered

minor if either the Db2 modpack or the Db2 fixpack changes—for example, going from version 11.5.9.0 to 11.5.9.1, or from 11.5.9.0 to 11.5.10.0, with exceptions to provide catalog table updates. (Amazon RDS takes care of these exceptions.)

build

The build number is the fifth part of the version number, for example, sb00000000 in 11.5.9.0.sb00000000. A build number where the number portion is all zeroes indicates a standard build. A build number where the number portion isn't all zeroes indicates a special build. A build number changes if there is a security fix or special build of an existing Db2 version. A build number change also indicates that Amazon RDS automatically applied a new minor version.

revision

The revision number is the sixth part of the version number, for example, r1 in 11.5.9.0.sb00000000.r1. A revision is an Amazon RDS revision to an existing Db2 release. A revision number change indicates that Amazon RDS automatically applied a new minor version.

Topics

- Upgrade management for Amazon RDS Db2 instances
- Supported Db2 major versions on Amazon RDS

Upgrade management for Amazon RDS Db2 instances

To see the current list of supported Db2 minor versions on RDS, use one of the following commands:

```
aws rds describe-db-engine-versions --engine db2-se
aws rds describe-db-engine-versions --engine db2-ae
```

Amazon RDS also supports upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

You can specify any currently supported Db2 version when creating a new DB instance. You can specify the major version (such as Db2 11.5) and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically

the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the describe-db-engine-versions AWS Command Line Interface (AWS CLI) command.

For example, to list the supported engine versions for Amazon RDS for Db2, run the following AWS CLI command. Replace *region* with your AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --filters Name=engine,Values=db2-ae,db2-se \
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" \
    --region region
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --filters Name=engine,Values=db2-ae,db2-se ^
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" ^
    --region region
```

This command produces output similar to the following example:

```
[
    {
    "Engine": "db2-ae",
    "EngineVersion": "11.5.9.0.sb00000000.r1",
    "DBParameterGroupFamily": "db2-ae-11.5"
    },
    {
    "Engine": "db2-se",
    "EngineVersion": "11.5.9.0.sb00000000.r1",
    "DBParameterGroupFamily": "db2-se-11.5"
    }
]
```

The default Db2 version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default

version for an AWS Region for db2-ae and db2-se database engines by running the `describe-db-engine-versions` command. The following example returns the default version for db2-ae in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --default-only --engine db2-ae \
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" \
    --region us-east-1
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --default-only --engine db2-ae ^
    --query "DBEngineVersions[].{Engine:Engine, EngineVersion:EngineVersion,
 DBParameterGroupFamily:DBParameterGroupFamily}" ^
    --region us-east-1
```

This command produces output similar to the following example:

```
[
    {
    "Engine": "db2-ae",
    "EngineVersion": "11.5.9.0.sb00000000.r1",
    "DBParameterGroupFamily": "db2-ae-11.5"
    }
]
```

With Amazon RDS, you control when to upgrade your Db2 instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific Db2 versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, Amazon RDS automatically upgrades your DB instances to new Db2 minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

Except for Db2 versions 11.5.9.1 and 11.5.10.0, automatic upgrades to new Db2 minor version includes automatic upgrades to new builds and revisions. For 11.5.9.1 and 11.5.10.0, manually upgrade minor versions.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version.

Supported Db2 major versions on Amazon RDS

RDS for Db2 major versions are available under standard support at least until IBM end of support (base) for the corresponding IBM version. The following table shows the dates that you can use to plan your testing and upgrade cycles. If Amazon extends support for an RDS for Db2 version for longer than originally stated, we plan to update this table to reflect the later date.

You can use the following dates to plan your testing and upgrade cycles.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.
> You can view the major versions of your Db2 databases by running the describe-db-major-engine-versions AWS CLI command or by using the DescribeDBMajorEngineVersions RDS API operation.

Db2 major version	IBM release date	RDS release date	IBM end of support (Standard and Advanced Edition)	IBM end of support (extended)	
Db2 11.5	27 June 2019	27 November 2023	30 April 2027	30 April 2031	

Amazon RDS for Db2 licensing options

Amazon RDS for Db2 has two licensing options: bring your own license (BYOL) and Db2 license through AWS Marketplace.

Topics

- Bring your own license (BYOL) for Db2
- Db2 license through AWS Marketplace
- Switching between Db2 licenses

Bring your own license (BYOL) for Db2

In the BYOL model, you use your existing Db2 database licenses to deploy databases on Amazon RDS. Verify that you have the appropriate Db2 database license for the DB instance class and Db2 database edition that you want to run. You must also follow IBM policies for licensing IBM database software in the cloud computing environment.

> **Note**
>
> Multi-AZ DB instances are cold standbys because the Db2 database is installed but not running. Standbys aren't readable, running, or serving requests. For more information, see IBM Db2 licensing information on the IBM website.

In this model, you continue to use your active IBM support account, and you contact IBM directly for Db2 database service requests. If you have an Support account with case support, you can contact Support for Amazon RDS issues. Amazon Web Services and IBM have a multi-vendor support process for cases that require assistance from both organizations.

Amazon RDS supports the BYOL model for Db2 Standard Edition and Db2 Advanced Edition.

Topics

- IBM IDs for bring your own license (BYOL) for Db2
- Adding IBM IDs to a parameter group for RDS for Db2 DB instances
- Integrating with AWS License Manager

IBM IDs for bring your own license (BYOL) for Db2

In the BYOL model, you need your IBM Customer ID and your IBM Site ID to create, modify, or restore RDS for Db2 DB instances. You must create a custom parameter group with your IBM Customer ID and your IBM Site ID *before* you create an RDS for Db2 DB instance. For more information, see Adding IBM IDs to a parameter group for RDS for Db2 DB instances. You can run multiple RDS for Db2 DB instances with different IBM Customer IDs and IBM Site IDs in the same AWS account or AWS Region.

> **Important**
>
> If we can't verify your license by your IBM Customer ID and your IBM Site ID, we might terminate any DB instances running with these unverified licenses.

If you're a new IBM Db2 customer, you must first purchase a Db2 software license from IBM. After you purchase a Db2 software license, you will receive a Proof of Entitlement from IBM, which lists your IBM Customer ID and your IBM Site ID.

If you're an existing IBM Db2 customer, you can find your IBM Customer ID and your IBM Site ID on your Proof of Entitlement certificate from IBM.

You can also find your IBM Customer ID and your IBM Site ID in your IBM Passport Advantage Online account. After your log in, you can view both IDs on either the main page or the Software downloads page.

Adding IBM IDs to a parameter group for RDS for Db2 DB instances

Because you can't modify default parameter groups, you must create a custom parameter group and then modify it to include the values for your IBM Customer ID and your IBM Site ID. For information about parameter groups, see DB parameter groups for Amazon RDS DB instances.

> **Important**
>
> You must create a custom parameter group with your IBM Customer ID and your IBM Site ID *before* you create an RDS for Db2 DB instance.

Use the parameter settings in the following table.

Parameter	Value
rds.ibm_customer_id	<your IBM Customer ID>
rds.ibm_site_id	<your IBM Site ID>
ApplyMethod	immediate ,pending-reboot

These parameters are dynamic, which means that any changes to them take effect immediately and that you don't need to reboot the DB instance. If you don't want the changes to take effect immediately, you can set `ApplyMethod` to `pending-reboot` and schedule these changes to be made during a maintenance window.

You can create and modify a custom parameter group by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

Console

To add your IBM Customer ID and your IBM Site ID to a parameter group

1. Create a new DB parameter group. For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameter group that you created. For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

AWS CLI

To add your IBM Customer ID and your IBM Site ID to a parameter group

1. Create a custom parameter group by running the create-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values: `db2-se-11.5`, `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by running the modify-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

RDS API

To add your IBM Customer ID and your IBM Site ID to a parameter group

1. Create a custom DB parameter group by using the Amazon RDS API CreateDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `DBParameterGroupFamily`
   - `Description`

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by using the RDS API ModifyDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `Parameters`

For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

Now you are ready to create a DB instance and attach the custom parameter group to the DB instance. For more information, see Creating an Amazon RDS DB instance and Associating a DB parameter group with a DB instance in Amazon RDS.

Integrating with AWS License Manager

To aid in monitoring RDS for Db2 license usage in the BYOL model, AWS License Manager integrates with RDS for Db2. License Manager supports tracking of RDS for Db2 engine editions based on virtual CPUs (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

To track license usage of your RDS for Db2 DB instances, you must create self-managed licenses. You can create self-managed licenses by using the AWS Management Console, the AWS License Manager CLI, and the AWS License Manager API. Or, you can automate the creation of self-managed licenses with CloudFormation and Terraform templates.

RDS for Db2 resources that match the product information filter are automatically associated with the self-managed license. Discovery of RDS for Db2 DB instances can take up to 24 hours.

The following table shows available values for the Engine Edition product information filter for RDS for Db2.

Value	Description
`db2-se`	Db2 Standard Edition
`db2-ae`	Db2 Advanced Edition

Topics

- Terminology
- Creating a self-managed license in AWS License Manager
- Automating the creation of self-managed licenses in AWS License Manager with templates
- Settings for creating self-managed licenses

Terminology

This page uses the following terminology when discussing the Amazon RDS integration with AWS License Manager.

Self-managed license

Self-managed license is a term used in AWS License Manager. The Amazon RDS console refers to the license as an AWS License Manager configuration. A self-managed license contains licensing rules based on the terms of your enterprise agreements. The rules that you create determine how AWS processes commands that consume licenses. While creating a self-managed license, work closely with your organization's compliance team to review your enterprise agreements. For more information, see Self-managed licenses in License Manager.

Creating a self-managed license in AWS License Manager

You can create a self-managed license by using the AWS Management Console, the AWS License Manager CLI, and the AWS License Manager API.

> **Note**
>
> If you create an RDS for Db2 DB instance by using the AWS Management Console, you will create a self-managed license by entering a name for the license. Then Amazon RDS associates the DB instance with this license. (In the Amazon RDS console, this license is referred to as an AWS License Manager configuration.) If you want to create an RDS for Db2 DB instance by using the AWS License Manager CLI or AWS License Manager API, you must first create a self-managed license with the following steps. The same situation applies to restoring an RDS for Db2 DB instance to a point in time or from a snapshot.

Console

To create a self-managed license to track the license usage of your RDS for Db2 DB instances

1. Go to https://console.aws.amazon.com/license-manager/.
2. Create a self-managed license.

   For instructions, see Create a self-managed license in the *AWS License Manager User Guide*.

   Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

For more information, see ProductInformation in the *AWS License Manager API Reference*.

AWS License Manager CLI

> **Note**
>
> This procedure uses an AWS License Manager CLI command.

To create a self-managed license by using the AWS CLI, run the AWS License Manager create-license-configuration command. Use the `--cli-input-json` or `--cli-input-yaml` options to pass the options to the command.

For more information, see the section called "Settings for creating self-managed licenses".

The following command creates a self-managed license for Db2 Standard Edition.

```
aws license-manager create-license-configuration --cli-input-json file://rds-db2-
se.json
```

The following JSON is the content of the `rds-db2-se.json` file used in the previous command.

```
{
    "Name": "rds-db2-se",
    "Description": "RDS Db2 Standard Edition",
    "LicenseCountingType": "vCPU",
    "LicenseCountHardLimit": false,
    "ProductInformationList": [
        {
            "ResourceType": "RDS",
            "ProductInformationFilterList": [
                {
                    "ProductInformationFilterName": "Engine Edition",
                    "ProductInformationFilterValue": ["db2-se"],
                    "ProductInformationFilterComparator": "EQUALS"
                }
            ]
        }
    ]
}
```

For more information about product information, see Automated discovery of resource inventory in the *AWS License Manager User Guide*.

For more information about the `--cli-input` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the *AWS CLI User Guide*.

AWS License Manager API

> **Note**
>
> This procedure uses an AWS License Manager API command.

To create a self-managed license, use the `CreateLicenseConfiguration` AWS License Manager API operation with the following required parameters:

- `Name`
- `LicenseCountingType`
- `ProductInformationList`
- `ResourceType`
- `ProductInformationFilterList`
- `ProductInformationFilterName`
- `ProductInformationFilterValue`
- `ProductInformationFilterComparator`

For more information about the parameters, see the section called "Settings for creating self-managed licenses".

Automating the creation of self-managed licenses in AWS License Manager with templates

You can automate the creation of self-managed licenses by using CloudFormation and Terraform templates.

The following example CloudFormation template creates self-managed licenses for Db2 Standard Edition on RDS for Db2. For a template for Db2 Advanced Edition, update the values for `Name`, `Description`, and `ProductInformationFilter`.

```
AWSTemplateFormatVersion: "2010-09-09"
Description: CloudFormation template to create a License Configuration for Db2 Standard
 Edition on RDS for Db2.

Resources:
  Db2LicenseConfiguration:
    Type: "AWS::LicenseManager::LicenseConfiguration"
    Properties:
      Name: "rds-db2-se"
      Description: "Db2 Standard Edition on RDS for Db2"
      LicenseCountingType: "vCPU"
      LicenseCountHardLimit: false
      ProductInformationList:
        - ResourceType: "RDS"
          ProductInformationFilterList:
            - ProductInformationFilterName: "Engine Edition"
              ProductInformationFilterValue:
                - "db2-se"
              ProductInformationFilterComparator: "EQUALS"
```

For more information about using CloudFormation with Amazon RDS, see Creating Amazon RDS resources with AWS CloudFormation.

The following example Terraform template creates self-managed licenses for Db2 Standard Edition on RDS for Db2. Replace *us-east-1* with your AWS Region. For a template for Db2 Advanced Edition, update the values for `name`, `description`, and `product_information_filter`.

```
provider "aws" {
  region = "us-east-1"
}

resource "aws_licensemanager_license_configuration" "rds_db2_license_config" {
  name                     = "rds-db2-se"
  description              = "Db2 Standard Edition on RDS for Db2
  license_counting_type    = "vCPU"
  license_count_hard_limit = false

  product_information_list {
    resource_type = "RDS"

    product_information_filter {
      name        = "Engine Edition"
```

```
      comparator = "EQUALS"
      value      = ["db2-se"]
    }
  }
}
```

For more information about using Terraform and Amazon RDS, see Using Terraform as an IaC tool for the AWS Cloud and Best practices for using the Terraform AWS Provider in *AWS Prescriptive Guidance*.

Settings for creating self-managed licenses

In the following table, you can find details about the settings for creating self-managed licenses by using the AWS License Manager CLI, the AWS License Manager API, an CloudFormation template, and a Terraform template. The parameter name in the following table appears in the format of the name used in the AWS License Manager API and the CloudFormation template.

Parameter name	Data type	Required	Description
Name	string	Yes	The name of the license configuration.
Description	string	No	The description of the license configuration.
LicenseCountingType	string	Yes	The dimension used to track the license inventory. Valid value: vCPU.
LicenseCountHardLimit	boolean	No	Indicates whether hard or soft license enforcement is used. Exceeding a hard limit blocks the launch of new instances.

Parameter name	Data type	Required	Description
ProductInformationList	array of objects	Yes	A list of product information for a license configuration.
ResourceType	string	Yes	The resource type. Valid value: RDS.
ProductInformationFilterList	array of objects	Yes	A list of product information filters for a license configuration.
ProductInformationFilterName	string	Yes	The name of the type of filter being declared. Valid value: `Engine Edition`.
ProductInformationFilterValue	array of strings	Yes	The value to filter on. You must only specify one value. Valid values: `db2-se` or `db2-ae`.
ProductInformationFilterComparator	string	Yes	The logical operator for `ProductInformation FilterName` . Valid value: EQUALS.

Db2 license through AWS Marketplace

In the Db2 license through AWS Marketplace model, you pay an hourly rate to subscribe to Db2 licenses. This model helps you get started quickly with RDS for Db2 without needing to purchase licenses.

To use Db2 license through AWS Marketplace, you need an active AWS Marketplace subscription for the particular IBM Db2 edition that you want to use. If you don't already have one, subscribe to AWS Marketplace for that IBM Db2 edition.

Amazon RDS supports Db2 license through AWS Marketplace for IBM Db2 Standard Edition and IBM Db2 Advanced Edition.

Topics

- Terminology
- Payments and billing
- Subscribing to Db2 Marketplace listings and registering with IBM
- Obtaining a private offer

Terminology

This page uses the following terminology when discussing the Amazon RDS integration with AWS Marketplace.

SaaS subscription

: In AWS Marketplace, software-as-a-service (SaaS) products such as the pay-as-you-go license model adopt a usage-based subscription model. IBM, the software seller for Db2, tracks your usage and you pay only for what you use.

Public offer

: Public offers allow you to purchase AWS Marketplace products directly from the AWS Management Console.

Private offer

: Private offers are a purchasing program that allow sellers and buyers to negotiate custom prices and end user licensing agreement (EULA) terms for purchases in AWS Marketplace.

Db2 Marketplace fees

: Fees charged for the Db2 software license usage by IBM. These service fees are metered through AWS Marketplace and appear on your AWS bill under the AWS Marketplace section.

Amazon RDS fees

Fees that AWS charges for the RDS for Db2 services, which excludes licenses when using AWS Marketplace for Db2 licenses. Fees are metered through the Amazon RDS service being used and appear on your AWS bill.

Payments and billing

RDS for Db2 integrates with AWS Marketplace to offer hourly, pay-as-you-go licenses for Db2. The Db2 Marketplace fees cover the license costs of the Db2 software, and the Amazon RDS fees cover the costs of your RDS for Db2 DB instance usage. For information about pricing, see Amazon RDS for Db2 pricing.

To stop these fees, you must delete any RDS for Db2 DB instances. In addition, you can remove your subscriptions to AWS Marketplace for Db2 licenses. If you remove your subscriptions without deleting your DB instances, Amazon RDS will continue to bill you for the use of the DB instances. For more information, see the section called “Deleting a DB instance”.

You can view bills and manage payments for your RDS for Db2 DB instances that use Db2 license through AWS Marketplace in the AWS Billing console. Your bills includes two charges: one for your usage of Db2 license through AWS Marketplace and one for your usage of Amazon RDS. For more information about billing, see Viewing your bill in the *AWS Billing and Cost Management User Guide*.

Subscribing to Db2 Marketplace listings and registering with IBM

To use Db2 license through AWS Marketplace, you must use the AWS Management Console to complete the following two tasks. You can't complete these tasks through the AWS CLI or the RDS API.

> **Note**
>
> If you want to create your DB instances by using the AWS CLI or the RDS API, you must complete these two tasks first.

Topics

- Task 1: Subscribe to Db2 in AWS Marketplace

- Task 2: Register your subscription with IBM

Task 1: Subscribe to Db2 in AWS Marketplace

To use Db2 license with AWS Marketplace, you need to have an active AWS Marketplace subscription for Db2. Because subscriptions are associated with a specific IBM Db2 edition, you need to subscribe to Db2 in AWS Marketplace for each edition of Db2 that you want to use: IBM Db2 Advanced Edition, IBM Db2 Standard Edition. For information about AWS Marketplace subscriptions, see Saas usage-based subscriptions in the *AWS Marketplace Buyer Guide*.

We recommend that you subscribe to Db2 in AWS Marketplace *before* you start to create a DB instance.

Task 2: Register your subscription with IBM

After you subscribe to Db2 in AWS Marketplace, complete the registration of your IBM order from the AWS Marketplace page for the type of Db2 subscription that you chose. On the AWS Marketplace page, choose **View purchase options**, and then choose **Set up your account**. You can register either with your existing IBM account or by creating a free IBM account.

Obtaining a private offer

You can request an AWS Marketplace private offer for Db2 from IBM. For more information, see Private offers in the *AWS Marketplace Buyer Guide*.

> **Note**
>
> If you are an AWS Organizations user and received a private offer that was issued to your payer and member accounts, follow the procedure below to subscribe to Db2 directly on each account in your organization.

To obtain a Db2 private offer

1. After a private offer has been issued, sign in to the AWS Marketplace Console.
2. Open the email with a Db2 private offer link.
3. Follow the link to directly access the private offer.

> **Note**
>
> Following this link before logging in to the correct account will result in a **Page note found** (404) error.

4. Review the terms and conditions.
5. Choose **Accept terms**.

> **Note**
>
> If an AWS Marketplace private offer is not accepted, the Db2 service fees from AWS Marketplace will continue to be billed at the public hourly rate.

6. To verify the offer details, select **Show details** in the product listing.

After you've completed the procedure, you can create your DB instance by following the steps in the section called "Creating a DB instance". In the AWS Management Console, under **License**, make sure that you choose **Through AWS Marketplace**.

Switching between Db2 licenses

You can switch between Db2 licenses in RDS for Db2. For example, you can start with bring your own license (BYOL), and then switch to Db2 license through AWS Marketplace.

> **Important**
>
> If you want to switch to Db2 license through AWS Marketplace, make sure that you have an active AWS Marketplace subscription for the IBM Db2 edition that you want to use. If you don't, first subscribe to Db2 in AWS Marketplace for that Db2 edition, and then complete the restore procedure.

Console

To switch between Db2 licenses

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Automated backups**.

   The automated backups are displayed on the **Current Region** tab.
3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time you want to restore the instance to.

   > **Note**
   >
   > Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/ Central Daylight Time.
6. For **DB engine**, choose the Db2 license you want to use.
7. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
8. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.

   For information about each setting, see Settings for DB instances.
9. Choose **Restore to point in time**.

For more information, see Restoring a DB instance to a specified time for Amazon RDS.

AWS CLI

To switch between Db2 licenses, run the restore-db-instance-to-point-in-time command. The following example restores the latest point-in-time version, sets the DB engine to IBM Db2 Advanced Edition, and sets the license model to Db2 license through AWS Marketplace.

You can specify other settings. For information about each setting, see Settings for DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-identifier my_source_db_instance \
    --target-db-instance-identifier my_target_db_instance \
    --use-latest-restorable-time \
    --engine db2-ae \
    --license-model marketplace-license
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-identifier my_source_db_instance ^
    --target-db-instance-identifier my_target_db_instance ^
    --use-latest-restorable-time ^
    --engine db2-ae ^
    --license-model marketplace-license
```

For more information, see Restoring a DB instance to a specified time for Amazon RDS.

RDS API

To switch between Db2 licenses, call the Amazon RDS API `RestoreDBInstanceToPointInTime` operation with the following parameters:

- `SourceDBInstanceIdentifier`
- `TargetDBInstanceIdentifier`
- `RestoreTime`
- `Engine`
- `LicenseModel`

For more information, see Restoring a DB instance to a specified time for Amazon RDS.

Amazon RDS for Db2 instance classes

The computation and memory capacity of a DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

Supported RDS for Db2 instance classes

The supported Amazon RDS for Db2 instance classes are a subset of the Amazon RDS DB instance classes. For the complete list of Amazon RDS instance classes, see DB instance classes.

Topics

- Supported RDS for Db2 instance classes for Db2 Standard Edition
- Supported RDS for Db2 instance classes for Db2 Advanced Edition

Supported RDS for Db2 instance classes for Db2 Standard Edition

The following table lists all instance classes supported for the Db2 Standard Edition of Db2 database version 11.5.9.0. These instance classes are available for both bring your own license (BYOL) and Db2 license through AWS Marketplace.

Instance class type	Instance class
General purpose instance classes with 3rd generation Intel Xeon Scalable processors, SSD storage, and network optimization	db.m6idn.large–db.m6idn.8xlarge
General purpose instance classes powered by 3rd generation Intel Xeon Scalable processors	db.m6in.large–db.m6in.8xlarge
General purpose instance classes	db.m7i.large–db.m7i.8xlarge db.m6i.large–db.m6i.8xlarge
Memory optimized instance classes with local NVMe-based SSDs, powered by 3rd generation Intel Xeon Scalable processors	db.x2iedn.xlarge
Memory optimized instance classes powered by 3rd generation Intel Xeon Scalable processors	db.r6idn.large–db.r6idn.4xlarge db.r6in.large–db.r6in.4xlarge
Memory optimized instance classes	db.r7i.large–db.r7i.8xlarge

Instance class type	Instance class
	db.r6i.large–db.r6i.4xlarge
Burstable performance instance classes	db.t3.small–db.t3.2xlarge

Supported RDS for Db2 instance classes for Db2 Advanced Edition

The following table lists all instance classes supported for the Db2 Advanced Edition of Db2 database version 11.5.9.0. These instance classes are available for both bring your own license (BYOL) and Db2 license through AWS Marketplace.

Instance class type	Instance class
General purpose instance classes with 3rd generation Intel Xeon Scalable processors, SSD storage, and network optimization	db.m6idn.large–db.m6idn.32xlarge
General purpose instance classes powered by 3rd generation Intel Xeon Scalable processors	db.m6in.large–db.m6in.32xlarge
General purpose instance classes	db.m6i.large–db.m7i.48xlarge db.m7i.large–db.m7i.48xlarge
Memory optimized instance classes with local NVMe-based SSDs, powered by 3rd generation Intel Xeon Scalable processors	db.x2iedn.xlarge–db.x2iedn.32xlarge
Memory optimized instance classes powered by 3rd generation Intel Xeon Scalable processors	db.r6idn.large–db.r6idn.32xlarge db.r6in.8xlarge–db.r6in.32xlarge
Memory optimized instance classes	db.r6i.large–db.r7i.48xlarge db.r7i.large–db.r7i.48xlarge

Instance class type	Instance class
Burstable performance instance classes	db.t3.small–db.t3.2xlarge

Amazon RDS for Db2 default roles

RDS for Db2 adds the following six roles and grants them to the `master_user_role` with the `ADMIN` option. When the database is provisioned, RDS for Db2 grants `master_user_role` to the master user. The master user can in turn grant these roles to other users, groups, or roles with native `GRANT` statements by connecting to the database.

- **DBA** – RDS for Db2 creates this empty role with `DATAACCESS` authorization. The master user can add more authorizations or privileges to this role, and then grant the role to other users, groups, or roles.
- **DBA_RESTRICTED** – RDS for Db2 creates this empty role. The master user can add privileges to this role, and then grant the role to other users, groups, or roles.
- **DEVELOPER** – RDS for Db2 creates this empty role with `DATAACCESS` authorization. The master user can add more authorizations or privileges to this role, and then grant the role to other users, groups, or roles.
- **ROLE_NULLID_PACKAGES** – RDS for Db2 grants `EXECUTE` privileges to this role on `ALL NULLID` packages that were bound by Db2 when `CREATE DATABASE` was run.
- **ROLE_PROCEDURES** – RDS for Db2 grants `EXECUTE` privileges to this role on all `SYSIBM` procedures.
- **ROLE_TABLESPACES** – RDS for Db2 grants `USAGE` privileges on tablespaces created by the `CREATE DATABASE` command.

Amazon RDS for Db2 parameters

Amazon RDS for Db2 uses three types of parameters: database manager configuration parameters, registry variables, and database configuration parameters. You can manage the first two types through parameter groups and the last type through the rdsadmin.update_db_param stored procedure.

By default, an RDS for Db2 DB instance uses a DB parameter group that is specific to a Db2 database and DB instance. This parameter group contains parameters for the IBM Db2 database

engine, specifically the database manager configuration parameters and registry variables. For information about working with parameter groups, see Parameter groups for Amazon RDS.

RDS for Db2 database configuration parameters are set to the default values of the storage engine that you have selected. For more information about Db2 parameters, see the Db2 database configuration parameters in the IBM Db2 documentation.

Topics

- Viewing the parameters in parameter groups
- Viewing all parameters with Db2 commands
- Modifying the parameters in parameter groups
- Modifying the database configuration parameters with Db2 commands

Viewing the parameters in parameter groups

The database manager configuration parameters and the registry variables are set in parameter groups. You can view the database manager configuration parameters and the registry variables for a specific Db2 version by using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To view the parameter values for a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.

   The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

AWS CLI

You can view the database manager configuration parameters and the registry variables for a Db2 version by running the describe-engine-default-parameters command. Specify one of the following values for the `--db-parameter-group-family` option:

- `db2-ae-11.5`
- `db2-se-11.5`

For example, to view the parameters for Db2 Standard Edition 11.5, run the following command:

```
aws rds describe-engine-default-parameters --db-parameter-group-family db2-se-11.5
```

This command produces output similar to the following example:

```
{
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "agent_stack_sz",
                "ParameterValue": "1024",
                "Description": "You can use this parameter to determine the amount of
 memory that is allocated by Db2 for each agent thread stack.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "integer",
                "AllowedValues": "256-32768",
                "IsModifiable": false
            },
            {
                "ParameterName": "agentpri",
                "ParameterValue": "-1",
                "Description": "This parameter controls the priority given to all
 agents and to other database manager instance processes and threads by the operating
 system scheduler. This priority determines how CPU time is allocated to the database
 manager processes, agents, and threads relative to other processes and threads running
 on the machine.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "integer",
                "AllowedValues": "1-99",
                "IsModifiable": false
            },
            ...
        ]
    }
}
```

To list only the modifiable parameters for Db2 Standard Edition 11.5, run the following command:

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters \
    --db-parameter-group-family db2-se-11.5 \
    --query 'EngineDefaults.Parameters[?IsModifiable==`true`].
{ParameterName:ParameterName, DefaultValue:ParameterValue}'
```

For Windows:

```
aws rds describe-engine-default-parameters ^
    --db-parameter-group-family db2-se-11.5 ^
    --query 'EngineDefaults.Parameters[?IsModifiable==`true`].
{ParameterName:ParameterName, DefaultValue:ParameterValue}'
```

RDS API

To view the parameter values for a DB parameter group, use the `DescribeDBParameters` operation with the following required parameter.

- `DBParameterGroupName`

Viewing all parameters with Db2 commands

You can view the settings for database manager configuration parameters, database configuration parameters, and registry variables by using Db2 commands.

To view the settings

1. Connect to your Db2 database. In the following example, replace *database_name*, *master_username*, and *master_password* with your information.

   ```
   db2 "connect to database_name user master_username using master_password"
   ```

2. Find the supported Db2 version.

   ```
   db2 "select service_level, fixpack_num from table(sysproc.env_get_inst_info()) as
    instanceinfo"
   ```

3. View the parameters for a specific Db2 version.

   - View database manager configuration parameters by running the following command:

```
db2 "select cast(substr(name,1,24) as varchar(24)) as name, case
    when value_flags = 'NONE' then '' else value_flags end flags,
    cast(substr(value,1,64) as varchar(64)) as current_value
    from sysibmadm.dbmcfg
    order by name asc with UR"
```

- View all of your database configuration parameters by running the following command:

```
db2 "select cast(substr(name,1,24) as varchar(24)) as name, case
    when value_flags = 'NONE' then '' else value_flags end flags,
    cast(substr(value,1,64) as varchar(64)) as current_value
    from table(db_get_cfg(null)) order by name asc, member asc with UR"
```

- View the currently set registry variables by running the following command:

```
db2 "select cast(substr(reg_var_name,1,50) as varchar(50)) as reg_var_name,
    cast(substr(reg_var_value,1,50) as varchar(50)) as reg_var_value,
    level from table(env_get_reg_variables(null))
    order by reg_var_name,member with UR"
```

Modifying the parameters in parameter groups

You can modify the database manager configuration parameters and the registry variables in custom parameter groups by using the AWS Management Console, the AWS CLI, or the RDS API. For more information, see DB parameter groups for Amazon RDS DB instances.

Console

To modify database manager configuration parameters and registry variables

1. Create a custom parameter group. For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameters in that custom parameter group. For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

AWS CLI

To modify database manager configuration parameters and registry variables

1. Create a custom parameter group by running the create-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values: `db2-se-11.5`, `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the parameters in the custom parameter group that you created by running the modify-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

RDS API

To modify database manager configuration parameters and registry variables

1. Create a custom DB parameter group by using the CreateDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `DBParameterGroupFamily`

- `Description`

For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by using the ModifyDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `Parameters`

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

Modifying the database configuration parameters with Db2 commands

You can modify the database configuration parameters with Db2 commands.

To modify the database configuration parameters

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Change the database configuration parameters by calling the `rdsadmin.update_db_param` stored procedure. For more information, see rdsadmin.update_db_param.

```
db2 "call rdsadmin.update_db_param(
    'database_name',
    'parameter_to_modify',
    'changed_value',
    'restart_database')"
```

EBCDIC collation for Db2 databases on Amazon RDS

Amazon RDS for Db2 supports EBCDIC collation for Db2 databases. You can only specify an EBCDIC collation sequence for a database when you create the database by using the Amazon RDS the section called “rdsadmin.create_database” stored procedure.

When you create an RDS for Db2 DB instance by using the AWS Management Console, AWS CLI, or RDS API, you can specify a database name. If you specify a database name, Amazon RDS creates a database with the default collation of SYSTEM. If you need to create a database with EBCDIC collation, don't specify a database name when you create a DB instance.

The collation for a database in RDS for Db2 is set at the time of creation and is immutable.

To create a Db2 database with EBCDIC collation

1. If you don't have an RDS for Db2 DB instance, create a DB instance but don't specify a database name You can create a DB instance by using the AWS Management Console, AWS CLI, or RDS API. For more information, see Creating a DB instance.
2. Create a Db2 database and set the collation option to an EBCDIC value by calling the `rdsadmin.create_database` stored procedure. For more information, see rdsadmin.create_database.

   > **Important**
   >
   > After you create a database using the stored procedure, you can't change the collation sequence. If you want a database to use a different collation sequence, drop the database by calling the the section called “rdsadmin.drop_database” stored procedure. Then, create a database with the required collation sequence.

Local time zone for Amazon RDS for Db2 DB instances

The time zone of an Amazon RDS DB instance running Db2 is set by default. The default is Coordinated Universal Time (UTC). To match the time zone of your applications, you can set the time zone of your DB instance to a local time zone instead.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the RDS API, or the AWS CLI. For more information, see Creating a DB instance.

If your DB instance is part of a Multi-AZ deployment, then when it fails over, its time zone remains the local time zone that you set.

You can restore your DB instance to a point in time that you specify. The time appears in your local time zone. For more information, see Restoring a DB instance to a specified time for Amazon RDS.

Setting the local time zone on your DB instance has the following limitations:

- You can't modify the time zone of an existing Amazon RDS for Db2 DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to another, then you must audit your queries and applications for the effects of the time zone change.

Available time zones

You can use the following values for the time zone setting.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/

Zone	Time zone
	Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo, Europe/Stockholm
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Prerequisites for creating an Amazon RDS for Db2 DB instance

The following items are prerequisites before creating a DB instance.

Topics

- Administrator account
- Additional considerations

Administrator account

When you create a DB instance, you must designate an administrator account for the instance. Amazon RDS grants `DBADM` authority to this local database administrator account.

The administrator account has the following characteristics, capabilities, and limitations:

- Is a local user and not an AWS account.
- Doesn't have Db2 instance-level authorities such as `SYSADM`, `SYSMAINT`, or `SYSCTRL`.
- Can't stop or start a Db2 instance.
- Can't drop a Db2 database if you specified the name when you created the DB instance.
- Has full access to the Db2 database including catalog tables and views.
- Can create local users and groups by using Amazon RDS stored procedures.
- Can grant and revoke authorities and privileges.

The administrator account can perform the following tasks:

- Create, modify, or delete DB instances.
- Create DB snapshots.
- Initiate point-in-time restores.
- Create automated backups of DB snapshots.
- Create manual backups of DB snapshots.
- Use other Amazon RDS features.

Additional considerations

Before creating a DB instance, consider the following items:

- Each Amazon RDS for Db2 DB instance can host up to 50 Db2 databases. For more information, see Multiple databases on an Amazon RDS for Db2 DB instance.
- Initial database name
  - If you don't provide a database name when you create a DB instance, Amazon RDS doesn't create a database.
  - Don't provide a database name under the following circumstances:
    - You want to modify the `db2_compatibility_vector` parameter. For more information, see Setting the db2_compatibility_vector parameter.
- In the bring your own license (BYOL) model, you must first create a custom parameter group that contains your IBM Customer ID and your IBM Site ID. For more information, see Bring your own license (BYOL) for Db2.
- In the Db2 license through AWS Marketplace model, you need an active AWS Marketplace subscription for the particular IBM Db2 edition that you want to use. If you don't already have one, subscribe to Db2 in AWS Marketplace for the IBM Db2 edition that you want to use. For more information, see Db2 license through AWS Marketplace.

Multiple databases on an Amazon RDS for Db2 DB instance

You can create multiple databases on a single RDS for Db2 DB instance by calling the rdsadmin.create_database stored procedure. A single RDS for Db2 DB instance is limited to 50 databases. This number includes databases in both activated and deactivated states.

> **Note**
>
> If you create multiple databases on an RDS for Db2 DB instance that was created before November 15, 2024, then you must reboot the DB instance to enable support for multiple databases.

By default, Amazon RDS activates databases when you create them. To optimize memory resources, you can deactivate databases that you use infrequently and then activate them later when needed. For more information, see the section called “Deactivating a database” and the section called “Activating a database”.

The number of activated databases on a DB instance depends on the available memory resources on the server. Memory resources differ based on the DB instance class and the amount of memory configured for the database. For information about DB instance classes, see the section called “DB instance classes”. For information about how to update the memory for an RDS for Db2 database, see the section called “rdsadmin.update_db_param”.

We recommend that you choose a DB instance class that has 2 GB of memory for common database tasks, operating system requirements, and other Amazon RDS automation tasks such as backups. For more information about changing the DB instance class, see the section called “Modifying a DB instance”.

In addition, IBM recommends a minimum of 1 GB of memory for each active database. For more information, see Disk and memory requirements in the IBM documentation.

You can calculate the maximum number of active databases a DB instance can have with the following formula:

```
Active database limit = (total server memory - 2 GB) / 1 GB
```

The following example shows the maximum number of active databases for a DB instance with a db.m6i.xlarge DB instance class:

```
Active database limit = (total server memory - 2 GB) / 1 GB
                      = (16 GB - 2 GB) / 1 GB
                      = 14 databases
```

When Amazon RDS recovers a database after a crash, it activates the database if it was previously active. In certain cases, such as when you modify a DB instance class to a lower memory configuration, there might be insufficient memory to activate all databases on the DB instance. In those cases, Amazon RDS activates databases in the order in which they were created.

> **Note**
>
> Any databases that Amazon RDS can't activate because of insufficient memory remain in a deactivated state.

Connecting to your Db2 DB instance

After Amazon RDS provisions your Amazon RDS for Db2 DB instance, you can use any standard SQL client application to connect to the DB instance. Because Amazon RDS is a managed service, you can't sign in as `SYSADM`, `SYSCTRL`, `SECADM`, or `SYSMAINT`.

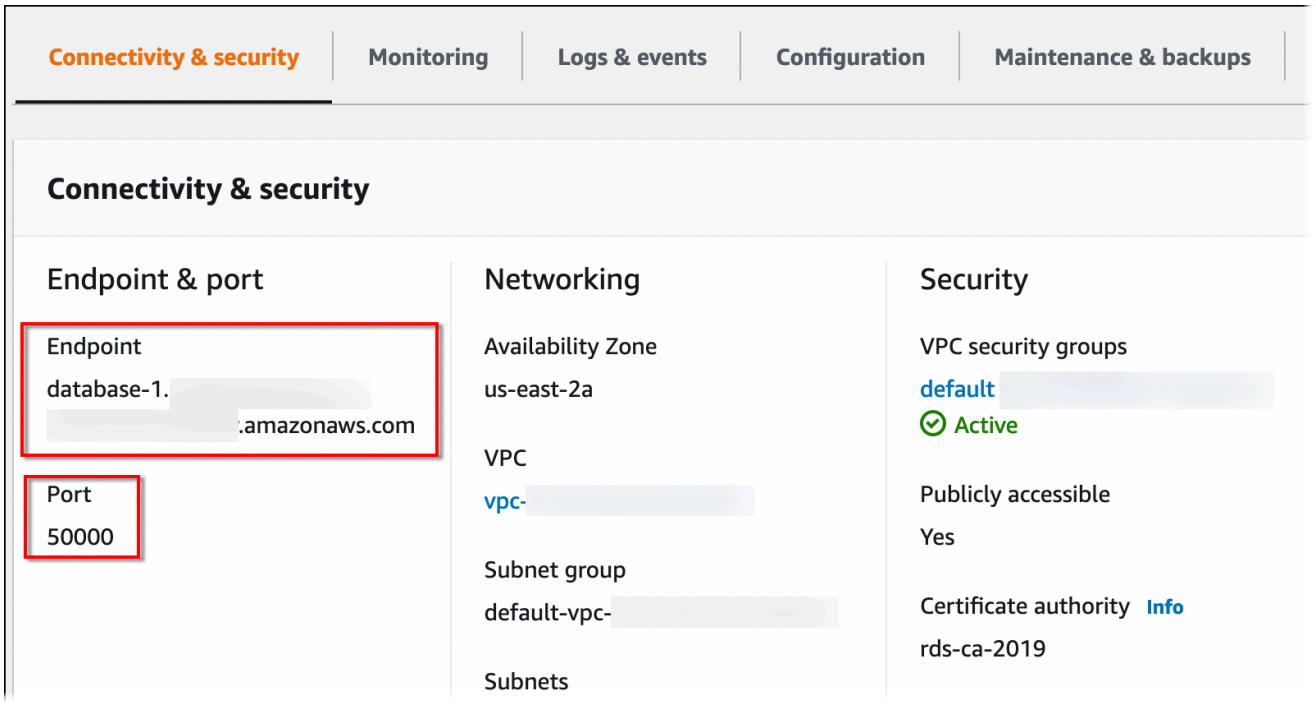
You can connect to a DB instance that is running the IBM Db2 database engine by using IBM Db2 CLP, IBM CLPPlus, DBeaver, or IBM Db2 Data Management Console.

> **Note**
>
> Connecting to a Db2 database can fail if your RDS for Db2 DB instance doesn't have sufficient memory. For more information, see the section called “Database connection error”.

Topics

- Finding the endpoint of your Amazon RDS for Db2 DB instance
- Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP
- Connecting to your Amazon RDS for Db2 DB instance with IBM CLPPlus
- Connecting to your Amazon RDS for Db2 DB instance with DBeaver
- Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console
- Considerations for security groups with Amazon RDS for Db2

Finding the endpoint of your Amazon RDS for Db2 DB instance



Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your Amazon RDS for Db2 DB instance with a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance by using the AWS Management Console or the AWS CLI.

Console

To find the endpoint of an RDS for Db2 DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your RDS for Db2 DB Instance.
   a. Choose **Databases** to display a list of your DB instances.
   b. Choose the RDS for Db2 DB instance name to display the instance details.
   c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

AWS CLI

To find the endpoint of an RDS for Db2 DB instance, run the describe-db-instances command. In the following example, replace *database-1* with the name of your DB instance.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
```

```
    --db-instance-identifier database-1 \
    --query 'DBInstances[].
{DBInstanceIdentifier:DBInstanceIdentifier,DBName:DBName,Endpoint:Endpoint}' \
    --output json
```

For Windows:

```
aws rds describe-db-instances ^
    --db-instance-identifier database-1 ^
    --query 'DBInstances[].
{DBInstanceIdentifier:DBInstanceIdentifier,DBName:DBName,Endpoint:Endpoint}' ^
    --output json
```

This command produces output similar to the following example. The `Address` line in the output contains the DNS name.

```
[
    {
        "DBInstanceIdentifier": "database-1",
        "DBName": "DB2DB",
        "Endpoint": {
            "Address": "database-1.123456789012.us-east-2.amazonaws.com",
            "Port": 50000,
            "HostedZoneId": "Z2OC4A7DETW6VH"
        }
    }
]
```

Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP

You can use a command line utility such as IBM Db2 CLP to connect to Amazon RDS for Db2 DB instances. This utility is part of IBM Data Server Runtime Client. To download the client from IBM Fix Central, see IBM Data Server Client Packages Version 11.5 Mod 8 Fix Pack 0 in IBM Support.

Topics

- Terminology
- Installing the client
- Connecting to a DB instance
- Troubleshooting connections to your RDS for Db2 DB instance

Terminology

The following terms help explain commands used when connecting to your RDS for Db2 DB instance.

catalog tcpip node

This command registers a remote database node with a local Db2 client, which makes the node accessible to the client application. To catalog a node, you provide information such as the server's host name, port number, and communication protocol. The cataloged node then represents a target server where one or more remote databases reside. For more information, see CATALOG TCPIP/TCPIP4/TCPIP6 NODE command in the IBM Db2 documentation.

catalog database

This command registers a remote database with a local Db2 client, which makes the database accessible to the client application. To catalog a database, you provide information such as the database's alias, the node on which it resides, and the authentication type needed to connect to the database. For more information, see CATALOG DATABASE command in the IBM Db2 documentation.

Installing the client

After downloading the package for Linux, install the client using root or administrator privileges.

> **Note**
>
> To install the client on AIX or Windows, follow the same procedure but modify the commands for your operating system.

To install the client on Linux

1. Run **`./db2_install -f sysreq`** and choose **`yes`** to accept the license.
2. Choose the location to install the client.
3. Run **`clientInstallDir/instance/db2icrt -s client`** ***`instance_name`***. Replace *`instance_name`* with a valid operating system user on Linux. In Linux, the Db2 DB instance name is tied to the operating system username.

This command creates a **sqllib** directory in the home directory of the designated user on Linux.

Connecting to a DB instance

To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance.

To connect to an RDS for Db2 DB instance with IBM Db2 CLP

1. Sign in with the username that you specified during the IBM Db2 CLP client installation.
2. Catalog your RDS for Db2 DB instance. In the following example, replace *node_name*, *dns_name*, and *port* with a name for the node in the local catalog, the DNS name for your DB instance, and the port number.

   ```
   db2 catalog TCPIP node node_name remote dns_name server port
   ```

   Example

   ```
   db2 catalog TCPIP node remnode remote database-1.123456789012.us-
   east-1.amazonaws.com server 50000
   ```

3. Catalog the `rdsadmin` database and your database. This will allow you to connect to the `rdsadmin` database to perform some administrative tasks using Amazon RDS stored procedures. For more information, see Administering your RDS for Db2 DB instance.

   In the following example, replace *database_alias*, *node_name*, and *database_name* with aliases for this database, the name of the node defined in the previous step, and the name of your database. `server_encrypt` encrypts your username and password over the network.

   ```
   db2 catalog database rdsadmin [ as database_alias ] at node node_name
    authentication server_encrypt

   db2 catalog database database_name [ as database_alias ] at node node_name
    authentication server_encrypt
   ```

Example

```
db2 catalog database rdsadmin at node remnode authentication server_encrypt

db2 catalog database testdb as rdsdb2 at node remnode authentication server_encrypt
```

4. Connect to your RDS for Db2 database. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with the name of your database, the master username, and master password of your RDS for Db2 DB instance.

```
db2 connect to rds_database_alias user master_username using master_password
```

This command produces output similar to the following example:

```
Database Connection Information

    Database server        = DB2/LINUXX8664 11.5.9.0
    SQL authorization ID   = ADMIN
    Local database alias   = TESTDB
```

5. Run queries and view results. The following example shows a SQL statement that selects the database you created.

```
db2 "select current server from sysibm.dual"
```

This command produces output similar to the following example:

```
1
    ------------------
    TESTDB

    1 record(s) selected.
```

Troubleshooting connections to your RDS for Db2 DB instance

If you receive the following `NULLID` error, it usually indicates that your client and RDS for Db2 server versions don't match. For supported Db2 client versions, see Supported combinations of clients, drivers and server levels in the IBM Db2 documentation.

```
db2 "select * from syscat.tables"
SQL0805N Package "NULLID.SQLC2O29 0X4141414141454A69" was not found.
SQLSTATE=51002
```

After you receive this error, you must bind packages from your older Db2 client to a Db2 server version supported by RDS for Db2.

To bind packages from an older Db2 client to a newer Db2 server

1. Locate the bind files on the client machine. Typically, these files are located in the **bnd** directory of the Db2 client's installation path and have the extension **.bnd**.
2. Connect to the Db2 server. In the following example, replace *database_name* with the name of your Db2 server. Replace *master_username* and *master_password* with your information. This user has DBADM authority.

   ```
   db2 connect to database_name user master_username using master_password
   ```
3. Run the bind command to bind the packages.

   a. Navigate to the directory where the bind files exist on the client machine.

   b. Run the bind command for each file.

   The following options are required:

   - `blocking all` – Binds all packages in the bind file in a single database request.
   - `grant public` – Grants permission to public to execute the package.
   - `sqlerror continue` – Specifies that the bind process continues even if errors occur.

   For more information about the bind command see BIND command in the IBM Db2 documentation.
4. Verify that the bind was successful by either querying the `syscat.package` catalog view or checking the message returned after the bind command.

For more information, see DB2 v11.5 Bind File and Package Name List in IBM Support.

Connecting to your Amazon RDS for Db2 DB instance with IBM CLPPlus

You can use a utility such as IBM CLPPlus to connect to an Amazon RDS for Db2 DB instance. This utility is part of IBM Data Server Runtime Client. To download the client from IBM Fix Central, see IBM Data Server Client Packages Version 11.5 Mod 8 Fix Pack 0 in IBM Support.

Important

We recommend that you run IBM CLPPlus on an operating system that supports graphical user interfaces such as macOS, Windows, or Linux with Desktop. If running headless Linux, use switch **-nw** with CLPPlus commands.

Topics

- Installing the client
- Connecting to a DB instance
- Retrieving CLOB Data from DB2 Stored Procedures

Installing the client

After downloading the package for Linux, install the client.

Note

To install the client on AIX or Windows, follow the same procedure but modify the commands for your operating system.

To install the client on Linux

1. Run **`./db2_install`**.
2. Run **`clientInstallDir/instance/db2icrt -s client`** ***`instance_name`***. Replace *`instance_name`* with a valid operating system user on Linux. In Linux, the Db2 DB instance name is tied to the operating system username.

   This command creates a **`sqllib`** directory in the home directory of the designated user on Linux.

Connecting to a DB instance

To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance.

To connect to an RDS for Db2 DB instance with IBM CLPPlus

1. Review the command syntax. In the following example, replace *clientDir* with the location where the client is installed.

```
cd clientDir/bin
    ./clpplus -h
```

2. Configure your Db2 server. In the following example, replace *dsn_name*, *database_name*, *endpoint*, and *port* with the DSN name, database name, endpoint, and port for your RDS for Db2 DB instance. For more information, see Finding the endpoint of your Amazon RDS for Db2 DB instance.

```
db2cli writecfg add -dsn dsn_name -database database_name -host endpoint -port port
 -parameter "Authentication=SERVER_ENCRYPT"
```

3. Connect to your RDS for Db2 DB instance. In the following example, replace *master_username* and *dsn_name* with the master username and DSN name.

```
./clpplus -nw master_username@dsn_name
```

4. A Java Shell window opens. Enter the master password for your RDS for Db2 DB instance.

> **Note**
>
> If a Java Shell window doesn't open, run **`./clpplus -nw`** to use the same command line window.

```
Enter password: *********
```

A connection is made and produces output similar to the following example:

```
Database Connection Information :
--------------------------------
Hostname = database-1.abcdefghij.us-east-1.rds.amazonaws.com
Database server = DB2/LINUXX8664  SQL110590
SQL authorization ID = admin
Local database alias = DB2DB
Port = 50000
```

5. Run queries and view results. The following example shows a SQL statement that selects the database you created.

```
SQL > select current server from sysibm.dual;
```

This command produces output similar to the following example:

```
1
    --------------------
    DB2DB
    SQL>
```

Retrieving CLOB Data from DB2 Stored Procedures

Stored procedures like rdsadmin.db2pd_command return results in CLOB columns, which support up to 2 GB of data. However, DB2 CLP limits CLOB output to 8 KB (8192 bytes), truncating any data beyond this threshold. To retrieve the complete output, use CLPPLUS instead.

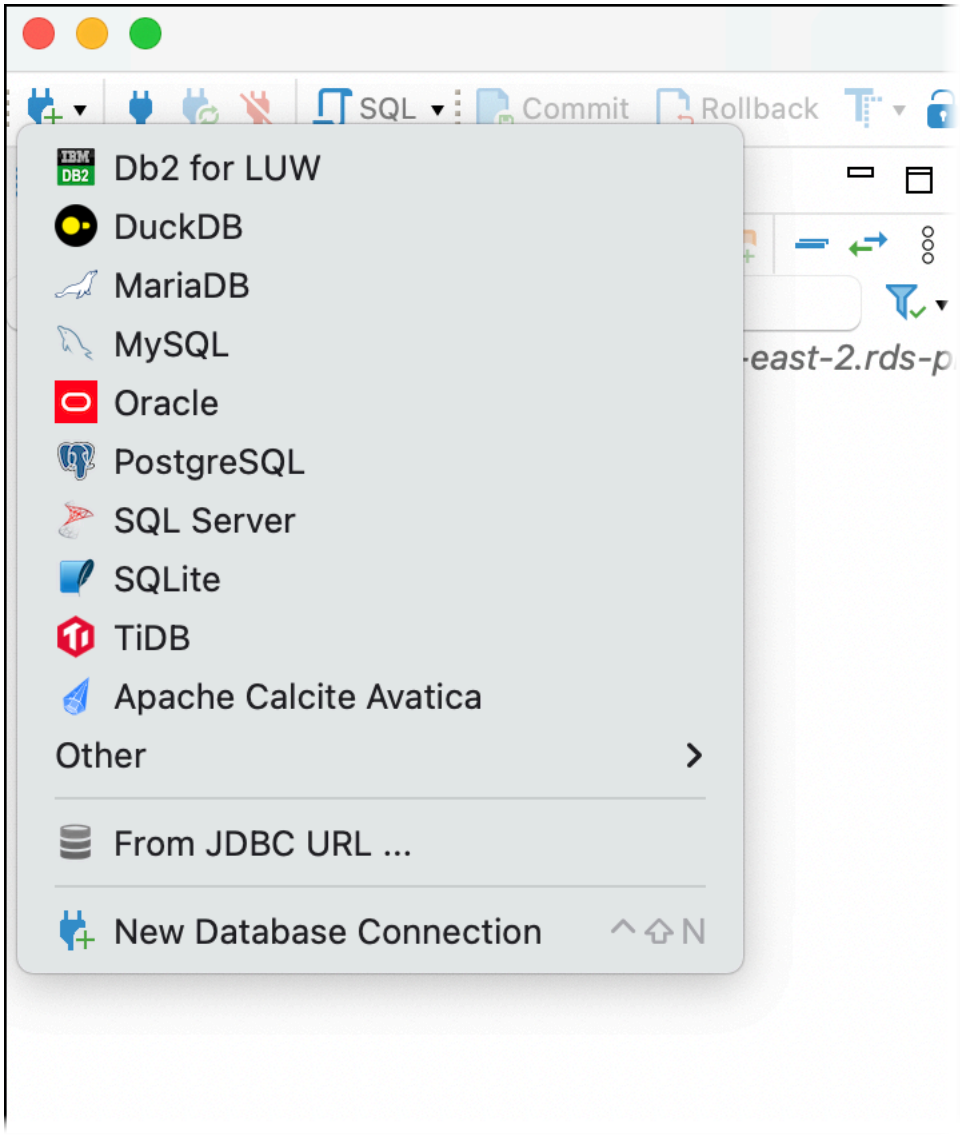
1. Get Task ID (task_id)

```
db2 "select task_id, task_type, database_name, lifecycle,
 varchar(bson_to_json(task_input_params), 500) as task_params,
cast(task_output as varchar(500)) as task_output, CREATED_AT, LAST_UPDATED_AT from
 table(rdsadmin.get_task_status(null,null,null))"
```

2. Execute CLPPLUS Command

After obtaining the task_id, execute the following command from the Unix prompt (replace TASK_ID with the actual numeric task ID):

```
$ (echo "select task_output from
 table(rdsadmin.get_task_status(task_id,null,null));" ; echo "disconnect;" ; echo
 "exit;") | clpplus -nw -silent masteruser/MasterUserPassword@hostname:port_num/
rdsadmin
```



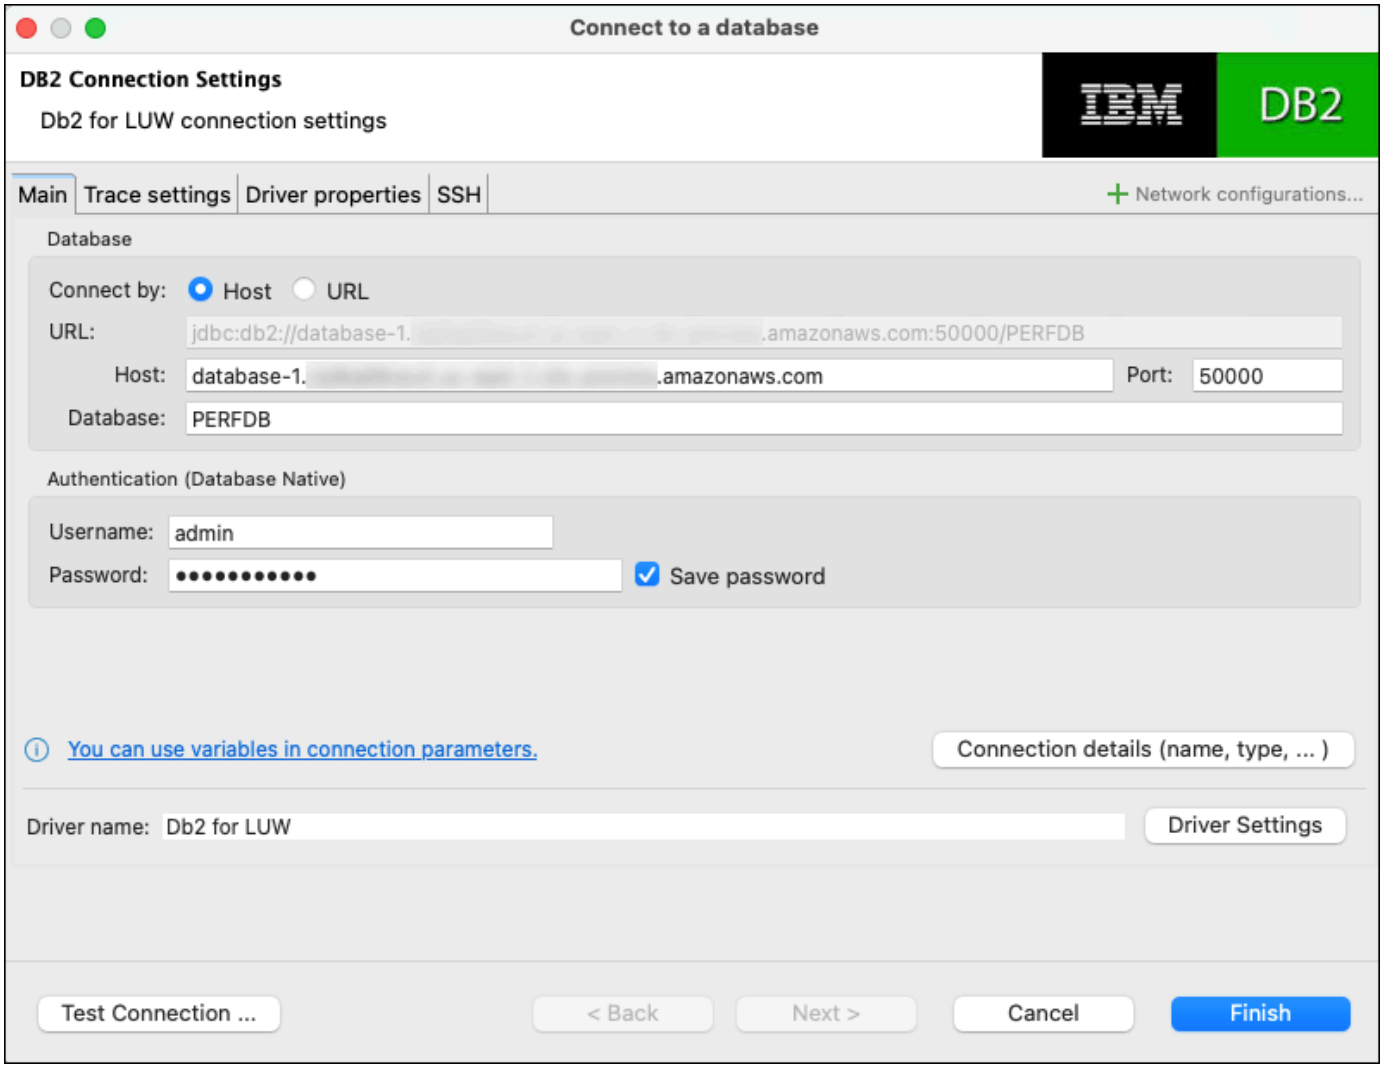
Connecting to your Amazon RDS for Db2 DB instance with DBeaver

You can use third-party tools such as DBeaver to connect to Amazon RDS for Db2 DB instances. To download this utility, see DBeaver Community.

To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance.

To connect to an RDS for Db2 DB instance with DBeaver

1. Start **DBeaver**.
2. Choose the **New Connection** icon in the toolbar and then choose **Db2 for LUW**.



3. In the **Connect to a database** window, provide information for your RDS for Db2 DB instance.

   a. Enter the following information:

      - For **Host**, enter the DNS name of the DB instance.
      - For **Port**, enter the port number for the DB instance.
      - For **Database**, enter the name of the database.
      - For **Username**, enter the name of the database administrator for the DB instance.
      - For **Password**, enter the password of the database administrator for the DB instance.

   b. Select **Save password**.

   c. Choose **Driver Settings**.

4. In the **Edit Driver** window, specify additional security properties.

   a. Choose the **Driver properties** tab.

   b. Add two **User Properties**.

      i. Open the context (right-click) menu, and then choose **Add new property**.

      ii. For **Property Name**, add **encryptionAlgorithm**, and then choose **OK**.

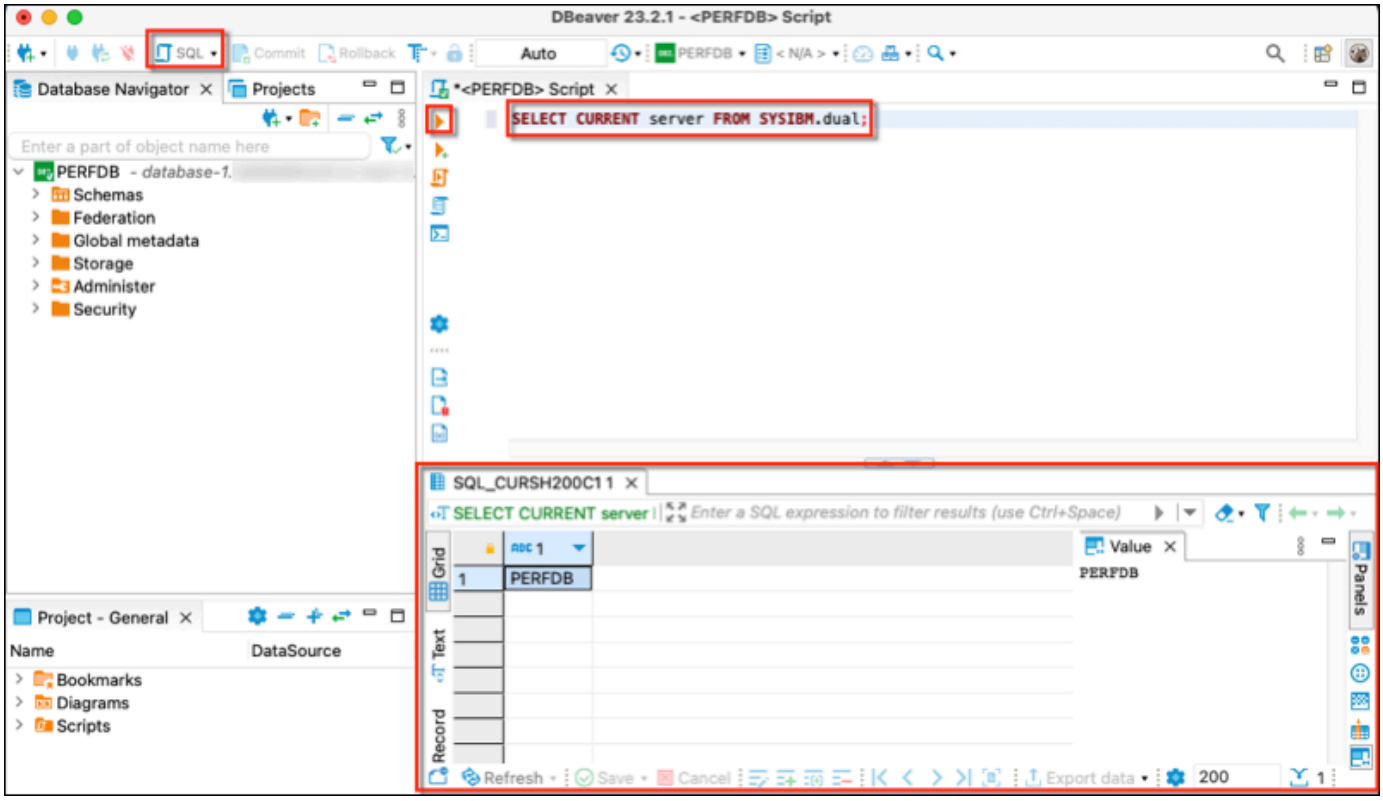
      iii. With the **encryptionAlgorithm** row selected, choose the **Value** column and add **2**.

      iv. Open the context (right-click) menu, and then choose **Add new property**.

      v. For **Property Name**, add **securityMechanism**, and then choose **OK**.

      vi. With the **securityMechanism** row selected, choose the **Value** column and add **7**.

   c. Choose **OK**.



5. In the **Connect to a database** window, choose **Test Connection**. If you don't have a DB2 JBDC driver installed on your computer, then the driver automatically downloads.
6. Choose **OK**.
7. Choose **Finish**.
8. In the **Database Navigation** tab, choose the name of the database. You can now explore objects.

You are now ready to run SQL commands.

To run SQL commands and view the results

1. In the top menu, choose **SQL**. This opens a SQL script panel.
2. In the **Script** panel, enter a SQL command.
3. To run the command, choose the **Execute SQL query** button.
4. In the SQL results panel, view the results of your SQL queries.

Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console

You can connect to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console. IBM Db2 Data Management Console can administer and monitor several RDS for Db2 DB instances.

> **Note**
>
> You must have an Amazon EC2 Linux or Windows machine that is on the same VPC and security group as your RDS for Db2 DB instance. The VPC and security group controls the connection to your DB instance through the internal network.

IBM Db2 Data Management Console requires a repository Db2 database to store metadata and performance metrics but can't automatically create a repository database for RDS for Db2. Instead, you must first create a repository database to monitor one or more RDS for Db2 DB instances. Then you can install IBM Db2 Data Management Console and connect to your RDS for Db2 DB instance with IBM Db2 Data Management Console.

Topics

- Step 1: Creating a repository database to monitor DB instances
- Step 2: Installing and setting up IBM Db2 Data Management Console
- Step 3: Configuring the repository database and connecting to RDS for Db2 DB instances
- Using IBM Db2 Data Management Console

Step 1: Creating a repository database to monitor DB instances

You can use an existing properly sized RDS for Db2 DB instance as a repository for IBM Db2 Data Management Console to monitor other RDS for Db2 DB instances. However, because the admin user doesn't have SYSCTRL authority to create buffer pools and tablespaces, using IBM Db2 Data Management Console repository creation to create a repository database fails. Instead, you must create a repository database. This repository database monitors your RDS for Db2 DB instances.

You can create a repository database in two different ways. You can create an RDS for Db2 database and then manually create a buffer pool, a user tablespace, and a system temporary tablespace. Or, you can create a separate Amazon EC2 instance to host an IBM Db2 Data Management Console repository database.

Topics

- Manually creating a buffer pool, a user tablespace, and a system temporary tablespace
- Creating an Amazon EC2 instance to host an IBM Db2 Data Management Console repository

Manually creating a buffer pool, a user tablespace, and a system temporary tablespace

To create a buffer pool, a user tablespace, and a system temporary tablespace

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Create a buffer pool for IBM Db2 Data Management Console. In the following example, replace *`database_name`* with the name of the repository you created for IBM Db2 Data Management Console to monitor your RDS for Db2 DB instances.

   ```
   db2 "call rdsadmin.create_bufferpool('database_name',
   ```

```
     'BP4CONSOLE', 1000, 'Y', 'Y', 32768)"
```

3. Create a user tablespace for IBM Db2 Data Management Console. In the following example, replace *database_name* with the name of the repository you created for IBM Db2 Data Management Console to monitor your RDS for Db2 DB instances.

```
db2 "call rdsadmin.create_tablespace('database_name',
     'TS4CONSOLE', 'BP4CONSOLE', 32768)"
```

4. Create a system temporary tablespace for IBM Db2 Data Management Console. In the following example, replace *database_name* with the name of the repository you created for IBM Db2 Data Management Console to monitor your RDS for Db2 DB instances.

```
db2 "call rdsadmin.create_tablespace('database_name',
    'TS4CONSOLE_TEMP', 'BP4CONSOLE', 32768, 0, 0, 'S')"
```

You are now ready to install IBM Db2 Data Management Console. For more information about installation and setup, see Step 2: Installing and setting up IBM Db2 Data Management Console.

Creating an Amazon EC2 instance to host an IBM Db2 Data Management Console repository

You can create a separate Amazon Elastic Compute Cloud (Amazon EC2) instance to host an IBM Db2 Data Management Console repository. For information about creating an Amazon EC2 instance, see Tutorial: Get started with Amazon EC2 Linux instances in the *Amazon EC2 User Guide*.

Step 2: Installing and setting up IBM Db2 Data Management Console

After you create a buffer pool, a user tablespace, and a system temporary tablespace, you are ready to install and set up IBM Db2 Data Management Console.

> **Important**
>
> You must have an Amazon EC2 Linux or Windows machine that is on the same VPC and security group as your RDS for Db2 DB instance. The VPC and security group controls the connection to your DB instance through the internal network. Also, you must have already created a repository database for IBM Db2 Data Management Console.

To install and set up IBM Db2 Data Management Console

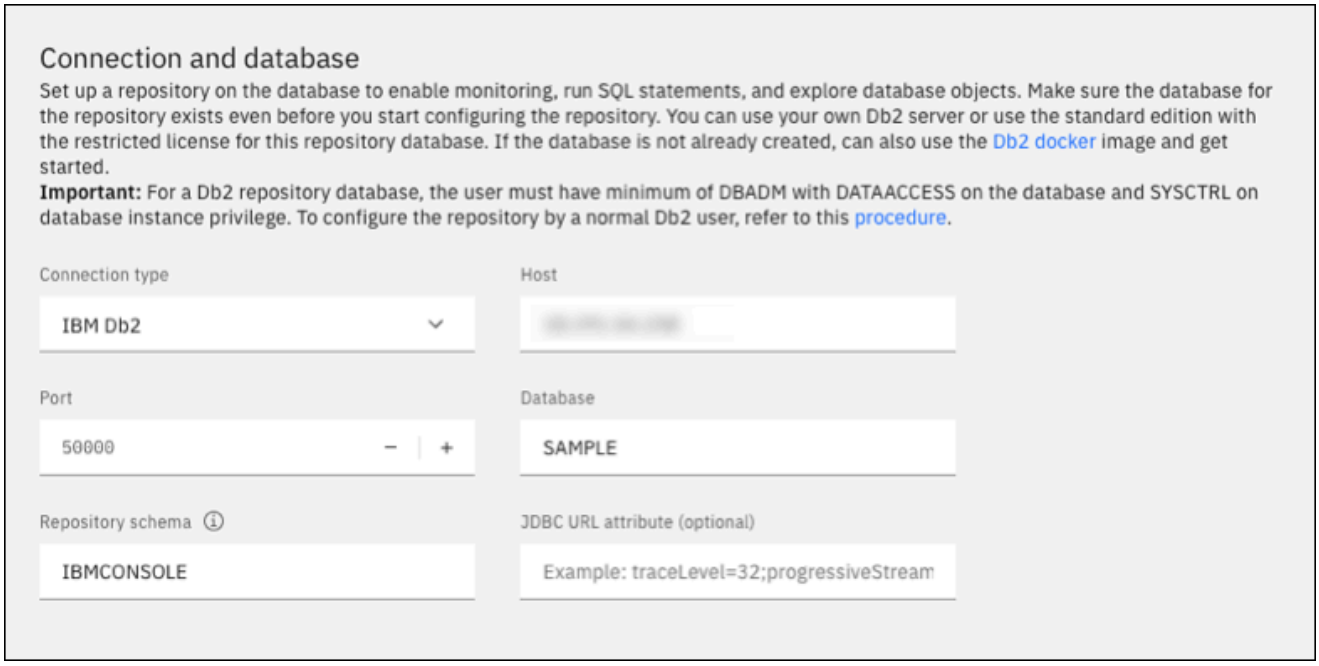
1. Download IBM Db2 Data Management Console from IBM Db2 Data Management Console Version 3.1x releases on the IBM Support website.
2. Install IBM Db2 Data Management Console.
3. Open IBM Db2 Data Management Console and use the IP address of your Amazon EC2 machine and the port number you used for the HTTP or HTTPS connection to your Amazon EC2 instance. For example, use `http://xx.xx.xx.xx:11080` or `https://xx.xx.xx.xx.11081`. Replace *xx.xx.xx.xx* with the IP address of your Amazon EC2 machine. `11080` and `11081` are the default ports for HTTP and HTTPS connections.
4. (Optional) If you want to use port 80 or 443 on your Amazon EC2 instance, you can use either Apache httpd or a Nginx HTTP server to proxy the IBM Db2 Data Management Console port to either port 80 or 443. For more information, see Apache HTTP Server Project and the nginx website.

   To allow connection to IBM Db2 Data Management Console, you must edit the inbound rules in your security group. If you use a proxy, change the TCP/IP port 80 or 443 to redirect to the IBM Db2 Data Management Console ports. If you aren't using a proxy, change the TCP/IP port 80 or 443 to the default ports 11080 (HTTP) or 11081 (HTTPS).

You are now ready to log in to IBM Db2 Data Management Console to configure the repository database and to connect to your RDS for Db2 DB instances. For more information, see Configuring the repository database and connecting to DB instances.

Step 3: Configuring the repository database and connecting to RDS for Db2 DB instances

When you connect to the repository database for the first time, IBM Db2 Data Management Console automatically configures the repository. After the repository database is configured, you can add database connections to IBM Db2 Data Management Console.



To connect to your RDS for Db2 DB instance, you need its DNS name and port number. For information about finding them, see Finding the endpoint. You also need to know the database name, master username, and master password that you defined when you created your RDS for Db2 DB instance. For more information about finding them, see Creating a DB instance. If you are connecting over the internet, allow traffic to the database port. For more information, see Creating a DB instance.

To connect to RDS for Db2 DB instances with IBM Db2 Data Management Console

1. Log in to IBM Db2 Data Management Console with the credentials you set during installation.
2. Configure the repository.

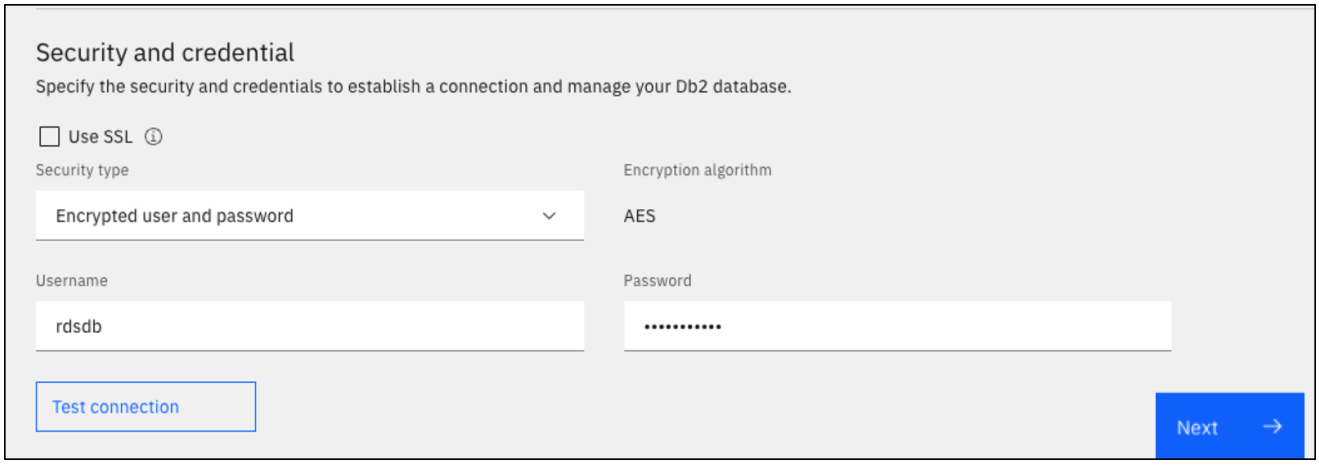
   a. In the **Connection and database** section, enter the following information for your RDS for Db2 DB instance:

   - For **Host**, enter the DNS name of the DB instance.
   - For **Port**, enter the port number for the DB instance.
   - For **Database**, enter the name of the database.

   b. In the **Security and credential** section, enter the following information for your RDS for Db2 DB instance:

   - For **Security type**, choose **Encrypted user and password**.
   - For **Username**, enter the name of the database administrator for the DB instance.
   - For **Password**, enter the password of the database administrator for the DB instance.

   c. Choose **Test connection**.

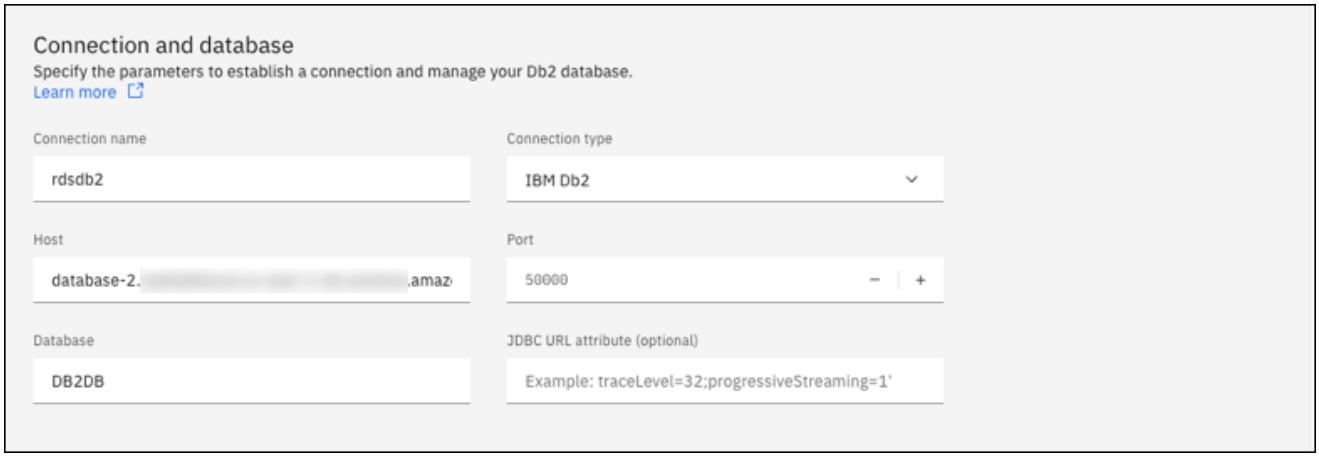


> **Note**
>
> If the connection is unsuccessful, confirm that the database port is open through the inbound rules in your security group. For more information, see Considerations for security groups with Amazon RDS for Db2.

If you didn't manually create a buffer pool, a user tablespace, and a system temporary tablespace in RDS for Db2, you might see the following error message:

Make sure that you created a buffer table, a tablespace, and objects for an IBM Db2 Data Management Console repository to monitor your RDS for Db2 DB instance. Or, you can use an Amazon EC2 Db2 DB instance to host an IBM Db2 Data Management Console repository to monitor your RDS for Db2 DB instance. For more information, see Step 1: Creating a repository database to monitor DB instances.

d. After you successfully test your connection, choose **Next**.



If IBM Db2 Data Management Console finds the buffer pool, the user tablespace, and the system temporary tablespace in the RDS for Db2 DB instance, then IBM Db2 Data Management Console automatically configures the repository database. If you use your Db2 instance on your Amazon EC2 instance as the repository database, then IBM Db2 Data Management Console automatically creates the buffer pool and other objects.

3. In the **Set statistics event monitor opt-in** window, choose **Next**.
4. (Optional) Add new connection. If you want to use a different RDS for Db2 DB instance for administration and monitoring, then add a connection to a non-repository RDS for Db2 DB instance.

   a. In the **Connection and database** section, enter the following information for the RDS for Db2 DB instance to use for administration and monitoring:

      - For **Connection name**, enter the Db2 database identifier.
      - For **Host**, enter the DNS name of the DB instance.
      - For **Port**, enter the port number for the DB instance.
      - For **Database**, enter the name of the database.

   b. In the **Security and credential** section, select **Enable monitoring data collection**.

   c. Enter the following information for your RDS for Db2 DB instance:

      - For **Username**, enter the name of the database administrator for the DB instance.
      - For **Password**, enter the password of the database administrator for the DB instance.

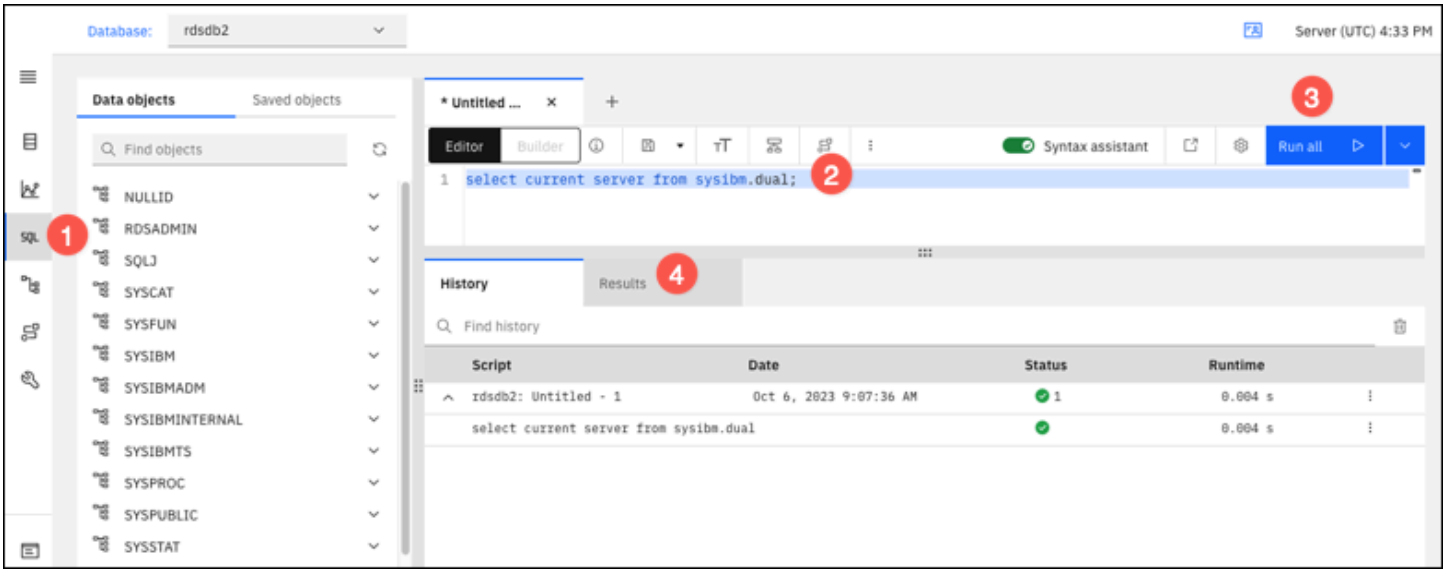
   d. Choose **Test connection**.

   e. After you successfully test your connection, choose **Save**.

After the connection is added, a window similar to the following appears. This window indicates that your database was successfully configured.

5. Choose **Go to Databases**. A Databases window similar to the following appears. This window is a dashboard that shows metrics, statuses, and connections.

You can now start using IBM Db2 Data Management Console.



Using IBM Db2 Data Management Console

You can use IBM Db2 Data Management Console to do the following types of tasks:

- Manage multiple RDS for Db2 DB instances.
- Run SQL commands.
- Explore, create, or change data and database objects.
- Create `EXPLAIN PLAN` statements in SQL.
- Tune queries.

To run SQL commands and view the results

1. In the left navigation bar, choose **SQL**.
2. Enter a SQL command.
3. Choose **Run all**.
4. To view the results, choose the **Results** tab.

Considerations for security groups with Amazon RDS for Db2

For you to connect to your Amazon RDS for Db2 DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your RDS for Db2 DB instance might use the default security group. If you assigned a default nonconfigured security group when you created the RDS for Db2 DB instance, then the firewall prevents internet connections. For information about creating a new security group, see Controlling access with security groups.

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance.

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL/TLS with an Amazon RDS for Db2 DB instance.

Securing Amazon RDS for Db2 DB instance connections

Amazon RDS for Db2 supports ways to improve security for your RDS for Db2 DB instance.

Topics

- Using SSL/TLS with an Amazon RDS for Db2 DB instance
- Using Kerberos authentication for Amazon RDS for Db2

Using SSL/TLS with an Amazon RDS for Db2 DB instance

SSL is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to TLS, but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Amazon RDS for Db2 DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your RDS for Db2 DB instance. SSL/TLS support is available in all AWS Regions for RDS for Db2.

To enable SSL/TLS encryption for an RDS for Db2 DB instance, add the Db2 SSL option to the parameter group associated with the DB instance. Amazon RDS uses a second port, as required by Db2, for SSL/TLS connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and a Db2 client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

Topics

- Creating an SSL/TLS connection
- Connect to your Db2 database server

Creating an SSL/TLS connection

To create an SSL/TLS connection, choose a certificate authority (CA), download a certificate bundle for all AWS Regions, and add parameters to a custom parameter group.

Step 1: Choose a CA and download a certificate

Choose a certificate authority (CA) and download a certificate bundle for all AWS Regions. For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

Step 2: Update parameters in a custom parameter group

> **Important**
>
> If you're using the bring your own license (BYOL) model for RDS for Db2, modify the custom parameter group that you created for your IBM Customer ID and your IBM Site ID. If you're using a different licensing model for RDS for Db2, then follow the procedure to add parameters to a custom parameter group. For more information, see Amazon RDS for Db2 licensing options.

You can't modify default parameter groups for RDS for Db2 DB instances. Therefore, you must create a custom parameter group, modify it, and then attach it to your RDS for Db2 DB instances. For information about parameter groups, see DB parameter groups for Amazon RDS DB instances.

Use the parameter settings in the following table.

Parameter	Value
`DB2COMM`	`TCPIP,SSL` or `SSL`
`SSL_SVCENAME`	`<any port number except the number used for the non-SSL port>`

To update parameters in a custom parameter group

1. Create a custom parameter group by running the create-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values: `db2-se-11-5`, `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Modify the parameters in the custom parameter group that you created by running the modify-db-parameter-group command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.
3. Associate the parameter group with your RDS for Db2 DB instance. For more information, see Associating a DB parameter group with a DB instance in Amazon RDS.

Connect to your Db2 database server

Instructions for connecting to your Db2 database server are language-specific.

Java

To connect to your Db2 database server using Java

1. Download the JDBC driver. For more information, see DB2 JDBC Driver Versions and Downloadsin the IBM Support documentation.
2. Create a shell script file with the following content. This script adds all certificates from the bundle to a Java KeyStore.

   Important

   Verify that `keytool` exists on the path in the script so that the script can locate it. If you use a Db2 client, you can locate the `keytool` under `~sqlib/java/jdk64/jre/bin`.

```
#!/bin/bash
PEM_FILE=$1
PASSWORD=$2
KEYSTORE=$3
```

```
# number of certs in the PEM file
CERTS=$(grep 'END CERTIFICATE' $PEM_FILE| wc -l)
for N in $(seq 0 $(($CERTS - 1))); do
    ALIAS="${PEM_FILE%.*}-$N"
    cat $PEM_FILE |
    awk "n==$N { print }; /END CERTIFICATE/ { n++ }" |
    keytool -noprompt -import -trustcacerts -alias $ALIAS -keystore $KEYSTORE -
storepass $PASSWORD
done
```

3. To run the shell script and import the PEM file with the certificate bundle into a Java KeyStore, run the following command. Replace *shell_file_name.sh* with the name of your shell script file and *password* with the password for your Java KeyStore.

```
./shell_file_name.sh global-bundle.pem password truststore.jks
```

4. To connect to your Db2 server, run the following command. Replace the following placeholders in the example with your RDS for Db2 DB instance information.

   - *ip_address* – The IP address for your DB instance endpoint.
   - *port* – The port number for the SSL connection. This can be any port number except the number that's used for the non-SSL port.
   - *database_name* – The name of your database in your DB instance.
   - *master_username* – The master username for your DB instance.
   - *master_password* – The master password for your DB instance.

```
export trustStorePassword=MyPassword
java -cp ~/dsdriver/jdbc_sqlj_driver/linuxamd64/db2jcc4.jar \
com.ibm.db2.jcc.DB2Jcc -url \
"jdbc:db2://ip_address:port/database_name:\
sslConnection=true;sslTrustStoreLocation=\
~/truststore.jks;\
sslTrustStorePassword=${trustStorePassword};\
sslVersion=TLSv1.2;\
encryptionAlgorithm=2;\
securityMechanism=7;" \
-user master_username -password master_password
```

Node.js

To connect to your Db2 database server using Node.js

1. Install the **node-ibm_db** driver. For more information, see Installing the node-ibm_db driver on Linux and UNIX systems in the IBM Db2 documentation.
2. Create a JavaScript file based on the following content. Replace the following placeholders in the example with your RDS for Db2 DB instance information.

   - *ip_address* – The IP address for your DB instance endpoint.
   - *master_username* – The master username for your DB instance.
   - *master_password* – The master password for your DB instance.
   - *database_name* – The name of your database in your DB instance.
   - *port* – The port number for the SSL connection. This can be any port number except the number that's used for the non-SSL port.

```
var ibmdb = require("ibm_db");
const hostname = "ip_address";
const username = "master_username";
const password = "master_password";
const database = "database_name";
const port = "port";
const certPath = "/root/qa-bundle.pem";
ibmdb.open("DRIVER={DB2};DATABASE=" + database + ";HOSTNAME=" +
 hostname + ";UID=" + username + ";PWD=" + password + ";PORT=" + port +
 ";PROTOCOL=TCPIP;SECURITY=SSL;SSLServerCertificate=" + certPath + ";", function
 (err, conn){
 if (err) return console.log(err);
 conn.close(function () {
 console.log('done');
 });
});
```

3. To run the JavaScript file, run the following command.

```
node ssl-test.js
```

Python

To connect to your Db2 database server using Python

1. Create a Python file with the following content. Replace the following placeholders in the example with your RDS for Db2 DB instance information.

   - *port* – The port number for the SSL connection. This can be any port number except the number that's used for the non-SSL port.
   - *master_username* – The master username for your DB instance.
   - *master_password* – The master password for your DB instance.
   - *database_name* – The name of your database in your DB instance.
   - *ip_address* – The IP address for your DB instance endpoint.

```
import click
import ibm_db
import sys

port = port;
master_user_id = "master_username" # Master id used to create your DB instance
master_password = "master_password" # Master password used to create your DB
 instance
db_name = "database_name" # If not given "db-name'
vpc_customer_private_ip = "ip_address" # Hosts end points - Customer private IP
 Addressicert_path = "/root/ssl/global-bundle.pem" # cert path

@click.command()
@click.option("--path", help="certificate path")
def db2_connect(path):

    try:
        conn =
 ibm_db.connect(f"DATABASE={db_name};HOSTNAME={vpc_customer_private_ip};PORT={port};

 PROTOCOL=TCPIP;UID={master_user_id};PWD={master_password};SECURITY=ssl;SSLServerCertifi
 "", "")
        try:
            ibm_db.exec_immediate(conn, 'create table tablename (a int);')
            print("Query executed successfully")
        except Exception as e:
```

```
            print(e)
        finally:
            ibm_db.close(conn)
            sys.exit(1)
    except Exception as ex:
        print("Trying to connect...")

if __name__ == "__main__":
    db2_connect()
```

2. Create the following shell script, which runs the Python file you created. Replace *python_file_name.py* with the name of your Python script file.

```
#!/bin/bash
PEM_FILE=$1
# number of certs in the PEM file
CERTS=$(grep 'END CERTIFICATE' $PEM_FILE| wc -l)

for N in $(seq 0 $(($CERTS - 1))); do
    ALIAS="${PEM_FILE%.*}-$N"
    cert=`cat $PEM_FILE | awk "n==$N { print }; /END CERTIFICATE/ { n++ }"`
    cat $PEM_FILE | awk "n==$N { print }; /END CERTIFICATE/ { n++ }" >
 $ALIAS.pem
    python3 <python_file_name.py> --path $ALIAS.pem
    output=`echo $?`
    if [ $output == 1 ]; then
        break
    fi
done
```

3. To import the PEM file with the certificate bundle and run the shell script, run the following command. Replace *shell_file_name.sh* with the name of your shell script file.

```
./shell_file_name.sh global-bundle.pem
```

Db2 CLP

To connect to your Db2 database server using Db2 CLP

1. To connect to your Db2 instance using Db2 CLP, you need GSKit, which you can download at IBM Fix Central. To use Db2 CLP, you also need the IBM Db2 client, which you can download from Download initial Version 11.5 clients and drivers in IBM Support.
2. Create a keystore.

```
gsk8capicmd_64 -keydb -create -db "directory/keystore-filename" -pw
 "changeThisPassword" -type pkcs12 -stash
```

3. Import the certificate bundles to the keystore.

```
gsk8capicmd_64 -cert -import -file global-bundle.pem -target directory/keystore-
filename> -target_stashed
```

4. Update the Db2 instance configuration.

```
db2 update dbm cfg using SSL_CLNT_KEYDB keystore-filename
 SSL_CLNT_STASH keystore stash file immediate
```

5. Catalog the node and database.

```
db2 catalog tcpip node ssluse1 REMOTE endpoint SERVER ssl_svcename security ssl

db2 catalog database testdb as ssltest at node ssluse1
```

6. Connect to the database.

```
db2 connect to ssltest user username using password
```

Using Kerberos authentication for Amazon RDS for Db2

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Db2 DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. You add the domain and other information of your AWS Managed Microsoft AD directory to your RDS for Db2 DB instance. When users authenticate with an RDS for Db2 DB instance joined to the trusting domain,

authentication requests are forwarded to the AWS Managed Microsoft AD directory that you created with Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your RDS for Db2 DB instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

For more information, see What is Directory Service? in the *AWS Directory Service Administration Guide*.

For information about Kerberos authentication, see the following topics:

Topics

- Setting up Kerberos authentication for Amazon RDS for Db2 DB instances
- Connecting to Amazon RDS for Db2 with Kerberos authentication

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information about version and Region availability of RDS for Db2 with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

> **Note**
>
> Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Db2 DB instances. For more information, see Amazon RDS for Db2 instance classes.

Overview of Kerberos authentication for RDS for Db2 DB instances

To set up Kerberos authentication for an RDS for Db2 DB instance, complete the following general steps, which are described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS Command Line Interface (AWS CLI), or Directory Service to create the directory. For more information, see Create your AWS Managed Microsoft AD directory in the *AWS Directory Service Administration Guide*.
2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The IAM role allows Amazon RDS to make calls to your directory.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.
3. Create or modify an RDS for Db2 DB instance by using the AWS Management Console, the AWS CLI, or the RDS API with one of the following methods:
   - Create a new RDS for Db2 DB instance using the console, the create-db-instance command, or the CreateDBInstance API operation. For instructions, see Creating an Amazon RDS DB instance.
   - Modify an existing RDS for Db2 DB instance using the console, the modify-db-instance command, or the ModifyDBInstance API operation. For instructions, see Modifying an Amazon RDS DB instance.
   - Restore an RDS for Db2 DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot command, or the RestoreDBInstanceFromDBSnapshot API operation. For instructions, see Restoring to a DB instance.
   - Restore an RDS for Db2 DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time command, or the RestoreDBInstanceToPointInTime API operation. For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

   You can locate the DB instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the RDS for Db2 DB instance, do the following tasks:
   - Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
   - Provide the name of the IAM role that you created.
   - Verify that the DB instance security group can receive inbound traffic from the directory security group.

4. Configure your Db2 client, and verify that traffic can flow between the client host and Directory Service for the following ports:
   - TCP/UDP port 53 – DNS
   - TCP 88 – Kerberos authentication
   - TCP 389 – LDAP
   - TCP 464 – Kerberos authentication

Managing a DB instance in a domain

You can use the AWS Management Console, the AWS CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, running the modify-db-instance CLI command, you can perform the following actions:

- Re-attempt enabling Kerberos authentication for a failed membership by specifying the current membership's directory ID for the `--domain` option.
- Disable Kerberos authentication on a DB instance by specifying `none` for the `--domain` option.
- Move a DB instance from one domain to another by specifying the domain identifier of the new domain for the `--domain` option.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the describe-db-instances command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.

- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before re-issuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If this happens, verify that you are using the correct IAM role, and then modify the DB instance to join the domain.

Setting up Kerberos authentication for Amazon RDS for Db2 DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for an RDS for Db2 DB instance. To set up Kerberos authentication, follow these steps:

Topics

- Step 1: Create a directory using AWS Managed Microsoft AD
- Step 2: Create a trust
- Step 3: Create an IAM role for Amazon RDS to access Directory Service
- Step 4: Create and configure users
- Step 5: Create an RDS for Db2 admin group in AWS Managed Microsoft AD
- Step 6: Modify DB parameter
- Step 7: Create or modify an RDS for Db2 DB instance
- Step 8: Retrieve the Active Directory group SID in PowerShell
- Step 9: Add SID to GroupName mappings to your RDS for Db2 DB instance

- Step 10: Configure a Db2 client

Step 1: Create a directory using AWS Managed Microsoft AD

Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the username `Admin` and the specified password. You use this account to manage your directory.

  > **Important**
  >
  > Make sure to save this password. Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the RDS for Db2 DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an organizational unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `Admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU.
- Create additional OUs and containers.
- Delegate authority.

- Restore deleted objects from the Active Directory Recycle Bin.
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Directory Service.

The `Admin` account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders).
- View DNS event logs.
- View security event logs.

To create a directory with AWS Managed Microsoft AD

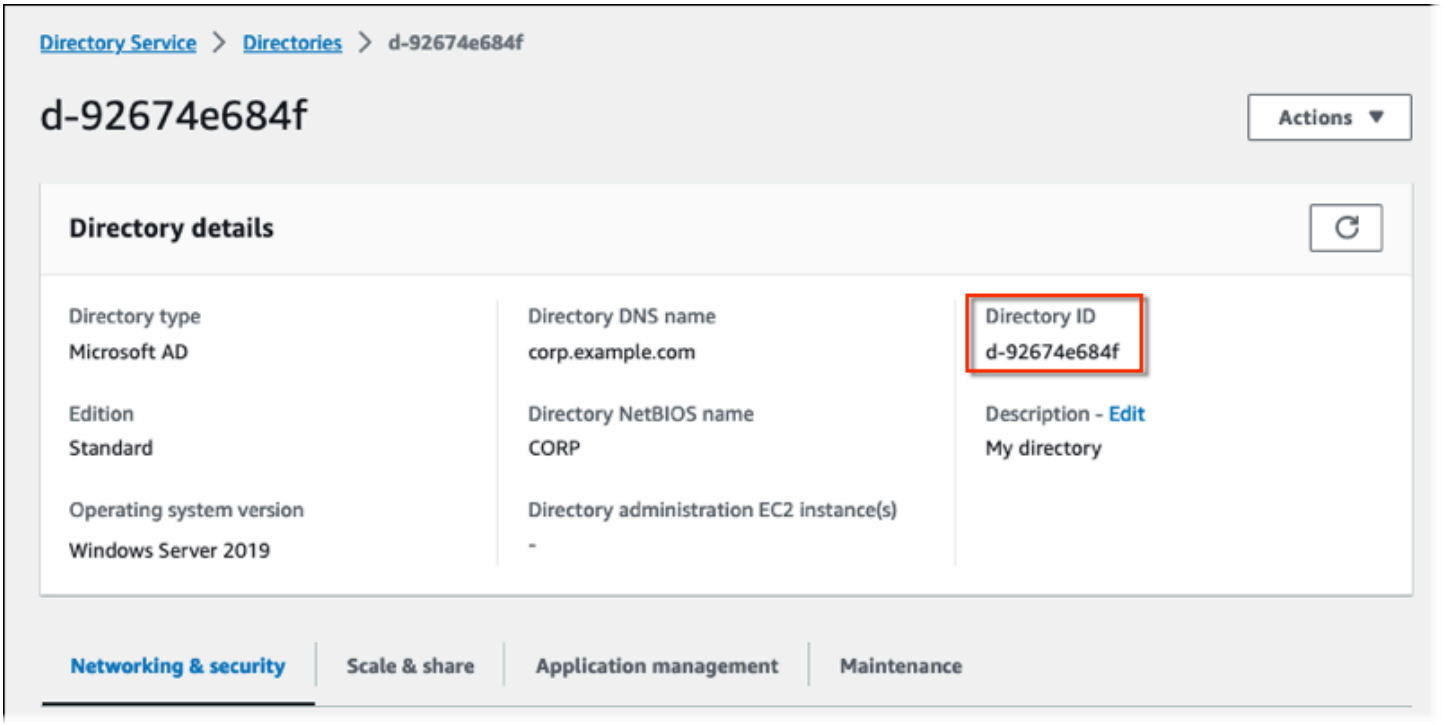
1. Sign in to the AWS Management Console and open the Directory Service console at https://console.aws.amazon.com/directoryservicev2/.
2. Choose **Set up directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
4. Choose **Next**.
5. On the **Enter directory information** page, provide the following information:

   - **Edition** – Choose the edition that meets your requirements.
   - **Directory DNS name** – The fully qualified name for the directory, such as `corp.example.com`.
   - **Directory NetBIOS name** – An optional short name for the directory, such as `CORP`.
   - **Directory description** – An optional description for the directory.
   - **Admin password** – The password for the directory administrator. The directory creation process creates an administrator account with the username `Admin` and this password.

     The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

     - Lowercase letters (a–z)
     - Uppercase letters (A–Z)
     - Numbers (0–9)

- Nonalphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)
- Confirm password – Retype the administrator password.



> **Important**
>
> Make sure that you save this password. Directory Service doesn't store this password, and it can't be retrieved or reset.

6. Choose **Next**.
7. On the **Choose VPC and subnets** page, provide the following information:
   - **VPC** – Choose the VPC for the directory. You can create the RDS for Db2 DB instance in this same VPC or in a different VPC.
   - **Subnets** – Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.
8. Choose **Next**.
9. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID under **Directory ID**. Make a note of the **Directory ID** value. You need this value when you create or modify your RDS for Db2 DB instance.

Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, skip to Step 3: Create an IAM role for Amazon RDS to access Directory Service.

To enable Kerberos authentication using your self-managed Active Directory, you must create a forest trust relationship between your self-managed Active Directory and the . A forest trust is a trust relationship between a Microsoft AD and a self-managed Active Directory and the AWS Managed Microsoft AD created in the previous step. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up forest trusts using Directory Service, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

Step 3: Create an IAM role for Amazon RDS to access Directory Service

For Amazon RDS to call Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you

must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Db2.

As an alternative to using the `AmazonRDSDirectoryServiceAccess` managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers, that are part of the domain and whose identities are being maintained in the directory.

To create users in an Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the Directory Service directory. At the same time, you must be signed in as a user that has privileges to create users. For more information, see Create a user in the *AWS Directory Service Administration Guide*.

Step 5: Create an RDS for Db2 admin group in AWS Managed Microsoft AD

RDS for Db2 doesn't support Kerberos authentication for the master user or the two Amazon RDS reserved users `rdsdb` and `rdsadmin`. Instead, you need to create a new group called `masterdba` in AWS Managed Microsoft AD. For more information, see Create a Group Account in Active Directory in the Microsoft documentation. Any users that you add to this group will have master user privileges.

After you enable Kerberos authentication, the master user loses the `masterdba` role. As a result, the master user won't be able to access the instance local user group membership unless you disable Kerberos authentication. To continue to use the master user with password login, create a user on AWS Managed Microsoft AD with the same name as the master user. Then, add that user to the group `masterdba`.

Step 6: Modify DB parameter

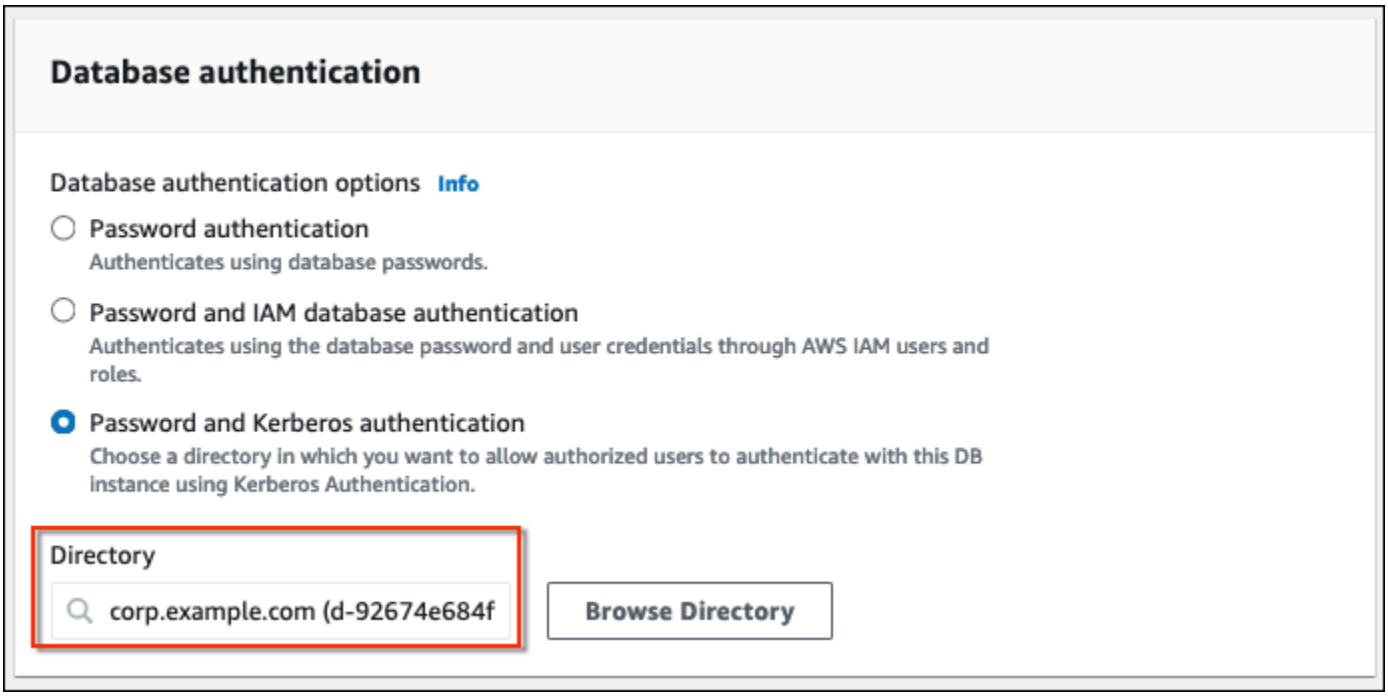
If you plan to use AWS Managed Microsoft AD only, skip to Step 7: Create or modify an RDS for Db2 DB instance.

To enable Kerberos authentication using your self-managed Active Directory, you must set the parameter `rds.active_directory_configuration` to `AWS_MANAGED_AD_WITH_TRUST` in your parameter group. By default, this parameter is set to `AWS_MANAGED_AD` for using AWS Managed Microsoft AD only.

For information about modifying DB parameters, see Modifying the parameters in parameter groups.

Step 7: Create or modify an RDS for Db2 DB instance

Create or modify an RDS for Db2 DB instance for use with your directory. You can use the AWS Management Console, the AWS CLI, or the RDS API to associate a DB instance with a directory. You can do this in one of the following ways:



- Create a new RDS for Db2 DB instance using the console, the create-db-instance command, or the CreateDBInstance API operation. For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing RDS for Db2 DB instance using the console, the modify-db-instance command, or the ModifyDBInstance API operation. For instructions, see Modifying an Amazon RDS DB instance.
- Restore an RDS for Db2 DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot command, or the RestoreDBInstanceFromDBSnapshot API operation. For instructions, see Restoring to a DB instance.
- Restore an RDS for Db2 DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time command, or the RestoreDBInstanceToPointInTime API operation. For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

Kerberos authentication is only supported for RDS for Db2 DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a

security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create directory** to use the Directory Service.

AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("`d-*`" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

The following example modifies a DB instance to use a directory. Replace the following placeholders in the example with your own values:

- *`db_instance_name`* – The name of your RDS for Db2 DB instance.

- *directory_id* – The ID of the AWS Directory Service for Microsoft Active Directory directory that you created.
- *role_name* – The name of the IAM role that you created.

```
aws rds modify-db-instance --db-instance-identifier db_instance_name --domain
 d-directory_id --domain-iam-role-name role_name
```

> **Important**
>
> If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 8: Retrieve the Active Directory group SID in PowerShell

A security ID (SID) uniquely identifies a security principal or security group. When a security group or account is created in Active Directory, Active Directory assigns a SID to the group. To retrieve the AD security group SID from Active Directory, use the `Get-ADGroup` cmdlet in a Windows client machine that is part of the Active Directory domain. The `Identity` parameter specifies the Active Directory group name that you want the SID for.

The following example returns the SID of the Active Directory group `adgroup1`.

```
C:\Users\Admin> Get-ADGroup -Identity adgroup1 | select SID

             SID
-----------------------------------------------
S-1-5-21-3168537779-1985441202-1799118680-1612
```

You must generate this mapping for all the groups that are relevant to the database.

Step 9: Add SID to GroupName mappings to your RDS for Db2 DB instance

You need to add the SID to GroupName mappings created in the previous step to your RDS for Db2 DB instance. For each mapping, call the following stored procedure. Replace the *SID* and *group_name* with your own information.

```
db2 connect to rdsadmin
db2 "call rdsadmin.set_sid_group_mapping(?, 'SID','group_name')"
```

For more information, see rdsadmin.set_sid_group_mapping.

For information about checking the task status, see rdsadmin.get_task_status.

Step 10: Configure a Db2 client

To configure a Db2 client

1. Create an **/etc/krb5.conf** file (or equivalent) to point to the domain.

   > **Note**
   >
   > For Windows operating systems, create a **C:\windows\krb5.ini** file.

2. Verify that traffic can flow between the client host and Directory Service. Use a network utility such as Netcat for the following tasks:

   a. Verify traffic over DNS for port 53.

   b. Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for Directory Service.

3. Verify that traffic can flow between the client host and the DB instance over the database port. You can use the command db2 to connect and access the database.

The following example is /etc/krb5.conf file content for AWS Managed Microsoft AD:

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
kdc = example.com
admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

Connecting to Amazon RDS for Db2 with Kerberos authentication

Use the following procedure to connect to your Amazon RDS for Db2 DB instance with Kerberos authentication.

To connect to RDS for Db2 with Kerberos authentication

1. At a command prompt, run the following command. In the following example, replace *username* with your Microsoft Active Directory username.

```
kinit username
```

2. If the RDS for Db2 DB instance is using a publicly accessible VPC, add the IP address for your DB instance endpoint to your `/etc/hosts` file on the Amazon EC2 client. The following example obtains the IP address and then adds it to the `/etc/hosts` file.

```
% dig +short Db2-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo "34.210.197.118  Db2-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
```

3. Use the following command to log in to an RDS for Db2 DB instance that is associated with Active Directory. Replace *database_name* with the name of your RDS for Db2 database.

```
db2 connect to database_name
```

Administering your Amazon RDS for Db2 DB instance

This topic covers the common management tasks that you perform with an Amazon RDS for Db2 DB instance. Some tasks are the same for all Amazon RDS DB instances. Other tasks are specific to RDS for Db2.

The following tasks are common to all RDS databases. There are also tasks specific to RDS for Db2, such as connecting to an RDS for Db2 database with a standard SQL client.

Task area	Relevant documentation
Instance classes, storage, and PIOPS If you are creating a production instance, learn how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance classes Amazon RDS storage types
Multi-AZ deployments A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	Configuring and managing a Multi-AZ deployment for Amazon RDS
Amazon VPC If your AWS account has a default virtual private cloud (VPC), then your DB instance is automatically created inside the default VPC. If your account doesn't have a default VPC, and you want the DB instance in a VPC, create the VPC and subnet groups before you create the DB instance.	Working with a DB instance in a VPC
Security groups By default, DB instances use a firewall that prevents access. Make sure that you create a security group with the correct IP addresses and network configuration to access the DB instance.	Controlling access with security groups
Parameter groups	Adding IBM IDs to a parameter group for RDS for Db2 DB instances

Task area	Relevant documentation
Because your RDS for Db2 DB instance requires that you add the `rds.ibm_customer_id` and `rds.ibm_site_id` parameters, create a parameter group before you create the DB instance. If your DB instance requires other specific database parameters, also add them to this parameter group before you create the DB instance.	Parameter groups for Amazon RDS
Option groups If your DB instance requires specific database options, create an option group before you create the DB instance.	Options for Amazon RDS for Db2 DB instances
Connecting to your DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance with any standard SQL client application such as IBM Db2 CLP.	Connecting to your Db2 DB instance
Backup and restore You can configure your DB instance to take automated storage backups, or take manual storage snapshots, and then restore instances from the backups or snapshots.	Backing up, restoring, and exporting data
Monitoring You can monitor an RDS for Db2 DB instance with IBM Db2 Data Management Console. You can also monitor an RDS for Db2 DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console Viewing metrics in the Amazon RDS console Viewing Amazon RDS events Monitoring OS metrics with Enhanced Monitoring

Task area	Relevant documentation
Log files You can access the log files for your RDS for Db2 DB instance.	Monitoring Amazon RDS log files

Topics

- Performing common system tasks for Amazon RDS for Db2 DB instances
- Performing common database tasks for Amazon RDS for Db2 DB instances

Performing common system tasks for Amazon RDS for Db2 DB instances

You can perform certain common database administrator tasks related to the system on your Amazon RDS DB instances running Db2. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For information about granting and revoking privileges and attaching to the remote database for RDS for Db2, see the following topics.

Topics

- Granting and revoking privileges for RDS for Db2
- Attaching to the remote RDS for Db2 DB instance

Creating a custom database endpoint

When you migrate to Amazon RDS for Db2, you can use custom database endpoint URLs to minimize changes to your application. For example, if you use `db2.example.com` as your current DNS record, you can add it to Amazon Route 53. In Route 53, you can use private hosted zones to map your current DNS database endpoint to an RDS for Db2 database endpoint. To add a custom `A` or `CNAME` record for an Amazon RDS database endpoint, see Registering and managing domains using Amazon Route 53 in the *Amazon Route 53 Developer Guide*.

> **Note**
>
> If you can't transfer your domain to Route 53, you can use your DNS provider to create a CNAME record for the RDS for Db2 database endpoint URL. Consult your DNS provider documentation.

Granting and revoking privileges for RDS for Db2

Users gain access to databases through membership in groups that are attached to databases.

Use the following procedures to grant and revoke privileges to control access to your database.

These procedures use IBM Db2 CLP running on a local machine to connect to an RDS for Db2 DB instance. Be sure to catalog the TCPIP node and the database to connect to your RDS for Db2 DB instance running on your local machine. For more information, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP.

Topics

- Granting a user access to your database
- Changing a user's password
- Adding groups to a user
- Removing groups from a user
- Removing a user
- Listing users
- Creating a role
- Granting a role
- Revoking a role
- Dropping a role
- Granting database authorization
- Revoking database authorization

Granting a user access to your database

To grant a user access to your database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

   This command produces output similar to the following example:

   ```
   Database Connection Information

   Database server        = DB2/LINUXX8664 11.5.8.0
   SQL authorization ID   = ADMIN
   Local database alias   = RDSADMIN
   ```

2. Add a user to your authorization list by calling `rdsadmin.add_user`. For more information, see rdsadmin.add_user.

   ```
   db2 "call rdsadmin.add_user(
       'username',
       'password',
       'group_name,group_name')"
   ```

3. (Optional) Add additional groups to the user by calling `rdsadmin.add_groups`. For more information, see rdsadmin.add_groups.

   ```
   db2 "call rdsadmin.add_groups(
       'username',
       'group_name,group_name')"
   ```

4. Confirm the authorities that are available to the user. In the following example, replace *`rds_database_alias`*, *`master_user`*, and *`master_password`* with your own information. Also, replace *`username`* with the user's username.

   ```
   db2 terminate
   db2 connect to rds_database_alias user master_user using master_password
   db2 "SELECT SUBSTR(AUTHORITY,1,20) AUTHORITY, D_USER, D_GROUP, D_PUBLIC
   ```

```
      FROM TABLE (SYSPROC.AUTH_LIST_AUTHORITIES_FOR_AUTHID ('username', 'U') ) AS
T
      ORDER BY AUTHORITY"
```

This command produces output similar to the following example:

```
AUTHORITY            D_USER D_GROUP D_PUBLIC
-------------------- ------ ------- --------
ACCESSCTRL           N      N       N
BINDADD              N      N       N
CONNECT              N      N       N
CREATETAB            N      N       N
CREATE_EXTERNAL_ROUT N      N       N
CREATE_NOT_FENCED_RO N      N       N
CREATE_SECURE_OBJECT N      N       N
DATAACCESS           N      N       N
DBADM                N      N       N
EXPLAIN              N      N       N
IMPLICIT_SCHEMA      N      N       N
LOAD                 N      N       N
QUIESCE_CONNECT      N      N       N
SECADM               N      N       N
SQLADM               N      N       N
SYSADM               *      N       *
SYSCTRL              *      N       *
SYSMAINT             *      N       *
SYSMON               *      N       *
WLMADM               N      N       N
```

5. Grant the RDS for Db2 roles ROLE_NULLID_PACKAGES, ROLE_TABLESPACES, and ROLE_PROCEDURES to the group that you added the user to. For more information, see Amazon RDS for Db2 default roles.

> **Note**
>
> We create RDS for Db2 DB instances in RESTRICTIVE mode. Therefore, the RDS for Db2 roles ROLE_NULLID_PACKAGES, ROLE_TABLESPACES, and ROLE_PROCEDURES grant execute privileges on NULLID packages for IBM Db2 CLP and Dynamic SQL. These roles also grant user privileges on tablespaces.

a. Connect to your Db2 database. In the following example, replace *database_name*, *master_user*, and *master_password* with your own information.

```
db2 connect to database_name user master_user using master_password
```

b. Grant the role ROLE_NULLED_PACKAGES to a group. In the following example, replace *group_name* with the name of the group that you want to add the role to.

```
db2 "grant role ROLE_NULLID_PACKAGES to group group_name"
```

c. Grant the role ROLE_TABLESPACES to the same group. In the following example, replace *group_name* with the name of the group that you want to add the role to.

```
db2 "grant role ROLE_TABLESPACES to group group_name"
```

d. Grant the role ROLE_PROCEDURES to the same group. In the following example, replace *group_name* with the name of the group that you want to add the role to.

```
db2 "grant role ROLE_PROCEDURES to group group_name"
```

6. Grant connect, bindadd, createtab, and IMPLICIT_SCHEMA authorities to the group that you added the user to. In the following example, replace *group_name* with the name of the second group that you added the user to.

```
db2 "grant usage on workload SYSDEFAULTUSERWORKLOAD to public"
db2 "grant connect, bindadd, createtab, implicit_schema on database to
 group group_name"
```

7. Repeat steps 4 through 6 for each additional group that you added the user to.

8. Test the user's access by connecting as the user, creating a table, inserting values into the table, and returning data from the table. In the following example, replace *rds_database_alias*, *username*, and *password* with the name of the database and the user's username and password.

```
db2 connect to rds_database_alias user username using password
db2 "create table t1(c1 int not null)"
db2 "insert into t1 values (1),(2),(3),(4)"
db2 "select * from t1"
```

Changing a user's password

To change a user's password

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Change the password by calling `rdsadmin.change_password`. For more information, see rdsadmin.change_password.

```
db2 "call rdsadmin.change_password(
    'username',
    'new_password')"
```

Adding groups to a user

To add groups to a user

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Add groups to a user by calling `rdsadmin.add_groups`. For more information, see rdsadmin.add_groups.

```
db2 "call rdsadmin.add_groups(
    'username',
    'group_name,group_name')"
```

Removing groups from a user

To remove groups from a user

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Remove groups by calling `rdsadmin.remove_groups`. For more information, see rdsadmin.remove_groups.

   ```
   db2 "call rdsadmin.remove_groups(
       'username',
       'group_name,group_name')"
   ```

Removing a user

To remove a user from the authorization list

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Remove a user from your authorization list by calling `rdsadmin.remove_user`. For more information, see rdsadmin.remove_user.

   ```
   db2 "call rdsadmin.remove_user('username')"
   ```

Listing users

To list users on an authorization list, call the `rdsadmin.list_users` stored procedure. For more information, see rdsadmin.list_users.

```
db2 "call rdsadmin.list_users()"
```

Creating a role

You can use the rdsadmin.create_role stored procedure to create a role.

To create a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Set Db2 to output content.

```
db2 set serveroutput on
```

3. Create a role. For more information, see the section called "rdsadmin.create_role".

```
db2 "call rdsadmin.create_role(
    'database_name',
    'role_name')"
```

4. Set Db2 to not output content.

```
db2 set serveroutput off
```

Granting a role

You can use the rdsadmin.grant_role stored procedure to assign a role to a role, user, or group.

To assign a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Set Db2 to output content.

```
db2 set serveroutput on
```

3. Assign a role. For more information, see the section called "rdsadmin.grant_role".

```
db2 "call rdsadmin.grant_role(
    'database_name',
    'role_name',
    'grantee',
    'admin_option')"
```

4. Set Db2 to not output content.

```
db2 set serveroutput off
```

Revoking a role

You can use the rdsadmin.revoke_role stored procedure to revoke a role from a role, user, or group.

To revoke a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Revoke a role. For more information, see the section called “rdsadmin.revoke_role”.

```
db2 "call rdsadmin.revoke_role(
    ?,
    'database_name',
    'role_name',
    'grantee')"
```

Dropping a role

You can use the rdsadmin.drop_role stored procedure to drop a role.

To drop a role

1. Connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Drop a role. For more information, see the section called “rdsadmin.drop_role”.

```
db2 "call rdsadmin.drop_role(
    ?,
    'database_name',
    'role_name')"
```

Granting database authorization

The master user, who has DBADM authorization, can grant DBADM, ACCESSCTRL, or DATAACCESS authorization to a role, user, or group.

To grant database authorization

1. Connect to the rdsadmin database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *master_username* and *master_password* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Grant a user access by calling rdsadmin.dbadm_grant. For more information, see rdsadmin.dbadm_grant.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'database_name,
    'authorization',
    'grantee')"
```

Example use case

The following procedure walks you through creating a role, granting DBADM authorization to the role, assigning the role to a user, and granting the role to a group.

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Create a role called `PROD_ROLE` for a database called `TESTDB`. For more information, see rdsadmin.create_role.

```
db2 "call rdsadmin.create_role(
    'TESTDB',
    'PROD_ROLE')"
```

3. Assign the role to a user called `PROD_USER`. The `PROD_USER` is given admin authorization to assign roles. For more information, see rdsadmin.grant_role.

```
db2 "call rdsadmin.grant_role(
    ?,
    'TESTDB',
    'PROD_ROLE',
    'USER PROD_USER',
    'Y')"
```

4. (Optional) Provide additional authorization or privileges. The following example grants `DBADM` authorization to a role named `PROD_ROLE` for a database called `FUNDPROD`. For more information, see rdsadmin.dbadm_grant.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'FUNDPROD',
    'DBADM',
    'ROLE PROD_ROLE')"
```

5. Terminate your session.

```
db2 terminate
```

6. Connect to the `TESTDB` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to TESTDB user master_username using master_password
```

7. Add more authorizations to the role.

```
db2 "grant connect, implicit_schema on database to role PROD_ROLE"
```

8. Grant the role PROD_ROLE to a group.

```
db2 "grant role PROD_ROLE to group PRODGRP"
```

Users who belong to the group PRODGRP can now perform actions such as connecting to the TESTDB database, creating tables, or creating schemas.

Revoking database authorization

The master user, who has DBADM authorization, can revoke DBADM, ACCESSCTRL, or DATAACCESS authorization from a role, user, or group.

To revoke database authorization

1. Connect to the rdsadmin database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *master_username* and *master_password* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Revoke user access by calling rdsadmin.dbadm_revoke. For more information, see rdsadmin.dbadm_revoke.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'database_name,
    'authorization',
    'grantee')"
```

Attaching to the remote RDS for Db2 DB instance

Use the following steps to attach to your remote RDS for Db2 DB instance and run `get snapshot` operations.

To attach to the remote RDS for Db2 DB instance

1. Run a client-side IBM Db2 CLP session. For information about cataloging your RDS for Db2 DB instance and database, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 CLP. Make a note of the master username and master password for your RDS for Db2 DB instance.
2. Attach to the RDS for Db2 DB instance. In the following example, replace *node_name*, *master_username*, and *master_password* with the TCPIP node name that you catalogued and the master username and master password for your RDS for Db2 DB instance.

```
db2 attach to node_name user master_username using master_password
```

After attaching to the remote RDS for Db2 DB instance, you can run the following commands and other `get snapshot` commands. For more information, see GET SNAPSHOT command in the IBM Db2 documentation.

```
db2 list applications
db2 get snapshot for all databases
db2 get snapshot for database manager
db2 get snapshot for all applications
```

Performing common database tasks for Amazon RDS for Db2 DB instances

You can perform certain common DBA tasks related to databases on your Amazon RDS for Db2 DB instances. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, the master user can't run commands or utilities requiring SYSADM, SYSMAINT, or SYSCTRL authorities.

For information about common tasks for buffer pools, databases, and tablespaces, see the following topics.

Topics

- Common tasks for buffer pools
- Common tasks for databases
- Common tasks for tablespaces

Common tasks for buffer pools

You can create, alter, or drop buffer pools for an RDS for Db2 database. Creating, altering, or dropping buffer pools requires higher-level SYSADM or SYSCTRL authority, which isn't available to the master user. Instead, use Amazon RDS stored procedures.

You can also flush buffer pools.

Topics

- Creating a buffer pool
- Altering a buffer pool
- Dropping a buffer pool
- Flushing the buffer pools

Creating a buffer pool

To create a buffer pool for your RDS for Db2 database, call the `rdsadmin.create_bufferpool` stored procedure. For more information, see CREATE BUFFERPOOL statement in the IBM Db2 documentation.

To create a buffer pool

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Create a buffer pool by calling `rdsadmin.create_bufferpool`. For more information, see rdsadmin.create_bufferpool.

   ```
   db2 "call rdsadmin.create_bufferpool(
   ```

```
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    page_size,
    number_block_pages,
    block_size)"
```

Altering a buffer pool

To alter a buffer pool for your RDS for Db2 database, call the `rdsadmin.alter_bufferpool` stored procedure. For more information, see ALTER BUFFERPOOL statement in the IBM Db2 documentation.

To alter a buffer pool

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Alter a buffer pool by calling `rdsadmin.alter_bufferpool`. For more information, see rdsadmin.alter_bufferpool.

   ```
   db2 "call rdsadmin.alter_bufferpool(
       'database_name',
       'buffer_pool_name',
       buffer_pool_size,
       'immediate',
       'automatic',
       change_number_blocks,
       number_block_pages,
       block_size)"
   ```

Dropping a buffer pool

To drop a buffer pool for your RDS for Db2 database, call the `rdsadmin.drop_bufferpool` stored procedure. For more information, see Dropping buffer pools in the IBM Db2 documentation.

Important

Make sure that no tablespaces are assigned to the buffer pool that you want to drop.

To drop a buffer pool

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Drop a buffer pool by calling `rdsadmin.drop_bufferpool`. For more information, see rdsadmin.drop_bufferpool.

```
db2 "call rdsadmin.drop_bufferpool(
    'database_name',
    'buffer_pool_name')"
```

Flushing the buffer pools

You can flush the buffer pools to force a checkpoint so that RDS for Db2 writes pages from memory to storage.

Note

You don't need to flush the buffer pools. Db2 writes logs synchronously before it commits transactions. The dirty pages might still be in a buffer pool, but Db2 writes them to storage asynchronously. Even if the system shuts down unexpectedly, when you restart the database, Db2 automatically performs crash recovery. During crash recovery, Db2 writes committed changes to the database or rolls back changes for uncommitted transactions.

To flush the buffer pools

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

2. Flush the buffer pools.

```
db2 flush bufferpools all
```

Common tasks for databases

You can create, drop, or restore databases on your RDS for Db2 DB instance. Creating, dropping, or restoring databases requires higher-level SYSADM authority, which isn't available to the master user. Instead, use Amazon RDS stored procedures.

You can also perform common management tasks such as monitoring, maintenance, and the collection of information about your databases.

Topics

- Creating a database
- Configuring settings for a database
- Modifying database parameters
- Configuring log retention
- Listing log information
- Using fine-grained access control (FGAC)
- Deactivating a database
- Activating a database
- Reactivating a database
- Dropping a database
- Backing up a database
- Copying archive logs to Amazon S3

- Restoring a database
- Listing databases
- Collecting information about databases
- Forcing applications off of databases
- Generating performance reports

Creating a database

To create a database on your RDS for Db2 DB instance, call the `rdsadmin.create_database` stored procedure. For more information, see CREATE DATABASE command in the IBM Db2 documentation.

> **Note**
>
> If you plan on modifying the `db2_compatibility_vector` parameter, modify the parameter before creating a database. For more information, see Setting the db2_compatibility_vector parameter.

To create a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Create a database by calling `rdsadmin.create_database`. For more information, see rdsadmin.create_database.

   ```
   db2 "call rdsadmin.create_database(
       'database_name',
       'database_page_size',
       'database_code_set',
       'database_territory',
       'database_collation',
       'database_autoconfigure_str',
       'database_non-restrictive')"
   ```

3. (Optional) Create additional databases by calling `rdsadmin.create_database` for each database you want to create. Each Db2 DB instance can contain up to 50 databases. For more information, see rdsadmin.create_database.

```
db2 "call rdsadmin.create_database('database_name')"
```

4. (Optional) Confirm that your database was created by using one of the following methods:

   - Call `rdsadmin.list_databases`. For more information, see rdsadmin.list_databases.
   - Run the following SQL command:

```
db2 "select varchar(r.task_type,25) as task_type, r.database_name,
    varchar(r.lifecycle,15) as lifecycle, r.created_at, r.database_name,
    varchar(bson_to_json(task_input_params),256) as input_params,
    varchar(r.task_output,1024) as task_output
    from table(rdsadmin.get_task_status(null,null,'create_database'))
    as r order by created_at desc"
```

Configuring settings for a database

To configure the settings for a database on your RDS for Db2 DB instance, call the `rdsadmin.set_configuration` stored procedure. For example, you could configure the number of buffers or buffer manipulators to create during a restore operation.

To configure settings for a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. (Optional) Check your current configuration settings by calling `rdsadmin.show_configuration`. For more information, see the section called "rdsadmin.show_configuration".

```
db2 "call rdsadmin.show_configuration('name')"
```

3. Configure the settings for the database by calling `rdsadmin.set_configuration`. For more information, see the section called "rdsadmin.set_configuration".

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

Modifying database parameters

Amazon RDS for Db2 uses three types of parameters: database manager configuration parameters, registry variables, and database configuration parameters. You can update the first two types through parameter groups and the last type through the rdsadmin.update_db_param stored procedure.

> **Note**
>
> You can only modify the values of existing parameters. You can't add new parameters that RDS for Db2 doesn't support.

For more information these parameters and how to modify their values, see the section called "Db2 parameters".

Configuring log retention

To configure how long Amazon RDS retains log files for your RDS for Db2 database, call the `rdsadmin.set_archive_log_retention` stored procedure.

To configure log retention for a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. (Optional) Check your current configuration for log retention by calling `rdsadmin.show_archive_log_retention`. For more information, see the section called "rdsadmin.show_archive_log_retention".

```
db2 "call rdsadmin.show_archive_log_retention(
    ?,
    'database_name')"
```

3. Configure log retention for the database by calling `rdsadmin.set_archive_log_retention`. For more information, see the section called "rdsadmin.set_archive_log_retention".

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'database_name',
    'archive_log_retention_hours')"
```

Listing log information

To list details about archive log files, including such details as total storage size used, call the `rdsadmin.list_archive_log_information` stored procedure.

To list log information for a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Return a list of log file information by calling `rdsadmin.list_archive_log_information`. For more information, see the section called "rdsadmin.list_archive_log_information".

```
db2 "call rdsadmin.list_archive_log_information(
    ?,
    'database_name')"
```

Using fine-grained access control (FGAC)

To use fine-grained access control commands to control access to table data in a database on an RDS for Db2 DB instance, call the `rdsadmin.fgac_command` stored procedure. You might want to

use FGAC to limit access to data based on user roles or data attributes. For example, you could limit access to patient health care data based on the type of data or to certain medical care providers.

To use fine-grained access control to control access to table data in a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Run various fine-grained access control commands by calling `rdsadmin.fgac_command`. For more information, see rdsadmin.fgac_command.

   ```
   db2 "call rdsadmin.fgac_command(
       ?,
       'database_name',
       'fgac_command')"
   ```

Deactivating a database

To deactivate a database on your RDS for Db2 DB instance, call the `rdsadmin.deactivate_database` stored procedure.

By default, Amazon RDS activates a database when you create a database on your RDS for Db2 DB instance. You can deactivate infrequently used databases to conserve memory resources.

To deactivate a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Deactivate a database by calling `rdsadmin.deactivate_database`. For more information, see rdsadmin.deactivate_database.

   ```
   db2 "call rdsadmin.deactivate_database(
       ?,
   ```

```
    'database_name')"
```

Activating a database

To activate a database on a standalone RDS for Db2 DB instance, call the `rdsadmin.activate_database` stored procedure.

By default, Amazon RDS activates a database when you create a database on your RDS for Db2 DB instance. You can deactivate infrequently used databases to conserve memory resources, and then later activate a deactivated database.

To activate a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Activate a database by calling `rdsadmin.activate_database`. For more information, see rdsadmin.activate_database.

   ```
   db2 "call rdsadmin.activate_database(
       ?,
       'database_name')"
   ```

Reactivating a database

To reactivate a database on a replica source RDS for Db2 DB instance, call the `rdsadmin.reactivate_database` stored procedure. After you make changes to database configurations, you might need to reactivate a database on an RDS for Db2 DB instance. To determine if you need to reactivate a database, connect to the database and run `db2 get db cfg show detail`.

You can also call this stored procedure to reactivate a database on a standalone RDS for Db2 DB instance after you make changes to database configurations. Or, you could reactivate a database on a standalone RDS for Db2 DB instance by first calling the `rdsadmin.deactivate_database`

stored procedure and then the `rdsadmin.activate_database` stored procedure. For more information, see Deactivating a database and Activating a database.

To reactivate a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Reactivate a database by calling `rdsadmin.reactivate_database`. For more information, see rdsadmin.reactivate_database.

```
db2 "call rdsadmin.reactivate_database(
    ?,
    'database_name')"
```

Dropping a database

To drop a database from your RDS for Db2 DB instance, call the `rdsadmin.drop_database` stored procedure. For more information, see Dropping databases in the IBM Db2 documentation.

> **Note**
>
> You can drop a database by calling the stored procedure only if certain conditions are met. For more information, see the section called "Usage notes" for `rdsadmin.drop_database`.

To drop a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Drop a database by calling `rdsadmin.drop_database`. For more information, see rdsadmin.drop_database.

```
db2 "call rdsadmin.drop_database('database_name')"
```

Backing up a database

To back up a database in your RDS for Db2 DB instance to Amazon S3, call the `rdsadmin.backup_database` stored procedure. For more information, see BACKUP DATABASE command in the IBM Db2 documentation.

> **Note**
>
> This stored procedure uses the integration with Amazon S3. Make sure that you have configured the integration before proceeding. For more information, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

To back up a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Create a VPC gateway endpoint for S3. If you already have a VPC gateway endpoint for S3, skip to Step 4.

   For an RDS for Db2 DB instance to be able to interact with Amazon S3, you must have a VPC and an Amazon S3 gateway endpoint for private subnets to use. For more information, see Step 1: Create a VPC gateway endpoint for Amazon S3.
3. Confirm the VPC gateway endpoint for S3. For more information, see Step 2: Confirm that your VPC gateway endpoint for Amazon S3 exists.
4. Back up a database by calling `rdsadmin.backup_database`. For more information, see rdsadmin.backup_database.

```
db2 "call rdsadmin.backup_database(
```

```
    ?,
    'database_name',
    's3_bucket_name',
    's3_prefix',
    'backup_type',
    'compression_option',
    'util_impact_priority',
    'num_files',
    'parallelism',
    'num_buffers')"
```

5. Terminate your connection.

```
terminate
```

6. (Optional) Confirm that the backup files were uploaded to your Amazon S3 bucket under *s3_prefix/dbi_resource_id/db_name*. If the files don't appear at *s3_prefix/dbi_resource_id/db_name*, check the status of backing up your database to identify any issues. For more information, see rdsadmin.get_task_status. If you can't resolve any identified issues, contact AWS Support.
7. (Optional) After the backup to Amazon S3 completes, you can restore the backup to an RDS for Db2 DB instance or to another location such as a local server. For information about restoring to an RDS for Db2 DB instance, see Restoring a database.

Copying archive logs to Amazon S3

Db2 archive logs can now be copied from your RDS for Db2 DB instance to Amazon S3. The archive logs combined with native backup created using `rdsadmin.backup_database` can be used to restore and rollforward database to point in time on another RDS for Db2 instance or EC2 database.

Before configuring this feature, use the stored procedure `rdsadmin.backup_database` to set up RDS for Db2 database.

This feature operates at the RDS for Db2 DB instance level, though archive log copying can be enabled or disabled per database.

To configure archive log copying to Amazon S3

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB Instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Setup archive log backup to S3 by calling the section called “rdsadmin.set_configuration”.

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

Example:

```
db2 "call rdsadmin.set_configuration('ARCHIVE_LOG_COPY_TARGET_S3_ARN',
 'arn:aws:s3:::my_rds_db2_backups/archive-log-copy/')"
```

3. Enable archive log copying for a database by calling `rdsadmin.enable_archive_log_copy`. Replace *`database_name`* with your database name.

```
db2 "call rdsadmin.enable_archive_log_copy(?, 'database_name')"
```

4. Similarly,to disable archive log copying for a database, call `rdsadmin.disable_archive_log_copy`.

```
db2 "call rdsadmin.disable_archive_log_copy(?, 'database_name')"
```

5. Confirm the archive log copy status by calling `rdsadmin.list_databases`.

```
db2 "select * from table(rdsadmin.list_databases())"
```

Sample output:

```
DATABASE_NAME   CREATE_TIME                DATABASE_UNIQUE_ID
                         ARCHIVE_LOG_RETENTION_HOURS ARCHIVE_LOG_COPY
 ARCHIVE_LOG_LAST_UPLOAD_FILE ARCHIVE_LOG_LAST_UPLOAD_FILE_TIME
 ARCHIVE_LOG_COPY_STATUS
```

```

```

Restoring a database

To move a database from an Amazon S3 bucket to your RDS for Db2 DB instance, call the `rdsadmin.restore_database` stored procedure. For more information, see RESTORE DATABASE command in the IBM Db2 documentation.

To restore a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. (Optional) Check your current configuration settings to optimize the restore operation by calling `rdsadmin.show_configuration`. For more information, see the section called “rdsadmin.show_configuration”.

   ```
   db2 "call rdsadmin.show_configuration('name')"
   ```

3. Configure the settings to optimize the restore operation by calling `rdsadmin.set_configuration`. Explicitly setting these values can improve the performance when restoring databases with large volumes of data. For more information, see the section called “rdsadmin.set_configuration”.

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

4. Restore the database by calling `rdsadmin.restore_database`. For more information, see the section called "rdsadmin.restore_database".

```
db2 "call rdsadmin.restore_database(
    ?,
    'database_name',
    's3_bucket_name',
    's3_prefix',
    restore_timestamp,
    'backup_type')"
```

5. (Optional) Confirm that your database was restored by calling `rdsadmin.list_databases` and checking that the restored database is listed. For more information, see rdsadmin.list_databases.

6. Bring the database back online and apply additional transaction logs by calling `rdsadmin.rollforward_database`. For more information, see the section called "rdsadmin.rollforward_database".

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'database_name',
    's3_bucket_name',
    s3_prefix,
    'rollforward_to_option',
    'complete_rollforward')"
```

7. (Optional) Check the status of the `rdsadmin.rollforward_database` stored procedure by calling the the section called "rdsadmin.rollforward_status" stored procedure.

8. If you set `complete_rollforward` to `FALSE` in the previous step, then you must finish bringing the database back online by calling `rdsadmin.complete_rollforward`. For more information, see the section called "rdsadmin.complete_rollforward".

```
db2 "call rdsadmin.complete_rollforward(
    ?,
    'database_name')"
```

9. (Optional) Check the status of the `rdsadmin.complete_rollforward` stored procedure by calling the the section called "rdsadmin.rollforward_status" stored procedure.

Listing databases

You can list all of your databases running on Amazon RDS for Db2 by calling the `rdsadmin.list_databases` user-defined function.

To list your databases

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. List your databases by calling `rdsadmin.list_databases`. For more information, see rdsadmin.list_databases.

```
db2 "select * from table(rdsadmin.list_databases())"
```

Collecting information about databases

To collect information about a database on a RDS for Db2 DB instance, call the `rdsadmin.db2pd_command` stored procedure. This information can help with monitoring your databases or troubleshooting issues.

To collect information about a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Collect information about the database by calling `rdsadmin.db2pd_command`. For more information, see rdsadmin.db2pd_command.

```
db2 "call rdsadmin.db2pd_command('db2pd_cmd')"
```

Forcing applications off of databases

To force applications off of a database on your RDS for Db2 DB instance, call the `rdsadmin.force_application` stored procedure. Before you perform maintenance on your databases, force applications off of your databases.

To force applications off of a database

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Force applications off of a database by calling `rdsadmin.force_application`. For more information, see rdsadmin.force_application.

   ```
   db2 "call rdsadmin.force_application(
       ?,
       'applications')"
   ```

Generating performance reports

You can generate performance reports with a procedure or a script. For information about using a procedure, see DBSUMMARY procedure - Generate a summary report of system and application performance metrics in the IBM Db2 documentation.

Db2 includes a `db2mon.sh` file in its `~sqllib/sample/perf` directory. Running the script produces a low-cost, extensive SQL metrics report. To download the `db2mon.sh` file and related script files, see the perf directory in the IBM db2-samples GitHub repository.

To generate performance reports with the script

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 connect to rdsadmin user master_username using master_password
```

2. Create a buffer pool named db2monbp with a page size of 4096 by calling `rdsadmin.create_bufferpool`. For more information, see rdsadmin.create_bufferpool.

```
db2 "call rdsadmin.create_bufferpool('database_name','db2monbp',4096)"
```

3. Create a temporary tablespace named db2montmptbsp that uses the db2monbp buffer pool by calling `rdsadmin.create_tablespace`. For more information, see rdsadmin.create_tablespace.

```
db2 "call rdsadmin.create_tablespace('database_name',\
    'db2montmptbsp','db2monbp',4096,1000,100,'T')"
```

4. Open the db2mon.sh script, and modify the line about connecting to a database.

   a. Remove the following line.

   ```
   db2 -v connect to $dbName
   ```

   b. Replace the line in the previous step with the following line. In the following example, replace *master_username* and *master_password* with the master username and master password for your RDS for Db2 DB instance.

   ```
   db2 -v connect to $dbName user master_username using master_password
   ```

   c. Remove the following lines.

   ```
   db2 -v create bufferpool db2monbp

   db2 -v create user temporary tablespace db2montmptbsp bufferpool db2monbp

   db2 -v drop tablespace db2montmptbsp

   db2 -v drop bufferpool db2monbp
   ```

5. Run the db2mon.sh script to output a report at specified intervals. In the following example, replace *absolute_path* with the complete path to the script file, *rds_database_alias* with the name of your database, and *seconds* with the number of seconds (0 to 3600) between report generation.

```
absolute_path/db2mon.sh rds_database_alias seconds | tee -a db2mon.out
```

Examples

The following example shows that the script file is located in the `perf` directory under the home directory.

```
/home/db2inst1/sqllib/samples/perf/db2mon.sh rds_database_alias seconds | tee -a
 db2mon.out
```

6. Drop the buffer pool and the tablespace that were created for the `db2mon.sh` file. In the following example, replace *master_username* and *master_password* with the master username and master password for your RDS for Db2 DB instance. Replace *database_name* with the name of your database. For more information, see rdsadmin.drop_tablespace and rdsadmin.drop_bufferpool.

```
db2 connect to rdsadmin user master_username using master_password

db2 "call rdsadmin.drop_tablespace('database_name','db2montmptbsp')"

db2 "call rdsadmin.drop_bufferpool('database_name','db2monbp')"
```

Managing storage

Db2 uses automatic storage to manage the physical storage for database objects such as tables, indexes, and temporary files. Instead of manually allocating storage space and keeping track of which storage paths are being used, automatic storage allows the Db2 system to create and manage storage paths as needed. This can simplify administration of Db2 databases and reduce the likelihood of errors due to human mistakes. For more information, see Automatic storage in the IBM Db2 documentation.

With RDS for Db2, you can dynamically increase the storage size with automatic expansion of the logical volumes and the file system. For more information, see Working with storage for Amazon RDS DB instances.

Common tasks for tablespaces

You can create, alter, rename, or drop tablespaces for an RDS for Db2 database. Creating, altering, renaming, or dropping tablespaces requires higher-level SYSADM authority, which isn't available to the master user. Instead, use Amazon RDS stored procedures.

Topics

- Creating a tablespace
- Altering a tablespace
- Renaming a tablespace
- Dropping a tablespace
- Checking the status of a tablespace
- Returning detailed information about tablespaces
- Listing the state and storage group for a tablespace
- Listing the tablespaces of a table
- Listing tablespace containers

Creating a tablespace

To create a tablespace for your RDS for Db2 database, call the `rdsadmin.create_tablespace` stored procedure. For more information, see CREATE TABLESPACE statement in the IBM Db2 documentation.

> **Important**
>
> To create a tablespace, you must have a buffer pool of the same page size to associate with the tablespace. For more information, see Common tasks for buffer pools.

To create a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Create a tablespace by calling `rdsadmin.create_tablespace`. For more information, see rdsadmin.create_tablespace.

```
db2 "call rdsadmin.create_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    tablespace_initial_size,
    tablespace_increase_size,
    'tablespace_type')"
```

Altering a tablespace

To alter a tablespace for your RDS for Db2 database, call the `rdsadmin.alter_tablespace` stored procedure. You can use this stored procedure to change the buffer pool of a tablespace, lower the high water mark, or bring a tablespace online. For more information, see ALTER TABLESPACE statement in the IBM Db2 documentation.

To alter a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

```
db2 "connect to rdsadmin user master_username using master_password"
```

2. Alter a tablespace by calling `rdsadmin.alter_tablespace`. For more information, see rdsadmin.alter_tablespace.

```
db2 "call rdsadmin.alter_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    buffer_pool_size,
    tablespace_increase_size,
    'max_size', 'reduce_max',
    'reduce_stop',
    'reduce_value',
    'lower_high_water',
    'lower_high_water_stop',
```

```
    'switch_online')"
```

Renaming a tablespace

To change the name of a tablespace for your RDS for Db2 database, call the `rdsadmin.rename_tablespace` stored procedure. For more information, see RENAME TABLESPACE statement in the IBM Db2 documentation.

To rename a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Rename a tablespace by calling `rdsadmin.rename_tablespace`. For more information, including restrictions on what you can name a tablespace, see rdsadmin.rename_tablespace.

   ```
   db2 "call rdsadmin.rename_tablespace(
       'database_name',
       'source_tablespace_name',
       'target_tablespace_name')"
   ```

Dropping a tablespace

To drop a tablespace for your RDS for Db2 database, call the `rdsadmin.drop_tablespace` stored procedure. Before you drop a tablespace, first drop any objects in the tablespace such as tables, indexes, or large objects (LOBs). For more information, see Dropping table spaces in the IBM Db2 documentation.

To drop a tablespace

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 "connect to rdsadmin user master_username using master_password"
   ```

2. Drop a tablespace by calling `rdsadmin.drop_tablespace`. For more information, see rdsadmin.drop_tablespace.

```
db2 "call rdsadmin.drop_tablespace(
    'database_name',
    'tablespace_name')"
```

Checking the status of a tablespace

You can check the status of a tablespace by using the `cast` function.

To check the status of a tablespace

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

2. Return a summary output.

   For a summary output:

```
db2 "select cast(tbsp_id as smallint) as tbsp_id,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(tbsp_type as varchar(3)) as tbsp_type,
cast(tbsp_state as varchar(10)) as state,
cast(tbsp_content_type as varchar(8)) as contents from
 table(mon_get_tablespace(null,-1)) order by tbsp_id"
```

Returning detailed information about tablespaces

You can return information about a tablespace for one member or all members by using the `cast` function.

To return detailed information about tablespaces

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

2. Return details about all tablespaces in the database for one member or for all members.

   For one member:

```
db2 "select cast(member as smallint) as member,
cast(tbsp_id as smallint) as tbsp_id,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(tbsp_type as varchar(3)) as tbsp_type,
cast(tbsp_state as varchar(10)) as state,
cast(tbsp_content_type as varchar(8)) as contents,
cast(tbsp_total_pages as integer) as total_pages,
cast(tbsp_used_pages as integer) as used_pages,
cast(tbsp_free_pages as integer) as free_pages,
cast(tbsp_page_top as integer) as page_hwm,
cast(tbsp_page_size as integer) as page_sz,
cast(tbsp_extent_size as smallint) as extent_sz,
cast(tbsp_prefetch_size as smallint) as prefetch_sz,
cast(tbsp_initial_size as integer) as initial_size,
cast(tbsp_increase_size_percent as smallint) as increase_pct,
cast(storage_group_name as varchar(12)) as stogroup from
 table(mon_get_tablespace(null,-1)) order by member, tbsp_id "
```

   For all members:

```
db2 "select cast(member as smallint) as member
cast(tbsp_id as smallint) as tbsp_id,
cast(tbsp_name as varchar(35)) as tbsp_name,
cast(tbsp_type as varchar(3)) as tbsp_type,
cast(tbsp_state as varchar(10)) as state,
cast(tbsp_content_type as varchar(8)) as contents,
cast(tbsp_total_pages as integer) as total_pages,
cast(tbsp_used_pages as integer) as used_pages,
cast(tbsp_free_pages as integer) as free_pages,
cast(tbsp_page_top as integer) as page_hwm,
```

```
cast(tbsp_page_size as integer) as page_sz,
cast(tbsp_extent_size as smallint) as extent_sz,
cast(tbsp_prefetch_size as smallint) as prefetch_sz,
cast(tbsp_initial_size as integer) as initial_size,
cast(tbsp_increase_size_percent as smallint) as increase_pct,
cast(storage_group_name as varchar(12)) as stogroup from
 table(mon_get_tablespace(null,-2)) order by member, tbsp_id "
```

Listing the state and storage group for a tablespace

You can list the state and storage group for a tablespace by running a SQL statement.

To list the state and storage group for a tablespace, run the following SQL statement:

```
db2 "SELECT varchar(tbsp_name, 30) as tbsp_name,
                  varchar(TBSP_STATE, 30) state,
                  tbsp_type,
                  varchar(storage_group_name,30) storage_group
FROM TABLE(MON_GET_TABLESPACE('',-2)) AS t"
```

Listing the tablespaces of a table

You can list the tablespaces for a table by running a SQL statement.

To list the tablespaces of a table, run the following SQL statement. In the following example, replace *SCHEMA_NAME* and *TABLE_NAME* with the names of your schema and table:

```
db2 "SELECT
   VARCHAR(SD.TBSPACE,30) AS DATA_SPACE,
   VARCHAR(SL.TBSPACE,30) AS LONG_SPACE,
   VARCHAR(SI.TBSPACE,30) AS INDEX_SPACE
 FROM
   SYSCAT.DATAPARTITIONS P
   JOIN SYSCAT.TABLESPACES SD ON SD.TBSPACEID = P.TBSPACEID
   LEFT JOIN SYSCAT.TABLESPACES SL ON SL.TBSPACEID = P.LONG_TBSPACEID
   LEFT JOIN SYSCAT.TABLESPACES SI ON SI.TBSPACEID = P.INDEX_TBSPACEID
 WHERE
    TABSCHEMA = 'SCHEMA_NAME'
 AND TABNAME   = 'TABLE_NAME'"
```

Listing tablespace containers

You can list all tablespace containers or specific tablespace containers by using the `cast` command.

To list the tablespace containers for a tablespace

1. Connect to your Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`rds_database_alias`*, *`master_username`*, and *`master_password`* with your own information:

   ```
   db2 connect to rds_database_alias user master_username using master_password
   ```

2. Return a list of all tablespace containers in the database or specific tablespace containers.

   For all tablespace containers:

   ```
   db2 "select cast(member as smallint) as member,
   cast(tbsp_name as varchar(35)) as tbsp_name,
   cast(container_id as smallint) as id,
   cast(container_name as varchar(60)) as container_path, container_type as type from
    table(mon_get_container(null,-2)) order by member,tbsp_id,container_id"
   ```

   For specific tablespace containers:

   ```
   db2 "select cast(member as smallint) as member,
   cast(tbsp_name as varchar(35)) as tbsp_name,
   cast(container_id as smallint) as id,
   cast(container_name as varchar(60)) as container_path, container_type as type from
    table(mon_get_container('TBSP_1',-2)) order by member, tbsp_id,container_id"
   ```

Integrating an Amazon RDS for Db2 DB instance with Amazon S3

You can transfer files between your Amazon RDS for Db2 DB instance and an Amazon Simple Storage Service (Amazon S3) bucket with Amazon RDS stored procedures. For more information, see Amazon RDS for Db2 stored procedure reference.

> **Note**
>
> Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

For RDS for Db2 to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket where your RDS for Db2 resides. If you don't currently have an S3 bucket, create a bucket.

Topics

- Step 1: Create an IAM policy
- Step 2: Create an IAM role and attach your IAM policy
- Step 3: Add your IAM role to your RDS for Db2 DB instance

Step 1: Create an IAM policy

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files from your Amazon S3 bucket to your RDS DB instance. This step assumes that you have already created an S3 bucket. For more information, see Creating a bucket in the *Amazon S3 User Guide*.

Before you create the policy, note the following pieces of information:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS Key Management Service (AWS KMS) key, if your bucket uses SSE-KMS or SSE-S3 encryption.

The IAM policy that you create should contain the following information. Replace *`{amzn-s3-demo-bucket}`* with the name of your S3 bucket.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3BucketAccess",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt",
                "s3:PutObject",
                "s3:GetObject",
                "s3:AbortMultipartUpload",
                "s3:ListBucket",
                "s3:GetObjectVersion",
                "s3:ListMultipartUploadParts",
                "s3:GetBucketAcl",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::${amzn-s3-demo-bucket}/*",
                "arn:aws:s3:::${amzn-s3-demo-bucket}"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

You can create an IAM policy by using the AWS Management Console or the AWS Command Line Interface (AWS CLI).

Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**, and then choose **JSON**.
4. Add actions by service. To transfer files from an Amazon S3 bucket to Amazon RDS, you must select bucket permissions and object permissions.
5. Expand **Resources**. You must specify your bucket and object resources.
6. Choose **Next**.
7. For **Policy name**, enter a name for this policy.
8. (Optional) For **Description**, enter a description for this policy.
9. Choose **Create policy**.

AWS CLI

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Create a JSON file that contains the following JSON policy document. Replace *{amzn-s3-demo-bucket}* with the name of your S3 bucket.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3BucketAccess",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt",
                "s3:PutObject",
                "s3:GetObject",
                "s3:AbortMultipartUpload",
```

```
                "s3:ListBucket",
                "s3:GetObjectVersion",
                "s3:ListMultipartUploadParts",
                "s3:GetBucketAcl",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::${amzn-s3-demo-bucket}/*",
                "arn:aws:s3:::${amzn-s3-demo-bucket}"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

2. Run the create-policy command. In the following example, replace *iam_policy_name* and *iam_policy_file_name* with a name for your IAM policy and the name of the JSON file you created in Step 1.

   For Linux, macOS, or Unix:

```
aws iam create-policy \
    --policy-name iam_policy_name \
    --policy-document '{
      "Version": "2012-10-17"                    ,
      "Statement": [
        {
          "Effect": "Allow",
          "Action": [
            "kms:GenerateDataKey",
            "kms:Decrypt",
            "s3:PutObject",
            "s3:GetObject",
            "s3:AbortMultipartUpload",
```

```
            "s3:ListBucket",
            "s3:DeleteObject",
            "s3:GetObjectVersion",
            "s3:ListMultipartUploadParts"
          ],
          "Resource": [
            "arn:aws:s3:::s3_bucket_name/*",
            "arn:aws:s3:::s3_bucket_name"
          ]
        }
      ]
    }'
```

For Windows:

```
aws iam create-policy ^
    --policy-name iam_policy_name ^
    --policy-document '{
      "Version": "2012-10-17"                    ,
      "Statement": [
        {
          "Effect": "Allow",
            "Action": [
              "s3:PutObject",
              "s3:GetObject",
              "s3:AbortMultipartUpload",
              "s3:ListBucket",
              "s3:DeleteObject",
              "s3:GetObjectVersion",
              "s3:ListMultipartUploadParts"
            ],
            "Resource": [
              "arn:aws:s3:::s3_bucket_name/*",
              "arn:aws:s3:::s3_bucket_name"
            ]
        }
      ]
    }'
```

3. After the policy is created, note the ARN of the policy. You need the ARN for [Step 2: Create an IAM role and attach your IAM policy].

For information about creating an IAM policy, see Creating IAM policies in the IAM User Guide.

Step 2: Create an IAM role and attach your IAM policy

This step assumes that you have created the IAM policy in Step 1: Create an IAM policy. In this step, you create a IAM role for your RDS for Db2 DB instance and then attach your IAM policy to the role.

You can create an IAM role for your DB instance by using the AWS Management Console or the AWS CLI.

Console

To create an IAM role and attach your IAM policy to it

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **Trusted entity type**, select **AWS service**.
5. For **Service or use case**, select **RDS**, and then select **RDS – Add Role to Database**.
6. Choose **Next**.
7. For **Permissions policies**, search for and select the name of the IAM policy that you created.
8. Choose **Next**.
9. For **Role name**, enter a role name.
10. (Optional) For **Description**, enter a description for the new role.
11. Choose **Create role**.

AWS CLI

To create an IAM role and attach your IAM policy to it

1. Create a JSON file that contains the following JSON policy document:

   JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

2. Run the create-role command. In the following example, replace *iam_role_name* and *iam_assume_role_policy_file_name* with a name for your IAM role and the name of the JSON file that you created in Step 1.

   For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name iam_role_name \
    --assume-role-policy-document '{
      "Version": "2012-10-17"                    ,
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

   For Windows:

```
aws iam create-role ^
    --role-name iam_role_name ^
    --assume-role-policy-document '{
      "Version": "2012-10-17"                    ,
      "Statement": [
        {
```

```
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

3. After the role is created, note the ARN of the role. You need the ARN for Step 3: Add your IAM role to your RDS for Db2 DB instance.
4. Run the attach-role-policy command. In the following example, replace *iam_policy_arn* with the ARN of the IAM policy that you created in Step 1: Create an IAM policy. Replace *iam_role_name* with the name of the IAM role that you just created.

   For Linux, macOS, or Unix:

   ```
   aws iam attach-role-policy \
      --policy-arn iam_policy_arn \
      --role-name iam_role_name
   ```

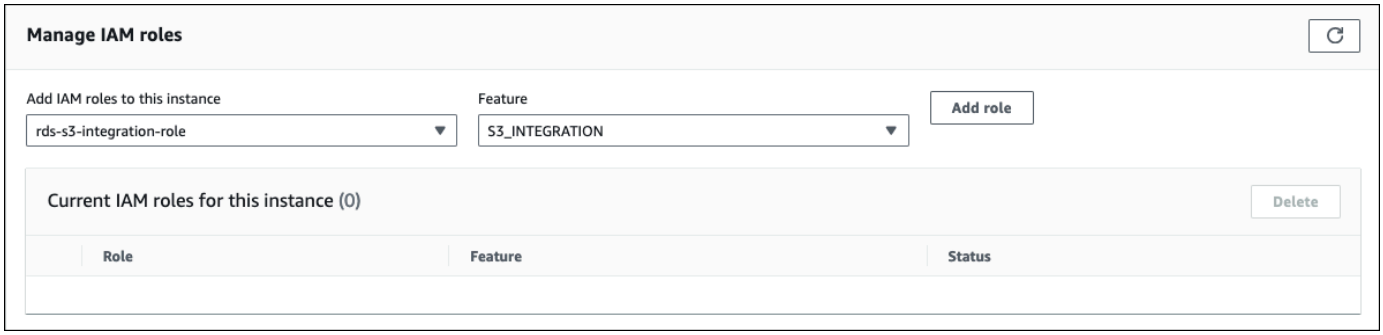
   For Windows:

   ```
   aws iam attach-role-policy ^
      --policy-arn iam_policy_arn ^
      --role-name iam_role_name
   ```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

Step 3: Add your IAM role to your RDS for Db2 DB instance

In this step, you add your IAM role to your RDS for Db2 DB instance. Note the following requirements:



- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Db2 DB instance at a time.
- Your RDS for Db2 DB instance must be in the **Available** state.

You can add an IAM role to your DB instance by using the AWS Management Console or the AWS CLI.

Console

To add an IAM role to your RDS for Db2 DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose your RDS for Db2 DB instance name.
4. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
5. For **Add IAM roles to this instance**, choose the role that you created in Step 2: Create an IAM role and attach your IAM policy.
6. For **Feature**, choose **S3_INTEGRATION**.
7. Choose **Add role**.

AWS CLI

To add an IAM role to your RDS for Db2 DB instance, run the add-role-to-db-instance command. In the following example, replace *region*, *db_instance_name*, and *iam_role_arn* with the name of the AWS Region where your DB instance exists, the name of your DB instance, and the ARN of the IAM role that you created in Step 2: Create an IAM role and attach your IAM policy.

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --region $region \
    --db-instance-identifier $db_instance_name \
```

```
    --feature-name S3_INTEGRATION \
    --role-arn $iam_role_arn \
```

For Windows:

```
aws rds add-role-to-db-instance ^
    --region $region \
    --db-instance-identifier db_instance_name ^
    --feature-name S3_INTEGRATION ^
    --role-arn iam_role_arn ^
```

To confirm that the role was successfully added to your RDS for Db2 DB instance, run the describe-db-instances command. In the following example, replace *db_instance_name* with the name of your DB instance.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
    --filters "Name=db-instance-id,Values=db_instance_name" \
    --query 'DBInstances[].AssociatedRoles'
```

For Windows:

```
aws rds describe-db-instances ^
    --filters "Name=db-instance-id,Values=db_instance_name" ^
    --query 'DBInstances[].AssociatedRoles'
```

This command produces output similar to the following example:

```
[
    [
        {
            "RoleArn": "arn:aws:iam::0123456789012:role/rds-db2-s3-role",
            "FeatureName": "S3_INTEGRATION",
            "Status": "ACTIVE"
        }
    ]
]
```

Migrating data to Amazon RDS for Db2

You can migrate self-managed Db2 databases to Amazon RDS for Db2 by using either AWS or native Db2 tools.

For information about migrating from your Db2 database to Amazon RDS for Db2 using AWS services, see Using AWS services to migrate data from Db2 to Amazon RDS for Db2.

For information about migrating from your Db2 database to Amazon RDS for Db2 using native Db2 tools, see Using native Db2 tools to migrate data from Db2 to Amazon RDS for Db2.

Using AWS services to migrate data from Db2 to Amazon RDS for Db2

In Amazon RDS, there are several ways you can migrate data from a Db2 database to Amazon RDS for Db2. You can perform a one-time migration of your Db2 database from Linux, AIX, or Windows environments to Amazon RDS for Db2. To minimize downtime, you can perform a near-zero downtime migration. You can migrate your data by saving it to Amazon S3 and loading it one table at a time into your Db2 database. You can also perform a synchronous migration through replication or use AWS Database Migration Service.

For one-time migrations for Linux-based Db2 databases, Amazon RDS only supports offline and online backups. Amazon RDS doesn't support incremental and Delta backups. For near-zero downtime migrations for Linux-based Db2 databases, Amazon RDS requires online backups. We recommend that you use online backups for near-zero downtime migrations and offline backups for migrations that can handle downtime.

Topics

- Migrating from Linux to Linux for Amazon RDS for Db2
- Migrating from Linux to Linux with near-zero downtime for Amazon RDS for Db2
- Migrating synchronously from Linux to Linux for Amazon RDS for Db2
- Migrating from AIX or Windows to Linux for Amazon RDS for Db2
- Migrating Db2 data through Amazon S3 to Amazon RDS for Db2
- Migrating to Amazon RDS for Db2 with AWS Database Migration Service (AWS DMS)

Migrating from Linux to Linux for Amazon RDS for Db2

With this migration approach, you back up your self-managed Db2 database to an Amazon S3 bucket. Then, you use Amazon RDS stored procedures to restore your Db2 database to an Amazon

RDS for Db2 DB instance. For more information about using Amazon S3, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

Backup and restore for RDS for Db2 follows the IBM Db2 supported upgrade paths and restrictions. For more information, see Supported upgrade paths for Db2 servers and Upgrade restrictions for Db2 servers in the IBM Db2 documentation.

Topics

- Limitations and recommendations for using native restore
- Backing up your database to Amazon S3
- Creating a default automatic storage group
- Restoring your Db2 database

Limitations and recommendations for using native restore

The following limitations and recommendations apply to using native restore:

- Amazon RDS only supports migrating on-premises versions of Db2 that match supported RDS for Db2 versions. For more information about the supported versions, see Upgrade management for Amazon RDS Db2 instances.
- Amazon RDS only supports offline and online backups for native restore. Amazon RDS doesn't support incremental or Delta backups.
- You can't restore from an Amazon S3 bucket in an AWS Region that is different from the Region where your RDS for Db2 DB instance is located.
- Amazon S3 limits the size of files that are uploaded to an Amazon S3 bucket to 5 TB. If your database backup file exceeds 5 TB, then split the backup file into smaller files.
- Amazon RDS doesn't support non-fenced external routines, incremental restores, or Delta restores.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.

The restoration process differs depending on your configuration.

If you set `USE_STREAMING_RESTORE` to `TRUE`, Amazon RDS directly streams your backup from your S3 bucket during restoration. Streaming significantly reduces storage requirements. You only

need to provision storage space equal to or greater than either the size of the backup or the size of the original database, whichever is larger.

If you set `USE_STREAMING_RESTORE` to `FALSE`, Amazon RDS first downloads the backup to your RDS for Db2 DB instance and then extracts the backup. Extraction requires additional storage space. You must provision storage space equal to or greater than the sum of the size of the backup plus the size of the original database.

The maximum size of the restored database equals the maximum supported database size minus any space required for temporary storage during the restoration process.

Backing up your database to Amazon S3

To back up your database on Amazon S3, you need the following AWS components:

- *An Amazon S3 bucket to store your backup files*: Upload any backup files that you want to migrate to Amazon RDS. We recommend that you use offline backups for migrations that can handle downtime. If you already have an S3 bucket, you can use that bucket. If you don't have an S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.

  > **Note**
  >
  > If your database is large and would take a long time to transfer to an S3 bucket, you can order an AWS Snow Family device and ask AWS to perform the backup. After you copy your files to the device and return it to the Snow Family team, the team transfers your backed-up images to your S3 bucket. For more information, see the AWS Snow Family documentation.

- *An IAM role to access the S3 bucket*: If you already have an IAM role, you can use that role. If you don't have a role, see Step 2: Create an IAM role and attach your IAM policy.
- *An IAM policy with trust relationships and permissions attached to your IAM role*: For more information, see Step 1: Create an IAM policy.
- *The IAM role added to your RDS for Db2 DB instance*: For more information, see Step 3: Add your IAM role to your RDS for Db2 DB instance.

Creating a default automatic storage group

Your source database must have a default automatic storage group. If your database doesn't have a default automatic storage group, you must create one.

To create a default automatic storage group

1. Connect to your source database. In the following example, replace *source_database* with the name of your database.

```
db2 connect to source_database
```

2. Create an automatic storage group and set it as the default. In the following example, replace *storage_path* with the absolute path to where the storage group is located.

```
db2 "create stogroup IBMSTOGROUP ON storage_path set as default"
```

3. Terminate backend processes.

```
db2 terminate
```

4. Deactivate the database and stop all database services. In the following example, replace *source_database* with the name of the database that you created the storage group for.

```
db2 deactivate db source_database
```

5. Back up the database. In the following example, replace *source_database* with the name of the database that you created the storage group for. Replace *file_system_path* with the absolute path to where you want to back up the database.

```
db2 backup database source_database to file_system_path
```

Restoring your Db2 database

After you back up your database on Amazon S3 and create an automatic storage group, you are ready to restore your Db2 database to your RDS for Db2 DB instance.

To restore your Db2 database from your Amazon S3 bucket to your RDS for Db2 DB instance

1. Connect to your RDS for Db2 DB instance. For more information, see Connecting to your Db2 DB instance.
2. (Optional) To ensure that your database is configured with the optimal settings, check the values for the following parameters by calling the section called "rdsadmin.show_configuration":

- RESTORE_DATABASE_NUM_BUFFERS
- RESTORE_DATABASE_PARALLELISM
- RESTORE_DATABASE_NUM_MULTI_PATHS
- USE_STREAMING_RESTORE

Use the section called "rdsadmin.set_configuration" to modify these values as needed. Properly configuring these parameters can significantly improve performance when restoring databases with large volumes of data. For most migration scenarios, we recommend setting USE_STREAMING_RESTORE to TRUE because it reduces storage requirements and can improve restoration speed.

3. Restore your database by calling `rdsadmin.restore_database`. For more information, see rdsadmin.restore_database.

Migrating from Linux to Linux with near-zero downtime for Amazon RDS for Db2

With this migration approach, you migrate a Linux-based Db2 database from one self-managed Db2 database (source) to Amazon RDS for Db2. This approach results in minimal to no outage or downtime for the application or users. This approach backs up your database and restores it with log replay, which helps prevent disruptions to ongoing operations and provides high availability of your database.

To achieve near-zero downtime migration, RDS for Db2 implements restore with log replay. This approach takes a backup of your self-managed Linux-based Db2 database and restores it on the RDS for Db2 server. With Amazon RDS stored procedures, you then apply subsequent transaction logs to bring the database up to date.

Topics

- Limitations and recommendations for near-zero downtime migration
- Backing up your database to Amazon S3
- Creating a default automatic storage group
- Migrating your Db2 database

Limitations and recommendations for near-zero downtime migration

The following limitations and recommendations apply to using near-zero downtime migration:

- Amazon RDS requires an online backup for near-zero downtime migration. This is because Amazon RDS keeps your database in a rollforward pending state as you upload your archived transaction logs. For more information, see the section called “Migrating your Db2 database”.
- You can't restore from an Amazon S3 bucket in an AWS Region that is different from the Region where your RDS for Db2 DB instance is located.
- Amazon S3 limits the size of files uploaded to an S3 bucket to 5 TB. If your database backup file exceeds 5 TB, then split the backup file into smaller files.
- Amazon RDS doesn't support non-fenced external routines, incremental restores, or Delta restores.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.

The restoration process differs depending on your configuration.

If you set `USE_STREAMING_RESTORE` to `TRUE`, Amazon RDS directly streams your backup from your S3 bucket during restoration. Streaming significantly reduces storage requirements. You only need to provision storage space equal to or greater than either the size of the backup or the size of the original database, whichever is larger.

If you set `USE_STREAMING_RESTORE` to `FALSE`, Amazon RDS first downloads the backup to your RDS for Db2 DB instance and then extracts the backup. Extraction requires additional storage space. You must provision storage space equal to or greater than the sum of the size of the backup plus the size of the original database.

The maximum size of the restored database equals the maximum supported database size minus any space required for temporary storage during the restoration process.

Backing up your database to Amazon S3

To back up your database on Amazon S3, you need the following AWS components:

- *An Amazon S3 bucket to store your backup files*: Upload any backup files that you want to migrate to Amazon RDS. Amazon RDS requires an online backup for near-zero downtime migration. If you already have an S3 bucket, you can use that bucket. If you don't have an S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.

> **Note**
>
> If your database is large and would take a long time to transfer to an S3 bucket, you can order an AWS Snow Family device and ask AWS to perform the backup. After you copy your files to the device and return it to the Snow Family team, the team transfers your backed-up images to your S3 bucket. For more information, see the AWS Snow Family documentation.

- *An IAM role to access the S3 bucket*: If you already have an AWS Identity and Access Management (IAM) role, you can use that role. If you don't have a role, see Step 2: Create an IAM role and attach your IAM policy.
- *An IAM policy with trust relationships and permissions attached to your IAM role*: For more information, see Step 1: Create an IAM policy.
- *The IAM role added to your RDS for Db2 DB instance*: For more information, see Step 3: Add your IAM role to your RDS for Db2 DB instance.

Creating a default automatic storage group

Your source database must have a default automatic storage group. If your database doesn't have a default automatic storage group, you must create one.

To create a default automatic storage group

1. Connect to your source database. In the following example, replace *source_database* with the name of your database.

```
db2 connect to source_database
```

2. Create an automatic storage group and set it as the default. In the following example, replace *storage_path* with the absolute path to where the storage group is located.

```
db2 "create stogroup IBMSTOGROUP ON storage_path set as default"
```

3. Terminate backend processes.

```
db2 terminate
```

Migrating your Db2 database

After you set up for near-zero downtime migration, you are ready to migrate your Db2 database from your Amazon S3 bucket to your RDS for Db2 DB instance.

To perform a near-zero downtime migration of backup files from your Amazon S3 bucket to your RDS for Db2 DB instance

1. Perform an online backup of your source database. For more information, see BACKUP DATABASE command in the IBM Db2 documentation.
2. Copy the backup of your database to an Amazon S3 bucket. For information about using Amazon S3, see the Amazon Simple Storage Service User Guide.
3. Connect to the `rdsadmin` server with the *`master_username`* and *`master_password`* for your RDS for Db2 DB instance.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

4. (Optional) To ensure that your database is configured with the optimal settings, check the values for the following parameters by calling the section called "rdsadmin.show_configuration":

   - `RESTORE_DATABASE_NUM_BUFFERS`
   - `RESTORE_DATABASE_PARALLELISM`
   - `RESTORE_DATABASE_NUM_MULTI_PATHS`
   - `USE_STREAMING_RESTORE`

   Use the section called "rdsadmin.set_configuration" to modify these values as needed. Properly configuring these parameters can significantly improve performance when restoring databases with large volumes of data. For most migration scenarios, we recommend setting `USE_STREAMING_RESTORE` to `TRUE` because it reduces storage requirements and can improve restoration speed.
5. Restore the backup on the RDS for Db2 server by calling `rdsadmin.restore_database`. Set `backup_type` to `ONLINE`. For more information, see rdsadmin.restore_database.
6. Copy your archive logs from your source server to your S3 bucket. For more information, see Archive logging in the IBM Db2 documentation.

7. Apply archive logs as many times as needed by calling `rdsadmin.rollforward_database`. Set `complete_rollforward` to `FALSE` to keep the database in a `ROLL-FORWARD PENDING` state. For more information, see rdsadmin.rollforward_database.
8. After you apply all of the archive logs, bring the database online by calling `rdsadmin.complete_rollforward`. For more information, see rdsadmin.complete_rollforward.
9. Switch application connections to the RDS for Db2 server by either updating your application endpoints for the database or by updating the DNS endpoints to redirect traffic to the RDS for Db2 server. You can also use the Db2 automatic client reroute feature on your self-managed Db2 database with the RDS for Db2 database endpoint. For more information, see Automatic client reroute description and setup in the IBM Db2 documentation.
10. (Optional) Shut down your source database.

Migrating synchronously from Linux to Linux for Amazon RDS for Db2

With this migration approach, you set up replication between your self-managed Db2 database and your Amazon RDS for Db2 DB instance. Changes made to the self-managed database replicates to the RDS for Db2 DB instance in near real-time. This approach can provide continuous availability and minimize downtime during the migration process.

Migrating from AIX or Windows to Linux for Amazon RDS for Db2

With this migration approach, you use native Db2 tools to back up your self-managed Db2 database to an Amazon S3 bucket. Native Db2 tools include the `export` utility, the `db2move` system command, or the `db2look` system command. Your Db2 database can either be self-managed or in Amazon Elastic Compute Cloud (Amazon EC2). You can move data from your AIX or Windows system to your Amazon S3 bucket. Then, use a Db2 client to load data directly from the S3 bucket to your Amazon RDS for Db2 database. Downtime depends on the size of your database. For more information about using Amazon S3, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

To migrate your Db2 database to RDS for Db2

1. Prepare to back up your database. Configure sufficient storage amount to hold the backup on your self-managed Db2 system.
2. Back up your database.

a. Run the db2look system command to extract the data definition language (DDL) file for all objects.

b. Run either the Db2 export utility, the db2move system command, or a CREATE EXTERNAL TABLE statement to unload the Db2 table data to storage on your Db2 system.

3. Move your backup to an Amazon S3 bucket. For more information, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

> **Note**
>
> If your database is large and would take a long time to transfer to an S3 bucket, you can order an AWS Snow Family device and ask AWS to perform the backup. After you copy your files to the device and return it to the Snow Family team, the team transfers your backed-up images to your S3 bucket. For more information, see the AWS Snow Family documentation.

4. Use a Db2 client to load data directly from your S3 bucket to your RDS for Db2 database. For more information, see Migrating with Amazon S3.

Migrating Db2 data through Amazon S3 to Amazon RDS for Db2

With this migration approach, you first save data from a single table into a data file that you place in an Amazon S3 bucket. Then, you use the LOAD command to load the data from that data file into a table in your Amazon RDS for Db2 database. For more information about using Amazon S3, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.

Topics

- Saving your data to Amazon S3
- Loading your data into RDS for Db2 tables

Saving your data to Amazon S3

To save data from a single table to Amazon S3, use a database utility to extract the data from your database management system (DBMS) into a CSV file. Then, upload the data file to Amazon S3.

For storing data files on Amazon S3, you need the following AWS components:

- *An Amazon S3 bucket to store your backup files*: If you already have an S3 bucket, you can use that bucket. If you don't have an S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.
- *An IAM role to access the S3 bucket*: If you already have an IAM role, you can use that role. If you don't have a role, see Step 2: Create an IAM role and attach your IAM policy.
- *An IAM policy with trust relationships and permissions attached to your IAM role*: For more information, see Step 1: Create an IAM policy.
- *The IAM role added to your RDS for Db2 DB instance*: For more information, see Step 3: Add your IAM role to your RDS for Db2 DB instance.

Loading your data into RDS for Db2 tables

After you save your data files to Amazon S3, you can load the data from these files into individual tables on your RDS for Db2 DB instance.

To load your Db2 table data into your RDS for Db2 DB database table

1. Connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

2. Catalog a storage access alias that points to the Amazon S3 bucket where your saved files are stored. Take note of the name of this alias for use in the next step. You only need to perform this step once if you plan to load multiple tables from data files stored in the same Amazon S3 bucket.

   The following example catalogs an alias named *`my_s3_alias`* that grants a user named *`jorge_souza`* access to a bucket named *`amzn-s3-demo-bucket`*.

   ```
   db2 "call rdsadmin.catalog_storage_access(?, 'my_s3_alias', 'amzn-s3-demo-bucket',
    'USER', 'jorge_souza')"
   ```

   For more information about this stored procedure, See the section called "rdsadmin.catalog_storage_access".

3. Run the LOAD command using the storage access alias that points to your Amazon S3 bucket.

> **Note**
>
> If the LOAD command returns an error, then you might need to create a VPC gateway endpoint for Amazon S3 and add outbound rules to the security group. For more information, see the section called “File I/O error”.

The following example loads data from a data file named *my_s3_datafile.csv* into a table named *my_db2_table*. The example assumes that the data file is in the Amazon S3 bucket that the alias named *my_s3_alias* points to.

```
db2 "load from db2remote://my_s3_alias//my_s3_datafile.csv of DEL insert
 into my_db2_table";
```

The following example loads LOBs from a data file named *my_table1_export.ixf* into a table named *my_db2_table*. The example assumes that the data file is in the Amazon S3 bucket that the alias named *my_s3_alias* points to.

```
db2 "call sysproc.admin_cmd('load from
 "db2remote://my_s3_alias//my_table1_export.ixf" of ixf
        lobs from "db2remote://my_s3_alias//" xml from "db2remote://my_s3_alias//"
        modified by lobsinfile implicitlyhiddeninclude identityoverride
 generatedoverride periodoverride transactionidoverride
        messages on server
        replace into "my_schema"."my_db2_table"
                              nonrecoverable
        indexing mode incremental allow no access')"
```

Repeat this step for each data file in the Amazon S3 bucket that you want to load into a table in your RDS for Db2 DB instance.

For more information about the LOAD command, see LOAD command.

Migrating to Amazon RDS for Db2 with AWS Database Migration Service (AWS DMS)

You can use AWS DMS for one-time migrations and then synchronize from Db2 on Linux, Unix (such as AIX), and Windows to Amazon RDS for Db2. For more information, see What is AWS Database Migration Service?.

Using native Db2 tools to migrate data from Db2 to Amazon RDS for Db2

You can use several native Db2 tools, utilities, and commands to move data directly from a Db2 database to an Amazon RDS for Db2 database. To use these native Db2 tools, you must be able to connect your client machine to an RDS for Db2 DB instance. For more information, see Connecting a client machine to an Amazon RDS for Db2 DB instance.

> **Note**
>
> Another way to move your data is to first save it to an Amazon S3 bucket, and then use the `LOAD` command to transfer that data into a table in your RDS for Db2 database. This method provides the best performance when migrating a large amount of data because of good network connectivity between RDS for Db2 and S3. For more information, see the section called "Migrating with Amazon S3".

Tool name	Use case	Limitations
db2look	Copying metadata from a self-managed Db2 database to an RDS for Db2 database.	• You must modify the syntax for creating buffer pools, creating tablespaces, and creating roles to match the syntax used by the RDS for Db2 stored procedures.
IMPORT command	Migrating small tables and tables with large objects (LOBs) from a client machine	• Slower than the `LOAD` utility because of `INSERT` and `DELETE` logging operations.

Tool name	Use case	Limitations
	to the RDS for Db2 DB instance.	• Poor performance with limited network bandwidth.
INGEST utility	Continually streaming data from files and pipes *without* large objects (LOBs) on the client machine to the RDS for Db2 DB instance. Supports `INSERT` and `MERGE` operation s.	• Can't stream data files that contain LOBs. Use the `IMPORT` command instead. • Connectivity required between self-managed Db2 database and RDS for Db2 database.
INSERT command	Copying data in small tables from a self-managed Db2 database to an RDS for Db2 database.	• Connectivity required between self-managed Db2 database and RDS for Db2 database. • Poor performance with limited network bandwidth.
LOAD CLIENT command	Migrating small tables *without* large objects (LOBs) from a client machine to the RDS for Db2 DB instance.	• Can't migrate data files that contain LOBs. Use the `IMPORT` command instead. • Poor performance with limited network bandwidth.

Connecting a client machine to an Amazon RDS for Db2 DB instance

To use any of the native Db2 tools to move data from a Db2 database to an Amazon RDS for Db2 database, you must first connect your client machine to an RDS for Db2 DB instance.

The client machine can be any of the following:

- An Amazon Elastic Compute Cloud (Amazon EC2) instance on Linux, Windows, or macOS. This instance should be in the same virtual private cloud (VPC) as your RDS for Db2 DB instance, AWS Cloud9, or AWS CloudShell.

- A self-managed Db2 instance in an Amazon EC2 instance. The instances should be in the same VPC.
- A self-managed Db2 instance in an Amazon EC2 instance. The instances can be in different VPCs if you enabled VPC peering. For more information, see Create a VPC peering connection in the *Amazon Virtual Private Cloud VPC Peering Guide*.
- A local machine running Linux, Windows, or macOS in a self-managed environment. You must either have public connectivity to RDS for Db2 or enable VPN connectivity between self-managed Db2 instances and AWS.

To connect your client machine to your RDS for Db2 DB instance, log in to your client machine with IBM Db2 Data Management Console. For more information, see Creating an Amazon RDS DB instance and IBM Db2 Data Management Console.

You can use AWS Database Migration Service (AWS DMS) to run queries against the database, run an SQL execution plan, and monitor the database. For more information, see What is AWS Database Migration Service? in the *AWS Database Migration Service User Guide*.

After you successfully connect your client machine to your RDS for Db2 DB instance, you are ready to use any native Db2 tool to copy data. For more information, see Using native Db2 tools to migrate data from Db2 to Amazon RDS for Db2.

Copying database metadata from Db2 to Amazon RDS for Db2 with db2look

`db2look` is a native Db2 tool that extracts data definition language (DDL) files, objects, authorizations, configurations, WLM, and database layouts. You can use `db2look` to copy database metadata from a self-managed Db2 database to an Amazon RDS for Db2 database. For more information, see Mimicking databases using db2look in the IBM Db2 documentation.

To copy the database metadata

1. Run the `db2look` tool on your self-managed Db2 system to extract the DDL file. In the following example, replace *`database_name`* with the name of your Db2 database.

   ```
   db2look -d database_name -e -l -a -f -wlm -cor -createdb -printdbcfg -o db2look.sql
   ```

2. If your client machine has access to the source (self-managed Db2) database and the RDS for Db2 DB instance, you can create the `db2look.sql` file on the client machine by directly attaching to the remote instance. Then catalog the remote self-managed Db2 instance.

a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

```
db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
```

b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

```
db2 catalog database source_database_name as source_database_alias at node
 srcnode \
    authentication server_encrypt
```

c. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias that you created in the previous step and the user ID and password for the self-managed Db2 database.

```
db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
    -cor -createdb -printdbcfg -o db2look.sql
```

3. If you can't access the remote self-managed Db2 database from the client machine, copy the `db2look.sql` file to the client machine. Then catalog the RDS for Db2 DB instance.

a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the RDS for Db2 DB instance.

```
db2 catalog tcpip node remnode REMOTE dns_ip_address server port
```

b. Catalog the database. In the following example, replace *rds_database_name* and *rds_database_alias* with the name of the RDS for Db2 database and the alias that you want to use for this database.

```
db2 catalog database rds_database_name as rds_database_alias at node remnode \
    authentication server_encrypt
```

c. Catalog the admin database that manages RDS for Db2. You can't use this database to store any data.

```
db2 catalog database rdsadmin as rdsadmin at node remnode authentication
 server_encrypt
```

4. Create buffer pools and tablespaces. The administrator doesn't have privileges to create buffer pools or tablespaces. However, you can use Amazon RDS stored procedures to create them.

   a. Find the names and definitions of the buffer pools and tablespaces in the `db2look.sql` file.

   b. Connect to Amazon RDS using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

   ```
   db2 connect to rdsadmin user master_username using master_password
   ```

   c. Create a buffer pool by calling `rdsadmin.create_bufferpool`. For more information, see rdsadmin.create_bufferpool.

   ```
   db2 "call rdsadmin.create_bufferpool(
       'database_name',
       'buffer_pool_name',
       buffer_pool_size,
       'immediate',
       'automatic',
       page_size,
       number_block_pages,
       block_size)"
   ```

   d. Create a tablespace by calling `rdsadmin.create_tablespace`. For more information, see rdsadmin.create_tablespace.

   ```
   db2 "call rdsadmin.create_tablespace(
       'database_name',
       'tablespace_name',
       'buffer_pool_name',
       tablespace_initial_size,
       tablespace_increase_size,
       'tablespace_type')"
   ```

   e. Repeat steps c or d for each additional buffer pool or tablespace that you want to add.

   f. Terminate your connection.

```
db2 terminate
```

5. Create tables and objects.

   a. Connect to your RDS for Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_name*, *master_username*, and *master_password* with your own information.

   ```
   db2 connect to rds_database_name user master_username using master_password
   ```

   b. Run the `db2look.sql` file.

   ```
   db2 -tvf db2look.sql
   ```

   c. Terminate your connection.

   ```
   db2 terminate
   ```

Importing data from a client machine to Amazon RDS for Db2 with the IMPORT command

You can use the `IMPORT` command from a client machine to import your data into the Amazon RDS for Db2 server.

> **Important**
>
> The `IMPORT` command method is useful for migrating small tables and tables that include large objects (LOBs). The `IMPORT` command is slower than the `LOAD` utility because of the `INSERT` and `DELETE` logging operations. If your network bandwidth between the client machine and RDS for Db2 is limited, we recommend that you use a different migration approach. For more information, see Using native Db2 tools to migrate data from Db2 to Amazon RDS for Db2.

To import data into the RDS for Db2 server

1. Log in to your client machine with IBM Db2 Data Management Console. For more information, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console.
2. Catalog the RDS for Db2 database on the client machine.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

   ```
   db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
   ```

   b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

   ```
   db2 catalog database source_database_name as source_database_alias at node
    srcnode \
       authentication server_encrypt
   ```

3. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias you created in the previous step and the user ID and password for the self-managed Db2 database.

   ```
   db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
       -cor -createdb -printdbcfg -o db2look.sql
   ```

4. Generate the data file by using the EXPORT command on your self-managed Db2 system. In the following example, replace *directory* with the directory on your client machine where your data file exists. Replace *file_name* and *table_name* with the name of the data file and the name of the table.

   ```
   db2 "export to /directory/file_name.txt of del lobs to /directory/lobs/ \
       modified by coldel\| select * from table_name"
   ```

5. Connect to your RDS for Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username,* and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

6. Use the IMPORT command to import data from a file on the client machine into the remote RDS for Db2 database. For more information, see IMPORT command in the IBM Db2 documentation. In the following example, replace *directory* and *file_name* with the directory on your client machine where your data file exists and the name of the data file. Replace *SCHEMA_NAME* and *TABLE_NAME* with the name of your schema and table.

```
db2 "IMPORT from /directory/file_name.tbl OF DEL LOBS FROM /directory/lobs/ \
    modified by coldel\| replace into SCHEMA_NAME.TABLE_NAME"
```

7. Terminate your connection.

```
db2 terminate
```

Importing data from a client machine to Amazon RDS for Db2 with the LOAD command

You can use the LOAD CLIENT command to load data from a file on a client machine to the RDS for Db2 server. Because no SSH connectivity exists to the RDS for Db2 server, you can use the LOAD CLIENT command on either your self-managed Db2 server or your Db2 client machine.

> **Important**
>
> The LOAD CLIENT command method is useful for migrating small tables. If your network bandwidth between the client and RDS for Db2 is limited, we recommend that you use a different migration approach. For more information, see the Using native Db2 tools to migrate data from Db2 to Amazon RDS for Db2.
>
> If your data file includes references to large object file names, then the LOAD command won't work because large objects (LOBs) need to reside on the Db2 server. If you try to load LOBs from the client machine to the RDS for Db2 server, you will receive an SQL3025N error. Use the IMPORT command instead.

To load data to the RDS for Db2 server

1. Log in to your client machine with IBM Db2 Data Management Console. For more information, see Connecting to your Amazon RDS for Db2 DB instance with IBM Db2 Data Management Console.
2. Catalog the RDS for Db2 database on the client machine.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

   ```
   db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
   ```

   b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

   ```
   db2 catalog database source_database_name as source_database_alias at node
    srcnode \
       authentication server_encrypt
   ```

3. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias you that created in the previous step and the user ID and password for the self-managed Db2 database.

   ```
   db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
       -cor -createdb -printdbcfg -o db2look.sql
   ```

4. Generate the data file by using the EXPORT command on your self-managed Db2 system. In the following example, replace *directory* with the directory on your client machine where your data file exists. Replace *file_name* and *TABLE_NAME* with the name of the data file and the name of the table.

   ```
   db2 "export to /directory/file_name.txt of del modified by coldel\| \
       select * from TPCH.TABLE_NAME"
   ```

5. Connect to your RDS for Db2 database using the master username and master password for your RDS for Db2 DB instance. In the following example, replace *rds_database_alias*, *master_username*, and *master_password* with your own information.

```
db2 connect to rds_database_alias user master_username using master_password
```

6. Use the LOAD command to load data from a file on the client machine to the remote RDS for Db2 database. For more information, see LOAD command in the IBM Db2 documentation. In the following example, replace *directory* with the directory on your client machine where your data file exists. Replace *file_name* and *TABLE_NAME* with the name of the data file and the name of the table.

```
db2 "LOAD CLIENT from /directory/file_name.txt \
    modified by coldel\| replace into TPCH.TABLE_NAME \
    nonrecoverable without prompting"
```

7. Terminate your connection.

```
db2 terminate
```

Importing data from Db2 to Amazon RDS for Db2 with the INSERT command

You can use the INSERT command from a self-managed Db2 server to insert your data into an Amazon RDS for Db2 database. With this migration approach, you use a nickname for the remote RDS for Db2 DB instance. Your self-managed Db2 database (source) must be able to connect to the RDS for Db2 database (target).

> **Important**
>
> The INSERT command method is useful for migrating small tables. If your network bandwidth between your self-managed Db2 database and RDS for Db2 database is limited, we recommend that you use a different migration approach. For more information, see Using native Db2 tools to migrate data from Db2 to Amazon RDS for Db2.

To copy data from a self-managed Db2 database to an RDS for Db2 database

1. Catalog the RDS for Db2 DB instance on the self-managed Db2 instance.

   a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

```
db2 catalog tcpip node remnode REMOTE dns_ip_address SERVER port
```

b. Catalog the database. In the following example, replace *rds_database_name* with the name of the database on your RDS for Db2 DB instance.

```
db2 catalog database rds_database_name as remdb at node remnode \
    authentication server_encrypt
```

2. Enable federation on the self-managed Db2 instance. In the following example, replace *source_database_name* with the name of your database on the self-managed Db2 instance.

```
db2 update dbm cfg using FEDERATED YES source_database_name
```

3. Create tables on the RDS for Db2 DB instance.

a. Catalog the node. In the following example, replace *dns_ip_address* and *port* with the DNS name or the IP address and the port number of the self-managed Db2 database.

```
db2 catalog tcpip node srcnode REMOTE dns_ip_address server port
```

b. Catalog the database. In the following example, replace *source_database_name* and *source_database_alias* with the name of the self-managed Db2 database and the alias that you want to use for this database.

```
db2 catalog database source_database_name as source_database_alias at node
 srcnode \
    authentication server_encrypt
```

4. Attach to the source database. In the following example, replace *source_database_alias*, *user_id*, and *user_password* with the alias that you created in the previous step and the user ID and password for the self-managed Db2 database.

```
db2look -d source_database_alias -i user_id -w user_password -e -l -a -f -wlm \
    -cor -createdb -printdbcfg -o db2look.sql
```

5. Set up federation, and create a nickname for the RDS for Db2 database table on the self-managed Db2 instance.

a. Connect to your local database. In the following example, replace *source_database_name* with the name of the database on your self-managed Db2 instance.

```
db2 connect to source_database_name
```

b. Create a wrapper to access Db2 data sources.

```
db2 create wrapper drda
```

c. Define a data source on a federated database. In the following example, replace *admin* and *admin_password* with your credentials for your self-managed Db2 instance. Replace *rds_database_name* with the name of the database on your RDS for Db2 DB instance.

```
db2 "create server rdsdb2 type DB2/LUW version '11.5.9.0' \
    wrapper drda authorization "admin" password "admin_password" \
    options( dbname 'rds_database_name', node 'remnode')"
```

d. Map the users on the two databases. In the following example, replace *master_username* and *master_password* with your credentials for your RDS for Db2 DB instance.

```
db2 "create user mapping for user server rdsdb2 \
    options (REMOTE_AUTHID 'master_username', REMOTE_PASSWORD
 'master_password')"
```

e. Verify the connection to the RDS for Db2 server.

```
db2 set passthru rdsdb2
```

f. Create a nickname for the table in the remote RDS for Db2 database. In the following example, replace *NICKNAME* and *TABLE_NAME* with a nickname for the table and the name of the table.

```
db2 create nickname REMOTE.NICKNAME for RDSDB2.TABLE_NAME.NICKNAME
```

6. Insert data into the table in the remote RDS for Db2 database. Use the nickname in a `select` statement on the local table in the self-managed Db2 instance. In the following example, replace *NICKNAME* and *TABLE_NAME* with a nickname for the table and the name of the table.

```
db2 "INSERT into REMOTE.NICKNAME select * from RDS2DB2.TABLE_NAME.NICKNAME"
```

Importing data from Db2 to Amazon RDS for Db2 with the INGEST utility

You can use the INGEST utility to continually stream data from files and pipes on a client machine to a target Amazon RDS for Db2 DB instance. The INGEST utility supports INSERT and MERGE operations. For more information, see Ingest utility in the IBM Db2 documentation.

Because the INGEST utility supports nicknames, you can use the utility to transfer data from your self-managed Db2 database to an RDS for Db2 database. This approach works as long as network connectivity exists between the two databases.

> **Important**
>
> The INGEST utility doesn't support large objects (LOBs). Use the IMPORT command instead.

To use the RESTARTABLE feature of the INGEST utility, run the following command on the RDS for Db2 database.

```
db2 "call sysproc.sysinstallobjects('INGEST','C',NULL,NULL)"
```

Amazon RDS for Db2 federation

You can use your Amazon RDS for Db2 database as a federated database. After setting up federation for RDS for Db2, you will be able to access and query data across multiple databases from your RDS for Db2 database. Federation saves you from needing to migrate data to your RDS for Db2 database or consolidate data into a single database.

By using your RDS for Db2 database as a federated database, you can continue to access to all RDS for Db2 features and can take advantage of various AWS services, all while keeping your data in different databases. You can set up both homogeneous federation which connects different databases of the same type, or heterogeneous federation which connects different databases of different types.

You first connect your Db2 database in RDS for Db2 to remote databases. Then you can run queries against all your connected databases. For example, you can run a SQL JOIN statement that joins tables in your RDS for Db2 database with tables in a remote Db2 on z/OS database.

Topics

- Homogeneous federation
- Heterogeneous federation

Homogeneous federation

You can set up homogeneous federation between your RDS for Db2 database and the following Db2 family of products:

- Db2 for Linux, UNIX, Windows (LUW)
- Db2 iSeries
- Db2 for z/OS

RDS for Db2 homogeneous federation doesn't support the following actions:

- Running `CATALOG` commands to set up a node directory and a remote database on an RDS for Db2 host database
- Settting up Workload Balancing (WLB) when federating to Db2 on z/OS
- Configuring the IBM data server driver configuration file (`db2dsdriver.cfg`)

RDS for Db2 homogeneous federation has the following requirements:

- You must create the DRDA wrapper in UNFENCED mode. If you don't, then federation won't work in RDS for Db2.
- You must allow incoming and outgoing traffic from your RDS for Db2 host database to your remote host databases. For more information, see Provide access to your DB instance in your VPC by creating a security group.

Topics

- Step 1: Create a DRDA wrapper and a federated server
- Step 2: Create a user mapping
- Step 3: Check the connection

Step 1: Create a DRDA wrapper and a federated server

For homogeneous federation, create a DRDA wrapper and a federated server. The connection to the remote host uses HOST, PORT, and DBNAME.

Choose one of the following methods based on the type of your remote Db2 database:

- **Db2 for Linux, UNIX, and Windows (LUX) database** – Run the following SQL commands. In the following example, replace *server_name* with the name of the server that you will use for federation. Replace *db2_version* with the version of your remote Db2 database. Replace *username* and *password* with your credentials for the remote Db2 database you want to connect to. Replace *db_name*, *dns_name*, and *port* with the appropriate values for the remote Db2 database you want to connect to.

```
create wrapper drda options(DB2_FENCED 'N');
create server server_name type DB2/LUW wrapper drda version 'db2_version'
 authorization "master_username" password "master_password" options (add DBNAME
 'db_name',add HOST 'dns_name',add PORT 'port');
```

Example

```
create wrapper drda options(DB2_FENCED 'N');
```

```
create server SERVER1 type DB2/LUW wrapper drda version '11.5' authorization
 "sysuser" password "******" options (add DBNAME 'TESTDB2',add HOST
 'ip-123-45-67-899.us-west-1.compute.internal',add PORT '25010');
```

- **Db2 iSeries** – Run the following SQL commands. In the following example, replace *wrapper_name* and *library_name* with a name for your DRDA wrapper and the wrapper library file. Replace *server_name* with the name of the server that you will use for federation. Replace *db2_version* with the version of your remote Db2 database. Replace *username* and *password* with your credentials for the remote Db2 database you want to connect to. Replace *dns_name*, *port*, and *db_name* with the appropriate values for the remote Db2 database you want to connect to.

```
create wrapper wrapper_name library 'library name' options(DB2_FENCED 'N');
create server server_name type db2/mvs version db2_version wrapper wrapper_name
 authorization "sername" password "password" options (HOST 'dns_name', PORT 'port',
 DBNAME 'db_name');
```

Example

```
create wrapper WRAPPER1 library 'libdb2drda.so' options(DB2_FENCED 'N');
create server SERVER1 type db2/mvs version 11 wrapper WRAPPER1 authorization
 "sysuser" password "******" options (HOST 'test1.123.com', PORT '446', DBNAME
 'STLEC1');
```

- **Db2 for z/OS** – Run the following SQL commands. In the following example, replace *wrapper_name* and *library_name* with a name for your DRDA wrapper and the wrapper library file. Replace *server_name* with the name of the server that you will use for federation. Replace *db2_version* with the version of your remote Db2 database. Replace *username* and *password* with your credentials for the remote Db2 database you want to connect to. Replace *dns_name*, *port*, and *db_name* with the appropriate values for the remote Db2 database you want to connect to.

```
create wrapper wrapper_name library 'library_name' options(DB2_FENCED 'N');
create server server_name type db2/mvs version db2_version wrapper wrapper_name
 authorization "username" password "password" options (HOST 'dns_name', PORT 'port',
 DBNAME 'db_name');
```

Example

```
create wrapper WRAPPER1 library 'libdb2drda.so' OPTIONS(DB2_FENCED 'N');
create server SERVER1 type db2/mvs version 11 wrapper WRAPPER1 authorization
 "sysuser" password "******" options (HOST 'test1.123.com', PORT '446', DBNAME
 'STLEC1');
```

Step 2: Create a user mapping

Create a user mapping to associate your federated server with your data source server by running the following SQL command. In the following example, replace *server_name* with the name of the remote server than you want to perform operations on. This is the server that you created in step 1. Replace *username* and *password* with your credentials for this remote server.

```
create user mapping for user server server_name options (REMOTE_AUTHID 'username',
 REMOTE_PASSWORD 'password');
```

For more information, see User mappings in the IBM Db2 documentation.

Step 3: Check the connection

Confirm that setting up your federation was successful by checking the connection. Open a session to send native SQL commands to your remote data source using the SET PASSTHRU command, and then create a table on the remote data server.

1. Open and close a session to submit SQL to a data source. In the following example, replace *server_name* with the name of the server that you created for federation in step 1.

   ```
   set passthru server_name;
   ```

2. Create a new table. In the following example, replace *column_name*, *data_type*, and *value* with the appropriate items for your table.

   ```
   create table table_name
    ( column_name data_type(value), column_name data_type(value);
   ```

   For more information, see CREATE TABLE statement in the IBM Db2 documentation.

3. Create an index, insert values for rows into the table, and reset the connection. Resetting the connection drops the connection but retains the back-end processes. In the following

example, replace *index_name*, *table_name*, *column_name*, and *columnx_value* with your information.

```
create index index_name on table_name(column_name);
insert into table_name values(column1_value,column2_value,column3_value);
insert into table_name values(column1_value,column2_value,column3_value);
set passthru reset;

connect reset;
```

4. Connect to your remote Db2 database, create a nickname for your remote server, and perform operations. When you are done accessing data in the remote Db2 database, reset and then terminate the connection. In the following example, replace *database_name* with the name of your remote Db2 database. Replace *nickname* with a name. Replace *server_name* and *table_name* with the name of the remote server and table on that server that you want to perform operations on. Replace *username* with the information for your remote server. Replace *sql_command* with the operation to perform on the remote server.

```
connect to database_name;
create nickname nickname for server_name."username"."table_name";
select sql_command from nickname;
connect reset;
terminate;
```

Example

The following example creates a pass-through session to allow operations on the federated server `testdb10`.

Next, it creates the table `t1` with three columns with different data types.

Then, the example creates the index `i1_t1` on three columns in table `t1`. Afterwards, it inserts two rows with values for these three columns, and then disconnects.

Last, the example connects to the remote Db2 database `testdb2` and creates a nickname for the table `t1` in the federated server `testdb10`. It creates the nickname with the username TESTUSER for that data source. An SQL command outputs all data from the table `t1`. The example disconnects and ends the session.

```
set passthru testdbl0;
```

```
create table t1 ( c1 decimal(13,0), c2 char(200), c3 int);

create index i1_t1 on t1(c3);
insert into t1 values(1,'Test',1);
insert into t1 values(2,'Test 2',2);
connect reset;

connect to testdb2;
create nickname remote_t1 for testdb10."TESTUSER"."T1";
select * from remote_t1;
connect reset;
terminate;
```

Heterogeneous federation

You can set up heterogeneous federation between your RDS for Db2 database and other data sources such as Oracle and Microsoft SQL Server. For a complete list of data sources that Db2 LUW supports, see Data Source Support Matrix of Federation Bundled in Db2 LUW V11.5 on the IBM Support site.

RDS for Db2 heterogeneous federation doesn't support the following items:

- Native wrappers for the other data sources
- JDBC wrappers for the other data sources
- Federation to Sybase, Informix, and Teradata data sources because these data sources require client software installation on RDS for Db2

RDS for Db2 heterogeneous federation has the following requirements:

- RDS for Db2 only supports the ODBC wrapper method.
- If you create an explicit definition of a wrapper, then you must set the option `DB2_FENCED` to `'N'`. For a list of valid wrapper options for ODBC, see ODBC options in the IBM Db2 documentation.
- You must allow incoming and outgoing traffic from your RDS for Db2 host database to your remote host database. For more information, see Provide access to your DB instance in your VPC by creating a security group.

For information about federation to Oracle, see How to query Oracle by using Db2 Federation and the ODBC driver? on the IBM Support site.

For more information about data sources that support federation, see Data Source Support Matrix of Federation Bundled in Db2 LUW V11.5 on the IBM Support site.

Topics

- Step 1: Create an ODBC wrapper
- Step 2: Create a federated server
- Step 3: Create a user mapping
- Step 4: Check the connection

Step 1: Create an ODBC wrapper

Create a wrapper by running the following command:

```
db2 "create wrapper odbc options( module '/home/rdsdb/sqllib/federation/odbc/lib/
libodbc.so')"
```

Step 2: Create a federated server

Create a federated server by running the following command. In the following example, replace *server_name* with the name of the server that you will use for federation. Replace *wrapper_type* with the appropriate wrapper. Replace *db_version* with the version of your remote database. Replace *dns_name*, *port*, and *service_name* with the appropriate values for the remote database that you want to connect to.

```
db2 "create server server_name type wrapper_type version db_version options (HOST
 'dns_name', PORT 'port', SERVICE_NAME 'service_name')“
```

For information about wrapper types, see Data Source Support Matrix of Federation Bundled in Db2 LUW V11.5 on the IBM Support site.

Example

The following example creates a federated server for a remote Oracle database.

```
db2 "create server server1 type oracle_odbc version 12.1 options (HOST
 'test1.amazon.com', PORT '1521', SERVICE_NAME 'pdborcl.amazon.com')“
```

Step 3: Create a user mapping

Create a user mapping to associate your federated server with your data source server by running the following SQL command. In the following example, replace *server_name* with the name of the remote server than you want to perform operations on. This is the server that you created in step 2. Replace *username* and *password* with your credentials for this remote server.

```
create user mapping for user server server_name options (REMOTE_AUTHID 'username',
 REMOTE_PASSWORD 'password');
```

For more information, see User mappings in the IBM Db2 documentation.

Step 4: Check the connection

Confirm that setting up your federation was successful by checking the connection. Open a session to send native SQL commands to your remote data source using the SET PASSTHRU command, and then create a table on the remote data server.

1. Open and close a session to submit SQL to a data source. In the following example, replace *server_name* with the name of the server that you created for federation in step 2.

   ```
   set passthru server_name;
   ```

2. Create a new table. In the following example, replace *column_name*, *data_type*, and *value* with the appropriate items for your table.

   ```
   create table table_name
    ( column_name data_type(value), column_name data_type(value);
   ```

   For more information, see CREATE TABLE statement in the IBM Db2 documentation.

3. Create an index, insert values for rows into the table, and reset the connection. Resetting the connection drops the connection but retains the back-end processes. In the following example, replace *index_name*, *table_name*, *column_name*, and *columnx_value* with your information.

   ```
   create index index_name on table_name(column_name);
   ```

```
insert into table_name values(column1_value,column2_value,column3_value);
insert into table_name values(column1_value,column2_value,column3_value);
set passthru reset;

connect reset;
```

4. Connect to your remote Db2 database, create a nickname for your remote server, and perform operations. When you are done accessing data in the remote Db2 database, reset and then terminate the connection. In the following example, replace *database_name* with the name of your remote Db2 database. Replace *nickname* with a name. Replace *server_name* and *table_name* with the name of the remote server and table on that server that you want to perform operations on. Replace *username* with the information for your remote server. Replace *sql_command* with the operation to perform on the remote server.

```
connect to database_name;
create nickname nickname for server_name."username"."table_name";
select sql_command from nickname;
connect reset;
terminate;
```

Example

The following example creates a pass-through session to allow operations on the federated server `testdb10`.

Next, it creates the table `t1` with three columns with different data types.

Then, the example creates the index `i1_t1` on three columns in table `t1`. Afterwards, it inserts two rows with values for these three columns, and then disconnects.

Last, the example connects to the remote Db2 database `testdb2` and creates a nickname for the table `t1` in the federated server `testdb10`. It creates the nickname with the username TESTUSER for that data source. An SQL command outputs all data from the table `t1`. The example disconnects and ends the session.

```
set passthru testdbl0;

create table t1 ( c1 decimal(13,0), c2 char(200), c3 int);

create index i1_t1 on t1(c3);
```

```
insert into t1 values(1,'Test',1);
insert into t1 values(2,'Test 2',2);
connect reset;

connect to testdb2;
create nickname remote_t1 for testdbl0."TESTUSER"."T1";
select * from remote_t1;
connect reset;
terminate;
```

Working with replicas for Amazon RDS for Db2

RDS for Db2 supports creating replica databases to provide read scaling and disaster recovery capabilities. You can create replicas in two modes: read-only replicas for offloading read workloads, and standby replicas for cross-region disaster recovery. RDS for Db2 uses IBM Db2 High Availability Disaster Recovery (HADR) technology for replication. For more information, see High availability disaster recovery (HADR) in the IBM Db2 documentation.

A *Db2 replica* database is a physical copy of your primary database. A Db2 replica in read-only mode is called a *read replica*. A Db2 replica in standby mode is called a *standby replica*. Db2 doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted replica has the replicated data to the point when the request was made to promote it. For more information, see Promoting a read replica to be a standalone DB instance.

For a summary of the features and behaviors of RDS for Db2 replicas, see Differences between read replicas for DB engines.

Read-only and standby replicas

When creating or modifying a Db2 replica, you can place it in either of the following modes:

Read-only

This is the default. HADR transmits and applies changes from the source database to all read replica databases. For read-only replicas, the Db2 environment variable `DB2_HADR_ROS` is set to `ON`. The isolation level for read queries on the replica database is `Uncommitted Read`. For more information, see Isolation level on the active standby database in the IBM Db2 documentation.

For general information about read replicas that applies to all DB engines, see Working with DB instance read replicas. For more information about Db2 HADR, see High availability disaster recovery (HADR) in the IBM Db2 documentation.

Standby

For standby replicas, the Db2 environment variable `DB2_HADR_ROS` is set to `OFF` so that the replica databases don't accept user connections. The primary use for standby replicas is cross-Region disaster recovery.

A standby replica can't serve a read-only workload. The standby replica doesn't have any archive logs.

You can create up to three replicas from one source DB instance. You can create a combination of read-only and standby DB replicas for the same source DB instance. After you create a replica, you can change the replica mode. for more information, see Modifying the RDS for Db2 replica mode.

Before creating replicas, make sure that you meet all requirements. For more information, see Requirements and considerations for RDS for Db2 replicas.

Database activations

Db2 HADR is configured at the database level. After you create replicas, HADR is set for all Db2 databases, including `rdsadmin`, which RDS fully manages. Before you create Db2 replicas, you must explicitly activate all databases. Otherwise, creation of replicas fails and Amazon RDS emits an event. After a DB instance has one or more replicas, you can't activate or deactivate any databases on the DB instance by using the `rdsadmin.activate_database` or `rdsadmin.deactivate_database` stored procedures. For more information, see Stored procedures for databases for RDS for Db2.

HADR configurations

You can see all HADR configurations for a database by connecting to the database and then running `db2 get db cfg`.

Archive log retention

Amazon RDS purges logs from a primary DB instance after the following conditions have been met:

- The logs are at least two hours old.
- The setting for archive log retention hours has passed.
- The archive logs were successfully replicated to all replica DB instances. This condition applies both to DB instances in the same AWS Region and to cross-Region DB instances.

For information about setting archive log retention hours, see rdsadmin.set_archive_log_retention.

Amazon RDS checks and cleans up each database individually. If a database loses the HADR connection or if information about the connection isn't available, then Amazon RDS skips the database and doesn't purge the archive logs.

Outages during Db2 replication

When you create a replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. When the DB snapshot operation begins, the source DB instance experiences a very brief I/O suspension. The I/O suspension typically lasts about one second. However, if the source DB instance is a Multi-AZ deployment, then the source DB instance doesn't experience any I/O suspension. This is because with Multi-AZ deployments, the snapshot is taken from the secondary DB instance.

The DB snapshot becomes the Db2 replica. Amazon RDS sets the necessary parameters and permissions for the source database and replica without any service interruption. Similarly, if you delete a replica, no outage occurs.

Requirements and considerations for RDS for Db2 replicas

Db2 replica requirements fall into several categories: licensing and versioning, backup and restore considerations, replication behavior, and general operational considerations. Before creating a Db2 replica, familiarize yourself with the following requirements and considerations.

Version and licensing requirements for RDS for Db2 replicas

Before you create an RDS for Db2 replica, review the following information about versions and licensing models:

- **Supported versions** – All Db2 11.5 versions support replica DB instances.

  Source and replica DB instances must use the same major version. Db2 replicas support minor version upgrades but not major version upgrades. For information about upgrading DB instances, see Upgrading a DB instance engine version.

  > **Note**
  >
  > When upgrading a source DB instance, all replicas are automatically upgraded to maintain version compatibility.

- **Valid licensing models and replica modes** – Both Db2 Advanced Edition (AE) and Standard Edition (SE) can create replicas in read-only or standby mode for both the Bring Your Own License (BYOL) model and the Db2 license through AWS Marketplace model.
- **Custom parameter group** – You must specify a custom parameter group for the replica.

For replicas that use the BYOL model, this custom parameter group must include your IBM Site ID and IBM Customer ID. For more information, see IBM IDs for bring your own license (BYOL) for Db2. You can specify this custom parameter group for the replica by using the AWS Management Console, the AWS CLI , or the RDS API.

- **vCPU count** varies by replica mode and licensing model:
  - **Standby replicas** always use two vCPUs regardless of DB instance size.
    - **BYOL model** – AWS License Manager configurations show that RDS for Db2 DB instances use two vCPUs.
    - **Db2 license through AWS Marketplace model** – Bills reflect license costs for two vCPUs.
  - **Read-only replicas** use the same vCPU count as the DB instance size.
    - **BYOL model** – AWS License Manager configurations show that RDS for Db2 DB instances use the same number of vCPUs that match the DB instance size.
    - **Db2 license through AWS Marketplace model** – Bills reflect license costs for the same number of vCPUs that match the DB instance size.

Backup and restore considerations for RDS for Db2 replicas

Replica backups have different behavior than primary database backups. Consider the following backup and restore requirements:

- To create snapshots of RDS for Db2 replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.
- When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The *database time* refers to the latest applied transaction time of the data in the backup. The difference is significant because a replica can lag behind the primary database for minutes or hours. When there are multiple databases, RDS for Db2 uses the earliest database time.

  To find the difference, run the AWS CLI describe-db-snapshots command or call the RDS API DescribeDBSnapshots operation. Compare the `SnapshotDatabaseTime` value to the `OriginalSnapshotCreateTime` value. The `SnapshotDatabaseTime` value is the database time of the replica backup. The `OriginalSnapshotCreateTime` value is the latest applied transaction on the primary database.

For more information about backups and restoring backups, see Working with RDS for Db2 replica backups.

Replication considerations for RDS for Db2 replicas

Db2 replicas use HADR technology with specific limitations and behaviors. Review the following replication considerations:

- Replication uses Db2 HADR for all databases on the RDS for Db2 DB instance.
- Replication doesn't support the LOAD command. If you run the LOAD command from the source DB instance, you will receive inconsistent data.
- RDS for Db2 doesn't replicate the following items:
  - Storage access. Be aware of data, such as external tables, that rely on storage access.
  - Non-inline LOBs that are not logged.
  - Binaries of external stored procedures (in C or Java).
- For standby replicas, RDS for Db2 replicates the following items:
  - Local users, except master users
  - Database configuration parameters
- For read-only replicas, RDS for Db2 replicates the following items:
  - Local users, except master users
  - SID group mappings

Miscellaneous considerations for RDS for Db2 replicas

Additional operational considerations apply to Db2 replicas. Review the following items:

- RDS for Db2 replicates database configurations to the replicas. When RDS for Db2 promotes a replica, it deactivates and activates each database.
- RDS for Db2 replicates the local users, but not the master user, and SID group mappings to the replicas. You can modify the master user on the replica. For more information, see Modifying an Amazon RDS DB instance.
- All databases must be in an active state. For information about activating databases, see Stored procedures for databases for RDS for Db2.

- All stored procedures for creating, dropping, restoring, or rolling forward databases must be completed before creating a replica. For information about these stored procedures, see Stored procedures for databases for RDS for Db2.
- When the replica is created, Amazon RDS sets the database-level parameter `blocknonlogged` for all databases on the source DB instance to `YES`. When the source replica becomes a standalone instance again, Amazon RDS sets the value back to `NO`. For more information, see blocknonlogged - Block creation of tables that allow non-logged activity configuration parameter in the IBM Db2 documentation.
- When the replica is created, Amazon RDS sets the database-level parameter `logindexbuild` for all databases on the source DB instance to `YES`. When the source replica becomes a standalone instance again, Amazon RDS sets the value back to `NO`. For more information, see logindexbuild - Log index pages created configuration parameter in the IBM Db2 documentation.

Preparing to create an RDS for Db2 replica

Before creating an RDS for Db2 replica, you must complete the following tasks for successful replication. These tasks help prevent common issues and ensure optimal performance.

Task 1: Enable automatic backups

Before a DB instance can serve as a source DB instance, you must enable automatic backups on the source DB instance. This is a prerequisite for all replica creation operations. To learn how to perform this procedure, see Enabling automated backups.

For information about backups specific to Db2 replicas, see Working with RDS for Db2 replica backups.

Task 2: Plan compute and storage resources

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource capacity, the replica stops receiving or applying changes from its source. For information about monitoring replica performance and resource utilization, see Monitoring read replication.

RDS for Db2 doesn't intervene to mitigate high replica lag between a source DB instance and its replicas. If you experience high replica lag, see Monitoring Db2 replication lag for troubleshooting guidance.

You can modify the storage and CPU resources of a replica independently from its source and other replicas. For more information, see Modifying an Amazon RDS DB instance.

Task 3: Prepare databases

Before creating a replica, confirm that your databases are ready based on the following points:

- The DB instance contains all databases that you want present on the DB instance. After replica creation, you can't create, drop, or native restore a database on the DB instance. Any calls to the rdsadmin.create_database, rdsadmin.drop_database, or rdsadmin.restore_database stored procedures fail.
- All databases on the DB instance are in an active state. If any database is in an inactive state, replica creation will fail. For information about activating databases, see Stored procedures for databases for RDS for Db2.

Next steps

After completing all the preparation tasks, you are ready to create a Db2 replica.

- To create a read-only replica, see Creating a read replica.
- To create a standby replica, see Creating a standby Db2 replica.

Creating an RDS for Db2 replica in standby mode

By default, Db2 replicas are created in read-only mode. You can create a replica in standby mode for disaster recovery purposes. Standby replicas don't accept user connections but provide faster failover capabilities for cross-Region scenarios.

Before creating a standby replica, make sure that you have completed the preparation tasks. For more information, see Preparing to create an RDS for Db2 replica. After creating a standby replica, you can change the replica mode. For more information, see Modifying the RDS for Db2 replica mode.

You can create a standby replica using the AWS Management Console, the AWS CLI, or the RDS API. For information about creating a read-only replica, see Creating a read replica.

Console

To create a standby replica from a source RDS for Db2 DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the RDS for Db2 DB instance that you want to use as the source for a standby replica.
4. For **Actions**, choose **Create replica**.
5. For **Replica mode**, choose **Standby**.
6. Choose the settings that you want to use. For **DB instance identifier**, enter a name for the standby replica. Adjust other settings as needed.
7. For **Regions**, choose the AWS Region where the standby replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the standby replica.
9. For **Multi-AZ deployment**, choose **Create a standby instance** to create a standby of your replica in another Availability Zone for failover support for the standby replica.
10. Choose the other settings that you want to use.
11. Choose **Create replica**.

In the **Databases** page, the standby replica has the role **Replica**.

AWS CLI

To create a Db2 replica in standby mode, use the AWS CLI command create-db-instance-read-replica with `--replica-mode` set to `mounted`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier my_standby_replica \
    --source-db-instance-identifier my_db_instance \
    --replica-mode mounted
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier my_standby_replica ^
    --source-db-instance-identifier my_db_instance ^
    --replica-mode mounted
```

RDS API

To create a Db2 replica in standby mode, specify `ReplicaMode=mounted` in the RDS API operation CreateDBInstanceReadReplica.

Modifying the RDS for Db2 replica mode

You can change the replica mode of an existing Db2 replica between read-only and standby modes. This flexibility allows you to adapt your replica configuration based on changing requirements for read workloads or disaster recovery needs.

You might want to change replica modes in the following scenarios:

- **Read-only to standby** – When you no longer need read capacity but want to maintain disaster recovery capabilities
- **Standby to read-only** – When you need to add read capacity for reporting or analytics workloads

Before changing replica modes, make sure the following conditions are met:

- The replica is in an available state.
- No active maintenance operations are running on the replica.
- You have the necessary permissions to modify the DB instance.

The change operation can take a few minutes. During the operation, the DB instance status changes to **modifying**. For more information about status changes, see Viewing Amazon RDSDB instance status. When you change from read-only to standby mode, the replica disconnects all active connections.

> **Important**
>
> Because changing replica modes temporarily interrupts service, plan the change during a maintenance window to minimize impact on your applications.

You can modify the replica mode using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To change the replica mode of a Db2 replica

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the replica database that you want to modify.
4. Choose **Modify**.
5. For **Replica mode**, choose the desired mode:
   - **Read-only** – For read workloads
   - **Standby** – For disaster recovery
6. Choose the other settings that you want to change.
7. Choose **Continue**.
8. For **Scheduling of modifications**, choose **Apply immediately**.
9. Choose **Modify DB instance**.
10. After the modification completes, verify the replica mode change in the **Databases** page. The replica status should show as **Available** when the change is complete.

AWS CLI

To change a Db2 replica from read-only mode to standby mode, set `--replica-mode` to `mounted` in the AWS CLI command modify-db-instance. To change a Db2 replica from standby mode to read-only mode, set `--replica-mode` to `open-read-only`.

The following example changes a replica from read-only to standby mode:

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my_db2_replica \
    --replica-mode mounted
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my_db2_replica ^
    --replica-mode mounted
```

The following example changes a replica from standby to read-only mode:

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my_db2_replica \
    --replica-mode open-read-only
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my_db2_replica ^
    --replica-mode open-read-only
```

RDS API

To change a Db2 replica from read-only mode to standby mode, set `ReplicaMode=mounted` in ModifyDBInstance. To change a Db2 replica from standby mode to read-only mode, set `ReplicaMode=open-read-only`.

The following is an example API call to change the replica mode from read-only to standby:

```
{
    "DBInstanceIdentifier": "my_db2_replica",
    "ReplicaMode": "mounted",
```

```
    "ApplyImmediately": true
}
```

The following is an example API call to change the replica mode from standby to read-only:

```
{
    "DBInstanceIdentifier": "my_db2_replica",
    "ReplicaMode": "open-read-only",
    "ApplyImmediately": true
}
```

For information about the differences between replica modes, see Working with replicas for Amazon RDS for Db2. For troubleshooting replica issues, see Troubleshooting RDS for Db2 replication issues.

Working with RDS for Db2 replica backups

You can create and restore backups of an RDS for Db2 replica just like a primary database. However, there are important differences in how replica backups work, particularly regarding restore timing and backup retention settings.

RDS for Db2 supports both automatic backups and manual snapshots for replicas. RDS for Db2 doesn't support point-in-time restore. For information about RDS backups, see Backing up, restoring, and exporting data.

Key differences for replica backups

Replica backups differ from primary database backups in several important ways:

- Automatic backups aren't enabled by default for replicas.
- Restore operations use database time rather than backup creation time.
- Replica lag can affect the actual data restored. For information about monitoring replica lag, see Monitoring Db2 replication lag.

Enabling automatic backups for RDS for Db2 replicas

Unlike primary databases, RDS for Db2 replicas don't have automated backups enabled by default. You must manually configure the backup retention period to enable automatic backups. Enable automated backups by setting the backup retention period to a positive nonzero value.

Console

To enable automatic backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose a positive nonzero value, for example three days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI modify-db-instance command.

Include the following parameters:

- `--db-instance-identifier`
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

The following example enables automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my_db_instance  \
    --backup-retention-period 3 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my_db_instance  ^
    --backup-retention-period 3 ^
    --apply-immediately
```

RDS API

To enable automated backups, use the RDS API ModifyDBInstance operation with the following required parameters:

- `DBInstanceIdentifier`
- `BackupRetentionPeriod`

Restoring an RDS for Db2 replica backup

You can restore an RDS for Db2 replica backup the same way that you can restore a backup of the primary database. For more information, see Restoring to a DB instance.

The most important consideration when restoring replica backups is understanding the difference between database time and backup creation time, especially when replica lag is present.

You can monitor replication lag and ensure that your backups contain the expected data. For information about the ReplicaLag metric, see Amazon CloudWatch metrics for Amazon RDS.

Understanding timing differences

When you restore a replica backup, you must determine the point in time to which you are restoring. The *database time* refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup completed. The difference is significant because a replica can lag behind the primary database by minutes or hours. Thus, the database time of a replica backup might be much earlier than the snapshot creation time.

To find the difference between database time and creation time, run the AWS CLI describe-db-snapshots command or call the RDS API DescribeDBSnapshots operation. Compare the `SnapshotDatabaseTime` value and the `OriginalSnapshotCreateTime` value. The `SnapshotDatabaseTime` value is the earliest database time among all the databases of the replica backup. The `OriginalSnapshotCreateTime` value is the latest applied transaction on

the primary database. Note that replication lags could be different for multiple databases, and the database time could be in between these two times.

The following AWS CLI example shows the difference between the two times:

For Linux, macOS, or Unix:

```
aws rds describe-db-snapshots \
    --db-instance-identifier my_db2_replica \
    --db-snapshot-identifier my_replica_snapshot
```

For Windows:

```
aws rds describe-db-snapshots ^
    --db-instance-identifier my_db2_replica ^
    --db-snapshot-identifier my_replica_snapshot
```

This command produces output similar to the following example.

```
{
    "DBSnapshots": [
        {
            "DBSnapshotIdentifier": "my_replica_snapshot",
            "DBInstanceIdentifier": "my_db2_replica",
            "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
            ...
            "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
        }
    ]
}
```

Troubleshooting RDS for Db2 replication issues

This topic describes common RDS for Db2 replication issues and provides troubleshooting guidance for both read-only and standby replicas. In addition to reviewing the following troubleshooting information, make sure that you followed the requirements and considerations, and completed the preparation steps before creating Db2 replicas.

Replica creation failures

Replica creation can fail for several reasons:

- **Inactive databases** – All databases on the source DB instance must be active before creating replicas.

  For information about activating databases, see Stored procedures for databases for RDS for Db2.
- **Missing automatic backups** – The source DB instance must have automatic backups enabled.

  For information about enabling backups, see Enabling automatic backups for RDS for Db2 replicas.
- **Parameter group issues** – Custom parameter groups are required for replicas. For BYOL licensing, the parameter group must include the IBM Site ID and IBM Customer ID.

  For more information, see IBM IDs for bring your own license (BYOL) for Db2.

Monitoring Db2 replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS `ReplicaLag` metric. For more information about replication lag time, see Monitoring read replication and Amazon CloudWatch metrics for Amazon RDS. For information about setting up CloudWatch alarms for replica lag, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

For a read-only replica, if the lag time is too long, query the `MON_GET_HADR` table for the status of the replica DB instance.

For a standby replica, if the lag time is too long, query the `MON_GET_HADR` table for the status of the source DB instance. Don't query the replica DB instance because replica DB instances don't accept user connections.

Common causes of high replication lag include the following reasons:

- Insufficient compute resources on the replica
- Network connectivity issues between the source and the replica
- High write activity on the source database
- Storage performance limitations on the replica

If high replication lag persists, consider scaling your replica resources. For more information, see Modifying an Amazon RDS DB instance.

Db2 replication errors

Db2 replication can be in an error state for a number of reasons. Perform the following actions:

- Monitor events and the DB instance state to make sure that the DB instance is replicating.

  For more information, see Working with Amazon RDS event notification.
- Check the diagnostic logs for the Db2 replica in the Amazon RDS console. In the logs, look for errors in HADR messages. Compare the log sequence number to the primary sequence number.

  For information about accessing and interpreting Db2 diagnostic logs, see Amazon RDS for Db2 database log files. For information about Db2 HADR configuration and troubleshooting, see Working with replicas for Amazon RDS for Db2.

If replication errors persist, you might need to recreate the replica.

Connection issues

If you can't connect to your replica, review the following information about the replica modes:

- **Standby replicas** – They don't accept user connections by design. Use read-only replicas for read workloads.
- **Read-only replicas** – Check your security group settings, network ACLs, and parameter group configurations.

  For more information, see Control traffic to your AWS resources using security groups in the *Amazon VPC User Guide*, Control subnet traffic with network access control lists in the *Amazon VPC User Guide*, and Parameter groups for Amazon RDS.

Performance issues

If replica performance is poor, review the following suggestions:

- Ensure the replica has adequate compute and storage resources.
- Monitor the `ReplicaLag` metric in Amazon CloudWatch.
- Consider scaling up the replica DB instance class.

For information about modifying resources or instance classes, see Modifying an Amazon RDS DB instance.

For information monitoring replication lag, see Monitoring replication lag and Amazon CloudWatch metrics for Amazon RDS. For information about setting up CloudWatch alarms for replica lag, see Monitoring Amazon RDS metrics with Amazon CloudWatch.

Options for Amazon RDS for Db2 DB instances

The following shows the options, or additional features, that are available for Amazon RDS instances running the Db2 DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for Db2:

Option	Option ID
Db2 audit logging	DB2_AUDIT

Db2 audit logging

With Db2 audit logging, Amazon RDS records database activity, including users logging on to the database and queries run against the database. RDS uploads the completed audit logs to your Amazon S3 bucket, using the AWS Identity and Access Management (IAM) role that you provide.

Topics

- Setting up Db2 audit logging
- Managing Db2 audit logging
- Viewing audit logs
- Troubleshooting Db2 audit logging

Setting up Db2 audit logging

To enable audit logging for an Amazon RDS for Db2 database, you enable the `DB2_AUDIT` option on the RDS for Db2 DB instance. Then, configure an audit policy to enable the feature for the specific database. To enable the option on the RDS for Db2 DB instance, you configure the option settings for the `DB2_AUDIT` option. You do so by providing the Amazon Resource Names (ARNs) for your Amazon S3 bucket and the IAM role with permissions to access your bucket.

To set up Db2 audit logging for an RDS for Db2 database, complete the following steps.

Topics

- Step 1: Create an Amazon S3 bucket
- Step 2: Create an IAM policy
- Step 3: Create an IAM role and attach your IAM policy
- Step 4: Configure an option group for Db2 audit logging
- Step 5: Configure the audit policy
- Step 6: Check the audit configuration

Step 1: Create an Amazon S3 bucket

If you haven't already done so, create an Amazon S3 bucket where Amazon RDS can upload your RDS for Db2 database's audit log files. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as your RDS for Db2 DB instance.
- It must not be open to the public.
- The bucket owner must also be the IAM role owner.

To learn how to create an Amazon S3 bucket, see Creating a bucket in the *Amazon S3 User Guide*.

After you enable audit logging, Amazon RDS automatically sends the logs from your DB instance to the following locations:

- DB instance level logs – *bucket_name*/db2-audit-logs/*dbi_resource_id*/*date_time_utc*/
- Database level logs – *bucket_name*/db2-audit-logs/*dbi_resource_id*/*date_time_utc*/*db_name*/

Take note of the Amazon Resource Name (ARN) for your bucket. This information is needed to complete subsequent steps.

Step 2: Create an IAM policy

Create an IAM policy with the permissions required to transfer audit log files from your DB instance to your Amazon S3 bucket. This step assumes that you have an S3 bucket.

Before you create the policy, gather the following information:

- The ARN for your bucket.
- The ARN for your AWS Key Management Service (AWS KMS) key, if your bucket uses SSE-KMS encryption.

Create an IAM policy that includes the following permissions:

```
"s3:ListBucket",
 "s3:GetBucketAcl",
 "s3:GetBucketLocation",
 "s3:PutObject",
 "s3:ListMultipartUploadParts",
 "s3:AbortMultipartUpload",
 "s3:ListAllMyBuckets"
```

> **Note**
>
> Amazon RDS needs the `s3:ListAllMyBuckets` action internally to verify that the same AWS account owns both the S3 bucket and the RDS for Db2 DB instance.

If your bucket uses SSE-KMS encryption, also include the following permissions for your IAM role and AWS KMS key.

Include the following permissions to the policy for your IAM role.

```
"kms:GenerateDataKey",
 "kms:Decrypt"
```

Include the following permissions to the key policy for your AWS KMS key. Replace *111122223333* with your account number and *AR0A123456789EXAMPLE* with your IAM role name.

```
{
  "Sid": "Allow RDS role to use the key",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "arn:aws:sts::111122223333:assumed-role/AR0A123456789EXAMPLE/RDS-Db2Audit",
      "arn:aws:iam::111122223333:role/AR0A123456789EXAMPLE"
    ]
  },
  "Action": [
    "kms:GenerateDataKey",
    "kms:Decrypt"
  ],
  "Resource": "*"
}
```

You can create an IAM policy by using the AWS Management Console or the AWS Command Line Interface (AWS CLI).

Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**, and then choose **JSON**.
4. In **Add actions**, filter by **S3**. Add access **ListBucket**, **GetBucketAcl**, and **GetBucketLocation**.
5. For **Add a resource**, choose **Add**. For **Resource type**, choose **bucket**, and enter the name of your bucket. Then, choose **Add resource**.
6. Choose **Add new statement**.
7. In **Add actions**, filter by **S3**. Add access **PutObject**, **ListMultipartUploadParts**, and **AbortMultipartUpload**.
8. For **Add a resource**, choose **Add**. For **Resource type**, choose **object**, and enter *`your bucket name/*`*. Then, choose **Add resource**.
9. Choose **Add new statement**.
10. In **Add actions**, filter by **S3**. Add access **ListAllMyBuckets**.
11. For **Add a resource**, choose **Add**. For **Resource type**, choose **All Resources**. Then, choose **Add resource**.
12. If you're using your own KMS keys to encrypt the data:
    1. Choose **Add new statement**.
    2. In **Add actions**, filter by KMS. Add access **GenerateDataKey** and **Decrypt**.
    3. For **Add a resource**, choose **Add**. For **Resource type**, choose **All Resources**. Then, choose **Add resource**.
13. Choose **Next**.
14. For **Policy name**, enter a name for this policy.
15. (Optional) For **Description**, enter a description for this policy.
16. Choose **Create policy**.

AWS CLI

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Run the create-policy command. In the following example, replace *iam_policy_name* and *amzn-s3-demo-bucket* with a name for your IAM policy and the name of your target Amazon S3 bucket.

   For Linux, macOS, or Unix:

```
aws iam create-policy \
    --policy-name iam_policy_name \
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "Statement1",
                "Effect": "Allow",
                "Action": [
                    "s3:ListBucket",
                    "s3:GetBucketAcl",
                    "s3:GetBucketLocation"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket"
                ]
            },
            {
                "Sid": "Statement2",
                "Effect": "Allow",
                "Action": [
                    "s3:PutObject",
                    "s3:ListMultipartUploadParts",
                    "s3:AbortMultipartUpload"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"
                ]
            },
            {
                "Sid": "Statement3",
                "Effect": "Allow",
                "Action": [
```

```
                    "s3:ListAllMyBuckets"
                ],
                "Resource": [
                    "*"
                ]
            },
            {
                "Sid": "Statement4",
                "Effect": "Allow",
                "Action": [
                    "kms:GenerateDataKey",
                    "kms:Decrypt"
                ],
                "Resource": [
                    "*"
                ]
            }
        ]
  }'
```

For Windows:

```
aws iam create-policy ^
    --policy-name iam_policy_name ^
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "Statement1",
                "Effect": "Allow",
                "Action": [
                    "s3:ListBucket",
                    "s3:GetBucketAcl",
                    "s3:GetBucketLocation"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket"
                ]
            },
            {
                "Sid": "Statement2",
                "Effect": "Allow",
                "Action": [
```

```
                    "s3:PutObject",
                    "s3:ListMultipartUploadParts",
                    "s3:AbortMultipartUpload"
                ],
                "Resource": [
                    "arn:aws:s3:::amzn-s3-demo-bucket/*"
                ]
            },
            {
                "Sid": "Statement3",
                "Effect": "Allow",
                "Action": [
                    "s3:ListAllMyBuckets"
                ],
                "Resource": [
                    "*"
                ]
            },
            {
                "Sid": "Statement4",
                "Effect": "Allow",
                "Action": [
                    "kms:GenerateDataKey",
                    "kms:Decrypt"
                ],
                "Resource": [
                    "*"
                ]
            }
        ]
    }'
```

2. After the policy is created, note the ARN of the policy. You need the ARN for Step 3: Create an IAM role and attach your IAM policy.

For information about creating an IAM policy, see Creating IAM policies in the IAM User Guide.

Step 3: Create an IAM role and attach your IAM policy

This step assumes that you created the IAM policy in Step 2: Create an IAM policy. In this step, you create an IAM role for your RDS for Db2 DB instance and then attach your IAM policy to the role.

You can create an IAM role for your DB instance by using the console or the AWS CLI.

Console

To create an IAM role and attach your IAM policy to it

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **Trusted entity type**, select **AWS service**.
5. For **Service or use case**, select **RDS**, and then select **RDS – Add Role to Database**.
6. Choose **Next**.
7. For **Permissions policies**, search for and select the name of the IAM policy that you created.
8. Choose **Next**.
9. For **Role name**, enter a role name.
10. (Optional) For **Description**, enter a description for the new role.
11. Choose **Create role**.

AWS CLI

To create an IAM role and attach your IAM policy to it

1. Run the create-role command. In the following example, replace *iam_role_name* with a name for your IAM role.

   For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name iam_role_name \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
```

```
      ]
    }'
```

For Windows:

```
aws iam create-role ^
    --role-name iam_role_name ^
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "rds.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

2. After the role is created, note the ARN of this role. You need this ARN for the next step, Step 4: Configure an option group for Db2 audit logging.
3. Run the attach-role-policy command. In the following example, replace *iam_policy_arn* with the ARN of the IAM policy that you created in Step 2: Create an IAM policy. Replace *iam_role_name* with the name of the IAM role that you just created.

   For Linux, macOS, or Unix:

   ```
   aws iam attach-role-policy \
      --policy-arn iam_policy_arn \
      --role-name iam_role_name
   ```

   For Windows:

   ```
   aws iam attach-role-policy ^
      --policy-arn iam_policy_arn ^
      --role-name iam_role_name
   ```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

Step 4: Configure an option group for Db2 audit logging

The process for adding the Db2 audit logging option to an RDS for Db2 DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the Db2 audit logging option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

To add and configure Db2 audit logging on a DB instance's option group

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group, and use that option group. For more information, see Creating an option group.
2. Add the **DB2_AUDIT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group.
   - For **IAM_ROLE_ARN**, enter the ARN of the IAM role that you created in the section called "Create an IAM role and attach your IAM policy".
   - For **S3_BUCKET_ARN**, enter the ARN of the S3 bucket to use for your Db2 audit logs. The bucket must be in the same Region as your RDS for Db2 DB instance. The policy associated with the IAM role you entered must allow the required operations on this resource.
3. Apply the option group to a new or existing DB instance. Choose one of the following:
   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Step 5: Configure the audit policy

To configure the audit policy for your RDS for Db2 database, connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. Then, call the

`rdsadmin.configure_db_audit` stored procedure with the DB name of your database and the applicable parameter values.

The following example connects to the database and configures an audit policy for `testdb` with the categories AUDIT, CHECKING, OBJMAINT, SECMAINT, SYSADMIN, and VALIDATE. The status value `BOTH` logs success and failures, and the `ERROR TYPE` is `NORMAL` by default. For more information about how to use this stored procedure, see the section called "rdsadmin.configure_db_audit".

```
db2 "connect to rdsadmin user master_user using master_password"
db2 "call rdsadmin.configure_db_audit('testdb', 'ALL', 'BOTH', ?)"
```

Step 6: Check the audit configuration

To make sure that your audit policy is set up correctly, check the status of your audit configuration.

To check the configuration, connect to the `rdsadmin` database using the master username and master password for your RDS for Db2 DB instance. Then, run the following SQL statement with the DB name of your database. In the following example, the DB name is *testdb*.

```
db2 "select task_id, task_type, database_name, lifecycle,
    varchar(bson_to_json(task_input_params), 500) as task_params,
    cast(task_output as varchar(500)) as task_output
    from table(rdsadmin.get_task_status(null,'testdb','CONFIGURE_DB_AUDIT'))"

Sample Output

TASK_ID              TASK_TYPE            DATABASE_NAME       LIFECYCLE
-------------------- -------------------- --------------- -------------
                   2  CONFIGURE_DB_AUDIT            DB2DB       SUCCESS

... continued ...
TASK_PARAMS
------------------------------------------------------------
{ "AUDIT_CATEGORY" : "ALL", "CATEGORY_SETTING" : "BOTH" }

... continued ...
                                        TASK_OUTPUT
-------------------------------------------------
2023-12-22T20:27:03.029Z Task execution has started.
```

```
2023-12-22T20:27:04.285Z Task execution has completed successfully.
```

Managing Db2 audit logging

After you set up Db2 audit logging, you can modify the audit policy for a specific database, or disable audit logging at the database level or for the entire DB instance. You can also change the Amazon S3 bucket where your log files are uploaded to.

Topics

- Modifying a Db2 audit policy
- Modifying the location of your log files
- Disabling Db2 audit logging

Modifying a Db2 audit policy

To modify the audit policy for a specific RDS for Db2 database, run the `rdsadmin.configure_db_audit` stored procedure. With this stored procedure, you can change the categories, category settings, and error type configuration of the audit policy. For more information, see the section called "rdsadmin.configure_db_audit".

Modifying the location of your log files

To change the Amazon S3 bucket where your log files are uploaded to, do one of the following:

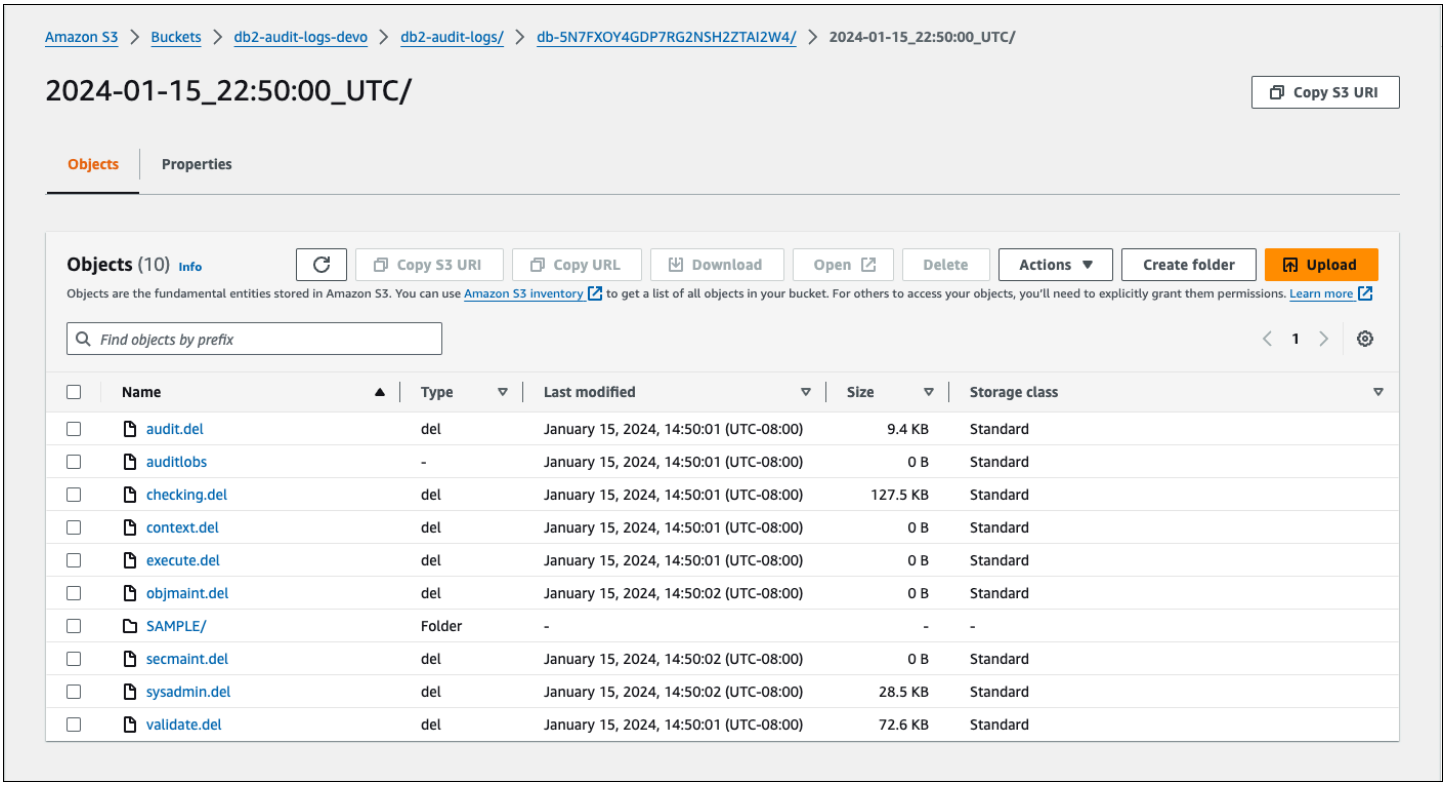
- Modify the current option group attached to your RDS for Db2 DB instance – Update the `S3_BUCKET_ARN` setting for the `DB2_AUDIT` option to point to the new bucket. Also, make sure to update the IAM policy attached to the IAM role specified by the `IAM_ROLE_ARN` setting in the attached option group. This IAM policy must provide your new bucket with the required access permissions. For information about the permissions required in the IAM policy, see Create an IAM policy.
- Attach your RDS for Db2 DB instance to a different option group – Modify your DB instance to change the option group that's attached to it. Make sure that the new option group is configured with the correct `S3_BUCKET_ARN` and `IAM_ROLE_ARN` settings. For information about how to configure these settings for the `DB2_AUDIT` option, see Configure an option group.

When you modify the option group, make sure that you apply the changes immediately. For more information, see the section called "Modifying a DB instance".

Disabling Db2 audit logging

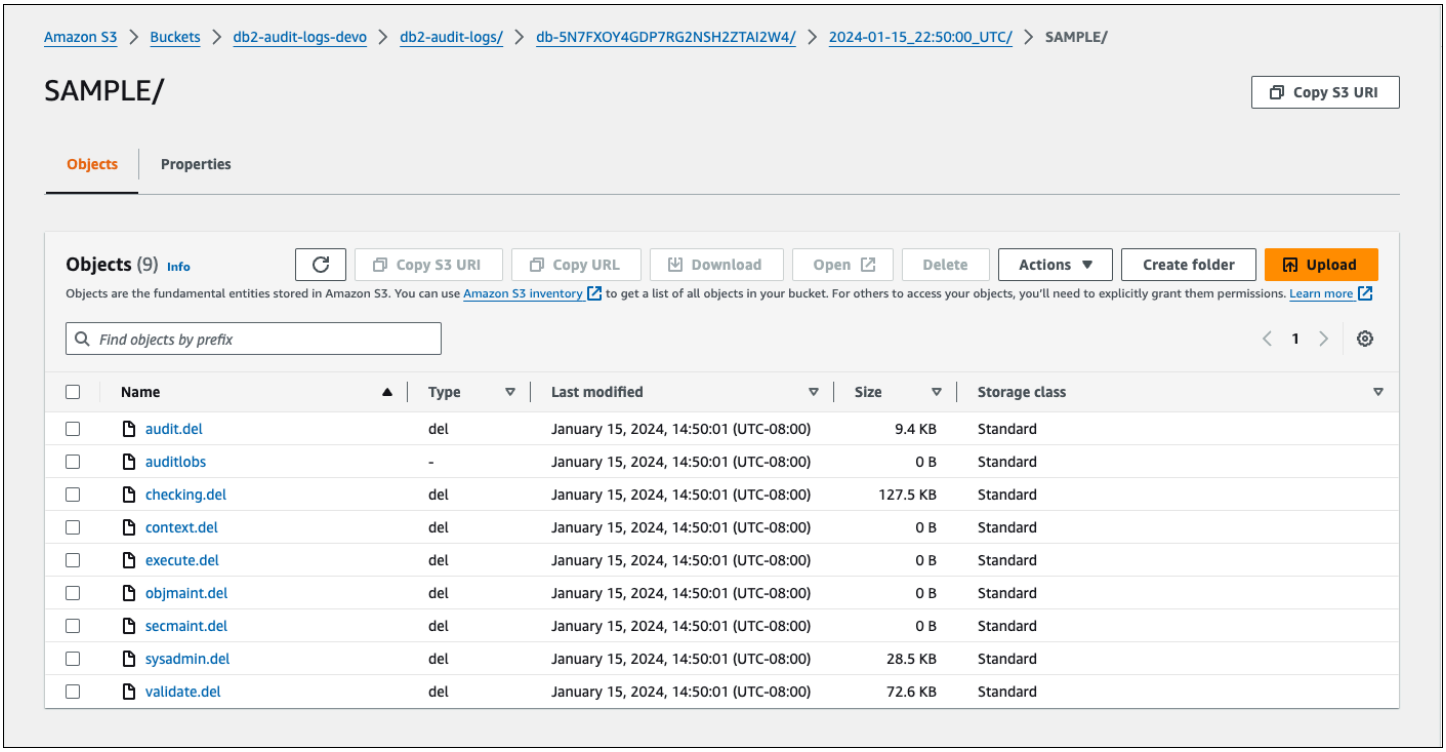
To disable Db2 audit logging, do one of the following:

- Disable audit logging for the RDS for Db2 DB instance – Modify your DB instance and remove the option group with the `DB2_AUDIT` option from it. For more information, see the section called "Modifying a DB instance".
- Disable audit logging for a specific database – Stop audit logging and remove the audit policy by calling `rdsadmin.disable_db_audit` with the DB name of your database. For more information, see the section called "rdsadmin.disable_db_audit".



```
db2 "call rdsadmin.disable_db_audit(
    'db_name',
    ?)"
```

Viewing audit logs



After you enable Db2 audit logging, wait for at least one hour before viewing the audit data in your Amazon S3 bucket. Amazon RDS automatically sends the logs from your RDS for Db2 DB instance to the following locations:

- DB instance level logs – *bucket_name*`/db2-audit-logs/`*dbi_resource_id*`/`*date_time_utc*`/`
- Database level logs – *bucket_name*`/db2-audit-logs/`*dbi_resource_id*`/`*date_time_utc*`/`*db_name*`/`

The following example screenshot of the Amazon S3 console shows a list of folders for RDS for Db2 DB instance level log files.

The following example screenshot of the Amazon S3 console shows database level log files for the RDS for Db2 DB instance.

Troubleshooting Db2 audit logging

Use the following information to troubleshoot common issues with Db2 audit logging.

Can't configure the audit policy

If calling the stored procedure `rdsadmin.configure_db_audit` returns an error, it could be that the option group with the `DB2_AUDIT` option isn't associated with the RDS for Db2 DB instance. Modify the DB instance to add the option group, and then try calling the stored procedure again. For more information, see Modifying an Amazon RDS DB instance.

No data in the Amazon S3 bucket

If logging data is missing from the Amazon S3 bucket, check the following:

- The Amazon S3 bucket is in the same Region as your RDS for Db2 DB instance.
- The role you specified in the `IAM_ROLE_ARN` option setting is configured with the required permissions to upload logs to your Amazon S3 bucket. For more information, see Create an IAM policy.
- The ARNs for the `IAM_ROLE_ARN` and `S3_BUCKET_ARN` option settings are correct in the option group associated with your RDS for Db2 DB instance. For more information, see Configure an option group.

You can check the task status of your audit logging configuration by connecting to the database and running a SQL statement. For more information, see Check the audit configuration.

You can also check events to find out more about why logs might be missing. For information about how to view events, see the section called “Viewing logs, events, and streams in the Amazon RDS console”.

External stored procedures for Amazon RDS for Db2

You can create external routines and register them with your Amazon RDS for Db2 databases as external stored procedures. Currently, RDS for Db2 only supports Java-based routines for external stored procedures.

Java-based external stored procedures

Java-based external stored procedures are external Java routines that you register with your RDS for Db2 database as external stored procedures.

Topics

- Limitations for Java-based external stored procedures
- Configuring Java-based external stored procedures

Limitations for Java-based external stored procedures

Before you develop your external routine, consider the following limitations and restrictions.

To create your external routine, make sure to use the Java Development Kit (JDK) provided by Db2. For more information, see Java software support for Db2 database products.

Your Java program can create files only in the `/tmp` directory, and Amazon RDS doesn't support enabling executable or Set User ID (SUID) permissions on these files. Your Java program also can't use socket system calls or the following system calls:

- _sysctl
- acct
- afs_syscall
- bpf
- capset
- chown
- chroot
- create_module
- delete_module

- fanotify_init
- fanotify_mark
- finit_module
- fsconfig
- fsopen
- fspick
- get_kernel_syms
- getpmsg
- init_module
- mount
- move_mount
- nfsservctl
- open_by_handle_at
- open_tree
- pivot_root
- putpmsg
- query_module
- quotactl
- reboot
- security

For additional restrictions on external routines for Db2, see Restrictions on external routines in the IBM Db2 documentation.

Configuring Java-based external stored procedures

To configure an external stored procedure, create a .jar file with your external routine, install it on your RDS for Db2 database, and then register it as an external stored procedure.

Topics

- Step 1: Enable external stored procedures
- Step 2: Install the .jar file with your external routine
- Step 3: Register the external stored procedure
- Step 4: Validate the external stored procedure

Step 1: Enable external stored procedures

To enable external stored procedures, in a custom parameter group associated with your DB instance, set the parameter `db2_alternate_authz_behaviour` to one of the following values:

- `EXTERNAL_ROUTINE_DBADM` – Implicitly grants any user, group, or role with `DBADM` authority the `CREATE_EXTERNAL_ROUTINE` permission.
- `EXTERNAL_ROUTINE_DBAUTH` – Allows a user with `DBADM` authority to grant `CREATE_EXTERNAL_ROUTINE` permission to any user, group, or role. In this case, no user, group, or role is implicitly granted this permission, not even a user with `DBADM` authority.

For more information about this setting, see GRANT (database authorities) statement in the IBM Db2 documentation.

You can create and modify a custom parameter group by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

Console

To configure the db2_alternate_authz_behaviour parameter in a custom parameter group

1. If you want to use a different custom DB parameter group than the one your DB instance is using, create a new DB parameter group. If you're using the bring your own license (BYOL) model, make sure that the new custom parameter group includes the IBM IDs. For information

about these IDs, see the section called "IBM IDs for bring your own license (BYOL) for Db2". For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

2. Set the value for the `db2_alternate_authz_behaviour` parameter in your custom parameter group. For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

AWS CLI

To configure the db2_alternate_authz_behaviour parameter in a custom parameter group

1. If you want to use a different custom DB parameter group than the one your DB instance is using, create a custom parameter group by running the create-db-parameter-group command. If you're using the bring your own license (BYOL) model, make sure that the new custom parameter group includes the IBM IDs. For information about these IDs, see the section called "IBM IDs for bring your own license (BYOL) for Db2".

   Include the following required options:

   - `--db-parameter-group-name` – A name for the parameter group that you are creating.
   - `--db-parameter-group-family` – The Db2 engine edition and major version. Valid values are `db2-se-11.5` and `db2-ae-11.5`.
   - `--description` – A description for this parameter group.

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.

   The following example shows you how to create a custom parameter group named `MY_EXT_SP_PARAM_GROUP` for the parameter group family `db2-se-11.5`.

   For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
--region us-east-1 \
--db-parameter-group-name MY_EXT_SP_PARAM_GROUP \
--db-parameter-group-family db2-se-11.5 \
--description "test db2 external routines"
```

For Windows:

```
aws rds create-db-parameter-group ^
--region us-east-1 ^
--db-parameter-group-name MY_EXT_SP_PARAM_GROUP ^
--db-parameter-group-family db2-se-11.5 ^
--description "test db2 external routines"
```

2. Modify the `db2_alternate_authz_behaviour` parameter in your custom parameter group by running the [modify-db-parameter-group] command.

   Include the following required options:

   - `--db-parameter-group-name` – The name of the parameter group that you created.
   - `--parameters` – An array of parameter names, values, and the application methods for the parameter update.

   For more information about modifying a parameter group, see [Modifying parameters in a DB parameter group in Amazon RDS].

   The following example shows you how to modify the parameter group `MY_EXT_SP_PARAM_GROUP` by setting the value of `db2_alternate_authz_behaviour` to `EXTERNAL_ROUTINE_DBADM`.

   For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name MY_EXT_SP_PARAM_GROUP \
    --parameters
 "ParameterName='db2_alternate_authz_behaviour',ParameterValue='EXTERNAL_ROUTINE_DBADM',App
```

   For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name MY_EXT_SP_PARAM_GROUP ^
    --parameters
 "ParameterName='db2_alternate_authz_behaviour',ParameterValue='EXTERNAL_ROUTINE_DBADM',App
```

RDS API

To configure the db2_alternate_authz_behaviour parameter in a custom parameter group

1. If you want to use a different custom DB parameter group than the one your DB instance is using, create a new DB parameter group by using the Amazon RDS API CreateDBParameterGroup operation. If you're using the bring your own license (BYOL) model, make sure that the new custom parameter group includes the IBM Db2 IDs. For information about these IDs, see the section called “IBM IDs for bring your own license (BYOL) for Db2”.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `DBParameterGroupFamily`
   - `Description`

   For more information about creating a DB parameter group, see Creating a DB parameter group in Amazon RDS.
2. Modify the `db2_alternate_authz_behaviour` parameter in your custom parameter group that you created by using the RDS API ModifyDBParameterGroup operation.

   Include the following required parameters:

   - `DBParameterGroupName`
   - `Parameters`

   For more information about modifying a parameter group, see Modifying parameters in a DB parameter group in Amazon RDS.

Step 2: Install the .jar file with your external routine

After you create your Java routine, create the .jar file and then run `db2 "call sqlj.install_jar('file:`*`file_path`*`',`*`jar_ID`*`)"` to install it on your RDS for Db2 database.

The following example shows you how to create a Java routine and install it on an RDS for Db2 database. The example includes sample code for a simple routine that you can use to test the process. This example makes the following assumptions:

- The Java code is compiled on a server where Db2 is installed. This is a best practice because not compiling with the IBM-provided JDK can result in unexplained errors.
- The server has the RDS for Db2 database cataloged locally.

If you'd like to try out the process with the following sample code, copy it and then save it to a file named `MYJAVASP.java`.

```
import java.sql.*;
public class MYJAVASP
{
public static void my_JAVASP (String inparam) throws SQLException, Exception
{
try
{
// Obtain the calling context's connection details.
Connection myConn = DriverManager.getConnection("jdbc:default:connection");
String myQuery = "INSERT INTO TEST.TEST_TABLE VALUES (?, CURRENT DATE)";
PreparedStatement myStmt = myConn.prepareStatement(myQuery);
myStmt.setString(1, inparam);
myStmt.executeUpdate();
}
catch (SQLException sql_ex)
{
throw sql_ex;
}
catch (Exception ex)
{
throw ex;
}
}
```

The following command compiles the Java routine.

```
~/sqllib/java/jdk64/bin/javac MYJAVASP.java
```

The following command creates the .jar file.

```
~/sqllib/java/jdk64/bin/jar cvf MYJAVASP.jar MYJAVASP.class
```

The following commands connect to the database named MY_DB2_DATABASE and install the .jar file.

```
db2 "connect to MY_DB2_DATABASE user master_username using master_password"

db2 "call sqlj.install_jar('file:/tmp/MYJAVASP.jar','MYJAVASP')"
db2 "call sqlj.refresh_classes()"
```

Step 3: Register the external stored procedure

After you install the .jar file on your RDS for Db2 database, register it as a stored procedure by running the db2 CREATE PROCEDURE or db2 REPLACE PROCEDURE command.

The following example shows you how to connect to the database and register the Java routine created in the previous step as a stored procedure.

```
db2 "connect to MY_DB2_DATABASE user master_username using master_password"

create procedure TESTSP.MYJAVASP (in input char(6))
specific myjavasp
dynamic result sets 0
deterministic
language java
parameter style java
no dbinfo
fenced
threadsafe
modifies sql data
program type sub
external name 'MYJAVASP!my_JAVASP';
```

Step 4: Validate the external stored procedure

Use the following steps to test the sample external stored procedure that was registered in the previous step.

To validate the external stored procedure

1. Create a table like TEST.TEST_TABLE in the following example.

   ```
   db2 "create table TEST.TEST_TABLE(C1 char(6), C2 date)"
   ```

2. Call the new external stored procedure. The call returns a status of `0`.

```
db2 "call TESTSP.MYJAVASP('test')"
Return Status = 0
```

3. Query the table you created in step 1 to verify the results of the stored procedure call.

```
db2 "SELECT * from TEST.TEST_TABLE"
```

The query produces output similar to the following example:

```
C1     C2
------ ----------
test   02/05/2024
```

Known issues and limitations for Amazon RDS for Db2

The following items are known issues and limitations for working with Amazon RDS for Db2:

Topics

- Authentication limitation
- Non-fenced routines
- Non-automatic storage tablespaces during migration
- Setting the db2_compatibility_vector parameter
- Migrating databases that contain INVALID packages

Authentication limitation

Amazon RDS sets `db2auth` to `JCC_ENFORCE_SECMEC` by default. However, if you don't want to enforce userid and password encryption over the wire, you can override this setting by changing the `db2auth` parameter to `CLEAR_TEXT` in the parameter group. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

Non-fenced routines

RDS for Db2 doesn't support the creation of non-fenced routines and the migration of these routines by backing up and restoring data. To check if your database contains any non-fenced routines, run the following SQL command:

```
SELECT 'COUNT:' || count(*) FROM SYSCAT.ROUTINES where fenced='N' and routineschema not
 in ('SQLJ','SYSCAT','SYSFUN','SYSIBM','SYSIBMADM','SYSPROC','SYSTOOLS')
```

Non-automatic storage tablespaces during migration

RDS for Db2 doesn't support the creation of new non-automatic storage tablespaces. When you use native restore for a one-time migration of your database, RDS for Db2 automatically converts your non-automatic storage tablespaces to automatic ones, and then restores your database to RDS for Db2. For information about one-time migrations, see Migrating from Linux to Linux for Amazon RDS for Db2 and Migrating from AIX or Windows to Linux for Amazon RDS for Db2.

Setting the db2_compatibility_vector parameter

With Amazon RDS, you can create an initial database when you create the DB instance and then modify parameters in an associated parameter group. However, for Db2, if you want to set the `db2_compatibility_vector` parameter in a parameter group, you must first modify the parameter in a custom parameter group, create the DB instance without a database, and then create a database using the `rdsadmin.create_database` stored procedure.

To set the `db2_compatibility_vector` parameter

1. Create a custom parameter group. (You can't modify parameters in default parameter groups.)
2. Modify the parameter.
3. Create a DB instance.
4. Create a database using the `rdsadmin.create_database` stored procedure.
5. Associate the parameter group with the DB instance that contains the database.

Migrating databases that contain INVALID packages

If you migrate Db2 databases that contain `INVALID` packages to RDS for Db2 by using the `RESTORE` command, you could encounter issues when you start to use the databases. `INVALID` packages can cause issues because of the authorization setup for the DB instance user `rdsdb` and the removal of authorization from `PUBLIC`. `INVALID` packages cause the following commands to fail:

- `db2updv115`
- `db2 "call SYSPROC.ADMIN_REVALIDATE_DB_OBJECTS()"`

Before migrating your database with the `RESTORE` command, ensure that your database doesn't contain `INVALID` packages by running the following command:

```
db2 "SELECT 'COUNT:' || count(*) FROM SYSCAT.INVALIDOBJECTS"
```

If the command returns a count greater than zero, then call the following command:

```
db2 "call SYSPROC.ADMIN_REVALIDATE_DB_OBJECTS()"
```

Afterwards, call the previous command to confirm that your database no longer contains `INVALID` packages.

```
db2 "SELECT 'COUNT:' || count(*) FROM SYSCAT.INVALIDOBJECTS"
```

Now you are ready to make a backup of your database and restore it to your RDS for Db2 DB instance.

Amazon RDS for Db2 stored procedure reference

You can manage your Amazon RDS for Db2 DB instances running the Db2 engine by calling built-in stored procedures.

Stored procedure	Category	Description
the section called “rdsadmin.activate_database”	Databases	Use the `rdsadmin.activate_database` stored procedure to activate a database on a standalone RDS for Db2 DB instance.
the section called “rdsadmin.add_groups”	Granting and revoking privileges	Use the `rdsadmin.add_groups` stored procedure to add one or more groups to a user for a database on an RDS for Db2 DB instance.
the section called “rdsadmin.add_user”	Granting and revoking privileges	Use the `rdsadmin.add_user` stored procedure to add a user to an authorization list for a database on an RDS for Db2 DB instance.
the section called “rdsadmin.alter_bufferpool”	Buffer pools	Use the `rdsadmin.alter_bufferpool` stored procedure to modify a buffer pool for a database on an RDS for Db2 DB instance.
the section called “rdsadmin.alter_tablespace”	Tablespaces	Use the `rdsadmin.alter_tablespace` stored procedure to modify a tablespace for a database on an RDS for Db2 DB instance.
the section called “rdsadmin.backup_database”	Database	Use the `rdsadmin.backup_database` stored procedure to back up a database on an RDS for Db2 DB instance to an Amazon S3 bucket. Then you can restore the backup from Amazon S3 to an RDS for Db2 DB instance or to another location such as a local server.
the section called “rdsadmin.catalog_storage_access”	Storage access	Use the `rdsadmin.catalog_storage_access` stored procedure to catalog a storage alias for accessing an Amazon S3 bucket with

Stored procedure	Category	Description
		Db2 data files for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.change_password"	Granting and revoking privileges	Use the `rdsadmin.change_password` stored procedure to change a user's password for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.complete_rollforward"	Databases	Use the `rdsadmin.complete_rollforward` stored procedure to bring a database on an RDS for Db2 DB instance online from a `ROLL-FORWARD PENDING` state. A `ROLL-FORWARD PENDING` state occurs when you called the section called "rdsadmin.rollforward_database" but set the `complete_rollforward` parameter to `FALSE`.
the section called "rdsadmin.configure_db_audit"	Audit policies	Use the `rdsadmin.configure_db_audit` stored procedure to modify an audit policy for a database on an RDS for Db2 DB instance. If no audit policy exists, running this stored procedure creates an audit policy.
the section called "rdsadmin.create_bufferpool"	Buffer pools	Use the `rdsadmin.create_bufferpool` stored procedure to create a buffer pool for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.create_database"	Databases	Use the `rdsadmin.create_database` stored procedure to create a database on an RDS for Db2 DB instance.
the section called "rdsadmin.create_role"	Granting and revoking privileges	Use the `rdsadmin.create_role` stored procedure to create a role to attach to a database on an RDS for Db2 DB instance.

Stored procedure	Category	Description
the section called "rdsadmin.create_tablespace"	Tablespaces	Use the `rdsadmin.create_tablespace` stored procedure to create a tablespace for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.db2pd_command"	Databases	Use the `rdsadmin.db2pd_command` stored procedure collect information about a database on an RDS for Db2 DB instance. This information can help with monitoring and troubleshooting databases in RDS for Db2.
the section called "rdsadmin.db2support_command"	Databases	Use the `rdsadmin.db2support_command` stored procedure to collect diagnostic information about a database on an RDS for Db2 DB instance and upload it to an Amazon S3 bucket.
the section called "rdsadmin.dbadm_grant"	Granting and revoking privileges	Use the `rdsadmin.dbadm_grant` stored procedure to grant one or more authorization types (`DBADM`, `ACCESSCTRL` , or `DATAACCESS`) to one or more roles, users, or groups for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.dbadm_revoke"	Granting and revoking privileges	Use the `rdsadmin.dbadm_revoke` stored procedure to revoke one or more authorization types (`DBADM`, `ACCESSCTRL` , or `DATAACCESS`) from one or more roles, users, or groups for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.deactivate_database"	Databases	Use the `rdsadmin.deactivate_database` stored procedure to deactivate a database on an RDS for Db2 DB instance. You can deactivate databases to conserve memory resources.

Stored procedure	Category	Description
the section called “rdsadmin.disable_db_audit”	Audit policies	Use the `rdsadmin.disable_db_audit` stored procedure to stop audit logging and remove an audit policy from a database on an RDS for Db2 DB instance.
the section called “rdsadmin.drop_bufferpool”	Buffer pools	Use the `rdsadmin.drop_bufferpool` stored procedure to drop a buffer pool from a database on an RDS for Db2 DB instance.
the section called “rdsadmin.drop_database”	Databases	Use the `rdsadmin.drop_database` stored procedure to drop a database from an RDS for Db2 DB instance.
the section called “rdsadmin.drop_role”	Granting and revoking privileges	Use the `rdsadmin.drop_role` stored procedure to delete a role from a database on an RDS for Db2 DB instance.
the section called “rdsadmin.drop_tablespace”	Tablespaces	Use the `rdsadmin.drop_tablespace` stored procedure to drop a tablespace from a database on an RDS for Db2 DB instance.
the section called “rdsadmin.fgac_command”	Databases	Use the `rdsadmin.fgac_command` stored procedure to control access at the row or column level to table data in your database on an RDS for Db2 DB instance.
the section called “rdsadmin.force_application”	Databases	Use the `rdsadmin.force_application` stored procedure to force applications off of a database on an RDS for Db2 DB instance to perform maintenance.

Stored procedure	Category	Description
the section called "rdsadmin.grant_role"	Granting and revoking privileges	Use the `rdsadmin.grant_role` stored procedure to assign a role to a grantee role, user, or group in a database on an RDS for Db2 DB instance. You can also use this stored procedure to give the grantee role `DBADM` authorization to assign roles.
the section called "rdsadmin.list_archive_log_information"	Databases	Use the `rdsadmin.list_archive_log_information` stored procedure to return information about archive logs for a database on an RDS for Db2 DB instance. This information includes details such as size and creation date of individual log files, and the total storage used by the archive log files.
the section called "rdsadmin.list_sid_group_mapping"	Granting and revoking privileges	Use the `rdsadmin.list_sid_group_mapping` stored procedure to return a list of all security ID (SID) and Active Directory group mappings configured on an RDS for Db2 DB instance.
the section called "rdsadmin.list_users"	Granting and revoking privileges	Use the `rdsadmin.list_users` stored procedure to return a list of users on an authorization list for a database on an RDS for Db2 DB instance.

Stored procedure	Category	Description
the section called "rdsadmin.reactivate_database"	Databases	Use the `rdsadmin.reactivate_database` stored procedure to reactivate a database on an RDS for Db2 DB instance after you make database configuration changes. For a database on a standalone DB instance, you can use either this stored procedure or the rdsadmin.activate_database stored procedure. For a database on a replica source DB instance, you must use the `rdsadmin.reactivate_database` stored procedure.
the section called "rdsadmin.remove_groups"	Granting and revoking privileges	Use the `rdsadmin.remove_groups` stored procedure to remove one or more groups from a user for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.remove_sid_group_mapping"	Granting and revoking privileges	Use the `rdsadmin.remove_sid_group_mapping` stored procedure to remove a security ID (SID) and its corresponding Active Directory group mapping from an RDS for Db2 DB instance.
the section called "rdsadmin.remove_user"	Granting and revoking privileges	Use the `rdsadmin.remove_user` stored procedure to remove a user from an authorization list for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.rename_tablespace"	Tablespaces	Use the `rdsadmin.rename_tablespace` stored procedure to rename a tablespace for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.restore_database"	Databases	Use the `rdsadmin.restore_database` stored procedure to restore a database on an RDS for Db2 DB instance from an Amazon S3 bucket.

Stored procedure	Category	Description
the section called "rdsadmin.revoke_role"	Granting and revoking privileges	Use the `rdsadmin.revoke_role` stored procedure to revoke a role from a grantee role, user, or group in a database on an RDS for Db2 DB instance.
the section called "rdsadmin.rollforward_database"	Databases	Use the `rdsadmin.rollforward_database` stored procedure to bring a database on an RDS for Db2 DB instance online, and to apply transaction logs after you restored a database on an RDS for Db2 DB instance by calling the section called "rdsadmin.restore_database".
the section called "rdsadmin.rollforward_status"	Databases	Use the `rdsadmin.rollforward_status` stored procedure to query the rollforward status of calling the the section called "rdsadmin.rollforward_database" or the section called "rdsadmin.complete_rollforward" stored procedure on an RDS for Db2 DB instance.
the section called "rdsadmin.set_archive_log_retention"	Databases	Use the `rdsadmin.set_archive_log_retention` stored procedure to configure how long to retain archive log files for a database on an RDS for Db2 DB instance. You can also use this stored procedure to disable archive log retention.
the section called "rdsadmin.set_configuration"	Databases	Use the `rdsadmin.set_configuration` stored procedure to configure certain settings for a database on an RDS for Db2 DB instance.

Stored procedure	Category	Description
the section called "rdsadmin.set_sid_group_mapping"	Granting and revoking privileges	Use the `rdsadmin.set_sid_group_mapping` stored procedure to create a mapping between a security ID (SID) and the corresponding Active Directory group on an RDS for Db2 DB instance.
the section called "rdsadmin.show_archive_log_retention"	Databases	Use the `rdsadmin.show_archive_log_retention` stored procedure to return the current archive log retention setting for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.show_configuration"	Databases	Use the `rdsadmin.show_configuration` stored procedure to return one or more settings that are modifiable for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.uncatalog_storage_access"	Storage access	Use the `rdsadmin.uncatalog_storage_access` stored procedure to remove a storage alias for accessing an Amazon S3 bucket with Db2 data files.
the section called "rdsadmin.update_db_param"	Databases	Use the `rdsadmin.update_db_param` stored procedure to update database parameters for a database on an RDS for Db2 DB instance.
the section called "rdsadmin.enable_archive_log_copy"	Databases	Use the `rdsadmin.enable_archive_log_copy` stored procedure to enables RDS Db2 database archive log copy to Amazon S3.
the section called "rdsadmin.disable_archive_log_copy"	Databases	Use the `rdsadmin.disable_archive_log_copy` stored procedure to disable RDS Db2 database archive log copy to Amazon S3.

Topics

- Considerations for Amazon RDS for Db2 stored procedures
- Stored procedures for granting and revoking privileges for RDS for Db2
- Stored procedures for audit policies for RDS for Db2
- Stored procedures for buffer pools for RDS for Db2
- Stored procedures for databases for RDS for Db2
- Stored procedures for storage access for RDS for Db2
- Stored procedures for tablespaces for RDS for Db2

Considerations for Amazon RDS for Db2 stored procedures

Before using the Amazon RDS system stored procedures for RDS for Db2 DB instances running the Db2 engine, review the following information:

- Before running the stored procedures, you must first connect to the `rdsadmin` database as the master user for your RDS for Db2 DB instance. In the following example, replace *`master_username`* and *`master_password`* with your own information.

  ```
  db2 "connect to rdsadmin user master_username using master_password"
  ```

- The stored procedures return the ERR_MESSAGE parameter, which indicates whether the stored procedure ran successfully or not and why it didn't run successfully.

  Examples

  The following example indicates that the stored procedure ran successfully.

  ```
  Parameter Name : ERR_MESSAGE
  Parameter Value : -
  Return Status = 0
  ```

  The following example indicates that the stored procedure didn't run successfully because the Amazon S3 bucket name used in the stored procedure wasn't valid.

  ```
  Parameter Name : ERR_MESSAGE
  Parameter Value : Invalid S3 bucket name
  Return Status = -1006
  ```

  For error messages returned when calling stored procedures, see the section called “Stored procedure errors”.

For information about checking the status of a stored procedure, see rdsadmin.get_task_status.

Stored procedures for granting and revoking privileges for RDS for Db2

The built-in stored procedures described in this topic manage users, roles, groups, and authorization for Amazon RDS for Db2 databases. To run these procedures, the master user must first connect to the `rdsadmin` database.

For tasks that use these stored procedures, see Granting and revoking privileges and Setting up Kerberos authentication.

Refer to the following built-in stored procedures for information about their syntax, parameters, usage notes, and examples.

Stored procedures

- rdsadmin.create_role
- rdsadmin.grant_role
- rdsadmin.revoke_role
- rdsadmin.drop_role
- rdsadmin.add_user
- rdsadmin.change_password
- rdsadmin.list_users
- rdsadmin.remove_user
- rdsadmin.add_groups
- rdsadmin.remove_groups
- rdsadmin.dbadm_grant
- rdsadmin.dbadm_revoke
- rdsadmin.set_sid_group_mapping
- rdsadmin.list_sid_group_mapping
- rdsadmin.remove_sid_group_mapping

rdsadmin.create_role

Creates a role.

Syntax

```
db2 "call rdsadmin.create_role(
```

```
    'database_name',
    'role_name')"
```

Parameters

The following parameters are required:

database_name

The name of the database the command will run on. The data type is `varchar`.

role_name

The name of the role that you want to create. The data type is `varchar`.

Usage notes

For information about checking the status of creating a role, see rdsadmin.get_task_status.

Examples

The following example creates a role called `MY_ROLE` for database `DB2DB`.

```
db2 "call rdsadmin.create_role(
    'DB2DB',
    'MY_ROLE')"
```

rdsadmin.grant_role

Assigns a role to a role, user, or group.

Syntax

```
db2 "call rdsadmin.grant_role(
    ?,
    'database_name',
    'role_name',
    'grantee',
    'admin_option')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is `varchar`.

role_name

The name of the role that you want to create. The data type is `varchar`.

grantee

The role, user, or group to receive authorization. The data type is `varchar`. Valid values: `ROLE`, `USER`, `GROUP`, `PUBLIC`.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

The following input parameter is optional:

admin_option

Specifies whether the grantee `ROLE` has `DBADM` authorization to assign roles. The data type is `char`. The default is `N`.

Usage notes

For information about checking the status of assigning a role, see rdsadmin.get_task_status.

Examples

Example 1: Assigning role to role, user, and group, and granting authorization

The following example assigns a role called `ROLE_TEST` for database `TESTDB` to the role called `role1`, the user called `user1`, and the group called `group1`. `ROLE_TEST` is given admin authorization to assign roles.

```
db2 "call rdsadmin.grant_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'ROLE role1, USER user1, GROUP group1',
    'Y')"
```

Example 2: Assigning role to PUBLIC and not granting authorization

The following example assigns a role called ROLE_TEST for database TESTDB to PUBLIC. ROLE_TEST isn't given admin authorization to assign roles.

```
db2 "call rdsadmin.grant_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'PUBLIC')"
```

rdsadmin.revoke_role

Revokes a role from a role, user, or group.

Syntax

```
db2 "call rdsadmin.revoke_role(
    ?,
    'database_name',
    'role_name',
    'grantee')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is varchar.

role_name

The name of the role that you want to revoke. The data type is varchar.

grantee

The role, user, or group to lose authorization. The data type is varchar. Valid values: ROLE, USER, GROUP, PUBLIC.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

Usage notes

For information about checking the status of revoking a role, see rdsadmin.get_task_status.

Examples

Example 1: Revoking role from role, user, and group

The following example revokes a role called ROLE_TEST for database TESTDB from the role called role1, the user called user1, and the group called group1.

```
db2 "call rdsadmin.revoke_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'ROLE role1, USER user1, GROUP group1')"
```

Example 2: Revoking role from PUBLIC

The following example revokes a role called ROLE_TEST for database TESTDB from PUBLIC.

```
db2 "call rdsadmin.revoke_role(
    ?,
    'TESTDB',
    'ROLE_TEST',
    'PUBLIC')"
```

rdsadmin.drop_role

Drops a role.

Syntax

```
db2 "call rdsadmin.drop_role(
    ?,
    'database_name',
    'role_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is `varchar`.

role_name

The name of the role that you want to drop. The data type is `varchar`.

Usage notes

For information about checking the status of dropping a role, see rdsadmin.get_task_status.

Examples

The following example drops a role called `ROLE_TEST` for database `TESTDB`.

```
db2 "call rdsadmin.drop_role(
    ?,
    'TESTDB',
    'ROLE_TEST')"
```

rdsadmin.add_user

Adds a user to an authorization list.

Syntax

```
db2 "call rdsadmin.add_user(
    'username',
    'password',
    'group_name,group_name')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

password

A user's password. The data type is `varchar`.

The following parameter is optional:

group_name

The name of a group that you want to add the user to. The data type is `varchar`. The default is an empty string or null.

Usage notes

You can add a user to one or more groups by separating the group names with commas.

You can create a group when you create a new user, or when you add a group to an existing user. You can't create a group by itself.

> **Note**
>
> The maximum number of users that you can add by calling `rdsadmin.add_user` is 5,000.

For information about checking the status of adding a user, see rdsadmin.get_task_status.

Examples

The following example creates a user called `jorge_souza` and assigns the user to the groups called `sales` and `inside_sales`.

```
db2 "call rdsadmin.add_user(
    'jorge_souza',
    '*******',
    'sales,inside_sales')"
```

rdsadmin.change_password

Changes a user's password.

Syntax

```
db2 "call rdsadmin.change_password(
    'username',
    'new_password')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

new_password

A new password for the user. The data type is `varchar`.

Usage notes

For information about checking the status of changing a password, see rdsadmin.get_task_status.

Examples

The following example changes the password for `jorge_souza`.

```
db2 "call rdsadmin.change_password(
    'jorge_souza',
    '*******')"
```

rdsadmin.list_users

Lists users on an authorization list.

Syntax

```
db2 "call rdsadmin.list_users()"
```

Usage notes

For information about checking the status of listing users, see rdsadmin.get_task_status.

rdsadmin.remove_user

Removes user from authorization list.

Syntax

```
db2 "call rdsadmin.remove_user('username')"
```

Parameters

The following parameter is required:

username

A user's username. The data type is `varchar`.

Usage notes

For information about checking the status of removing a user, see rdsadmin.get_task_status.

Examples

The following example removes `jorge_souza` from being able to access databases in RDS for Db2 DB instances.

```
db2 "call rdsadmin.remove_user('jorge_souza')"
```

rdsadmin.add_groups

Adds groups to a user.

Syntax

```
db2 "call rdsadmin.add_groups(
    'username',
    'group_name,group_name')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

group_name

The name of a group that you want to add the user to. The data type is `varchar`. The default is an empty string.

Usage notes

You can add one or more groups to a user by separating the group names with commas. For information about checking the status of adding groups, see rdsadmin.get_task_status.

Examples

The following example adds the `direct_sales` and `b2b_sales` groups to user `jorge_souza`.

```
db2 "call rdsadmin.add_groups(
    'jorge_souza',
    'direct_sales,b2b_sales')"
```

rdsadmin.remove_groups

Removes groups from a user.

Syntax

```
db2 "call rdsadmin.remove_groups(
    'username',
    'group_name,group_name')"
```

Parameters

The following parameters are required:

username

A user's username. The data type is `varchar`.

group_name

The name of a group that you want to remove the user from. The data type is `varchar`.

Usage notes

You can remove one or more groups from a user by separating the group names with commas.

For information about checking the status of removing groups, see rdsadmin.get_task_status.

Examples

The following example removes the `direct_sales` and `b2b_sales` groups from user `jorge_souza`.

```
db2 "call rdsadmin.remove_groups(
    'jorge_souza',
    'direct_sales,b2b_sales')"
```

rdsadmin.dbadm_grant

Grants `DBADM`, `ACCESSCTRL`, or `DATAACCESS` authorization to a role, user, or group.

Syntax

```
db2 "call rdsadmin.dbadm_grant(
    ?,
```

```
    'database_name',
    'authorization',
    'grantee')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs the unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is `varchar`.

authorization

The type of authorization to grant. The data type is `varchar`. Valid values: `DBADM`, `ACCESSCTRL`, `DATAACCESS`.

Separate multiple types with commas.

grantee

The role, user, or group to receive authorization. The data type is `varchar`. Valid values: `ROLE`, `USER`, `GROUP`.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

Usage notes

The role to receive access must exist.

For information about checking the status of granting database admin access, see rdsadmin.get_task_status.

Examples

Example 1: Granting database admin access to role

The following example grants database admin access to the database named TESTDB for the role ROLE_DBA.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'TESTDB',
    'DBADM',
    'ROLE ROLE_DBA')"
```

Example 2: Granting database admin access to user and group

The following example grants database admin access to the database named TESTDB for user1 and group1.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, GROUP group1')"
```

Example 3: Granting database admin access to multiple users and groups

The following example grants database admin access to the database named TESTDB for user1, user2, group1, and group2.

```
db2 "call rdsadmin.dbadm_grant(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, user2, GROUP group1, group2')"
```

rdsadmin.dbadm_revoke

Revokes DBADM, ACCESSCTRL, or DATAACCESS authorization from a role, user, or group.

Syntax

```
db2 "call rdsadmin.dbadm_revoke(
```

```
    ?,
    'database_name',
    'authorization',
    'grantee')"
```

Parameters

The following output parameter is required:

?

The unique identifier for the task. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database the command will run on. The data type is varchar.

authorization

The type of authorization to revoke. The data type is varchar. Valid values: DBADM, ACCESSCTRL, DATAACCESS.

Separate multiple types with commas.

grantee

The role, user, or group to revoke authorization from. The data type is varchar. Valid values: ROLE, USER, GROUP.

Format must be value followed by name. Separate multiple values and names with commas. Example: 'USER *user1*, *user2*, GROUP *group1*, *group2*'. Replace the names with your own information.

Usage notes

For information about checking the status of revoking database admin access, see rdsadmin.get_task_status.

Examples

Example 1: Revoking database admin access from role

The following example revokes database admin access to the database named TESTDB for the role ROLE_DBA.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'TESTDB',
    'DBADM',
    'ROLE ROLE_DBA')"
```

Example 2: Revoking database admin access from user and group

The following example revokes database admin access to the database named TESTDB for user1 and group1.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, GROUP group1')"
```

Example 3: Revoking database admin access from multiple users and groups

The following example revokes database admin access to the database named TESTDB for user1, user2, group1, and group2.

```
db2 "call rdsadmin.dbadm_revoke(
    ?,
    'TESTDB',
    'DBADM',
    'USER user1, user2, GROUP group1, group2')"
```

rdsadmin.set_sid_group_mapping

Creates a mapping between a security ID (SID) and the corresponding Active Directory group.

Syntax

```
db2 "call rdsadmin.set_sid_group_mapping(
    ?,
    'SID',
```

```
    'group_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

SID

The security ID (SID). The data type is `varchar`.

group_name

The name of the Active Directory group to map to the SID. The data type is `varchar`.

Usage notes

Use this stored procedure to enable Kerberos authentication with Active Directory groups. If the `SID` or `group_name` already exists in the mapping, this stored procedure fails.

For information about how to find the SID for a group, see Step 8: Retrieve the Active Directory group SID in PowerShell.

For information about checking the status of creating a mapping, see rdsadmin.get_task_status.

Examples

The following example maps a SID to a group called `my_group`.

```
db2 "call rdsadmin.set_sid_group_mapping(
    ?,
    'S-1-5-21-9146495592-531070549-834388463-513',
    'my_group')"
```

rdsadmin.list_sid_group_mapping

Lists all security ID (SID) and Active Directory group mappings configured on the DB instance.

Syntax

```
db2 "call rdsadmin.list_sid_group_mapping()"
```

Usage notes

For information about checking the status of listing mappings, see rdsadmin.get_task_status.

rdsadmin.remove_sid_group_mapping

Removes a security ID (SID) and its corresponding Active Directory group mapping from a DB instance.

Syntax

```
db2 "call rdsadmin.remove_sid_group_mapping(
    ?,
    'SID')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

SID

The security ID (SID). The data type is `varchar`.

Usage notes

For information about how to find the SID for a group, see Step 8: Retrieve the Active Directory group SID in PowerShell.

For information about checking the status of removing mappings, see rdsadmin.get_task_status.

Examples

The following example removes a SID mapping from the group it was mapped to.

```
db2 "call rdsadmin.remove_sid_group_mapping(
    ?,
    'S-1-5-21-9146495592-531070549-834388463-513')"
```

Stored procedures for audit policies for RDS for Db2

The built-in stored procedures described in this topic manage audit policies for Amazon RDS for Db2 databases that use audit logging. For more information, see the section called “Db2 audit logging”. To run these procedures, the master user must first connect to the `rdsadmin` database.

Refer to the following built-in stored procedures for information about their syntax, parameters, usage notes, and examples.

Stored procedures

- rdsadmin.configure_db_audit
- rdsadmin.disable_db_audit

rdsadmin.configure_db_audit

Configures the audit policy for the RDS for Db2 database specified by *db_name*. If the policy you're configuring doesn't exist, calling this stored procedure creates it. If this policy does exist, calling this stored procedure modifies it with the parameter values that you provide.

Syntax

```
db2 "call rdsadmin.configure_db_audit(
    'db_name',
    'category',
    'category_setting',
    '?')"
```

Parameters

The following parameters are required.

db_name

The DB name of the RDS for Db2 database to configure the audit policy for. The data type is `varchar`.

category

The name of the category to configure this audit policy for. The data type is `varchar`. The following are valid values for this parameter:

- ALL – With ALL, Amazon RDS doesn't include the CONTEXT, EXECUTE, or ERROR categories.
- AUDIT
- CHECKING
- CONTEXT
- ERROR
- EXECUTE – You can configure this category with data or without data. With data means to also log input data values provided for any host variables and parameter markers. The default is without data. For more information, see the description of the *category_setting* parameter and the the section called "Examples".
- OBJMAINT
- SECMAINT
- SYSADMIN
- VALIDATE

For more information about these categories, see the IBM Db2 documentation.

category_setting

The setting for the specified audit category. The data type is varchar.

The following table shows the valid category setting values for each category.

Category	Valid category settings
ALL	BOTH|FAILURE|SUCCESS|NONE
AUDIT	
CHECKING	
CONTEXT	
OBJMAINT	
SECMAINT	
SYSADMIN	

Category	Valid category settings
VALIDATE	
ERROR	AUDIT|NORMAL . The default is NORMAL.
EXECUTE	BOTH,WITH|BOTH,WITHOUT|FAILURE,WITH|FAILURE,WITHOUT|SUCCESS,WITH|SUCCESS,WITHOUT|NONE

Usage notes

Before you call `rdsadmin.configure_db_audit`, make sure the RDS for Db2 DB instance with the database you're configuring the audit policy for is associated with an option group that has the `DB2_AUDIT` option. For more information, see the section called “Setting up Db2 audit logging”.

After you configure the audit policy, you can check the status of the audit configuration for the database by following the steps in Check the audit configuration.

Specifying `ALL` for the `category` parameter doesn't include the `CONTEXT`, `EXECUTE`, or `ERROR` categories. To add these categories to your audit policy, call `rdsadmin.configure_db_audit` separately with each category that you want to add. For more information, see the section called “Examples”.

Examples

The following examples create or modify the audit policy for a database named `TESTDB`. In examples 1 through 5, if the `ERROR` category wasn't previously configured, this category is set to `NORMAL` (the default). To change that setting to `AUDIT`, follow Example 6: Specifying the ERROR category.

Example 1: Specifying the ALL category

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'ALL', 'BOTH', ?)"
```

In the example, the call configures the `AUDIT`, `CHECKING`, `OBJMAINT`, `SECMAINT`, `SYSADMIN`, and `VALIDATE` categories in the audit policy. Specifying `BOTH` means that both successful and failing events will be audited for each of these categories.

Example 2: Specifying the EXECUTE category with data

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'EXECUTE', 'SUCCESS,WITH', ?)"
```

In the example, the call configures the EXECUTE category in the audit policy. Specifying SUCCESS,WITH means that logs for this category will include only successful events, and will include input data values provided for host variables and parameter markers.

Example 3: Specifying the EXECUTE category without data

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'EXECUTE', 'FAILURE,WITHOUT', ?)"
```

In the example, the call configures the EXECUTE category in the audit policy. Specifying FAILURE,WITHOUT means that logs for this category will include only failing events, and won't include input data values provided for host variables and parameter markers.

Example 4: Specifying the EXECUTE category without status events

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'EXECUTE', 'NONE', ?)"
```

In the example, the call configures the EXECUTE category in the audit policy. Specifying NONE means that no events in this category will be audited.

Example 5: Specifying the OBJMAINT category

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'OBJMAINT', 'NONE', ?)"
```

In the example, the call configures the OBJMAINT category in the audit policy. Specifying NONE means that no events in this category will be audited.

Example 6: Specifying the ERROR category

```
db2 "call rdsadmin.configure_db_audit('TESTDB', 'ERROR', 'AUDIT', ?)"
```

In the example, the call configures the ERROR category in the audit policy. Specifying AUDIT means that all errors, including errors occurring within audit logging itself, are captured in the logs. The default error type is NORMAL. With NORMAL, errors generated by the audit are ignored and only the SQLCODEs for errors associated with the operation being performed are captured.

rdsadmin.disable_db_audit

Stops audit logging for the RDS for Db2 database specified by *db_name* and removes the audit policy configured for it.

> **Note**
>
> This stored procedure only removes audit policies that were configured by calling the section called "rdsadmin.configure_db_audit".

Syntax

```
db2 "call rdsadmin.disable_db_audit('db_name', ?)"
```

Parameters

The following parameters are required.

db_name

The DB name of the RDS for Db2 database to disable audit logging for. The data type is `varchar`.

Usage notes

Calling `rdsadmin.disable_db_audit` doesn't disable audit logging for the RDS for Db2 DB instance. To disable audit logging at the DB instance level, remove the option group from the DB instance. For more information, see Disabling Db2 audit logging.

Examples

The following example disables audit logging for a database named `TESTDB`.

```
db2 "call rdsadmin.disable_db_audit('TESTDB', ?)"
```

Stored procedures for buffer pools for RDS for Db2

The built-in stored procedures described in this topic manage buffer pools for Amazon RDS for Db2 databases. To run these procedures, the master user must first connect to the `rdsadmin` database.

These stored procedures are used in a variety of tasks. This list isn't exhaustive.

- Common tasks for buffer pools
- Generating performance reports
- Copying database metadata with db2look
- Creating a repository database for IBM Db2 Data Management Console

Refer to the following built-in stored procedures for information about their syntax, parameters, usage notes, and examples.

Stored procedures

- rdsadmin.create_bufferpool
- rdsadmin.alter_bufferpool
- rdsadmin.drop_bufferpool

rdsadmin.create_bufferpool

Creates a buffer pool.

Syntax

```
db2 "call rdsadmin.create_bufferpool(
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    page_size,
    number_block_pages,
    block_size)"
```

Parameters

The following parameters are required:

database_name

The name of the database to run the command on. The data type is varchar.

buffer_pool_name

The name of the buffer pool to create. The data type is varchar.

The following parameters are optional:

buffer_pool_size

The size of the buffer pool in number of pages. The data type is integer. The default is -1.

immediate

Specifies whether the command runs immediately. The data type is char. The default is Y.

automatic

Specifies whether to set the buffer pool to automatic. The data type is char. The default is Y.

page_size

The page size of the buffer pool. The data type is integer. Valid values: 4096, 8192, 16384, 32768. The default is 8192.

number_block_pages

The number of block pages in the buffer pools. The data type is integer. The default is 0.

block_size

The block size for the block pages. The data type is integer. Valid values: 2 to 256. The default is 32.

Usage notes

For information about checking the status of creating a buffer pool, see rdsadmin.get_task_status.

Examples

Example 1: Creating buffer pool with default parameters

The following example creates a buffer pool called BP8 for a database called TESTDB with default parameters, so the buffer pool uses an 8 KB page size.

```
db2 "call rdsadmin.create_bufferpool(
    'TESTDB',
    'BP8')"
```

Example 2: Creating buffer pool to run immediately with automatic allocation

The following example creates a buffer pool called BP16 for a database called TESTDB that uses a 16 KB page size with an initial page count of 1,000 and is set to automatic. Db2 runs the command immediately. If you use an initial page count of -1, then Db2 will use automatic allocation of pages.

```
db2 "call rdsadmin.create_bufferpool(
    'TESTDB',
    'BP16',
    1000,
    'Y',
    'Y',
    16384)"
```

Example 3: Creating buffer pool to run immediately using block pages

The following example creates a buffer pool called BP16 for a database called TESTDB. This buffer pool has a 16 KB page size with an initial page count of 10,000. Db2 runs the command immediately using 500 block pages with a block size of 512.

```
db2 "call rdsadmin.create_bufferpool(
    'TESTDB',
    'BP16',
    10000,
    'Y',
    'Y',
    16384,
    500,
    512)"
```

rdsadmin.alter_bufferpool

Alters a buffer pool.

Syntax

```
db2 "call rdsadmin.alter_bufferpool(
    'database_name',
    'buffer_pool_name',
    buffer_pool_size,
    'immediate',
    'automatic',
    change_number_blocks,
    number_block_pages,
    block_size)"
```

Parameters

The following parameters are required:

database_name

The name of the database to run the command on. The data type is `varchar`.

buffer_pool_name

The name of the buffer pool to alter. The data type is `varchar`.

buffer_pool_size

The size of the buffer pool in number of pages. The data type is `integer`.

The following parameters are optional:

immediate

Specifies whether the command runs immediately. The data type is `char`. The default is `Y`.

automatic

Specifies whether to set the buffer pool to automatic. The data type is `char`. The default is `N`.

change_number_blocks

Specifies whether there is a change to the number of block pages in the buffer pool. The data type is `char`. The default is `N`.

number_block_pages

The number of block pages in the buffer pools. The data type is `integer`. The default is `0`.

block_size

The block size for the block pages. The data type is `integer`. Valid values: 2 to 256. The default is 32.

Usage notes

For information about checking the status of altering a buffer pool, see rdsadmin.get_task_status.

Examples

The following example alters a buffer pool called BP16 for a database called TESTDB to non-automatic, and changes the size to 10,000 pages. Db2 runs this command immediately.

```
db2 "call rdsadmin.alter_bufferpool(
    'TESTDB',
    'BP16',
    10000,
    'Y',
    'N')"
```

rdsadmin.drop_bufferpool

Drops a buffer pool.

Syntax

```
db2 "call rdsadmin.drop_bufferpool(
    'database_name',
    'buffer_pool_name'"
```

Parameters

The following parameters are required:

database_name

The name of the database that the buffer pool belongs to. The data type is `varchar`.

buffer_pool_name

The name of the buffer pool to drop. The data type is `varchar`.

Usage notes

For information about checking the status of dropping a buffer pool, see rdsadmin.get_task_status.

Examples

The following example drops a buffer pool called BP16 for a database called TESTDB.

```
db2 "call rdsadmin.drop_bufferpool(
    'TESTDB',
    'BP16')"
```

Stored procedures for databases for RDS for Db2

The built-in stored procedures described in this topic manage databases for Amazon RDS for Db2. To run these procedures, the master user must first connect to the `rdsadmin` database.

These stored procedures are used in a variety of tasks. This list isn't exhaustive.

- Common tasks for databases
- Creating databases with EBCDIC collation
- Collecting information about databases
- Modifying database configuration parameters
- Migrating from Linux to Linux
- Migrating from Linux to Linux with near-zero downtime

Refer to the following built-in stored procedures for information about their syntax, parameters, usage notes, and examples.

Stored procedures

- rdsadmin.create_database
- rdsadmin.deactivate_database
- rdsadmin.activate_database
- rdsadmin.reactivate_database
- rdsadmin.drop_database
- rdsadmin.update_db_param
- rdsadmin.set_configuration
- rdsadmin.show_configuration
- rdsadmin.backup_database
- rdsadmin.restore_database
- rdsadmin.rollforward_database
- rdsadmin.rollforward_status
- rdsadmin.complete_rollforward
- rdsadmin.db2pd_command
- rdsadmin.force_application

- rdsadmin.set_archive_log_retention
- rdsadmin.show_archive_log_retention
- rdsadmin.list_archive_log_information
- rdsadmin.enable_archive_log_copy
- rdsadmin.disable_archive_log_copy
- rdsadmin.fgac_command
- rdsadmin.db2support_command

rdsadmin.create_database

Creates a database.

Syntax

```
db2 "call rdsadmin.create_database(
    'database_name',
    'database_page_size',
    'database_code_set',
    'database_territory',
    'database_collation',
    'database_autoconfigure_str',
    'database_non-restrictive')"
```

Parameters

> **Note**
>
> This stored procedure doesn't validate the combination of required parameters. When you call rdsadmin.get_task_status, the user-defined function could return an error because of a combination of `database_codeset`, `database_territory`, and `database_collation` that is not valid. For more information, see Choosing the code page, territory, and collation for your database in the IBM Db2 documentation.

The following parameter is required:

database_name

The name of the database to create. The data type is `varchar`.

The following parameters are optional:

database_page_size

The default page size of the database. Valid values: 4096, 8192, 16384, 32768. The data type is integer. The default is 8192.

> **Important**
>
> Amazon RDS supports write atomicity for 4 KiB, 8 KiB, and 16 KiB pages. In contrast, 32 KiB pages risk *torn writes*, or partial data being written to the disk. If you use 32 KiB pages, we recommend that you enable point-in-time recovery and automated backups. Otherwise, you run the risk of being unable to recover from torn pages. For more information, see the section called "Introduction to backups" and the section called "Point-in-time recovery".

database_code_set

The code set for the database. The data type is varchar. The default is UTF-8.

database_territory

The two-letter country code for the database. The data type is varchar. The default is US.

database_collation

The collation sequence that determines how character strings stored in the database are sorted and compared. The data type is varchar.

Valid values:

- COMPATIBILITY – An IBM Db2 Version 2 collation sequence.
- EBCDIC_819_037 – ISO Latin code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_819_500 – ISO Latin code page, collation; CCSID 500 (EBCDIC International).
- EBCDIC_850_037 – ASCII Latin code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_850_500 – ASCII Latin code page, collation; CCSID 500 (EBCDIC International).
- EBCDIC_932_5026 – ASCII Japanese code page, collation; CCSID 5026 (EBCDIC US English).
- EBCDIC_932_5035 – ASCII Japanese code page, collation; CCSID 5035 (EBCDIC International).

- EBCDIC_1252_037 – Windows Latin code page, collation; CCSID 037 (EBCDIC US English).
- EBCDIC_1252_500 – Windows Latin code page, collation; CCSID 500 (EBCDIC International).
- IDENTITY – Default collation. Strings are compared byte for byte.
- IDENTITY_16BIT – The Compatibility Encoding Scheme for UTF-16: 8-bit (CESU-8) collation sequence. For more information, see Unicode Technical Report #26 on the Unicode Consortium website.
- NLSCHAR – Only for use with the Thai code page (CP874).
- SYSTEM – If you use SYSTEM, the database uses the collation sequence automatically for database_codeset and database_territory.

The default is IDENTITY.

Additionally, RDS for Db2 supports the following groups of collations: language-aware-collation and locale-sensitive-collation. For more information, see Choosing a collation for a Unicode database in the IBM Db2 documentation.

database_autoconfigure_str

The AUTOCONFIGURE command syntax, for example, 'AUTOCONFIGURE APPLY DB'. The data type is varchar. The default is an empty string or null.

For more information, see AUTOCONFIGURE command in the IBM Db2 documentation.

database_non-restrictive

The granting of default authorities and privileges within the database. The data type is varchar. The default is N.

Valid values:

- N – The created database is restrictive and doesn't grant authorities or privileges.
- Y – The created database is non-restrictive and grants a set of permissions to the special group PUBLIC. For more information, see Default privileges granted on creating a database in the IBM Db2 documentation.

Usage notes

If you plan on modifying the db2_compatibility_vector parameter, modify the parameter before creating a database. For more information, see Setting the db2_compatibility_vector parameter.

Special considerations:

- The `CREATE DATABASE` command sent to the Db2 instance uses the `RESTRICTIVE` option.
- RDS for Db2 only uses `AUTOMATIC STORAGE` tablespaces.
- RDS for Db2 uses the default values for `NUMSEGS` and `DFT_EXTENT_SZ`.
- RDS for Db2 uses storage encryption and doesn't support database encryption.

For more information about these considerations, see CREATE DATABASE command in the IBM Db2 documentation.

Before calling `rdsadmin.create_database`, you must connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your RDS for Db2 DB instance information:

```
db2 connect to rdsadmin user master_username using master_password
```

For information about checking the status of creating a database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.create_database`, see the section called "Stored procedure errors".

Examples

The following example creates a database called `TESTJP` with a correct combination of the *`database_code_set`*, *`database_territory`*, and *`database_collation`* parameters for Japan:

```
db2 "call rdsadmin.create_database('TESTJP', 4096, 'IBM-437', 'JP', 'SYSTEM')"
```

rdsadmin.deactivate_database

Deactivates a database.

Syntax

```
db2 "call rdsadmin.deactivate_database(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database to deactivate. The data type is `varchar`.

Usage notes

You can deactivate databases to conserve memory resources or to make other database configuration changes. To bring deactivated databases back online, call the rdsadmin.activate_database stored procedure.

You can't deactivate a database on a source DB instance during replication by calling the `rdsadmin.deactivate_database` stored procedure.

For information about checking the status of deactivating a database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.deactivate_database`, see the section called "Stored procedure errors".

Examples

The following example deactivates a database called `TESTDB`.

```
db2 "call rdsadmin.deactivate_database(?, 'TESTDB')"
```

rdsadmin.activate_database

Activates a database.

For information about the differences between rdsadmin.reactivate_database and `rdsadmin.activate_database`, see Usage notes.

Syntax

```
db2 "call rdsadmin.activate_database(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database to activate. The data type is `varchar`.

Usage notes

All databases are activated by default when they are created. If you deactivate a database on a standalone DB instance to conserve memory resources or to make other database configuration changes, call the `rdsadmin.activate_database` stored procedure to activate the database again.

This stored procedure only activates a database that is on a standalone DB instance and that was deactivated by calling the rdsadmin.deactivate_database stored procedure. To activate a database on a replica source DB instance, you must call the rdsadmin.reactivate_database stored procedure.

For information about checking the status of activating a database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.activate_database`, see the section called "Stored procedure errors".

Examples

The following example activates a database called `TESTDB`.

```
db2 "call rdsadmin.activate_database(?, 'TESTDB')"
```

rdsadmin.reactivate_database

Reactivates a database.

For information about differences between rdsadmin.activate_database and `rdsadmin.reactivate_database`, see Usage notes.

Syntax

```
db2 "call rdsadmin.reactivate_database(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database to reactivate. The data type is `varchar`.

Usage notes

When you call the `rdsadmin.reactivate_database` stored procedure, the stored procedure first deactivates the database by calling the rdsadmin.deactivate_database stored procedure, and then activates the database by calling the rdsadmin.activate_database stored procedure.

After you make changes to database configurations, you might need to reactivate a database on an RDS for Db2 DB instance. To determine if you need to reactivate a database, connect to the database and run `db2 get db cfg show detail`.

For a database on a standalone DB instance, you can use the `rdsadmin.reactivate_database` store procedure to reactivate the database. Or, if you already called the rdsadmin.deactivate_database stored procedure, you can call the rdsadmin.activate_database stored procedure instead.

For a database on a replica source DB instance, you must use the `rdsadmin.reactivate_database` stored procedure to reactivate the database.

For information about checking the status of reactivating a database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.reactivate_database`, see the section called "Stored procedure errors".

Examples

The following example reactivates a database called `TESTDB`.

```
db2 "call rdsadmin.reactivate_database(?, 'TESTDB')"
```

rdsadmin.drop_database

Drops a database.

Syntax

```
db2 "call rdsadmin.drop_database('database_name')"
```

Parameters

The following parameter is required:

database_name

The name of the database to drop. The data type is `varchar`.

Usage notes

You can drop a database by calling `rdsadmin.drop_database` only if the following conditions are met:

- You didn't specify the name of the database when you created your RDS for Db2 DB instance by using either the Amazon RDS console or the AWS CLI. For more information, see Creating a DB instance.
- You created the database by calling the the section called "rdsadmin.create_database" stored procedure.

- You restored the database from an offline or backed-up image by calling the the section called "rdsadmin.restore_database" stored procedure.

Before calling `rdsadmin.drop_database`, you must connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your RDS for Db2 DB instance information:

```
db2 connect to rdsadmin user master_username using master_password
```

For information about checking the status of dropping a database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.drop_database`, see the section called "Stored procedure errors".

Examples

The following example drops a database called TESTDB:

```
db2 "call rdsadmin.drop_database('TESTDB')"
```

rdsadmin.update_db_param

Updates database parameters.

Syntax

```
db2 "call rdsadmin.update_db_param(
    'database_name',
    'parameter_to_modify',
    'changed_value',
    'restart_database')"
```

Parameters

The following parameters are required:

`database_name`

The name of the database to run the task for. The data type is `varchar`.

parameter_to_modify

The name of the parameter to modify. The data type is `varchar`. For more information, see Amazon RDS for Db2 parameters.

changed_value

The value to change the parameter value to. The data type is `varchar`.

The following parameter is optional:

restart_database

Specifies whether RDS restarts the database if a restart is necessary. The data type is `varchar`. To modify `logprimary` and `logfilsiz`, set this parameter to `'YES'`.

Usage notes

For information about checking the status of updating database parameters, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.update_db_param`, see the section called "Stored procedure errors".

Examples

Example 1: Updating a parameter

The following example updates the `archretrydelay` parameter to `100` for a database called `TESTDB`:

```
db2 "call rdsadmin.update_db_param(
    'TESTDB',
    'archretrydelay',
    '100')"
```

Example 2: Deferring validation of objects

The following example defers the validation of created objects on a database called `TESTDB` to avoid dependency checking:

```
db2 "call rdsadmin.update_db_param(
    'TESTDB',
    'auto_reval',
    'deferred_force')"
```

rdsadmin.set_configuration

Configures specific settings for the database.

Syntax

```
db2 "call rdsadmin.set_configuration(
    'name',
    'value')"
```

Parameters

The following parameters are required:

name

The name of the configuration setting. The data type is `varchar`.

value

The value for the configuration setting. The data type is `varchar`.

Usage notes

The following table shows the configuration settings that you can control with `rdsadmin.set_configuration`.

Name	Description
RESTORE_DATABASE_NUM_BUFFERS	The number of buffers to create during a restore operation. This value must be less than the total memory size of the DB instance class. If this setting isn't configured, Db2 determines the value to use during the restore operation. For more information, see RESTORE DATABASE command in the IBM Db2 documentation.

Name	Description
RESTORE_DATABASE_PARALLELISM	The number of buffer manipulators to create during a restore operation. This value must be less than double the number of vCPUs for the DB instance. If this setting isn't configured, Db2 determines the value to use during the restore operation. For more information, see RESTORE DATABASE command in the IBM Db2 documentation.
RESTORE_DATABASE_NUM_MULTI_PATHS	The number of paths (or I/O streams) to use during a restore from Amazon S3 operation. To use this configuration setting, you must have multiple backup files. This value can improve performance when restoring databases with large volumes of data because it restores multiple database backup files in parallel. We recommend that you set this value to match the number of your database backup files. For more information, see BACKUP DATABASE command in the IBM Db2 documentation.
USE_STREAMING_RESTORE	Specifies whether to stream backup data directly during restoration rather than first downloading the entire backup to your RDS for Db2 DB instance and then extracting it. Setting USE_STREAMING_RESTORE to TRUE significantly reduces storage requirements and can improve restore performance. This setting requires IBM Db2 engine version 11.5.9.0.sb00063198.r1 or higher, and Amazon S3 connectivity through your database's elastic network interface (ENI). For more information, see Remote storage in the IBM Db2 documentation.

Examples

Example 1: Specifying number of buffers to create

The following example sets the RESTORE_DATABASE_NUM_BUFFERS configuration to 150.

```
db2 "call rdsadmin.set_configuration(
    'RESTORE_DATABASE_NUM_BUFFERS',
```

```
    '150')"
```

Example 2: Specifying number of buffer manipulators to create

The following example sets the RESTORE_DATABASE_PARALLELISM configuration to 8.

```
db2 "call rdsadmin.set_configuration(
    'RESTORE_DATABASE_PARALLELISM',
    '8')"
```

Example 3: Specifying number of paths or I/O streams to use during restore

The following example sets the RESTORE_DATABASE_NUM_MULTI_PATHS configuration to 5.

```
db2 "call rdsadmin.set_configuration(
    'RESTORE_DATABASE_NUM_MULTI_PATHS',
    '5')"
```

Example 4: Setting restoration to stream backup data

The following example sets the USE_STREAMING_RESTORE configuration to TRUE.

```
db2 "call rdsadmin.set_configuration(
    'USE_STREAMING_RESTORE',
    'TRUE')"
```

rdsadmin.show_configuration

Returns the current settings that you can set by using the stored procedure rdsadmin.set_configuration.

Syntax

```
db2 "call rdsadmin.show_configuration(
    'name')"
```

Parameters

The following parameter is optional:

name

The name of the configuration setting to return information about. The data type is `varchar`.

The following configuration names are valid:

- `RESTORE_DATABASE_NUM_BUFFERS` – The number of buffers to create during a restore operation.
- `RESTORE_DATABASE_PARALLELISM` – The number of buffer manipulators to create during a restore operation.
- `RESTORE_DATABASE_NUM_MULTI_PATHS` – The number of paths (or I/O streams) to use during a restore from Amazon S3 operation.
- `USE_STREAMING_RESTORE` – Specifies whether to stream backup data directly during restoration rather than first downloading the entire backup data to your RDS for Db2 DB instance and then extracting it.

Usage notes

If you don't specify the name of a configuration setting, `rdsadmin.show_configuration` returns information for all configuration settings that you can set by using the stored procedure `rdsadmin.set_configuration`.

Examples

The following example returns information about the current `RESTORE_DATABASE_PARALLELISM` configuration.

```
db2 "call rdsadmin.show_configuration(
    'RESTORE_DATABASE_PARALLELISM')"
```

rdsadmin.backup_database

Backs up a database from an RDS for Db2 DB instance to an Amazon S3 bucket.

Syntax

```
db2 "call rdsadmin.backup_database(
    ?,
    'database_name',
```

```
    's3_bucket_name',
    's3_prefix',
    'backup_type',
    'compression_option',
    'util_impact_priority',
    'num_files',
    'parallelism',
    'num_buffers')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the target database on an RDS for Db2 DB instance to back up. The data type is `varchar`.

The database must exist in the DB instance. You can't back up the `rdsadmin` database.

s3_bucket_name

The name of the Amazon S3 bucket where you want your backup to reside. The data type is `varchar`.

The S3 bucket must exist before calling `rdsadmin.backup_database`, be in the same AWS Region as the target database in the RDS for Db2 DB instance that you want to back up, and be accessible through the IAM role attached to the DB instance.

s3_prefix

The prefix of the path to Amazon S3 where RDS for Db2 uploads the backup files. The data type is `varchar`.

The prefix is limited to 1024 characters. It must not include a leading or trailing slash (/). Because of a limitation with IBM streaming to Amazon S3, we recommend that the prefix includes subdirectories.

For better file management, RDS for Db2 creates extra directories after *s3_prefix*. RDS for Db2 uploads all backup files to *s3_prefix/dbi_resource_id/db_name*. If you set *num_files* higher than 1, the *db_name* directory will contain more than one backup file.

The following is an example Amazon S3 location for backup files. In the example, `backups/daily` is the value set for the *s3_prefix* parameter.

```
backups/daily/db-5N7FXOY4GDP7RG2NSH2ZTAI2W4/SAMPLEDB
```

backup_type

The type of backup that determines if the database remains available during backup. The data type is `varchar`.

Valid values:

- `OFFLINE` – The database is unavailable during backup. This type is faster, but it causes downtime.
- `ONLINE` – The database remains available during backup. By default, `ONLINE` is set to `INCLUDE LOGS`.

The following parameters are optional:

compression_option

The type of compression algorithm used that impacts backup time, CPU usage, and storage costs. The data type is `varchar`. The default is `NONE`.

Valid values:

- `NONE` – The largest file size, the least CPU usage, and cheapest storage costs.
- `STANDARD` – Standard Db2 compression. Uses `libdb2compr.so`.
- `ZLIB` – Enhanced Db2 compression. Uses `libdb2zcompr.so`, but is more CPU-intensive and most expensive storage cost.

util_impact_priority

The setting that controls the impact of the backup on the system resources. The data type is `integer`. Valid values: `1`–`100` (from low to high). The default is `50`.

Lower values reduce the impact of the backup on the system resources, but might increase the time it takes to back up the database. Higher values might complete the backup of

the database faster, but could affect other operations. The actual impact depends on the overall system utilization and the `util_impact_lim` setting. You can view and modify the `util_impact_lim` setting in parameter groups. For more information, see Amazon RDS for Db2 parameters.

`num_files`

The number of parallel upload streams to Amazon S3. The data type is `integer`. Valid values: 1–256.

We recommend that you only set this parameter after observing the backup performance at the default that Amazon RDS automatically calculates. Higher values could improve performance for large backups, especially with high-bandwidth connections, but at a certain point, higher values degrade performance. Also, make sure to take into account your available system resources and network capacity.

`parallelism`

The number of tablespaces that the backup utility can read in parallel. The data type is `integer`. Valid values: 1–256.

We recommend that you only set this parameter after observing the backup performance at the default that the Db2 engine automatically calculates as the optimal value. If you set this parameter, Amazon RDS validates against the available processors and won't execute the backup request if processing power is insufficient.

`num_buffers`

The number of buffers to use. The data type is `integer`. Valid values: 1–268435456.

We recommend that you only set this parameter after observing the backup performance at the default that Amazon RDS automatically calculates based on memory. If you set this parameter, Amazon RDS validates against the available memory and won't execute the backup request if available memory is insufficient. If you are backing up to multiple locations (`num_files` is set to more than 1), then a higher number of buffers could improve performance. If you don't set `compression_option` to `NONE`, then you can improve performance by increasing `num_buffers` and `parallelism`.

Usage notes

This stored procedure creates asynchronous backup tasks that stream the backup of your database directly to your Amazon S3 bucket by using the Amazon S3 integration. You can make backups

both from your local server or from an RDS for Db2 DB instance, stream them to Amazon S3, and then restore them wherever you want. For information about restoring a database to an RDS for Db2 DB instance, see rdsadmin.restore_database.

Before calling the stored procedure, review the following considerations:

- You can only back up one database at a time.
- You can't perform a backup and restore together on a DB instance.
- Amazon S3 server-side encryption with AWS KMS (SSE-KMS) isn't supported. Even if the S3 bucket is set to SSE-KMS, the files uploaded to the S3 bucket won't use SSE-KMS encryption.
- To stream the backup files to Amazon S3, you must have already configured the integration. For more information, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.
- For an RDS for Db2 DB instance to be able to interact with Amazon S3, you must have a VPC and an Amazon S3 gateway endpoint for private subnets to use. For more information, see Step 1: Create a VPC gateway endpoint for Amazon S3 and Step 2: Confirm that your VPC gateway endpoint for Amazon S3 exists.

Before calling `rdsadmin.backup_database`, you must connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your RDS for Db2 DB instance information:

```
db2 connect to rdsadmin user master_username using master_password
```

After you back up your database, be sure to terminate the connection.

```
terminate
```

For information about checking the status of backing up a database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.backup_database`, see the section called "Stored procedure errors".

Examples

All the examples back up a database called `MYDB` to the Amazon S3 bucket called `amzn-s3-demo-bucket` and set the *`s3_prefix`* to `backups/daily`.

Example #1: Specifying database offline and unavailable with median utilization and a single upload stream

In the following example, the database is offline, which is faster but means that the database is unavailable during backup. The example performs no compression of the files, has median impact on system resources, and uses a single upload stream to Amazon S3.

```
db2 call "rdsadmin.backup_database(
    ?,
    'MYDB',
    'amzn-s3-demo-bucket',
    'backups/daily',
    'OFFLINE',
    'NONE',
    50,
    1)"
```

Example #2: Specifying database online and available with enhanced compression, median utilization, and few parallel upload streams

In the following example, the database in online and available during backup. The example performs enhanced compression, which results in a small file size, but is CPU-intensive. It has a slightly higher than median impact on system resources and uses five upload streams to Amazon S3.

```
db2 call "rdsadmin.backup_database(
    ?,
    'MYDB',
    'amzn-s3-demo-bucket',
    'backups/daily',
    'ONLINE',
    'ZLIB',
    60,
    5)"
```

Example #3: Specifying database offline and unavailable with defaults and system calculations

In the following example, the database is offline, which is faster but means that the database is unavailable during backup. The example uses the default compression of the files and impact on system resources. It also allows RDS for Db2 to calculate the number of parallel upload streams to Amazon S3, tablespaces to read in parallel, and buffers to use.

```
db2 "call rdsadmin.backup_database(
    ?,
    'MYDB',
    'amzn-s3-demo-bucket',
    'backups/daily',
    'OFFLINE')"
```

Example #4: Specifying database offline and unavailable with no compression, high utilization, and custom calculations

In the following example, the database is offline, which is faster but means that the database is unavailable during backup. The example performs no compression of the files, has a high impact on system resources, and uses 20 upload streams to Amazon S3. It sets the maximum number of tablespaces to read in parallel, which can cause the backup request to fail if processing power is insufficient. It also sets the maximum number of buffers to use, which can cause the backup request to fail if memory is insufficient.

```
db2 "call rdsadmin.backup_database(
    ?,
    'MYDB',
    'amzn-s3-demo-bucket',
    'backups/daily',
    'OFFLINE',
    'NONE',
    90,
    20,
    256,
    268435456)"
```

rdsadmin.restore_database

Restores a database from an Amazon S3 bucket to your RDS for Db2 DB instance.

Syntax

```
db2 "call rdsadmin.restore_database(
    ?,
    'database_name',
    's3_bucket_name',
    's3_prefix',
    restore_timestamp,
```

```
    'backup_type')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the target database to restore in RDS for Db2. The data type is `varchar`.

For example, if the source database name was `TESTDB` and you set *database_name* to `NEWDB`, then Amazon RDS restores `NEWDB` as the source database.

s3_bucket_name

The name of the Amazon S3 bucket where your backup resides. The data type is `varchar`.

s3_prefix

The prefix to use for file matching during download. The data type is `varchar`.

If this parameter is empty, then all files in the Amazon S3 bucket will be processed. The following is an example prefix:

```
backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101
```

restore_timestamp

The timestamp of the database backup image. The data type is `varchar`.

The timestamp is included in the backup file name. For example, `20230615010101` is the timestamp for the file name `SAMPLE.0.rdsdb.DBPART000.20230615010101.001`.

backup_type

The type of backup. The data type is `varchar`. Valid values: `OFFLINE`, `ONLINE`.

Use `ONLINE` for near-zero downtime migrations. For more information, see Migrating from Linux to Linux with near-zero downtime for Amazon RDS for Db2.

Usage notes

You can use this stored procedure to migrate a Db2 database to an RDS for Db2 DB instance. For more information, see Using AWS services to migrate data from Db2 to Amazon RDS for Db2. You can also use this stored procedure to create multiple copies of the same database with different database names that use the same restore image.

Before calling the stored procedure, review the following considerations:

- Before restoring a database, you must provision storage space for your RDS for Db2 DB instance that is greater than the original Db2 database on disk. If you enabled `USE_STREAMING_RESTORE`, then when you restore your backup, Amazon RDS streams the backup files directly from your S3 bucket to your RDS for Db2 DB instance. If you don't enable `USE_STREAMING_RESTORE`, you must provision storage space for your RDS for Db2 DB instance that is equal to or greater than the sum of the backup size plus the original Db2 database on disk. For more information, see Insufficient disk space.
- When you restore the backup, Amazon RDS extracts the backup file on your RDS for Db2 DB instance. Each backup file must be 5 TB or smaller. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- To restore all files using the `rdsadmin.restore_database` stored procedure, don't include the file number suffix after the timestamp in the file names. For example, the *`s3_prefix`* `backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101` restores the following files:

```
SAMPLE.0.rdsdb.DBPART000.20230615010101.001
SAMPLE.0.rdsdb.DBPART000.20230615010101.002
SAMPLE.0.rdsdb.DBPART000.20230615010101.003
SAMPLE.0.rdsdb.DBPART000.20230615010101.004
SAMPLE.0.rdsdb.DBPART000.20230615010101.005
```

- RDS for Db2 doesn't support non-automatic storage. For more information, see Tablespaces not restored.
- RDS for Db2 doesn't support non-fenced routines. For more information, see Non-fenced routines not allowed.
- To improve the performance of database restore operations, you can configure the number of buffers, buffer manipulators, and the number of multiple backup paths for RDS to use.

To optimize storage usage and to potentially improve performance, you can also directly stream a backup from Amazon S3. To check the current configuration, use the section called "rdsadmin.show_configuration". To change the configuration, use the section called "rdsadmin.set_configuration".

To bring the database online and apply additional transaction logs after restoring the database, see rdsadmin.rollforward_database.

For information about checking the status of restoring your database, see rdsadmin.get_task_status.

For error messages returned when calling `rdsadmin.restore_database`, see the section called "Stored procedure errors".

Examples

The following example restores an offline backup with a single file or multiple files that have the *s3_prefix* `backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101`:

```
db2 "call rdsadmin.restore_database(
    ?,
    'SAMPLE',
    'amzn-s3-demo-bucket',
    'backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101',
    20230615010101,
    'OFFLINE')"
```

rdsadmin.rollforward_database

Brings the database online and applies additional transaction logs after restoring a database by calling rdsadmin.restore_database.

Syntax

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'database_name',
    's3_bucket_name',
    s3_prefix,
    'rollforward_to_option',
```

```
    'complete_rollforward')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database to perform the operation on. The data type is `varchar`.

s3_bucket_name

The name of the Amazon S3 bucket where your backup resides. The data type is `varchar`.

s3_prefix

The prefix to use for file matching during download. The data type is `varchar`.

If this parameter is empty, then all files in the S3 bucket will be downloaded. The following example is an example prefix:

```
backupfolder/SAMPLE.0.rdsdb.DBPART000.20230615010101
```

The following input parameters are optional:

rollforward_to_option

The point to which you want to roll forward. The data type is `varchar`. Valid values: `END_OF_LOGS`, `END_OF_BACKUP` with the timestamp in the format `YYYY-MM-DD-HH.MM.SS`. The default is `END_OF_LOGS`.

complete_rollforward

Specifies whether to complete the roll-forward process. The data type is `varchar`. The default is `TRUE`.

If TRUE, then after completion, the database is online and accessible. If FALSE, then the database remains in a ROLL-FORWARD PENDING state.

Usage notes

You can use rds.rollforward_database for an online backup with include logs that are produced on-premises in many different scenarios.

Scenario 1: Restoring the database, rolling forward the included logs, and bringing the database online

After rdsadmin.restore_database() completes, use the syntax in Example 1 to bring the database with transaction logs online.

Scenario 2: Bringing the database online but not rolling forward the included logs.

After rdsadmin.restore_database() completes, use the syntax in Example 2 to bring the database without the transaction logs online.

Scenario 3: Rolling forward the included logs in the backup, and applying additional transaction logs as they are produced on-premises

After rdsadmin.restore_database() completes, use the syntax in Example 3 or Example 4 to rollforward logs without bringing the database online.

If you set complete_rollforward to FALSE, then your database is in a ROLL-FORWARD PENDING state and offline. To bring the database online, you must call rdsadmin.complete_rollforward.

For information about checking the status of rolling forward the database, see rdsadmin.rollforward_status.

Examples

Example 1: Bringing database with transaction logs online

The following example rolls forward to an online backup of the database with transaction logs and then brings the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
```

```
    null,
    null,
    'END_OF_LOGS',
    'TRUE')"
```

Example 2: Bringing database without transaction logs online

The following example rolls forward to an online backup of the database without transaction logs, and then brings the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'TESTDB',
    'amzn-s3-demo-bucket',
    'logsfolder/,
    'END_OF_BACKUP',
    'TRUE')"
```

Example 3: Not bringing database with transaction logs online

The following example rolls forward to an online backup of the database with transaction logs, and then doesn't bring the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'TESTDB',
    null,
    'onlinebackup/TESTDB',
    'END_OF_LOGS',
    'FALSE')"
```

Example 4: Not bringing database with additional transaction logs online

The following example rolls forward to an online backup of the database with additional transaction logs, and then doesn't bring the database online:

```
db2 "call rdsadmin.rollforward_database(
    ?,
    'TESTDB',
    'amzn-s3-demo-bucket',
    'logsfolder/S0000155.LOG',
    'END_OF_LOGS',
```

```
    'FALSE')"
```

rdsadmin.rollforward_status

Returns the output of `ROLLFORWARD DATABASE` *`database_name`* `QUERY STATUS`.

Syntax

```
db2 "call rdsadmin.rollforward_status(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

`database_name`

The name of the database to perform the operation on. The data type is `varchar`.

Usage notes

After you call rdsadmin.rollforward_database, you can call `rdsadmin.rollforward_status` to check on the status of the rollforward in the database.

For information about checking the status of this stored procedure, see rdsadmin.get_task_status.

rdsadmin.complete_rollforward

Brings database online from a `ROLL-FORWARD PENDING` state.

Syntax

```
db2 "call rdsadmin.complete_rollforward(
    ?,
```

```
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database that you want to bring online. The data type is `varchar`.

Usage notes

If you called rdsadmin.rollforward_database with `complete_rollforward` set to `FALSE`, then your database is in a `ROLL-FORWARD PENDING` state and offline. To complete the roll-forward process and bring the database online, call `rdsadmin.complete_rollforward`.

For information about checking the status of completing the rollforward process, see rdsadmin.rollforward_status.

Examples

The following example brings the TESTDB database online:

```
db2 "call rdsadmin.complete_rollforward(
    ?,
    'TESTDB')"
```

rdsadmin.db2pd_command

Collects information about an RDS for Db2 database.

Syntax

```
db2 "call rdsadmin.db2pd_command('db2pd_cmd')"
```

Parameters

The following input parameter is required:

db2pd_cmd

The name of the db2pd command that you want to run. The data type is `varchar`.

The parameter must start with a hyphen. For a list of parameters, see db2pd - Monitor and troubleshoot Db2 database command in the IBM Db2 documentation.

The following options aren't supported:

- `-addnode`
- `-alldatabases`
- `-alldbp`
- `-alldbs`
- `-allmembers`
- `-alm_in_memory`
- `-cfinfo`
- `-cfpool`
- `-command`
- `-dbpartitionnum`
- `-debug`
- `-dump`
- `-everything`
- `-file | -o`
- `-ha`
- `-interactive`
- `-member`
- `-pages`

> **Note**
>
> `-pages summary` is supported.

- `-pdcollection`
- `-repeat`
- `-stack`
- `-totalmem`

The `file` suboption isn't supported, for example, `db2pd -db testdb -tcbstats file=tcbstat.out`.

The use of the `stacks` option isn't supported, for example, `db2pd -edus interval=5 top=10 stacks`.

Usage notes

This stored procedure gathers information that can help with monitoring and troubleshooting RDS for Db2 databases.

The stored procedure uses the IBM db2pd utility to run various commands. The db2pd utility requires `SYSADM` authorization, which the RDS for Db2 master user doesn't have. However, with the Amazon RDS stored procedure, the master user is able to use the utility to run various commands. For more information about the utility, see db2pd - Monitor and troubleshoot Db2 database command in the IBM Db2 documentation.

The output is restricted to a maximum of 2 GB.

For information about checking the status of collecting information about the database, see rdsadmin.get_task_status.

Examples

Example 1: Returning uptime of DB instance

The following example returns the uptime of an RDS for Db2 DB instance:

```
db2 "call rdsadmin.db2pd_command('-')"
```

Example 2: Returning uptime of database

The following example returns the uptime of a database called `TESTDB`:

```
db2 "call rdsadmin.db2pd_command('-db TESTDB -')"
```

Example 3: Returning memory usage of DB instance

The following example returns the memory usage of an RDS for Db2 DB instance:

```
db2 "call rdsadmin.db2pd_command('-dbptnmem')"
```

Example 4: Returning memory sets of DB instance and database

The following example returns the memory sets of an RDS for Db2 DB instance and a database called TESTDB:

```
db2 "call rdsadmin.db2pd_command('-inst -db TESTDB -memsets')"
```

rdsadmin.force_application

Forces applications off of an RDS for Db2 database.

Syntax

```
db2 "call rdsadmin.force_application(
    ?,
    'applications')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

applications

The applications that you want to force off of an RDS for Db2 database. The data type is varchar. Valid values: ALL or *application_handle*.

Separate the names of multiple applications with commas. Example: '*application_handle_1*, *application_handle_2*'.

Usage notes

This stored procedure forces all applications off of a database so you can perform maintenance.

The stored procedure uses the IBM `FORCE APPLICATION` command. The `FORCE APPLICATION` command requires `SYSADM`, `SYSMAINT`, or `SYSCTRL` authorization, which the RDS for Db2 master user doesn't have. However, with the Amazon RDS stored procedure, the master user is able to use the command. For more information, see FORCE APPLICATION command in the IBM Db2 documentation.

For information about checking the status of forcing applications off of a database, see rdsadmin.get_task_status.

Examples

Example 1: Specifying all applications

The following example forces all applications off of an RDS for Db2 database:

```
db2 "call rdsadmin.force_application(
    ?,
    'ALL')"
```

Example 2: Specifying multiple applications

The following example forces application handles 9991, 8891, and 1192 off of an RDS for Db2 database:

```
db2 "call rdsadmin.force_application(
    ?,
    '9991, 8891, 1192')"
```

rdsadmin.set_archive_log_retention

Configures the amount of time (in hours) to retain archive log files for the specified RDS for Db2 database.

Syntax

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'database_name',
    'archive_log_retention_hours')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database to configure archive log retention for. The data type is `varchar`.

archive_log_retention_hours

The number of hours to retain the archive log files. The data type is `smallint`. The default is `0`, and the maximum is `840` (35 days).

If the value is `0`, Amazon RDS doesn't retain the archive log files.

Usage notes

By default, RDS for Db2 retains logs for 5 minutes. We recommend that if you use replication tools such as AWS DMS for change data capture (CDC) or IBM Q Replication, you set log retention in those tools for longer than 5 minutes.

You can view the current archive log retention setting by calling the section called "rdsadmin.show_archive_log_retention".

You can't configure the archive log retention setting on the `rdsadmin` database.

Examples

Example 1: Setting retention time

The following example sets the archive log retention time for a database called TESTDB to 24 hours.

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'TESTDB',
    '24')"
```

Example 2: Disabling retention time

The following example disables archive log retention for a database called TESTDB.

```
db2 "call rdsadmin.set_archive_log_retention(
    ?,
    'TESTDB',
    '0')"
```

rdsadmin.show_archive_log_retention

Returns the current archive log retention setting for the specified database.

Syntax

```
db2 "call rdsadmin.show_archive_log_retention(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database to show the archive log retention setting for. The data type is varchar.

Examples

The following example shows the archive log retention setting for a database called TESTDB.

```
db2 "call rdsadmin.show_archive_log_retention(?,'TESTDB')"
```

rdsadmin.list_archive_log_information

Returns details about the archive log files, such as the size, the creation date and time, and the name of individual log files for the specified database. It also returns the total storage amount used by the log files in the database.

Syntax

```
db2 "call rdsadmin.list_archive_log_information(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database to list archive log information for. The data type is varchar.

Examples

The following example returns archive log information for a database called TESTDB.

```
db2 "call rdsadmin.list_archive_log_information(
    ?,
    'TESTDB')"
```

rdsadmin.enable_archive_log_copy

Enables RDS Db2 database archive log copy to Amazon S3.

Syntax

```
db2 "call rdsadmin.enable_archive_log_copy(
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database for which to enable archive log copy to Amazon S3. The data type is `varchar`.

Examples

The following example enables archive log copy for a database called `TESTDB`.

```
db2 "call rdsadmin.enable_archive_log_copy(
    ?,
    'TESTDB')"
```

rdsadmin.disable_archive_log_copy

Disables RDS Db2 database archive log copy to Amazon S3.

Syntax

```
db2 "call rdsadmin.disable_archive_log_copy(
```

```
    ?,
    'database_name')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameter is required:

database_name

The name of the database for which to disable archive log copy to Amazon S3. The data type is varchar.

Examples

The following example disables archive log copy for a database called TESTDB.

```
db2 "call rdsadmin.disable_archive_log_copy(
    ?,
    'TESTDB')"
```

rdsadmin.fgac_command

Runs fine-grained access control (FGAC) commands.

Syntax

```
db2 "call rdsadmin.fgac_command(
    ?,
    'database_name',
    'fgac_cmd')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database that you want to run FGAC commands on. The data type is `varchar`.

fgac_cmd

The fine-grained access control command that you want to run. The data type is `varchar`.

The following commands are valid:

- `ALTER MASK` – Alters an existing column mask in row and column access control (RCAC).
- `ALTER PERMISSION` – Alters properties of an existing row permission in RCAC.
- `ALTER SECURITY POLICY` – Alters an existing security policy for RCAC.
- `ALTER SECURITY LABEL` – Alters properties of an existing security label in label-based access control (LBAC).
- `ALTER TABLE` – Alters table structure, including adding RCAC or LBAC controls.
- `CREATE MASK` – Creates a new column mask for RCAC.
- `CREATE PERMISSION` – Creates a new row permission for RCAC.
- `CREATE SECURITY LABEL` – Creates a new security label for LBAC.
- `CREATE SECURITY POLICY` – Creates a new security policy for RCAC.
- `DROP MASK` – Drops an existing column mask.
- `DROP PERMISSION` – Drops an existing row permission.
- `DROP SECURITY LABEL` – Drops a security label from LBAC.
- `DROP SECURITY POLICY` – Drops an existing RCAC security policy.
- `GRANT EXEMPTION ON RULE` – Allows a user to bypass specific LBAC rules.
- `GRANT SECURITY LABEL` – Assigns an LBAC security label to a user.
- `REVOKE EXEMPTION ON RULE` – Removes a user's exemption from LBAC rules.
- `REVOKE SECURITY LABEL` – Removes an LBAC security label from a user.

Usage notes

This stored procedure controls access at the row or column level to table data in your database on an RDS for Db2 DB instance. RDS for Db2 supports two types of FGAC on the database:

- Label-based access control (LBAC)
- Row and column access control (RCAC)

Before calling the stored procedure, review the following considerations:

- To escape a single quote ('), use an additional single quote. The following examples show how to escape `'apple'`, `'banana'`, and `'fruit'`.

```
db2 "call rdsadmin.fgac_command(
    ?,
    'testdb',
    'CREATE SECURITY LABEL COMPONENT FRUITSET SET{''apple'',''banana''}')"
```

```
db2 "call rdsadmin.fgac_command(
    ?,
    'testdb',
    'CREATE SECURITY LABEL COMPONENT FRUITTREE TREE(''fruit'' ROOT, ''apple'' UNDER
 ''fruit'', ''banana'' UNDER ''fruit'')')"
```

- To escape brackets ([ ]), use a backslash (\). The following example shows how to escape `[''apple'',''banana'']`.

```
db2 "call rdsadmin.fgac_command(
    ?, '
    testdb',
    'CREATE SECURITY LABEL COMPONENT FRUITARRAY ARRAY\[''apple'',''banana''\]')"
```

Examples

The following examples all run FGAC commands on a database called `testdb`.

Example 1: Creating a new security label called FRUITSET

```
db2 "call rdsadmin.fgac_command(
```

```
    ?,
    'testdb',
    'CREATE SECURITY LABEL COMPONENT FRUITSET SET{''apple'',''banana''}')"
```

Example 2: Creating a new mask for the EMP_ID column that is enabled when EMP_ID is set to less than three

```
db2 "call rdsadmin.fgac_command(
    ?,
    'testdb',
    'CREATE MASK id_MASK ON EMPLOYEE FOR COLUMN EMP_ID RETURN CASE WHEN (EMP_ID < 3)
 THEN EMP_ID ELSE NULL END ENABLE')"
```

Example 3: Creating a new mask for the DEPARTMENT column that is enabled when SESSION_USER is set to security_user

```
db2 "call rdsadmin.fgac_command(
    ?,
    'testdb',
    'CREATE MASK DEPARTMENT_MASK ON EMPLOYEE FOR COLUMN DEPARTMENT RETURN CASE  WHEN
 SESSION_USER = ''security_user'' THEN DEPARTMENT ELSE NULL END ENABLE')"
```

Example 4: Creating a new security label called treelabel

```
db2 "call rdsadmin.fgac_command(
    ?,
    'testdb',
    'CREATE SECURITY LABEL COMPONENT treelabel  TREE(''COMPANY'' ROOT, ''HR'' UNDER
 ''COMPANY'', ''FINANCE'' UNDER ''COMPANY'', ''IT'' UNDER ''COMPANY'')')"
```

rdsadmin.db2support_command

Collects diagnostic information about an RDS for Db2 database and uploads it to an Amazon S3 bucket.

Syntax

```
db2 "call rdsadmin.db2support_command(
    ?,
    'database_name',
    's3_bucket_name',
```

```
    's3_prefix')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

The following input parameters are required:

database_name

The name of the database to collect diagnostic information for. The data type is `varchar`.

s3_bucket_name

The name of the Amazon S3 bucket where you want to upload the diagnostic information. The data type is `varchar`.

s3_prefix

The prefix of the path to Amazon S3 where RDS for Db2 uploads the diagnostic files. The data type is `varchar`.

Usage notes

This stored procedure collects diagnostic information that can help with troubleshooting RDS for Db2 databases and uploads the information to an Amazon S3 bucket.

The stored procedure uses the IBM `db2support` utility to collect diagnostic data. For more information about the utility, see db2support - Problem analysis and environment collection tool command in the IBM Db2 documentation.

Before calling the stored procedure, review the following considerations:

- To upload the diagnostic files to Amazon S3, you must have already configured the integration. For more information, see Integrating an Amazon RDS for Db2 DB instance with Amazon S3.
- For an RDS for Db2 DB instance to be able to interact with Amazon S3, you must have a VPC and an Amazon S3 gateway endpoint for private subnets to use. For more information, see Step

1: Create a VPC gateway endpoint for Amazon S3 and Step 2: Confirm that your VPC gateway endpoint for Amazon S3 exists.

Before calling `rdsadmin.db2support_command`, you must connect to the `rdsadmin` database. In the following example, replace *`master_username`* and *`master_password`* with your RDS for Db2 DB instance information:

```
db2 connect to rdsadmin user master_username using master_password
```

For information about checking the status of collecting diagnostic information, see rdsadmin.get_task_status.

Examples

Example 1: Collecting diagnostic information for a database

The following example collects diagnostic information for a database called `TESTDB` and uploads it to the Amazon S3 bucket called `amzn-s3-demo-bucket` with the prefix `diagnostics/testdb`:

```
db2 "call rdsadmin.db2support_command(
    ?,
    'TESTDB',
    'amzn-s3-demo-bucket',
    'diagnostics/testdb')"
```

Example 2: Collecting diagnostic information with a date-based prefix

The following example collects diagnostic information for a database called `MYDB` and uploads it to the Amazon S3 bucket called `amzn-s3-demo-bucket` with a date-based prefix:

```
db2 "call rdsadmin.db2support_command(
    ?,
    'MYDB',
    'amzn-s3-demo-bucket',
    'support/2024/01/15')"
```

Stored procedures for storage access for RDS for Db2

The built-in stored procedures described in this topic manage storage access for RDS for Db2 databases that use Amazon S3 for migrating data. For more information, see the section called "Migrating with Amazon S3".

Refer to the following built-in stored procedures for information about their syntax, parameters, usage notes, and examples.

Stored procedures

- rdsadmin.catalog_storage_access
- rdsadmin.uncatalog_storage_access

rdsadmin.catalog_storage_access

Catalogs a storage alias for accessing an Amazon S3 bucket with Db2 data files.

Syntax

```
db2 "call rdsadmin.catalog_storage_access(
    ?,
    'alias',
    's3_bucket_name',
    'grantee_type',
    'grantee'
    )"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. The datatype is `varchar`.

The following input parameters are required:

alias

The alias name for accessing remote storage in an Amazon S3 bucket. The datatype is `varchar`.

s3_bucket_name

The name of the Amazon S3 bucket where your data resides. The data type is `varchar`.

grantee_type

The type of grantee to receive authorization. The data type is `varchar`. Valid values: USER, GROUP.

grantee

The user or group to receive authorization. The data type is `varchar`.

Usage notes

Amazon RDS includes the cataloged alias in the IAM role that you added to your RDS for Db2 DB instance. If you remove the IAM role from your DB instance, then Amazon RDS deletes the alias. For more information, see the section called “Migrating with Amazon S3”.

For information about checking the status of cataloging your alias, see rdsadmin.get_task_status.

Examples

The following example registers an alias called SAMPLE. The user `jorge_souza` is granted access to the Amazon S3 bucket called `amzn-s3-demo-bucket`.

```
db2 "call rdsadmin.catalog_storage_access(
    ?,
    'SAMPLE',
    'amzn-s3-demo-bucket',
    'USER',
    'jorge_souza')"
```

rdsadmin.uncatalog_storage_access

Removes a storage access alias.

Syntax

```
db2 "call rdsadmin.uncatalog_storage_access(
    ?,
    'alias')"
```

Parameters

The following output parameter is required:

?

A parameter marker that outputs an error message. The datatype is `varchar`.

The following input parameter is required:

alias

The name of the storage alias to remove. The datatype is `varchar`.

Usage notes

For information about checking the status of removing your alias, see rdsadmin.get_task_status.

Examples

The following example removes an alias called `SAMPLE`. This alias no longer provides access to the Amazon S3 bucket it was associated with.

```
db2 "call rdsadmin.uncatalog_storage_access(
    ?,
    'SAMPLE')"
```

Stored procedures for tablespaces for RDS for Db2

The built-in stored procedures described in this topic manage tablespaces for Amazon RDS for Db2 databases. To run these procedures, the master user must first connect to the `rdsadmin` database.

These stored procedures are used in a variety of tasks. This list isn't exhaustive.

- Common tasks for tablespaces
- Generating performance reports
- Copying database metadata with db2look
- Creating a repository database for IBM Db2 Data Management Console

Refer to the following built-in stored procedures for information about their syntax, parameters, usage notes, and examples.

Stored procedures

- rdsadmin.create_tablespace
- rdsadmin.alter_tablespace
- rdsadmin.rename_tablespace
- rdsadmin.drop_tablespace

rdsadmin.create_tablespace

Creates a tablespace.

Syntax

```
db2 "call rdsadmin.create_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    tablespace_page_size,
    tablespace_initial_size,
    tablespace_increase_size,
    'tablespace_type',
    'tablespace_prefetch_size')"
```

Parameters

The following parameters are required:

database_name

The name of the database to create the tablespace in. The data type is `varchar`.

tablespace_name

The name of the tablespace to create. The data type is `varchar`.

The tablespace name has the following restrictions:

- It can't be the same as the name of an existing tablespace in this database.
- It can only contain the characters `_$#@a-zA-Z0-9`.
- It can't start with _ or $.
- It can't start with SYS.

The following parameters are optional:

buffer_pool_name

The name of the buffer pool to assign the tablespace. The data type is `varchar`. The default is an empty string.

> **Important**
>
> You must already have a buffer pool of the same page size to associate with the tablespace.

tablespace_page_size

The page size of the tablespace in bytes. The data type is `integer`. Valid values: `4096`, `8192`, `16384`, `32768`. The default is the page size used when you created the database by calling rdsadmin.create_database.

> **Important**
>
> Amazon RDS supports write atomicity for 4 KiB, 8 KiB, and 16 KiB pages. In contrast, 32 KiB pages risk torn writes, or partial data being written to the desk. If you use 32

KiB pages, we recommend that you enable point-in-time recovery and automated backups. Otherwise, you run the risk of being unable to recover from torn pages. For more information, see the section called “Introduction to backups” and the section called “Point-in-time recovery”.

tablespace_initial_size

The initial size of the tablespace in kilobytes (KB). The data type is `integer`. Valid values: `48` or higher. The default is null.

If you don't set a value, Db2 sets an appropriate value for you.

Note

This parameter isn't applicable for temporary tablespaces because the system manages temporary tablespaces.

tablespace_increase_size

The percentage by which to increase the tablespace when it becomes full. The data type is `integer`. Valid values: `1`–`100`. The default is null.

If you don't set a value, Db2 sets an appropriate value for you.

Note

This parameter isn't applicable for temporary tablespaces because the system manages temporary tablespaces.

tablespace_type

The type of the tablespace. The data type is `char`. Valid values: `U` (for user data), `T` (for user temporary data), or `S` (for system temporary data). The default is `U`.

tablespace_prefetch_size

The prefetch page size of the tablespace. The data type is `char`. Valid values: `AUTOMATIC` (case insensitive), or non-zero positive integers that are less than or equal to `32767`.

Usage notes

RDS for Db2 always creates a large database for data.

For information about checking the status of creating a tablespace, see rdsadmin.get_task_status.

Examples

Example 1: Creating a tablespace and assigning a buffer pool

The following example creates a tablespace called SP8 and assigns a buffer pool called BP8 for a database called TESTDB. The tablespace has an initial tablespace page size of 4,096 bytes, an initial tablespace of 1,000 KB, and a table size increase set to 50%.

```
db2 "call rdsadmin.create_tablespace(
    'TESTDB',
    'SP8',
    'BP8',
    4096,
    1000,
    50)"
```

Example 2: Creating a temporary tablespace and assigning a buffer pool

The following example creates a temporary tablespace called SP8. It assigns a buffer pool called BP8 that is 8 KiB in size for a database called TESTDB.

```
db2 "call rdsadmin.create_tablespace(
    'TESTDB',
    'SP8',
    'BP8',
    8192,
    NULL,
    NULL,
    'T')"
```

Example 3: Creating a tablespace and assigning a prefetch page size

The following example creates a tablespace called SP8 for a database called TESTDB. The tablespace has an initial tablespace increase size of 50 and a prefetch page size of 800.

```
db2 "call rdsadmin.create_tablespace(
```

```
    'TESTDB',
    'SP8',
    NULL,
    NULL,
    NULL,
    50,
    NULL,
    '800')"
```

rdsadmin.alter_tablespace

Alters a tablespace.

Syntax

```
db2 "call rdsadmin.alter_tablespace(
    'database_name',
    'tablespace_name',
    'buffer_pool_name',
    tablespace_increase_size,
    'max_size',
    'reduce_max',
    'reduce_stop',
    'reduce_value',
    'lower_high_water',
    'lower_high_water_stop',
    'switch_online',
    'tablespace_prefetch_size')"
```

Parameters

The following parameters are required:

database_name

The name of the database that uses the tablespace. The data type is `varchar`.

tablespace_name

The name of the tablespace to alter. The data type is `varchar`.

The following parameters are optional:

buffer_pool_name

The name of the buffer pool to assign the tablespace. The data type is `varchar`. The default is an empty string.

> **Important**
>
> You must already have a buffer pool of the same page size to associate with the tablespace.

tablespace_increase_size

The percentage by which to increase the tablespace when it becomes full. The data type is `integer`. Valid values: `1`–`100`. The default is `0`.

max_size

The maximum size for the tablespace. The data type is `varchar`. Valid values: *integer* `K` | `M` | `G`, or `NONE`. The default is `NONE`.

reduce_max

Specifies whether to reduce the high water mark to its maximum limit. The data type is `char`. The default is `N`.

reduce_stop

Specifies whether to interrupt a previous `reduce_max` or `reduce_value` command. The data type is `char`. The default is `N`.

reduce_value

The number or percentage to reduce the tablespace high water mark by. The data type is `varchar`. Valid values: *integer* `K`| `M` | `G`, or `1`–`100`. The default is `N`.

lower_high_water

Specifies whether to run the `ALTER TABLESPACE LOWER HIGH WATER MARK` command. The data type is `char`. The default is `N`.

lower_high_water_stop

Specifies whether to run the `ALTER TABLESPACE LOWER HIGH WATER MARK STOP` command. The data type is `char`. The default is `N`.

switch_online

Specifies whether to run the ALTER TABLESPACE SWITCH ONLINE command. The data type is char. The default is N.

tablespace_prefetch_size

The prefetch page size of the tablespace. The data type is char. Valid values: AUTOMATIC (case insensitive), or non-zero positive integers that are less than or equal to 32767.

> **Note**
>
> This parameter only works with buffer_pool_name, table_increase_size, max_size, and switch_online. It doesn't work with reduce_max, reduce_stop, reduce_value, lower_high_water, and lower_high_water_stop.

Usage notes

Before calling the stored procedure, review the following considerations:

- The rdsadmin.alter_tablespace stored procedure won't work on a tablespace with the tablespace_type set to T for user temporary data.
- The optional parameters reduce_max, reduce_stop, reduce_value, lower_high_water, lower_high_water_stop, and switch_online are mutually exclusive. You can't combine them with any other optional parameter, such as buffer_pool_name, in the rdsadmin.alter_tablespace command. For more information, see Statement not valid.

For information about checking the status of altering a tablespace, see rdsadmin.get_task_status.

For error messages returned when calling stored procedures, see the section called "Stored procedure errors".

Examples

Example 1: Lowering the high water mark

The following example alters a tablespace called SP8 and assigns a buffer pool called BP8 for a database called TESTDB to lower the high water mark.

```
db2 "call rdsadmin.alter_tablespace(
```

```
    'TESTDB',
    'SP8',
    'BP8',
    NULL,
    NULL,
    'Y')"
```

Example 2: Reducing the high water mark

The following example runs the `REDUCE MAX` command on a tablespace called `TBSP_TEST` in the database `TESTDB`.

```
db2 "call rdsadmin.alter_tablespace(
    'TESTDB',
    'TBSP_TEST',
    NULL,
    NULL,
    NULL,
    'Y')"
```

Example 3: Interrupting commands to reduce high water mark

The following example runs the `REDUCE STOP` command on a tablespace called `TBSP_TEST` in the database `TESTDB`.

```
db2 "call rdsadmin.alter_tablespace(
    'TESTDB',
    'TBSP_TEST',
    NULL,
    NULL,
    NULL,
    NULL,
    'Y')"
```

Example 4: Changing existing prefetch page size

The following example runs the `ALTER TABLESPACE SWITCH ONLINE` command on a tablespace called `TSBP_TEST` and changes the existing prefetch page size to 64.

```
db2 "call rdsadmin.alter_tablespace(
    'TESTDB',
```

```
    'TBSP_TEST',
    NULL,
    NULL,
    NULL,
    NULL,
    NULL,
    NULL,
    NULL,
    NULL,
    ‘Y’,
    ‘64’)"
```

rdsadmin.rename_tablespace

Renames a tablespace.

Syntax

```
db2 "call rdsadmin.rename_tablespace(
    ?,
    'database_name',
    'source_tablespace_name',
    'target_tablespace_name')"
```

Parameters

The following parameters are required:

?

A parameter marker that outputs an error message. This parameter only accepts ?.

database_name

The name of the database that the tablespace belongs to. The data type is `varchar`.

source_tablespace_name

The name of the tablespace to rename. The data type is `varchar`.

target_tablespace_name

The new name of the tablespace. The data type is `varchar`.

The new name has the following restrictions:

- It can't be the same as the name of an existing tablespace.
- It can only contain the characters `_$#@a-zA-Z0-9`.
- It can't start with _ or $.
- It can't start with SYS.

Usage notes

For information about checking the status of renaming a tablespace, see rdsadmin.get_task_status.

You can't rename tablespaces that belong to the `rdsadmin` database.

Examples

The following example renames a tablespace called SP8 to SP9 in a database called TESTDB.

```
db2 "call rdsadmin.rename_tablespace(
    ?,
    'TESTDB',
    'SP8',
    'SP9')"
```

rdsadmin.drop_tablespace

Drops a tablespace.

Syntax

```
db2 "call rdsadmin.drop_tablespace(
    'database_name',
    'tablespace_name')"
```

Parameters

The following parameters are required:

database_name

The name of the database that the tablespace belongs to. The data type is `varchar`.

tablespace_name

The name of the tablespace to drop. The data type is `varchar`.

Usage notes

For information about checking the status of dropping a tablespace, see rdsadmin.get_task_status.

Examples

The following example drops a tablespace called SP8 from a database called TESTDB.

```
db2 "call rdsadmin.drop_tablespace(
    'TESTDB',
    'SP8')"
```

Amazon RDS for Db2 user-defined function reference

The following user-defined functions are available for Amazon RDS DB instances running the Db2 engine.

Topics

- rdsadmin.get_task_status
- rdsadmin.list_databases
- rdsadmin.list_modifiable_db_params

rdsadmin.get_task_status

Returns the status of a task.

Syntax

```
db2 "select task_id, task_type, database_name, lifecycle,
    varchar(bson_to_json(task_input_params), 500) as task_params,
    cast(task_output as varchar(500)) as task_output
    from table(rdsadmin.get_task_status(task_id,'database_name','task_type'))"
```

Parameters

The following parameters are optional. If you do not provide any parameters, the user-defined function returns the status of all tasks for all databases. Amazon RDS retains task history for 35 days.

task_id

The ID of the task being run. This ID is returned when you run a task. Default: `0`.

database_name

The name of the database for which the task is being run.

task_type

The type of the task to query. Valid values: `ADD_GROUPS`, `ADD_USER`, `ALTER_BUFFERPOOL`, `ALTER_TABLESPACE`, `CHANGE_PASSWORD`, `COMPLETE_ROLLFORWARD`, `CREATE_BUFFERPOOL`,

CREATE_DATABASE, CREATE_ROLE, CREATE_TABLESPACE, DROP_BUFFERPOOL, DROP_DATABASE, DROP_TABLESPACE, LIST_USERS, REMOVE_GROUPS, REMOVE_USER, RESTORE_DB, ROLLFORWARD_DB_LOG, ROLLFORWARD_STATUS, UPDATE_DB_PARAM.

Usage notes

You can use the `rdsadmin.get_task_status` user-defined function to check the status of the following tasks for Amazon RDS for Db2. This list is not exhaustive.

- Creating, altering, or dropping a buffer pool
- Creating, altering, or dropping a tablespace
- Creating or dropping a database
- Restoring a database backup from Amazon S3
- Rolling forward database logs from Amazon S3

Examples

The following example displays the columns returned when `rdsadmin.get_task_status` is called.

```
db2 "describe select * from table(rdsadmin.get_task_status())"
```

The following example lists the status of all tasks.

```
db2 "select task_id, task_type, database_name, lifecycle,
    varchar(bson_to_json(task_input_params), 500) as task_params,
    cast(task_output as varchar(500)) as task_output
    from table(rdsadmin.get_task_status(null,null,null))"
```

The following example lists the status of a specific task.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(1,null,null))"
```

The following example lists the status of a specific task and database.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(2,'SAMPLE',null))"
```

The following example lists the status of all ADD_GROUPS tasks.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(null,null,'add_groups'))"
```

The following example lists the status of all tasks for a specific database.

```
db2 "select task_id, task_type, database_name,
    varchar(bson_to_json(task_input_params), 500) as task_params
    from table(rdsadmin.get_task_status(null,'testdb', null))"
```

The following example outputs the JSON values as columns.

```
db2 "select varchar(r.task_type,25) as task_type, varchar(r.lifecycle,10) as lifecycle,
 r.created_at, u.* from
    table(rdsadmin.get_task_status(null,null,'restore_db')) as r,
 json_table(r.task_input_params, 'strict $' columns(s3_prefix varchar(500)
    null on empty, s3_bucket_name varchar(500) null on empty) error on error ) as U"
```

Response

The `rdsadmin.get_task_status` user-defined function returns the following columns:

`TASK_ID`

The ID of the task.

`TASK_TYPE`

Depends on the input parameters.

- ADD_GROUPS – Adds groups.
- ADD_USER – Adds a user.
- ALTER_BUFFERPOOL – Alters a buffer pool.

- ALTER_TABLESPACE – Alters a tablespace.
- CHANGE_PASSWORD – Changes a user's password.
- COMPLETE_ROLLFORWARD – Completes an rdsadmin.rollforward_database task and activates a database.
- CREATE_BUFFERPOOL – Creates a buffer pool.
- CREATE_DATABASE – Creates a database.
- CREATE_ROLE – Creates a Db2 role for a user.
- CREATE_TABLESPACE – Creates a tablespace.
- DROP_BUFFERPOOL – Drops a buffer pool.
- DROP_DATABASE – Drops a database.
- DROP_TABLESPACE – Drops a tablespace.
- LIST_USERS – Lists all users.
- REMOVE_GROUPS – Removes groups.
- REMOVE_USER – Removes a user.
- RESTORE_DB – Restores a full database.
- ROLLFORWARD_DB_LOG – Performs an rdsadmin.rollforward_database task on database logs.
- ROLLFORWARD_STATUS – Returns the status of an rdsadmin.rollforward_database task.
- UPDATE_DB_PARAM – Updates the data parameters.

DATABASE_NAME

The name of the database with which the task is associated.

COMPLETED_WORK_BYTES

The number of bytes restored by the task.

DURATION_MINS

The time taken to complete the task.

LIFECYCLE

The status of the task. Possible statuses:

- CREATED – After a task is submitted to Amazon RDS, Amazon RDS sets the status to CREATED.
- IN_PROGRESS – After a task starts, Amazon RDS sets the status to IN_PROGRESS. It can take up to 5 minutes for a status to change from CREATED to IN_PROGRESS.
- SUCCESS – After a task completes, Amazon RDS sets the status to SUCCESS.
- ERROR – If a restore task fails, Amazon RDS sets the status to ERROR. For more information about the error, see TASK_OUPUT.

CREATED_BY

The authid that created the command.

CREATED_AT

The date and time when the task was created.

LAST_UPDATED_AT

The data and time when the task was last updated.

TASK_INPUT_PARAMS

The parameters differ based on the task type. All of the input parameters are represented as a JSON object. For example, the JSON keys for the RESTORE_DB task are the following:

- DBNAME
- RESTORE_TIMESTAMP
- S3_BUCKET_NAME
- S3_PREFIX

TASK_OUTPUT

Additional information about the task. If an error occurs during native restore, this column includes information about the error.

Response examples

The following response example shows that a database called TESTJP was successfully created. For more information, see the the section called “rdsadmin.create_database” stored procedure.

```
`1 SUCCESS CREATE_DATABASE RDSDB 2023-10-24-18.32.44.962689 2023-10-24-18.34.50.038523
 1 TESTJP { "CODESET" : "IBM-437", "TERRITORY" : "JP", "COLLATION" : "SYSTEM",
 "AUTOCONFIGURE_CMD" : "", "PAGESIZE" : 4096 }
2023-10-24-18.33.30.079048 Task execution has started.

2023-10-24-18.34.50.038523 Task execution has completed successfully`.
```

The following response example explains why dropping a database failed. For more information, see the the section called “rdsadmin.drop_database” stored procedure.

```
1 ERROR DROP_DATABASE RDSDB 2023-10-10-16.33.03.744122 2023-10-10-16.33.30.143797 -
 2023-10-10-16.33.30.098857 Task execution has started.
2023-10-10-16.33.30.143797 Caught exception during executing task id 1, Aborting task.
Reason Dropping database created via rds CreateDBInstance api is not allowed.
Only database created using rdsadmin.create_database can be dropped
```

The following response example shows the successful restoration of a database. For more information, see the the section called “rdsadmin.restore_database” stored procedure.

```
1 RESTORE_DB  SAMPLE  SUCCESS

{ "S3_BUCKET_NAME" : "amzn-s3-demo-bucket", "S3_PREFIX" :
 "SAMPLE.0.rdsdb3.DBPART000.20230413183211.001", "RESTORE_TIMESTAMP" :
 "20230413183211", "BACKUP_TYPE" : "offline" }

2023-11-06-18.31.03.115795 Task execution has started.
2023-11-06-18.31.04.300231 Preparing to download
2023-11-06-18.31.08.368827 Download complete. Starting Restore
2023-11-06-18.33.13.891356 Task Completed Successfully
```

rdsadmin.list_databases

Returns a list of all databases running on an RDS for Db2 DB instance.

Syntax

```
db2 "select * from table(rdsadmin.list_databases())"
```

Usage notes

This user-defined function doesn't specify whether databases are in an activated or deactivated state.

If you don't see your databases in the list, call the the section called “rdsadmin.get_task_status” user-defined function and look for error messages.

Response

The `rdsadmin.list_databases` user-defined function returns the following columns:

`DATABASE_NAME`

The name of a database.

`CREATE_TIME`

The date and time when the database was created.

`DATABASE_UNIQUE_ID`

The RDS created GUID to uniquely identify Db2 database.

`ARCHIVE_LOG_RETENTION_HOUR`

The number of hours to retain the archive log files.

`ARCHIVE_LOG_COPY`

Displays if the feature is ENABLED or DISABLED for the database.

`ARCHIVE_LOG_LAST_UPLOAD_FILE`

Indicates last archive log uploaded to S3.

`ARCHIVE_LOG_LAST_UPLOAD_FILE_TIME`

Indicates the time when the log file was archived.

`ARCHIVE_LOG_COPY_STATUS`

Displays the status of the archive log copy.

UPLOADING : indicates that archive log files are being uploaded to S3.

CONFIGURATION_ERROR : indicates that there is a configuration issue requiring your attention.

To view detailed error look at RDS Event Messages for you Db Instance. The Event Messages can be viewed at Viewing Amazon RDS events.

Response examples

The following response example shows a list of databases and the times when they were created. `rdsadmin` is a database that Amazon RDS manages and always appears in the output.

```
DATABASE_NAME   CREATE_TIME                DATABASE_UNIQUE_ID
           ARCHIVE_LOG_RETENTION_HOURS ARCHIVE_LOG_COPY ARCHIVE_LOG_LAST_UPLOAD_FILE
 ARCHIVE_LOG_LAST_UPLOAD_FILE_TIME ARCHIVE_LOG_COPY_STATUS

                                0 DISABLED         -                              -
                             -
...
```

rdsadmin.list_modifiable_db_params

Returns a list of all the modifiable database configuration parameters.

Syntax

```
db2 "select * from table(rdsadmin.list_modifiable_db_params())"
```

Usage notes

This user-defined function displays a selected lists of modifiable database parameters. These parameters can be updated using the stored procedure the section called "rdsadmin.update_db_param".

Any database parameter not included in this list has been restricted and cannot be modified.

Response

The `rdsadmin.list_modifiable_db_params` user-defined function returns the following columns:

`PARAM_NAME`

The name of the parameter that can be modified.

`DEFAULT_VALUE`

Default parameter value at the time of database creation.

`RESTART_REQUIRED`

If database recycle is required of not.

Y = Yes, Database restart is required.

N = No, Database restart is not required.

Response examples

The following is a sample (truncated) list of expected output.

```
PARAM_NAME              DEFAULT_VALUE RESTART_REQUIRED
----------------------- ------------- ----------------
ACT_SORTMEM_LIMIT       NONE          N
ARCHRETRYDELAY          20            N
AUTHN_CACHE_DURATION    3             N
AUTHN_CACHE_USERS       0             N
AUTO_CG_STATS           OFF           N
...
```

Troubleshooting for Amazon RDS for Db2

The following content can help you troubleshoot issues that you encounter with RDS for Db2.

For more information about general Amazon RDS troubleshooting issues, see Troubleshooting for Amazon RDS.

Topics

- Database connection error
- File I/O error
- Stored procedure errors

Database connection error

The following error message indicates that a database failed to connect because the server doesn't have sufficient memory.

```
SQL1643C The database manager failed to allocate shared memory because the
database manager instance memory limit has been reached.
```

Increase the memory for your DB instance and then try to connect to your database again. For information about memory usage and recommendations for databases, see the section called "Multiple Db2 databases". For information about how to update the memory for an RDS for Db2 database, see the section called "rdsadmin.update_db_param".

File I/O error

You might encounter a file I/O error for different reasons, such as when you use the LOAD command or call the `rdsadmin.restore_database` stored procedure.

In this example, you run the following LOAD command.

```
db2 "call sysproc.admin_cmd('load from "DB2REMOTE://s3test//public/datapump/t6.del" of
 del lobs from "DB2REMOTE://s3test/public/datapump/" modified by lobsinfile MESSAGES ON
 SERVER insert INTO RDSDB.t6 nonrecoverable ')"
```

The LOAD command returns the following message:

```
  Result set 1
  --------------

  ROWS_READ            ROWS_SKIPPED         ROWS_LOADED          ROWS_REJECTED
 ROWS_DELETED         ROWS_COMMITTED       ROWS_PARTITIONED     NUM_AGENTINFO_ENTRIES
 MSG_RETRIEVAL

 MSG_REMOVAL
  -------------------- -------------------- -------------------- --------------------
 -------------------- -------------------- -------------------- --------------------
 ------------------------------------------------------------------------------------------
 ------------------------------------------------------------------------------------------
                      -                    -                    -                    -
                     -                    -                    -                    -
 SELECT SQLCODE, MSG FROM TABLE(SYSPROC.ADMIN_GET_MSGS('1594987316_285548770')) AS MSG

                                                                                    CALL
 SYSPROC.ADMIN_REMOVE_MSGS('1594987316_285548770')

  1 record(s) selected.

  Return Status = 0

SQL20397W  Routine "SYSPROC.ADMIN_CMD" execution has completed, but at least
one error, "SQL1652", was encountered during the execution. More information
is available.  SQLSTATE=01H52
```

To view the error message, you run the SQL command as suggested in the previous response. `SELECT SQLCODE, MSG FROM TABLE(SYSPROC.ADMIN_GET_MSGS('1594987316_285548770')) AS MSG` returns the following message:

```
SQLCODE   MSG
---------
 ------------------------------------------------------------------------------------------
```

```
SQL2025N  An I/O error occurred. Error code “438”. Media on which this error occurred:
 “DB2REMOTE://s3test//public/datapump/t6.del”

SQL3500W The utility is beginning the LOAD phase at time “07/05/2024 21:21:48.082954”

SQL1652N File I/O error occurred
```

The Db2 diagnostic logs contain a log file similar to the following one:

```
2024-07-05-21.20.09.440609+000 I1191321E864          LEVEL: Error
PID     : 2710                 TID : 139619509200640 PROC : db2sysc 0

```

This file I/O error could result from a number of different scenarios. For example, the VPC associated with the security group used to create your RDS for Db2 DB instance might lack an Amazon S3 gateway endpoint. This endpoint is essential for enabling RDS for Db2 to access Amazon S3. If your RDS for Db2 DB instance is in private subnets, then an Amazon S3 gateway endpoint is required. You can specify whether your DB instance uses private or public subnets by configuring Amazon RDS subnet groups. For more information, see Working with DB subnet groups.

Topics

- Step 1: Create a VPC gateway endpoint for Amazon S3
- Step 2: Confirm that your VPC gateway endpoint for Amazon S3 exists

Step 1: Create a VPC gateway endpoint for Amazon S3

For your RDS for Db2 DB instance to interact with Amazon S3, create a VPC and then an Amazon S3 gateway endpoint for private subnets to use.

To create a VPC gateway endpoint for S3

1. Create a VPC. For more information see Create a VPC in the *Amazon Virtual Private Cloud User Guide*.
2. Create an Amazon S3 gateway endpoint for private subnets to use. For more information, see Gateway endpoints in the *AWS PrivateLink Guide*.

Step 2: Confirm that your VPC gateway endpoint for Amazon S3 exists

Confirm that you successfully created an Amazon S3 gateway endpoint by using the AWS Management Console or the AWS CLI.

Console

To confirm an Amazon S3 gateway endpoint

1. Sign in to the AWS Management Console and open the Amazon VPC Console at https://console.aws.amazon.com/vpc.
2. In the upper-right corner of the console, choose the AWS Region of your VPC.
3. Select the VPC that you created.
4. On the **Resource map** tab, under **Network connections**, confirm that an Amazon S3 gateway endpoint is listed.

AWS CLI

To confirm an Amazon S3 gateway endpoint, run the describe-vpc-endpoints command. In the following example, replace *vpc_id* with the VPC ID, *region* with your AWS Region, and *profile* with your profile name.

For Linux, macOS, or Unix:

```
aws ec2 describe-vpc-endpoints \
    --filters "Name=vpc-id,Values=$vpc_id" \
```

```
    "Name=service-name,\
    Values=com.amazonaws.${region}.s3" \
    --region $region --profile=$profile \
    --query "VpcEndpoints[*].VpcEndpointId" --output text
```

For Windows:

```
aws ec2 describe-vpc-endpoints ^
    --filters "Name=vpc-id,Values=$vpc_id" ^
    "Name=service-name,^
    Values=com.amazonaws.${region}.s3" ^
    --region $region --profile=$profile ^
    --query "VpcEndpoints[*].VpcEndpointId" --output text
```

This command produces output similar to the following example if an Amazon S3 gateway endpoint exists.

```
[
    "vpce-0ea810434ff0b97e4"
]
```

This command produces output similar to the following example if an Amazon S3 gateway endpoint doesn't exist.

```
[]
```

If you don't see an Amazon S3 gateway endpoint listed, then Step 1: Create a VPC gateway endpoint for Amazon S3.

Stored procedure errors

This section describes various errors returned when calling stored procedures and how to resolve them.

Category	Stored procedure errors
Databases	rdsadmin.activate_database errors
Databases	rdsadmin.backup_database errors

Category	Stored procedure errors
Databases	rdsadmin.create_database errors
Databases	rdsadmin.deactivate_database errors
Databases	rdsadmin.drop_database errors
Databases	rdsadmin.reactivate_database errors
Databases	rdsadmin.restore_database errors
Databases	rdsadmin.update_db_param errors
Tablespaces	rdsadmin.alter_tablespace errors

rdsadmin.activate_database errors

The following errors can occur when you call the the section called “rdsadmin.activate_database” stored procedure.

Error	Error message
Failed to allocate shared memory	`SQL1643C The database manager failed to allocate shared memory because the database manager instance memory limit has been reached.`
Unable to activate because of running processes	`The database can’t be activated because it's in the process of being created or restored.`

Failed to allocate shared memory

The following error message indicates that the stored procedure failed to activate a database because the DB instance doesn't have sufficient memory.

```
SQL1643C The database manager failed to allocate shared memory because the database
 manager instance memory limit has been reached.
```

Increase the memory for your DB instance and then call the `rdsadmin.activate_database` stored procedure again. For information about memory usage and recommendations for databases, see the section called “Multiple Db2 databases”.

Unable to activate because of running processes

The following error message indicates that the stored procedure couldn't activate a database because the `rdsadmin.create_database` or `rdsadmin.restore_database` stored procedure is running.

```
The database can’t be activated because it's in the process of being created or
 restored.
```

Wait a few minutes, and then call the `rdsadmin.activate_database` stored procedure again.

rdsadmin.alter_tablespace errors

The following errors can occur when you call the the section called “rdsadmin.alter_tablespace” stored procedure.

Error	Error message

Statement not valid	`DB21034E The command was processed as an SQL statement because it was not a valid Command Line Processor command. During SQL processing it returned:`
	
	`SQL1763N Invalid ALTER TABLESPACE statement for table space "TBSP_TEST" due to reason "12"`

tablespace_prefetch_size value not valid	`Invalid tablespace_prefetch_size. Set value to AUTOMATIC or to a non-zero positive numerical value.`
tablespace_prefetch_size numerical value not valid	`Invalid tablespace_prefetch_size. The number of pages can't be greater than 32767.`
Parameter can't be used with tablespace_prefetch_size	`You can't use tablespace_prefetch_size with {parameter }.`

Error	Error message
Tablespace change failed	`The change to tablespace { tablespace_name} failed because you can only alter LARGE or REGULAR tablespaces.`

Statement not valid

The following error message indicates that the stored procedure combined mutually exclusive optional parameters with other optional parameters. The optional parameters `reduce_max`, `reduce_stop`, `reduce_value`, `lower_high_water`, `lower_high_water_stop`, and `switch_online` for the `rdsadmin.alter_tablespace` stored procedure are mutually exclusive. You can't combine them with any other optional parameter, such as `buffer_pool_name`, in the `rdsadmin.alter_tablespace` stored procedure. If you combine them, then when you call the `rdsadmin.get_task_status` user-defined function, Db2 will return this error message.

```
DB21034E The command was processed as an SQL statement because it was not a valid
 Command Line Processor command. During SQL processing it returned:
SQL1763N Invalid ALTER TABLESPACE statement for table space "TBSP_TEST" due to reason
 "12"
```

Call the `rdsadmin.alter_tablespace` stored procedure again without combining mutually exclusive optional parameters with other optional parameters. Then call the `rdsadmin.get_task_status` user-defined function. For more information, see rdsadmin.alter_tablespace and rdsadmin.get_task_status.

tablespace_prefetch_size value not valid

The following error message indicates that you didn't set `tablespace_prefetch_size` to `AUTOMATIC` or a non-positive numerical value. For example, you tried to set it to `testinput`.

```
Invalid tablespace_prefetch_size. Set value to AUTOMATIC or to a non-zero positive
 numerical value.
```

Call the `rdsadmin.alter_tablespace` stored procedure again and set `tablespace_prefetch_size` to `AUTOMATIC` or a non-positive numerical value.

tablespace_prefetch_size numerical value not valid

The following error message indicates that you set `tablespace_prefetch_size` to a numerical value larger than 32767.

```
Invalid tablespace_prefetch_size. The number of pages can't be greater than 32767.
```

Call the `rdsadmin.alter_tablespace` stored procedure again and set `tablespace_prefetch_size` to a non-zero positive numerical value less than or equal to 32767.

Parameter can't be used with tablespace_prefetch_size

The following error message indicates that you tried to use `tablespace_prefetch_size` with an incompatible parameter.

```
You can't use tablespace_prefetch_size with {parameter}.
```

Call the `rdsadmin.alter_tablespace` stored procedure again and only use `tablespace_prefetch_size` with compatible parameters. For information about parameters you can use with `tablespace_prefetch_size`, see rdsadmin.alter_tablespace.

Tablespace change failed

The following error message indicates that you tried to alter a tablespace.

```
The change to tablespace {tablespace_name} failed because you can only alter LARGE or
 REGULAR tablespaces.
```

rdsadmin.backup_database errors

The following errors can occur when you call the the section called “rdsadmin.backup_database” stored procedure.

Error	Error message
Insufficient disk space	`Aborting task. Reason Backing up your database failed because of insufficient disk space. Increase the storage for your DB instance and rerun the rdsadmin.backup_database stored procedure.`
Internal error	`Caught exception during executing task id 104, Aborting task. Reason Internal Error`

Insufficient disk space

The following error message indicates that your DB instance has insufficient disk space to back up your database:

```
Aborting task. Reason Backing up your database failed because of insufficient
 disk space. Increase the storage for your DB instance and rerun the
 rdsadmin.backup_database stored procedure.
```

When backing up a database to remote storage, make sure that you have sufficient free disk space for the backup session and the working files. Each backup session processes up to 5 GB of data, but additional space is needed for transaction logs, temporary files, and ongoing database operations.

We recommend that you have the following free disk space for backups based on the database size:

- For databases under 5 GB – The database size + 3 GB buffer
- For databases 5 GB and larger – At least 10 GB of free space

This amount of free disk space accounts for backup session processing, transaction log accumulation during backup, temporary working files, and parallel backup streams if configured. For more information, see Increasing DB instance storage capacity.

Increase your disk space and then call the rdsadmin.backup_database stored procedure again. To confirm that the database was backed up correctly, check the task status by using rdsadmin.get_task_status. You can also verify that the backup files exist in your Amazon S3 bucket under *s3_prefix/dbi_resource_id/db_name*.

Internal error

The following error message indicates that the stored procedure encountered an internal error:

```
Caught exception during executing task id 104, Aborting task. Reason Internal Error
```

Contact AWS Support.

rdsadmin.create_database errors

The following error can occur when you call the the section called “rdsadmin.create_database” stored procedure.

Error	Error message
Failed to allocate shared memory	`SQL1643C The database manager failed to allocate shared memory because the database manager instance memory limit has been reached.`

Failed to allocate shared memory

The following error message indicates that the stored procedure failed to create a database because the DB instance doesn't have sufficient memory.

```
SQL1643C The database manager failed to allocate shared memory because the database
 manager instance memory limit has been reached.
```

Increase the memory for your DB instance and then call the `rdsadmin.create_database` stored procedure again. For information about memory usage and recommendations for databases, see the section called “Multiple Db2 databases”.

To confirm that the database was created, call the the section called “rdsadmin.list_databases” user-defined function and check that the new database is listed.

rdsadmin.deactivate_database errors

The following error can occur when you call the the section called “rdsadmin.deactivate_database” stored procedure.

Error	Error message
Unable to deactivate because of running processes	`The database can’t be deactivated because it's in the process of being created or restored.`

Unable to deactivate because of running processes

The following error message indicates that the stored procedure couldn't deactivate a database because the `rdsadmin.create_database` or `rdsadmin.restore_database` stored procedure is running.

```
The database can’t be deactivated because it's in the process of being created or
 restored.
```

Wait a few minutes, and then call the `rdsadmin.deactivate_database` stored procedure again.

rdsadmin.drop_database errors

The following errors can occur when you call the the section called “rdsadmin.drop_database” stored procedure.

Error	Error message
Database name doesn't exist	`SQL0438N Application raised error or warning with diagnostic text: "Cannot drop database. Database with provided name does not exist". SQLSTATE=99993`
Return status = 0	`Return Status = 0`
Dropping database not allowed	`1 ERROR DROP_DATABASE RDSDB 2023-10-10-16.33.03.744122 2023-10-10-16.33.30.143797 - 2023-10-10-16.33.30.098857 Task execution has started. 2023-10-10-16.33.30.143797 Caught exception during executing task id 1, Aborting task. Reason Dropping database created via rds CreateDBInstance api is not allowed. Only database created using rdsadmin.create_database can be dropped`

Database name doesn't exist

The following error message indicates that you passed an incorrect database name in the `rdsadmin.drop_database` stored procedure.

```
SQL0438N Application raised error or warning with diagnostic text: "Cannot
drop database. Database with provided name does not exist". SQLSTATE=99993
```

Call the `rdsadmin.drop_database` stored procedure again with a correct database name. To confirm that the database was dropped, call the the section called “rdsadmin.list_databases” user-defined function and check that the dropped database isn't listed.

Return status = 0

The following error message indicates that the stored procedure couldn't be completed.

```
Return Status = 0
```

After you receive `Return Status = 0`, call the rdsadmin.get_task_status user-defined function.

Dropping database not allowed

The following error message indicates that you created the database by using either the Amazon RDS console or the AWS CLI. You can only use the `rdsadmin.drop_database` stored procedure if you created the database by calling the the section called “rdsadmin.create_database” stored procedure.

```
1 ERROR DROP_DATABASE RDSDB 2023-10-10-16.33.03.744122 2023-10-10-16.33.30.143797 -
 2023-10-10-16.33.30.098857 Task execution has started.
2023-10-10-16.33.30.143797 Caught exception during executing task id 1, Aborting task.
Reason Dropping database created via rds CreateDBInstance api is not allowed.
Only database created using rdsadmin.create_database can be dropped
```

To drop a database that you created by using either the Amazon RDS console or the AWS CLI, use a client to connect to the database and then run the appropriate command.

rdsadmin.reactivate_database errors

The following error can occur when you call the the section called “rdsadmin.reactivate_database” stored procedure.

Error	Error message
Failed to allocate shared memory	`SQL1643C The database manager failed to allocate shared memory because the database manager instance memory limit has been reached.`
Unable to reactivate because of running processes	`The database can’t be reactivated because it's in the process of being created or restored.`

Failed to allocate shared memory

The following error message indicates that the stored procedure failed to activate a database because the DB instance doesn't have sufficient memory.

```
SQL1643C The database manager failed to allocate shared memory because the database
 manager instance memory limit has been reached.
```

Increase the memory for your DB instance and then call the `rdsadmin.activate_database` stored procedure again. For information about memory usage and recommendations for databases, see the section called “Multiple Db2 databases”.

Unable to reactivate because of running processes

The following error message indicates that the stored procedure couldn't reactivate a database because the `rdsadmin.create_database` or `rdsadmin.restore_database` stored procedure is running.

```
The database can’t be reactivated because it's in the process of being created or
 restored.
```

Wait a few minutes, and then call the `rdsadmin.reactivate_database` stored procedure again.

rdsadmin.restore_database errors

The following errors can occur when you call the the section called “rdsadmin.restore_database” stored procedure:

Error	Error message
Insufficient disk space	`Aborting task. Reason Restoring your database failed because of insufficient disk space. Increase the storage for your DB instance and rerun the rdsadmin.restore_database stored procedure.`
Internal error	`Caught exception during executing task id 104, Aborting task. Reason Internal Error`
Non-fenced routines not allowed	`Caught exception during executing task id 2, Aborting task. Reason Non fenced routines are not allowed. Please delete the routines and retry the restore.`

Error	Error message
Tablespaces not restored	`Reason SQL0970N The system attempted to write to a read-only file. Reason SQL2563W The Restore process has completed successfully. However one or more table spaces from the backup were not restored.`

Insufficient disk space

The following error message indicates that your DB instance has insufficient disk space to restore your database:

```
Aborting task. Reason Restoring your database failed because of insufficient
 disk space. Increase the storage for your DB instance and rerun the
 rdsadmin.restore_database stored procedure.
```

The free space on your DB instance must be more than double the size of your backup image. If your backup image is compressed, the free space on your DB instance must be more than triple the size of your backup image. For more information, see the section called “Increasing DB instance storage capacity”.

Increase your disk space and then call the `rdsadmin.restore_database` stored procedure again. To confirm that the database was restored, call the the section called “rdsadmin.list_databases” user-defined function and check that the restored database is listed.

Internal error

The following error message indicates that the stored procedure encountered an internal error:

```
Caught exception during executing task id 104, Aborting task. Reason Internal Error
```

Contact AWS Support.

Non-fenced routines not allowed

The following error message indicates that your database contains non-fenced routines:

```
Caught exception during executing task id 2, Aborting task. Reason Non fenced routines
 are not allowed. Please delete the routines and retry the restore.
```

RDS for Db2 doesn't support non-fenced routines. Remove the non-fenced routines from the source database, and then call `rdsadmin.restore_database` again. To confirm that the database was restored, call the the section called “rdsadmin.list_databases” user-defined function and check that the restored database is listed. For more information, see the section called “Non-fenced routines”.

Tablespaces not restored

The following error message indicates that RDS for Db2 successfully restored your database, but couldn't restore one or more tablespaces:

```
Reason SQL0970N The system attempted to write to a read-only file.
Reason SQL2563W The Restore process has completed successfully. However one or more
 table spaces from the backup were not restored.
```

RDS for Db2 doesn't support non-automatic storage. Convert non-automatic storage to automatic storage and then call `rdsadmin.restore_database` again. For more information, see Converting a nonautomatic storage database to use automatic storage in the IBM Db2 documentation.

Databases with non-automatic SMS storage require manual restoration. If your database has non-automatic SMS storage, contact AWS Support.

For information about non-automatic storage and one-time migrations, see the section called “Non-automatic storage tablespaces during migration”.

rdsadmin.update_db_param errors

The following error can occur when you call the the section called “rdsadmin.update_db_param” stored procedure.

Error	Error message
Parameter not supported or modifiable	`SQL0438N Application raised error or warning with diagnostic text: "Parameter is either not supported or not modifiable to customers". SQLSTATE=99993`

Parameter not supported or modifiable

The following error message indicates that you tried to modify a database configuration parameter that either isn't supported or isn't modifiable.

```
SQL0438N Application raised error or warning with diagnostic text: "Parameter
is either not supported or not modifiable to customers". SQLSTATE=99993
```

You can see which parameters are modifiable by viewing your parameter groups. For more information, see the section called “View parameter values for a DB parameter group”.

Amazon RDS for MariaDB

Amazon RDS supports several versions of MariaDB for DB instances. For complete information about the supported versions, see MariaDB on Amazon RDS versions.

To create a MariaDB DB instance, use the Amazon RDS management tools or interfaces. You can then use the Amazon RDS tools to perform management actions for the DB instance. These include actions such as the following:

- Reconfiguring or resizing the DB instance
- Authorizing connections to the DB instance
- Creating and restoring from backups or snapshots
- Creating Multi-AZ secondaries
- Creating read replicas
- Monitoring the performance of your DB instance

To store and access the data in your DB instance, use standard MariaDB utilities and applications.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see Regions, Availability Zones, and Local Zones.

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance. AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

Before creating a DB instance, complete the steps in Setting up your Amazon RDS environment. When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores

- Automated backups
- Manual backups

You can use DB instances running MariaDB inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MariaDB DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for MariaDB as a high-availability, failover solution.

> **Important**
>
> To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

Topics

- MariaDB feature support on Amazon RDS

MariaDB feature support on Amazon RDS

RDS for MariaDB supports most of the features and capabilities of MariaDB. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **`MariaDB 2023`**.

> **Note**
>
> The following lists are not exhaustive.

For more information about MariaDB feature support on Amazon RDS, see the following topics.

Topics

- Supported storage engines for MariaDB on Amazon RDS
- Cache warming for MariaDB on Amazon RDS
- MariaDB features not supported by Amazon RDS

MariaDB feature support on Amazon RDS for MariaDB major versions

In the following sections, find information about MariaDB feature support on Amazon RDS for MariaDB major versions:

Topics

- MariaDB 11.8 support on Amazon RDS
- MariaDB 11.4 support on Amazon RDS
- MariaDB 10.11 support on Amazon RDS
- MariaDB 10.6 support on Amazon RDS
- MariaDB 10.5 support on Amazon RDS
- MariaDB 10.4 support on Amazon RDS

For information about supported minor versions of Amazon RDS for MariaDB, see MariaDB on Amazon RDS versions.

MariaDB 11.8 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 11.8 or higher.

> **Note**
>
> In MariaDB 11.8, the default value for `require_secure_transport` is now 1, requiring secure SSL/TLS connections. Set to `0` if non-secure connections are needed.

- **New default value for parameter** – The default value of `require_secure_transport` parameter changed from `0` to 1, enforcing secure transport connections by default. For more information, see Requiring SSL/TLS for all connections to a MariaDB DB instance on Amazon RDS.
- **Vector support** – You can use the MariaDB Vector to store and search AI-generated vectors directly in MariaDB. This feature introduces the following system variables:
  - The variable `mhnsw_default_distance` specifies the default distance metric for MHNSW vector indexing.
  - The variable `mhnsw_default_m` defines the default value for the `M` parameter in MHNSW vector indexing.
  - The variable `mhnsw_ef_search` defines the minimal number of result candidates for vector index searches.
  - The variable `mhnsw_max_cache_size` sets the upper limit for one MHNSW vector index cache.
- **Temporary file size limits** – You can now limit the size of created disk temporary files and tables using two system variables available in the RDS Maria DB 11.8 parameter group:
  - The variable `max_tmp_session_space_usage` limits the temporary space allowance per user.
  - The variable `max_tmp_total_space_usage` limits the temporary space allowance for all users.
- **Temporary tablespace management** – The temporary tablespace stores temporary tables and grows as data is added. When temporary tables are dropped, the space is not automatically reclaimed. You can use the mysql.rds_execute_operation procedure to shrink the temporary tablespace and reclaim disk space.

For a list of all MariaDB 11.8 features and their documentation, see Changes and improvements in MariaDB 11.8 and Release notes - MariaDB 11.8 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 11.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 11.4 or higher.

- **Crypographic library** – RDS for MariaDB replaced OpenSSL with AWS Libcrypto (AWS-LC), which is FIPS 140-3 certified.
- **Simple Password Check plugin** – You can use the MariaDB Simple Password Check Plugin to check whether a password contains at least a specific number of characters of a specific type. For more information, see the section called "Password validation plugins".
- **Cracklib Password Check plugin** – You can use the MariaDB Cracklib Password Check Plugin to check the strength of new passwords. For more information, see the section called "Password validation plugins".
- **InnoDB enhancements** – These enhancements include the following items:
  - The change buffer was removed. For more information, see InnoDB Change Buffering.
  - InnoDB Defragmentation was removed. For more information, see InnoDB Defragmentation.
- **New privilege** – The admin user now also has the `SHOW CREATE ROUTINE` privilege. This privilege permits the grantee to view the `SHOW CREATE` definition statement of a routine that's owned by another user. For more information, see Database Privileges.
- **Replication improvement** – MariaDB version 11.4 DB instances support binlog indexing. You can create a GTID index for each binlog file. These indexes improve the performance of replication by reducing the time it takes to locate a GTID. For more information, see Binlog Indexing.
- **Deprecated or removed parameters** – The following parameters have been deprecated or removed for MariaDB version 11.4 DB instances:
  - `engine_condition_pushdown` is removed from optimizer_switch
  - innodb_change_buffer_max_size
  - innodb_defragment
  - `TLSv1.0` and `TLSv1.1` are removed from tls_version
- **New default values for a parameter** – The default value of the innodb_undo_tablespaces parameter changed from `0` to `3`.

- **New valid values for parameters** – The following parameters have new valid values for MariaDB version 11.4 DB instances:
  - The valid values for the binlog_row_image parameter now include FULL_NODUP.
  - The valid values for the OLD_MODE parameter now include NO_NULL_COLLATION_IDS.
- **New parameters** – The following parameters are new for MariaDB version 11.4 DB instances:
  - The transaction_isolation parameter replaces the tx_isolation parameter.
  - The transaction_read_only parameter replaces the tx_read_only parameter.
  - The block_encryption_mode parameter defines the default block encryption mode for the AES_ENCRYPT() and AES_DECRYPT() functions.
  - The character_set_collations defines overrides for character set default collations.
  - The binlog_gtid_index, binlog_gtid_index_page_size, and binlog_gtid_index_span_min define the properties of the binlog GTID index. For more information, see Binlog Indexing.

For a list of all MariaDB 11.4 features and their documentation, see Changes and improvements in MariaDB 11.4 and Release notes - MariaDB 11.4 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.11 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.11 or higher.

- **Password Reuse Check plugin** – You can use the MariaDB Password Reuse Check plugin to prevent users from reusing passwords and to set the retention period of passwords. For more information, see Password Reuse Check Plugin.
- **GRANT TO PUBLIC authorization** – You can grant privileges to all users who have access to your server. For more information, see GRANT TO PUBLIC.
- **Separation of SUPER and READ ONLY ADMIN privileges** – You can remove READ ONLY ADMIN privileges from all users, even users that previously had SUPER privileges.
- **Security** – You can now set option `--ssl` as the default for your MariaDB client. MariaDB no longer silently disables SSL if the configuration is incorrect.
- **SQL commands and functions** – You can now use the `SHOW ANALYZE FORMAT=JSON` command and the functions `ROW_NUMBER`, `SFORMAT`, and `RANDOM_BYTES`. `SFORMAT` allows string formatting and is enabled by default. You can convert partition to table and table to partition

in a single command. There are also several improvements around `JSON_*()` functions. `DES_ENCRYPT` and `DES_DECRYPT` functions were deprecated for version 10.10 and higher. For more information, see SFORMAT.

- **InnoDB enhancements** – These enhancements include the following items:
  - Performance improvements in the redo log to reduce write amplification and to improve concurrency.
  - The ability for you to change the undo tablespace without reinitializing the data directory. This enhancement reduces control plane overhead. It requires restarting but it doesn't require reinitialization after changing undo tablespace.
  - Support for `CHECK TABLE ... EXTENDED` and for descending indexes internally.
  - Improvements to bulk insert.
- **Binlog changes** – These changes include the following items:
  - Logging `ALTER` in two phases to decrease replication latency. The `binlog_alter_two_phase` parameter is disabled by default, but can be enabled through parameter groups.
  - Logging `explicit_defaults_for_timestamp`.
  - No longer logging `INCIDENT_EVENT` if the transaction can be safely rolled back.
- **Replication improvement**s – MariaDB version 10.11 DB instances use GTID replication by default if the master supports it. Also, `Seconds_Behind_Master` is more precise.
- **Clients** – You can use new command-line options for `mysqlbinglog` and `mariadb-dump`. You can use `mariadb-dump` to dump and restore historical data.
- **System versioning** – You can modify history. MariaDB automatically creates new partitions.
- **Atomic DDL** – `CREATE OR REPLACE` is now atomic. Either the statement succeeds or it's completely reversed.
- **Redo log write** – Redo log writes asynchronously.
- **Stored functions** – Stored functions now support the same `IN`, `OUT`, and `INOUT` parameters as in stored procedures.
- **Deprecated or removed parameters** – The following parameters have been deprecated or removed for MariaDB version 10.11 DB instances:
  - innodb_change_buffering
  - innodb_disallow_writes
  - innodb_log_write_ahead_size

- innodb_prefix_index_cluster_optimization
- keep_files_on_create
- old

- **Dynamic parameters** – The following parameters are now dynamic for MariaDB version 10.11 DB instances:
  - innodb_log_file_size
  - innodb_write_io_threads
  - innodb_read_io_threads
- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.11 DB instances:
  - The default value of the explicit_defaults_for_timestamp parameter changed from `OFF` to `ON`.
  - The default value of the optimizer_prune_level parameter changed from 1 to 2.
- **New valid values for parameters** – The following parameters have new valid values for MariaDB version 10.11 DB instances:
  - The valid values for the old parameter were merged into those for the old_mode parameter.
  - The valid values for the histogram_type parameter now include `JSON_HB`.
  - The valid value range for the innodb_log_buffer_size parameter is now `262144` to `4294967295` (256KB to 4096MB).
  - The valid value range for the innodb_log_file_size parameter is now `4194304` to `512GB` (4MB to 512GB).
  - The valid values for the optimizer_prune_level parameter now include 2.
- **New parameters** – The following parameters are new for MariaDB version 10.11 DB instances:
  - The binlog_alter_two_phase parameter can improve replication performance.
  - The log_slow_min_examined_row_limit parameter can improve performance.
  - The log_slow_query parameter and the log_slow_query_file parameter are aliases for `slow_query_log` and `slow_query_log_file`, respectively.
  - optimizer_extra_pruning_depth
  - system_versioning_insert_history

For a list of all MariaDB 10.11 features and their documentation, see Changes and improvements in MariaDB 10.11 and Release notes - MariaDB 10.11 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.6 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.6 or higher:

- **MyRocks storage engine** – You can use the MyRocks storage engine with RDS for MariaDB to optimize storage consumption of your write-intensive, high-performance web applications. For more information, see Supported storage engines for MariaDB on Amazon RDS and MyRocks.
- **AWS Identity and Access Management (IAM) DB authentication** – You can use IAM DB authentication for better security and central management of connections to your MariaDB DB instances. For more information, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.
- **Upgrade options** – You can now upgrade to RDS for MariaDB version 10.6 from any prior major release (10.3, 10.4, 10.5). You can also restore a snapshot of an existing MySQL 5.6 or 5.7 DB instance to a MariaDB 10.6 instance. For more information, see Upgrades of the MariaDB DB engine.
- **Delayed replication** – You can now set a configurable time period for which a read replica lags behind the source database. In a standard MariaDB replication configuration, there is minimal replication delay between the source and the replica. With delayed replication, you can set an intentional delay as a strategy for disaster recovery. For more information, see Configuring delayed replication with MariaDB.
- **Oracle PL/SQL compatibility** – By using RDS for MariaDB version 10.6, you can more easily migrate your legacy Oracle applications to Amazon RDS. For more information, see SQL_MODE=ORACLE.
- **Atomic DDL** – Your dynamic data language (DDL) statements can be relatively crash-safe with RDS for MariaDB version 10.6. `CREATE TABLE`, `ALTER TABLE`, `RENAME TABLE`, `DROP TABLE`, `DROP DATABASE` and related DDL statements are now atomic. Either the statement succeeds, or it's completely reversed. For more information, see Atomic DDL.
- **Other enhancements** – These enhancements include a `JSON_TABLE` function for transforming JSON data to relational format within SQL, and faster empty table data load with Innodb. They also include new `sys_schema` for analysis and troubleshooting, optimizer enhancement for ignoring unused indexes, and performance improvements. For more information, see JSON_TABLE.

- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.6 DB instances:
  - The default value for the following parameters has changed from `utf8` to `utf8mb3`:
    - character_set_client
    - character_set_connection
    - character_set_results
    - character_set_system

    Although the default values have changed for these parameters, there is no functional change. For more information, see Supported Character Sets and Collations in the MariaDB documentation.
  - The default value of the collation_connection parameter has changed from `utf8_general_ci` to `utf8mb3_general_ci`. Although the default value has changed for this parameter, there is no functional change.
  - The default value of the old_mode parameter has changed from unset to `UTF8_IS_UTF8MB3`. Although the default value has changed for this parameter, there is no functional change.

For a list of all MariaDB 10.6 features and their documentation, see Changes and improvements in MariaDB 10.6 and Release notes - MariaDB 10.6 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.5 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

- **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see InnoDB: Performance Improvements etc. in the MariaDB documentation.
- **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables in the MariaDB documentation.
- **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the `innodb_log_files_in_group` parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.

If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the `innodb_log_file_size` parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the `innodb_log_file_size` parameter. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

- **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, the equivalent `SHOW REPLICA STATUS` command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

  Instead of using the `SHOW REPLICA STATUS` command, run the new `mysql.rds_replica_status` stored procedure to return similar information. For more information, see mysql.rds_replica_status.

- **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the `SHOW RELAYLOG EVENTS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, this command requires the `REPLICATION REPLICA ADMIN` privilege. This new privilege isn't granted to the RDS master user.

- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:

  - The default value of the max_connections parameter has changed to `LEAST({DBInstanceClassMemory/25165760},12000)`. For information about the `LEAST` parameter function, see DB parameter functions.
  - The default value of the innodb_adaptive_hash_index parameter has changed to `OFF` (`0`).
  - The default value of the innodb_checksum_algorithm parameter has changed to `full_crc32`.
  - The default value of the innodb_log_file_size parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see Changes and improvements in MariaDB 10.5 and Release notes - MariaDB 10.5 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

MariaDB 10.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

- **User account security enhancements** – Password expiration and account locking improvements
- **Optimizer enhancements** – Optimizer trace feature
- **InnoDB enhancements** – Instant DROP COLUMN support and instant VARCHAR extension for `ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPACT`
- **New parameters** – Including tcp_nodedelay, tls_version, and gtid_cleanup_batch_size

For a list of all MariaDB 10.4 features and their documentation, see Changes and improvements in MariaDB 10.4 and Release notes - MariaDB 10.4 series on the MariaDB website.

For a list of unsupported features, see MariaDB features not supported by Amazon RDS.

Supported storage engines for MariaDB on Amazon RDS

RDS for MariaDB supports the following storage engines.

Topics

- The InnoDB storage engine
- The MyRocks storage engine

Other storage engines aren't currently supported by RDS for MariaDB.

The InnoDB storage engine

Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB is the recommended storage engine for MariaDB DB instances on Amazon RDS. Amazon RDS features such as point-in-time restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version.

For more information, see InnoDB.

The MyRocks storage engine

The MyRocks storage engine is available in RDS for MariaDB version 10.6 and higher. Before using the MyRocks storage engine in a production database, we recommend that you perform thorough benchmarking and testing to verify any potential benefits over InnoDB for your use case.

The default parameter group for MariaDB version 10.6 includes MyRocks parameters. For more information, see Parameters for MariaDB and Parameter groups for Amazon RDS.

To create a table that uses the MyRocks storage engine, specify `ENGINE=RocksDB` in the `CREATE TABLE` statement. The following example creates a table that uses the MyRocks storage engine.

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=RocksDB;
```

We strongly recommend that you don't run transactions that span both InnoDB and MyRocks tables. MariaDB doesn't guarantee ACID (atomicity, consistency, isolation, durability) for transactions across storage engines. Although it is possible to have both InnoDB and MyRocks tables in a DB instance, we don't recommend this approach except during a migration from one storage engine to the other. When both InnoDB and MyRocks tables exist in a DB instance, each storage engine has its own buffer pool, which might cause performance to degrade.

MyRocks doesn't support `SERIALIZABLE` isolation or gap locks. So, generally you can't use MyRocks with statement-based replication. For more information, see MyRocks and Replication.

Currently, you can modify only the following MyRocks parameters:

- `rocksdb_block_cache_size`
- `rocksdb_bulk_load`
- `rocksdb_bulk_load_size`
- `rocksdb_deadlock_detect`
- `rocksdb_deadlock_detect_depth`
- `rocksdb_max_latest_deadlocks`

The MyRocks storage engine and the InnoDB storage engine can compete for memory based on the settings for the `rocksdb_block_cache_size` and `innodb_buffer_pool_size` parameters. In some cases, you might only intend to use the MyRocks storage engine on a particular DB instance. If so, we recommend setting the `innodb_buffer_pool_size minimal` parameter to a minimal value and setting the `rocksdb_block_cache_size` as high as possible.

You can access MyRocks log files by using the `DescribeDBLogFiles` and `DownloadDBLogFilePortion` operations.

For more information about MyRocks, see MyRocks on the MariaDB website.

Cache warming for MariaDB on Amazon RDS

InnoDB cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see Dumping and restoring the buffer pool in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.3 and higher DB instances.
To enable it, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see Parameter groups for Amazon RDS.

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don't commonly see a significant performance benefit.

Important

If your MariaDB DB instance doesn't shut down normally, such as during a failover, then the buffer pool state isn't saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool before the restart. To ensure that you have a recent state of the buffer pool available to warm the cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand.
You can create an event to dump the buffer pool automatically and at a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
```

```
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see Events in the MariaDB documentation.

Dumping and loading the buffer pool on demand

You can save and load the cache on demand using the following stored procedures:

- To dump the current state of the buffer pool to disk, call the mysql.rds_innodb_buffer_pool_dump_now stored procedure.
- To load the saved state of the buffer pool from disk, call the mysql.rds_innodb_buffer_pool_load_now stored procedure.
- To cancel a load operation in progress, call the mysql.rds_innodb_buffer_pool_load_abort stored procedure.

MariaDB features not supported by Amazon RDS

The following MariaDB features are not supported on Amazon RDS:

- S3 storage engine
- Authentication plugin – GSSAPI
- Authentication plugin – Unix Socket
- AWS Key Management encryption plugin
- Delayed replication for MariaDB versions lower than 10.6
- Native MariaDB encryption at rest for InnoDB and Aria

  You can enable encryption at rest for a MariaDB DB instance by following the instructions in Encrypting Amazon RDS resources.
- HandlerSocket
- JSON table type for MariaDB versions lower than 10.6
- MariaDB ColumnStore
- MariaDB Galera Cluster
- Multisource replication

- MyRocks storage engine for MariaDB versions lower than 10.6
- Password validation plugin, `simple_password_check`, and `cracklib_password_check` for MariaDB versions lower than 11.4
- Spider storage engine
- Sphinx storage engine
- TokuDB storage engine
- Storage engine-specific object attributes, as described in Engine-defined new Table/Field/Index attributes in the MariaDB documentation
- Table and tablespace encryption
- Hashicorp Key Management plugin
- Running two upgrades in parallel

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.

MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.5 to 10.6. A version change is considered minor if only the minor version number changes, for example going from version 10.6.14 to 10.6.16.

Supported MariaDB minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MariaDB.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.

The following table shows the minor versions of MariaDB 11.8 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
11.8.6	04 February 2026	10 February 2026	February 2027
11.8.5	14 November 2025	20 November 2025	November 2026
11.8.3	6 August 2025	25 August 2025	September 2026

The following table shows the minor versions of MariaDB 11.4 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
11.4.10	04 February 2026	10 February 2026	February 2027
11.4.9	6 November 2025	18 November 2025	November 2026
11.4.8	6 August 2025	13 August 2025	September 2026
11.4.7	22 May 2025	4 June 2025	September 2026
11.4.5	4 February 2025	24 February 2025	May 2026
11.4.4	1 November 2024	20 December 2024	May 2026
11.4.3	8 August 2024	15 October 2024	May 2026

The following table shows the minor versions of MariaDB 10.11 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.11.16	04 February 2026	10 February 2026	February 2027
10.11.15	6 November 2025	18 November 2025	November 2026
10.11.14	6 August 2025	13 August 2025	September 2026
10.11.13	22 May 2025	4 June 2025	September 2026
10.11.11	4 February 2025	24 February 2025	May 2026
10.11.10	1 November 2024	20 December 2024	May 2026
10.11.9	8 August 2024	4 September 2024	May 2026

The following table shows the minor versions of MariaDB 10.6 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.6.25	04 February 2026	10 February 2026	July 2026
10.6.24	6 November 2025	18 November 2025	July 2026
10.6.23	6 August 2025	13 August 2025	July 2026
10.6.22	6 May 2025	20 May 2025	July 2026
10.6.21	4 February 2025	24 February 2025	May 2026
10.6.20	1 November 2024	20 December 2024	May 2026
10.6.19	8 August 2024	4 September 2024	May 2026

The following table shows the minor versions of MariaDB 10.5 that Amazon RDS currently supports.

MariaDB engine version	Community release date	RDS release date	RDS end of standard support date
10.5.29	6 May 2025	20 May 2025	June 2026
10.5.28	4 February 2025	24 February 2025	June 2026
10.5.27	1 November 2024	20 December 2024	May 2026

You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as

well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MariaDB, run the following CLI command:

```
aws rds describe-db-engine-versions --engine mariadb --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region by running the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mariadb
 --engine-version major_engine_version --region region --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *major_engine_version* with the major engine version, and replace *region* with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.5 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mariadb --engine-version
 10.5 --region us-west-2 --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --
output text
```

MariaDB minor versions on Amazon RDS

Minor versions

- MariaDB version 11.8.6
- MariaDB version 11.8.5
- MariaDB version 11.8.3
- MariaDB version 11.4.10
- MariaDB version 11.4.9
- MariaDB version 11.4.8
- MariaDB version 11.4.7
- MariaDB version 11.4.5
- MariaDB version 11.4.4

- MariaDB version 10.11.16
- MariaDB version 10.11.15
- MariaDB version 10.11.14
- MariaDB version 10.11.13
- MariaDB version 10.11.11
- MariaDB version 10.11.10
- MariaDB version 10.6.25
- MariaDB version 10.6.24
- MariaDB version 10.6.23
- MariaDB version 10.6.22
- MariaDB version 10.6.21
- MariaDB version 10.6.20
- MariaDB version 10.5.29
- MariaDB version 10.5.28
- MariaDB version 10.5.27

MariaDB version 11.8.6

MariaDB version 11.8.6 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025c`.
- Fixed an issue which can cause some SQL statements to not get logged in the audit log.

MariaDB version 11.8.5

MariaDB version 11.8.5 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 11.8.3

MariaDB version 11.8.3 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- **New default value for parameter** – The default value of `require_secure_transport` parameter changed from `0` to `1`, enforcing secure transport connections by default. For more information, see Requiring SSL/TLS for all connections to a MariaDB DB instance on Amazon RDS.

MariaDB version 11.4.10

MariaDB version 11.4.10 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025c`.
- Fixed an issue which can cause some SQL statements to not get logged in the audit log.

MariaDB version 11.4.9

MariaDB version 11.4.9 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 11.4.8

MariaDB version 11.4.8 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 11.4.7

MariaDB version 11.4.7 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025b`.

MariaDB version 11.4.5

MariaDB version 11.4.5 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025a`.

MariaDB version 11.4.4

MariaDB version 11.4.4 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Reverted two MariaDB community changes that cause point-in-time recovery (PITR) to fail. For more information, see MariaDB Server Jira issue MDEV-35528.

MariaDB version 10.11.16

MariaDB version 10.11.16 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025c`.
- Fixed an issue which can cause some SQL statements to not get logged in the audit log.

MariaDB version 10.11.15

MariaDB version 10.11.15 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 10.11.14

MariaDB version 10.11.14 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 10.11.13

MariaDB version 10.11.13 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025b`.

MariaDB version 10.11.11

MariaDB version 10.11.11 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025a`.

MariaDB version 10.11.10

MariaDB version 10.11.10 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Reverted two MariaDB community changes that cause point-in-time recovery (PITR) to fail. For more information, see MariaDB Server Jira issue MDEV-35528.

MariaDB version 10.6.25

MariaDB version 10.6.25 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025c`.
- Fixed an issue which can cause some SQL statements to not get logged in the audit log.

MariaDB version 10.6.24

MariaDB version 10.6.24 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 10.6.23

MariaDB version 10.6.23 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

MariaDB version 10.6.22

MariaDB version 10.6.22 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025b`.

MariaDB version 10.6.21

MariaDB version 10.6.21 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025a`.

MariaDB version 10.6.20

MariaDB version 10.6.20 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Reverted two MariaDB community changes that cause point-in-time recovery (PITR) to fail. For more information, see MariaDB Server Jira issue MDEV-35528.

MariaDB version 10.5.29

MariaDB version 10.5.29 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025b`.

MariaDB version 10.5.28

MariaDB version 10.5.28 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025a`.

MariaDB version 10.5.27

MariaDB version 10.5.27 is now available on Amazon RDS. This release contains fixes and improvements added by the MariaDB community and Amazon RDS.

New features and enhancements

- Reverted two MariaDB community changes that cause point-in-time recovery (PITR) to fail. For more information, see MariaDB Server Jira issue MDEV-35528.

Supported MariaDB major versions on Amazon RDS

RDS for MariaDB major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. If Amazon extends support for an RDS for MariaDB version for longer than originally stated, we plan to update this table to reflect the later date.

> **Note**
>
> Dates with only a month and a year are approximate and are updated with an exact date when it's known.
> You can also view information about support dates for major engine versions by running the describe-db-major-engine-versions AWS CLI command or by using the DescribeDBMajorEngineVersions RDS API operation.

MariaDB major version	Community release date	RDS release date	Community end of life date	RDS end of standard support date
MariaDB 11.8	6 August 2025	25 August 2025	June 2030	June 2030
MariaDB 11.4	8 August 2024	15 October 2024	May 2029	May 2029

MariaDB major version	Community release date	RDS release date	Community end of life date	RDS end of standard support date
MariaDB 10.11	16 February 2023	21 August 2023	16 February 2028	February 2028
MariaDB 10.6	6 July 2021	3 February 2022	6 July 2026	August 2026
MariaDB 10.5	24 June 2020	21 January 2021	24 June 2025	August 2026

Working with the Database Preview environment

RDS for MariaDB DB instances in the Database Preview environment are functionally similar to other RDS for MariaDB DB instances. However, you can't use the Database Preview environment for production workloads.

Preview environments have the following limitations:

- Amazon RDS deletes all DB instances 60 days after you create them, along with any backups and snapshots.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

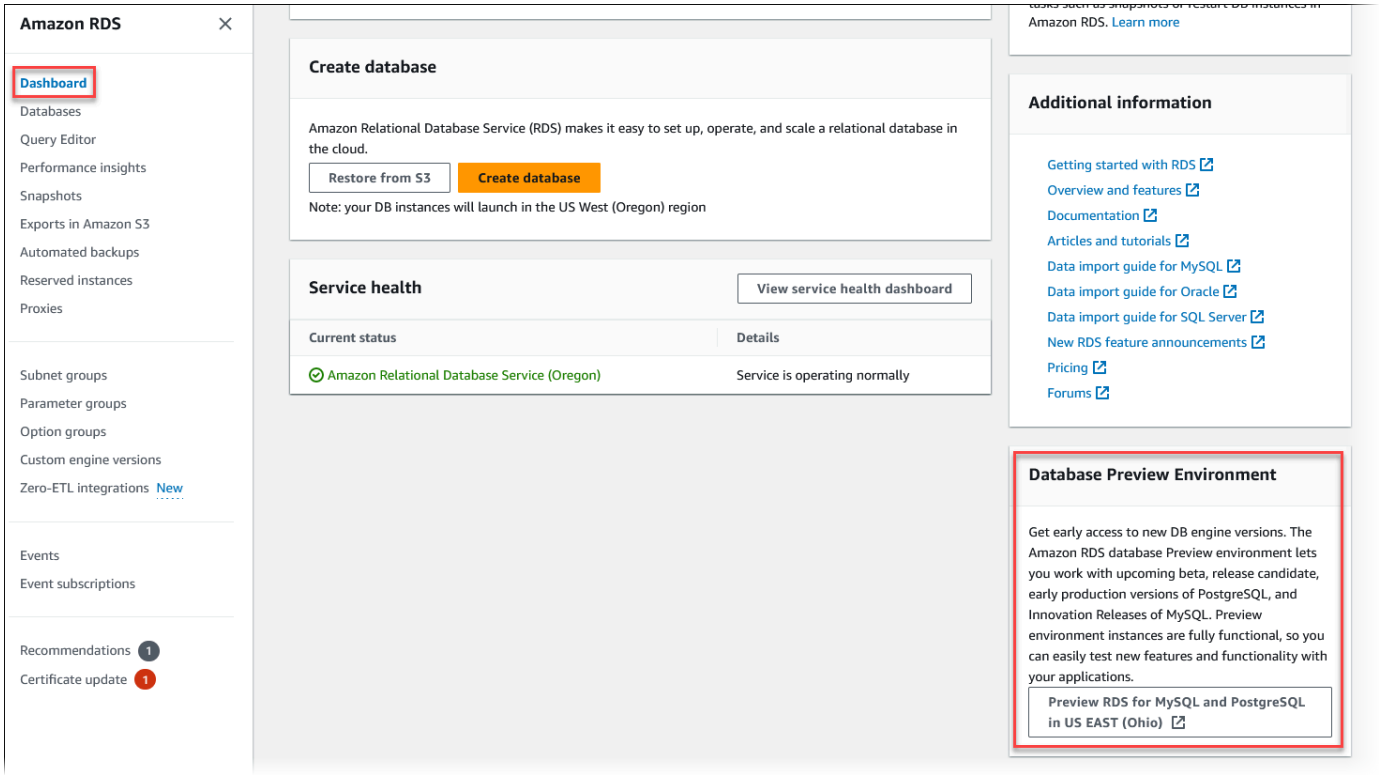
The following options are supported by the preview.

- You can create DB instances using db.m6i, db.r6i, db.m6g, db.m5, db.t3, db.r6g, and db.r5 DB instance classes. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and Multi-AZ deployments.
- You can use standard MariaDB dump and load functions to export databases from or import databases to the Database Preview environment.

Features not supported in the Database Preview environment

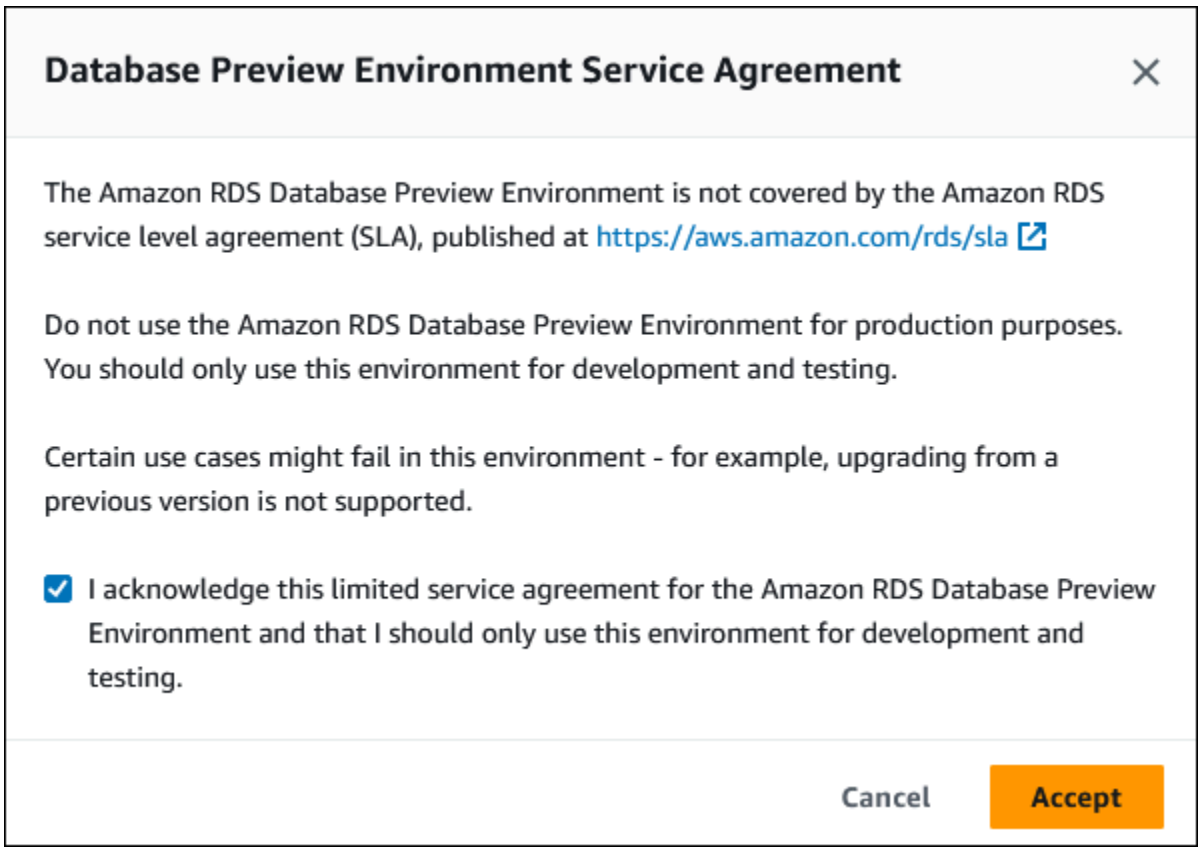
The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas
- RDS Proxy



Creating a new DB instance in the Database Preview environment

You can create a DB instance in the Database Preview environment using the AWS Management Console, AWS CLI, or RDS API.



Console

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Dashboard** from the navigation pane.
3. In the **Dashboard** page, locate the **Database Preview Environment** section, as shown in the following image.

You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.

4. To create the RDS for MariaDB DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

AWS CLI

To create a DB instance in the Database Preview environment using the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MariaDB DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the AWS CLI procedure in Creating a DB instance.

RDS API

To create a DB instance in the Database Preview environment using the RDS API, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MariaDB DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the RDS API procedure in Creating a DB instance.

MariaDB version 11.7 in the Database Preview environment

MariaDB version 11.7 is now available in the Amazon RDS Database Preview environment. MariaDB version 11.7 contains several improvements that are described in Changes and improvements in MariaDB 11.7. This version also includes support for the vector data type, indexing, and search. For more information, see Vector Overview in the MariaDB documentation.

You can use the Database Preview environment to test your workloads against this release before it is available in all AWS Regions for production workloads. For information on the Database Preview environment, see the section called “The Database Preview environment”. To access the Preview Environment from the console, select rds-preview/.

Deprecated versions for Amazon RDS for MariaDB

Amazon RDS for MariaDB versions 10.0, 10.1, 10.2, and 10.3 are deprecated.

For information about the Amazon RDS deprecation policy for MariaDB, see Amazon RDS FAQs.

Connecting to your MariaDB DB instance

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql command-line client in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the Download HeidiSQL page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command.

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command.

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command.

```
man mysql
```

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.

You can use SSL encryption on connections to a MariaDB DB instance. For information, see SSL/TLS support for MariaDB DB instances on Amazon RDS.

To find and connect to a RDS for MariaDB DB instance, see the following topics.

Topics

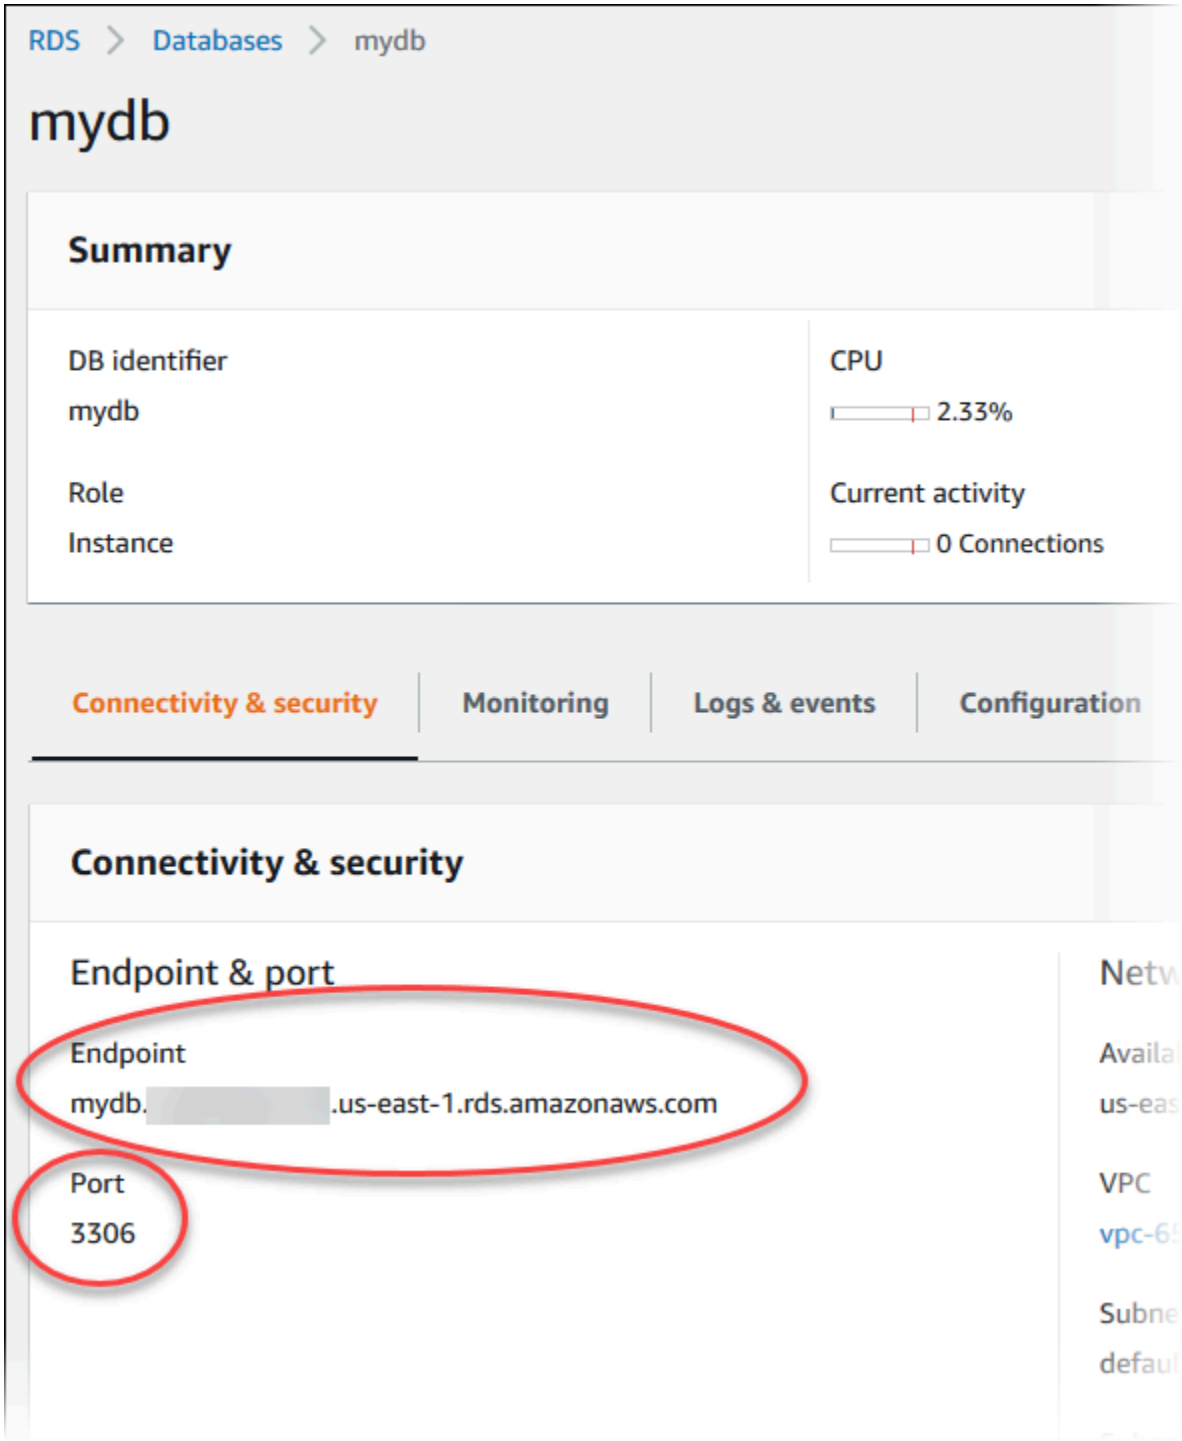
- Finding the connection information for a MariaDB DB instance
- Connecting from the MySQL command-line client (unencrypted) for RDS for MariaDB
- Connecting to RDS for MariaDB with the AWS JDBC Driver and AWS Python Driver;
- Troubleshooting connections to your MariaDB DB instance

Finding the connection information for a MariaDB DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.

To connect to a DB instance, use any client for the MariaDB DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.



To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MariaDB DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MariaDB DB instance by using the AWS CLI, run the describe-db-instances command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --filters "Name=engine,Values=mariadb" \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mariadb" ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
    [
        "mydb1",
        "mydb1.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ],
    [
        "mydb2",
        "mydb2.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the MySQL command-line client (unencrypted) for RDS for MariaDB

> **Important**
>
> Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting to your MariaDB DB instance on Amazon RDS with SSL/TLS from the MySQL command-line client (encrypted).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for your DB instance for *<endpoint>* and the master user name that you used for *<mymasteruser>*. Provide the master password that you used when prompted for a password.

```
mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.6.10-MariaDB-log Source distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Connecting to RDS for MariaDB with the AWS JDBC Driver and AWS Python Driver;

Connect to RDS for MariaDB DB instances with the AWS JDBC Driver and the AWS Python Driver. For more information, see the following topics.

Topics

- Connecting to RDS for MariaDB with the Amazon Web Services (AWS) JDBC Driver
- Connecting to RDS for MariaDB with the Amazon Web Services (AWS) Python Driver

Connecting to RDS for MariaDB with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community MySQL Connector/J driver and the community MariaDB Connector/J driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:mysql://` to `jdbc:aws-wrapper:mysql://`
- `jdbc:mariadb://` to `jdbc:aws-wrapper:mariadb://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to RDS for MariaDB with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC and Amazon RDS.

  You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.
- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Securing MariaDB DB instance connections

You can manage the security of your MariaDB DB instances.

Topics

- MariaDB security on Amazon RDS
- Using the password validation plugins for RDS for MariaDB
- Encrypting client connections with SSL/TLS to MariaDB DB instances on Amazon RDS
- Updating applications to connect to MariaDB instances using new SSL/TLS certificates

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS.
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Socket Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in stand-alone databases, as does directly modifying database schema tables.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- `alter`
- `alter routine`
- `create`
- `create routine`
- `create temporary tables`

- `create user`
- `create view`
- `delete`
- `drop`
- `event`
- `execute`
- `grant option`
- `index`
- `insert`
- `lock tables`
- `process`
- `references`
- `reload`

  This privilege is limited on MariaDB DB instances. It doesn't grant access to the `FLUSH LOGS` or `FLUSH TABLES WITH READ LOCK` operations.
- `replication client`
- `replication slave`
- `select`
- `show create routine`

  This privilege is only on MariaDB DB instances running version 11.4 and higher.
- `show databases`
- `show view`
- `trigger`
- `update`

For more information about these privileges, see User account management in the MariaDB documentation.

> **Note**
>
> Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the `ModifyDBInstance` API or the `modify-db-instance` AWS CLI and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the `rdsadmin` account results in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `mysql.rds_kill`, `mysql.rds_kill_query`, and `mysql.rds_kill_query_id` are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.

Using the password validation plugins for RDS for MariaDB

Starting with RDS for MariaDB version 11.4, you can use the following password validation plugins to enhance the security of your database connections:

- simple_password_check – checks whether a password contains at least a specific number of characters of a specific type.
- cracklib_password_check – checks whether a password appears in a dictionary file of the CrackLib library.

To enable these plugins, set the value of the parameter `simple_password_check` or `cracklib_password_check` to `FORCE_PLUS_PERMANENT` in the DB parameter group associated with the DB instance. When this value is set, the plugin can't be uninstalled by using the `UNINSTALL PLUGIN` statement at runtime.

To disable these plugins, set the value of the parameter `simple_password_check` or `cracklib_password_check` to `OFF` in the DB parameter group associated with the DB instance. When this value is set, the plugin validation rules no longer apply for new passwords.

For information about setting the values of parameters in parameter groups, see the section called "Modifying parameters in a DB parameter group".

Encrypting client connections with SSL/TLS to MariaDB DB instances on Amazon RDS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MariaDB DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MariaDB DB instance. SSL/TLS support is available in all AWS Regions.

With Amazon RDS, you can secure data in transit by encrypting client connections to MariaDB DB instances with SSL/TLS, requiring SSL/TLS for all connections to a MariaDB DB instance, and connecting from the MySQL command-line client with SSL/TLS (encrypted). The following sections provide guidance on configuring and utilizing SSL/TLS encryption for MariaDB DB instances on Amazon RDS.

Topics

- SSL/TLS support for MariaDB DB instances on Amazon RDS
- Requiring SSL/TLS for specific user accounts to a MariaDB DB instance on Amazon RDS
- Requiring SSL/TLS for all connections to a MariaDB DB instance on Amazon RDS
- Connecting to your MariaDB DB instance on Amazon RDS with SSL/TLS from the MySQL command-line client (encrypted)

SSL/TLS support for MariaDB DB instances on Amazon RDS

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases, but might fail if your application doesn't accept certificate chains. If your application doesn't accept certificate chains, try using an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions with SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For more information about using SSL/TLS with MySQL, see Updating applications to connect to MariaDB instances using new SSL/TLS certificates.

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.3, 1.2, 1.1, and 1.0. TLS support depends on the MariaDB minor version. The following table shows the TLS support for MariaDB minor versions.

TLS version	MariaDB 11.8	MariaDB 11.4	MariaDB 10.11	MariaDB 10.6	MariaDB 10.5	MariaDB 10.4
TLS 1.3	All minor versions	All minor versions	All minor versions	All minor versions	All minor versions	All minor versions
TLS 1.2	All minor versions	All minor versions	All minor versions	All minor versions	All minor versions	All minor versions
TLS 1.1	Not supported	Not supported	Not supported	10.6.16 and lower	10.5.23 and lower	10.4.32 and lower
TLS 1.0	Not supported	Not supported	Not supported	10.6.16 and lower	10.5.23 and lower	10.4.32 and lower

Requiring SSL/TLS for specific user accounts to a MariaDB DB instance on Amazon RDS

You can require SSL/TLS encryption for specified user account connections to your MariaDB DB instances on Amazon RDS. Protecting sensitive information from unauthorized access or interception is crucial to enforce security policies where data confidentiality is a concern.

To require SSL/TLS connections for specific users' accounts, use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account `encrypted_user`.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MariaDB, see Securing Connections for Client and Server in the MariaDB documentation.

Requiring SSL/TLS for all connections to a MariaDB DB instance on Amazon RDS

Use the `require_secure_transport` parameter to require that all user connections to your MariaDB DB instance use SSL/TLS. For versions 11.4 and earlier, the `require_secure_transport` parameter is set to `OFF` by default. For 11.8 and later versions, the default value is set to `ON`, enforcing SSL/TLS for connections to your DB instance. You can change the `require_secure_transport` parameter to `OFF` if non-secure connections are needed.

> **Note**
>
> The `require_secure_transport` parameter is only supported for MariaDB version 10.5 and higher.

You can set the `require_secure_transport` parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the `require_secure_transport` parameter is set to `ON` for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
ERROR 1045 (28000): Access denied for user 'USER'@'localhost' (using password: YES |
 NO)
```

For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

For more information about the `require_secure_transport` parameter, see the MariaDB documentation.

Connecting to your MariaDB DB instance on Amazon RDS with SSL/TLS from the MySQL command-line client (encrypted)

The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql  Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
   ```

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-verify-server-cert -P 3306 -u myadmin -p
   ```

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
```

3. Enter the master user password when prompted.

You should see output similar to the following.

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 31
Server version: 10.6.10-MariaDB-log Source distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Updating applications to connect to MariaDB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

> **Note**
>
> Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.
> You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and still connects successfully.

We recommend avoiding `preferred` mode. In `preferred` mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For information about using SSL/TLS with MariaDB DB instances, see SSL/TLS support for MariaDB DB instances on Amazon RDS.

Topics

- Determining whether a client requires certificate verification in order to connect
- Updating your application trust store
- Example Java code for establishing SSL connections

Determining whether a client requires certificate verification in order to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.
Specify a password other than the prompt shown here as a security best practice.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see Using TLS/SSL with MariaDB Connector/J in the MariaDB documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

> **Note**
>
> Specify passwords other than the prompts shown here as a security best practice.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
private static final String DB_USER = "admin";
```

```
        private static final String DB_USER = "user name";
        private static final String DB_PASSWORD = "password";
        // This key store has only the prod root ca.
        private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
        private static final String KEY_STORE_PASS = "keystore-password";

    public static void main(String[] args) throws Exception {
        Class.forName("org.mariadb.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-
public.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306?useSSL=true",properties);
        Statement stmt=connection.createStatement();

        ResultSet rs=stmt.executeQuery("SELECT 1 from dual");

        return;
    }
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Specify a password other than the prompt shown here as a security best practice.

Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for MariaDB with Amazon RDS Optimized Reads. An RDS for MariaDB DB instance that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance that doesn't use it.

Topics

- Overview of RDS Optimized Reads
- Use cases for RDS Optimized Reads
- Best practices for RDS Optimized Reads
- Using RDS Optimized Reads
- Monitoring DB instances that use RDS Optimized Reads
- Limitations for RDS Optimized Reads

Overview of RDS Optimized Reads

When you use an RDS for MariaDB DB instance that has RDS Optimized Reads turned on, your DB instance achieves faster query performance through the use of an instance store. An *instance store* provides temporary block-level storage for your DB instance. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see Amazon EC2 instance store in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

The workloads that generate temporary objects in MariaDB for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance, regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS

Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes and background engine operations, such as flushing and insert buffer merges.

> **Note**
>
> Both manual and automated RDS snapshots contain only the engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with `GROUP BY` and `ORDER BY` clauses
- Workloads that use internal temporary tables for query processing

  You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.
- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
- When your DB instance has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

  The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.
- Use the default value of `MIXED` for the `binlog_format`. Depending on the size of the transactions, setting `binlog_format` to `ROW` can result in large binlog cache files on the instance store.
- Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.

Using RDS Optimized Reads

When you provision an RDS for MariaDB DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment or Multi-AZ DB instance deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for MariaDB DB instance using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance.
- Modify an existing RDS for MariaDB DB instance to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called “DB instance classes”.

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".

If you don't want to use RDS Optimized Reads, modify your DB instance so that it doesn't use a DB instance class that supports the feature.

Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- `FreeLocalStorage`
- `ReadIOPSLocalStorage`
- `ReadLatencyLocalStorage`
- `ReadThroughputLocalStorage`
- `WriteIOPSLocalStorage`
- `WriteLatencyLocalStorage`
- `WriteThroughputLocalStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Limitations for RDS Optimized Reads

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for the following RDS for MariaDB versions:
  - All available minor versions of 11.4 and higher major releases
  - 10.11.4 and higher 10.11 versions
  - 10.6.7 and higher 10.6 versions
  - 10.5.16 and higher 10.5 versions
  - 10.4.25 and higher 10.4 versions

  For information about RDS for MariaDB versions, see MariaDB on Amazon RDS versions.

- You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.
- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MariaDB, any session that requires more storage than the value of `binlog_cache_size` writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.

Improving write performance with Amazon RDS Optimized Writes for MariaDB

You can improve the performance of write transactions with RDS Optimized Writes for MariaDB. When your RDS for MariaDB database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics

- Overview of RDS Optimized Writes
- Using RDS Optimized Writes
- Enabling RDS Optimized Writes on an existing database
- Limitations for RDS Optimized Writes

Overview of RDS Optimized Writes

When you turn on RDS Optimized Writes, your RDS for MariaDB databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MariaDB, provide the *ACID properties* of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MariaDB uses a data storage area called the *doublewrite buffer* that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MariaDB database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MariaDB doublewrite buffer, see InnoDB Doublewrite Buffer in the MariaDB documentation.

With RDS Optimized Writes turned on, RDS for MariaDB databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MariaDB databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter `rds.optimized_writes` to control the RDS Optimized Writes feature for RDS for MariaDB databases. Access this parameter in the DB parameter groups of RDS for MariaDB for the following versions:

- All available minor versions of 11.8 and higher major releases
- 11.4.3 and higher 11.4 versions
- 10.11.4 and higher 10.11 versions
- 10.6.10 and higher 10.6 versions

Set the parameter using the following values:

- `AUTO` – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- `OFF` – Turn off RDS Optimized Writes even if the database supports it.

If you migrate an RDS for MariaDB database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MariaDB doublewrite buffer.

To determine whether an RDS for MariaDB database is using RDS Optimized Writes, view the current value of the `innodb_doublewrite` parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to `FALSE` (`0`).

Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MariaDB database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
  - RDS Optimized Writes is supported for the following RDS for MariaDB versions:

- All available minor versions of 11.8 and higher major releases
- 11.4.3 and higher 11.4 versions
- 10.11.4 and higher 10.11 versions
- 10.6.10 and higher 10.6 versions

For information about RDS for MariaDB versions, see MariaDB on Amazon RDS versions.

- RDS Optimized Writes is supported for RDS for MariaDB databases that use the following DB instance classes:
  - db.m7i
  - db.m7g
  - db.m6g
  - db.m6gd
  - db.m6i
  - db.m5
  - db.m5d
  - db.r7i
  - db.r7g
  - db.r6g
  - db.r6gd
  - db.r6i
  - db.r5
  - db.r5b
  - db.r5d
  - db.x2idn
  - db.x2iedn

  For information about DB instance classes, see the section called “DB instance classes”.

  DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called “Determining DB instance class support in AWS Regions”.

- In the parameter group associated with the database, the `rds.optimized_writes` parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.
