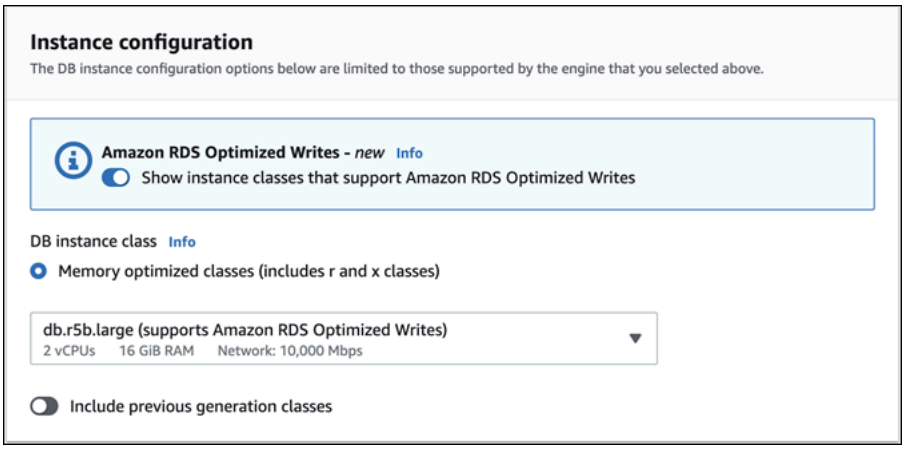
If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the `rds.optimized_writes` parameter to `OFF`. If you want the database to use RDS Optimized Writes later, you can set the parameter to `AUTO` to turn it on. For information about creating custom parameter groups and setting parameters, see Parameter groups for Amazon RDS.

For information about creating a DB instance, see Creating an Amazon RDS DB instance.



Console

When you use the RDS console to create an RDS for MariaDB database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MariaDB DB engine versions that support it in **Engine version**, and then choose a version.

Engine options
Engine type Info
Aurora (MySQL Compatible)
Aurora (PostgreSQL Compatible)
MySQL
MariaDB
PostgreSQL
Oracle
ORACLE
Microsoft SQL Server
Microsoft SQL Server
IBM Db2
IBM Db2
Engine version Info
View the engine versions that support the following database features.
Hide filters
Show versions that support the Amazon RDS Optimized Writes Info
Amazon RDS Optimized Writes improves write throughput by up to 2x at no additional cost.
Engine Version
MariaDB 10.6.10

In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.

After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MariaDB database with the console.

AWS CLI

To create a DB instance by using the AWS CLI, run the create-db-instance command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO. This example associates the default parameter group with the DB instance.

Example Creating a DB instance that uses RDS Optimized Writes

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mariadb \
    --engine-version 10.6.10 \
    --db-instance-class db.r5b.large \
    --manage-master-user-password \
    --master-username admin \
    --allocated-storage 200
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
```

```
    --engine mariadb ^
    --engine-version 10.6.10 ^
    --db-instance-class db.r5b.large ^
    --manage-master-user-password ^
    --master-username admin ^
    --allocated-storage 200
```

RDS API

You can create a DB instance using the CreateDBInstance operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`.

Enabling RDS Optimized Writes on an existing database

In order to modify an existing RDS for MariaDB database to turn on RDS Optimized Writes, the database must have been created with a supported DB engine version and DB instance class. In addition, the database must have been created *after* RDS Optimized Writes was released on March 7, 2023, as the required underlying file system configuration is incompatible with that of databases created before it was released. If these conditions are met, you can turn on RDS Optimized Writes by setting the `rds.optimized_writes` parameter to `AUTO`.

If your database was *not* created with a supported engine version, instance class, or file system configuration, you can use RDS Blue/Green Deployments to migrate to a supported configuration. While creating the blue/green deployment, do the following:

- Select **Enable Optimized Writes on green database**, then specify an engine version and DB instance class that supports RDS Optimized Writes. For a list of supported engine versions and instance classes, see the section called “Using with a new database”.
- Under **Storage**, choose **Upgrade storage file system configuration**. This option upgrades the database to a compatible underlying file system configuration.

When you create the blue/green deployment, if the `rds.optimized_writes` parameter is set to `AUTO`, RDS Optimized Writes will be automatically enabled on the green environment. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment.

For more information, see the section called “Creating a blue/green deployment”.

Limitations for RDS Optimized Writes

When you're restoring an RDS for MariaDB database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:

- The snapshot was created from a database that supports RDS Optimized Writes.
- The snapshot was created from a database that was created *after* RDS Optimized Writes was released.
- The snapshot is restored to a database that supports RDS Optimized Writes.
- The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to `AUTO`.

Upgrades of the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for RDS for MariaDB.

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see Upgrading a DB instance engine version.

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see MariaDB on Amazon RDS versions.

Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

Amazon RDS also supports upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

> **Tip**
>
> You can minimize the downtime required for DB instance upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Topics

- Considerations for MariaDB upgrades
- Finding valid upgrade targets
- MariaDB version numbers
- RDS version numbers in RDS for MariaDB
- Major version upgrades for RDS for MariaDB
- Upgrading a MariaDB DB instance
- Automatic minor version upgrades for RDS for MariaDB
- Using a read replica to reduce downtime when upgrading an RDS for MariaDB database
- Monitoring RDS for MariaDB DB engine upgrades with events

Considerations for MariaDB upgrades

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance *before* making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

> **Note**
>
> Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance.

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

Finding valid upgrade targets

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also run the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mariadb \
  --engine-version version_number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mariadb ^
  --engine-version version_number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MariaDB version 10.5.17 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mariadb \
  --engine-version 10.5.17 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mariadb ^
  --engine-version 10.5.17 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

MariaDB version numbers

The version numbering sequence for the RDS for MariaDB database engine is either in the form of *major.minor.patch.YYYYMMDD* or *major.minor.patch*, for example, 10.11.5.R2.20231201 or 10.4.30. The format used depends on the MariaDB engine version.

major

The major version number is both the integer and the first fractional part of the version number, for example, 10.11. A major version upgrade increases the major part of the version number. For example, an upgrade from *10.5*.20 to 10.6.12 is a major version upgrade, where *10.5* and *10.6* are the major version numbers.

minor

The minor version number is the third part of the version number, for example, the 5 in 10.11.5.

patch

The patch is the fourth part of the version number, for example, the R2 in 10.11.5.R2. An RDS patch version includes important bug fixes added to a minor version after its release.

YYYYMMDD

The date is the fifth part of the version number, for example, the 20231201 in 10.11.5.R2.20231201. An RDS date version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.

The following table explains the naming scheme for RDS for MariaDB version 10.11.

10.11 minor version	Naming scheme
≥5	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.11.5.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.11.5.R2, until your next major or minor version upgrade.
< 5	Existing DB instances use *major.minor.patch*, for example, 10.11.4.R2.

The following table explains the naming scheme for RDS for MariaDB version 10.6.

10.6 minor version	Naming scheme
≥ 14	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.6.14.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.6.14.R2, until your next major or minor version upgrade.
< 14	Existing DB instances use *major.minor.patch*, for example, 10.6.13.R2.

The following table explains the naming scheme for RDS for MariaDB version 10.5.

10.5 minor version	Naming scheme
≥ 21	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.5.21.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.5.21.R2, until your next major or minor version upgrade.

10.5 minor version	Naming scheme
< 21	Existing DB instances use *major.minor.patch*, for example, 10.5.20.R2.

The following table explains the naming scheme for RDS for MariaDB version 10.4.

10.4 minor version	Naming scheme
≥ 30	New DB instances use *major.minor.patch.YYMMDD*, for example, 10.4.30.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 10.4.30.R2, until your next major or minor version upgrade.
< 30	Existing DB instances use *major.minor.patch*, for example, 10.4.29.R2.

RDS version numbers in RDS for MariaDB

RDS version numbers use either the *major*.*minor*.*patch* or the *major*.*minor*.*patch*.*YYYYMMDD* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. An RDS date version (*YYMMDD*) is a security patch. A security patch doesn't include any fixes that might change the engine's behavior.

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

You can find out the RDS version number of your RDS for MariaDB database with the following SQL query:

```
mysql> select mysql.rds_version();
```

For example, querying an RDS for MariaDB 10.6.14 database returns the following output:

```
+---------------------+
| mysql.rds_version() |
+---------------------+
| 10.6.14.R2.20231201  |
+---------------------+
1 row in set (0.01 sec)
```

Major version upgrades for RDS for MariaDB

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

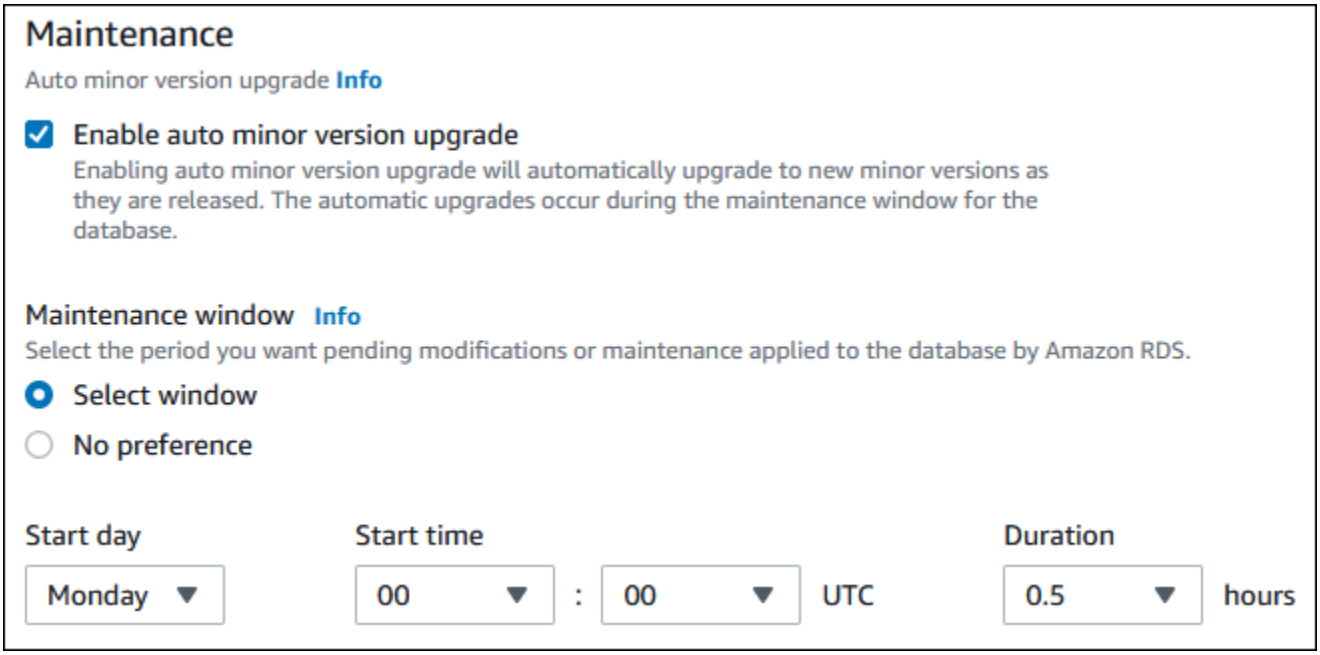
> **Note**
>
> In MariaDB 11.8, the default value for `require_secure_transport` is now 1, requiring secure SSL/TLS connections. Set to `0` if non-secure connections are needed.

Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:

- Any MariaDB version to MariaDB 11.8
- Any MariaDB version to MariaDB 11.4
- Any MariaDB version to MariaDB 10.11
- Any MariaDB version to MariaDB 10.6
- MariaDB 10.4 to MariaDB 10.5

If you are using a custom parameter group, and you perform a major version upgrade, you must specify either a default parameter group for the new DB engine version or create your own custom parameter group for the new DB engine version. Associating the new parameter group with the DB instance requires a customer-initiated database reboot after the upgrade completes. The instance's parameter group status will show `pending-reboot` if the instance needs to be rebooted to apply the parameter group changes. An instance's parameter group status can be viewed in the AWS Management Console or by running a "describe" call such as `describe-db-instances`.

Upgrading a MariaDB DB instance



For information about manually or automatically upgrading a MariaDB DB instance, see Upgrading a DB instance engine version.

Automatic minor version upgrades for RDS for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.

For more information about these settings, see Settings for DB instances.

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MariaDB community version
- Overall fleet stability since the minor version was released

> **Note**
>
> Support for using TLS version 1.0 and 1.1 was removed starting with specific minor versions of MariaDB. For information about supported MariaDB minor versions, see the section called "SSL/TLS support for MariaDB".

You can run the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version minor_version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version minor_version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.5.16 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
```

```
--engine mariadb \
--engine-version 10.5.16 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version 10.5.16 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  True        |  10.5.17        |
|  False       |  10.5.18        |
|  False       |  10.5.19        |
|  False       |  10.6.5         |
|  False       |  10.6.7         |
|  False       |  10.6.8         |
|  False       |  10.6.10        |
|  False       |  10.6.11        |
|  False       |  10.6.12        |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for MariaDB version 10.5.17. So, the automatic minor upgrade target is MariaDB version 10.5.17, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.

- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version.

Using a read replica to reduce downtime when upgrading an RDS for MariaDB database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MariaDB DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

If you can't use a blue/green deployment and your MariaDB DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MariaDB version 10.5 to MariaDB version 10.6. You can use the same general steps for upgrades to other major versions.

To upgrade a MariaDB database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a read replica of your MariaDB 10.5 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
    a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
    b. For **Actions**, choose **Create read replica**.
    c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MariaDB 10.5 DB instance.
    d. Choose **Create read replica**.

3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

   By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.

   a. In the console, choose **Databases**, and then choose the read replica that you just created.

   b. Choose **Modify**.

   c. For **Multi-AZ deployment**, choose **Create a standby instance**.

   d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.

   e. For **Scheduling of modifications**, choose **Apply immediately**.

   f. Choose **Modify DB instance**.

4. When the read replica **Status** shows **Available**, upgrade the read replica to MariaDB 10.6.

   a. In the console, choose **Databases**, and then choose the read replica that you just created.

   b. Choose **Modify**.

   c. For **DB engine version**, choose the MariaDB 10.6 version to upgrade to, and then choose **Continue**.

   d. For **Scheduling of modifications**, choose **Apply immediately**.

   e. Choose **Modify DB instance** to start the upgrade.

5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MariaDB 10.5 DB instance. To verify, connect to the read replica and run the `SHOW REPLICA STATUS` command. If the `Seconds_Behind_Master` field is `0`, then replication is up-to-date.

   > **Note**
   >
   > Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.6, then use `SHOW SLAVE STATUS`.

6. (Optional) Create a read replica of your read replica.

If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.

b. For **Actions**, choose **Create read replica**.

c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MariaDB 10.5 DB instance.

d. Choose **Create read replica**.

7. (Optional) Configure a custom DB parameter group for the read replica.

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

   a. Create a custom DB parameter group for MariaDB 10.6. For instructions, see Creating a DB parameter group in Amazon RDS.

   b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see Modifying parameters in a DB parameter group in Amazon RDS.

   c. In the console, choose **Databases**, and then choose the read replica.

   d. Choose **Modify**.

   e. For **DB parameter group**, choose the MariaDB 10.6 DB parameter group you just created, and then choose **Continue**.

   f. For **Scheduling of modifications**, choose **Apply immediately**.

   g. Choose **Modify DB instance** to start the upgrade.

8. Make your MariaDB 10.6 read replica a standalone DB instance.

   Important

   When you promote your MariaDB 10.6 read replica to a standalone DB instance, it is no longer a replica of your MariaDB 10.5 DB instance. We recommend that you promote your MariaDB 10.6 read replica during a maintenance window when your source MariaDB 10.5 DB instance is in read-only mode and all write operations are

suspended. When the promotion is completed, you can direct your write operations to the upgraded MariaDB 10.6 DB instance to ensure that no write operations are lost. In addition, we recommend that, before promoting your MariaDB 10.6 read replica, you perform all necessary data definition language (DDL) operations on your MariaDB 10.6 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MariaDB 10.6 read replica after it has been promoted. To promote a read replica, use the following procedure.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
b. For **Actions**, choose **Promote**.
c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see Introduction to backups.
d. Choose **Continue**.
e. Choose **Promote Read Replica**.

9. You now have an upgraded version of your MariaDB database. At this point, you can direct your applications to the new MariaDB 10.6 DB instance.

Monitoring RDS for MariaDB DB engine upgrades with events

When you upgrade the engine version of an RDS for MariaDB database, Amazon RDS emits a specific event during each phase of the process. To track the progress of an upgrade, you can view or subscribe to these events.

For more information about RDS events, see Monitoring Amazon RDS events.

For detailed information about a specific Amazon RDS event that occurs during your engine upgrade, see Amazon RDS event categories and event messages.

Upgrading a MariaDB DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your MariaDB DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your DB instance. You can upgrade the engine version for your DB snapshots.

For RDS for MariaDB, you can upgrade to all available engine versions. You can upgrade encrypted or unencrypted DB snapshots.

To view the available engine versions for your RDS for MariaDB DB snapshot, use the following AWS CLI example.

```
aws rds describe-db-engine-versions --engine mariadb --include-all --engine-
version example-engine-version --query "DBEngineVersions[*].ValidUpgradeTarget[*].
{EngineVersion:EngineVersion}" --output text
```

If you don't see results for your snapshot, your engine version might be deprecated. If your engine version is deprecated, we recommend that you upgrade to the newest major version upgrade target or to one of the other available upgrade targets for that version. For more information, see Upgrade options for DB snapshots with unsupported engine versions for RDS for MariaDB.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see the section called “Upgrades of the MariaDB DB engine”. To learn how to restore a DB snapshot, see the section called “Restoring to a DB instance”.

> **Note**
>
> You can't upgrade automated DB snapshots that were created during the automated backup process.

You can upgrade a DB snapshot using the AWS Management Console, AWS CLI, or RDS API.

Console

To upgrade a DB snapshot engine version using the AWS Management Console, use the following procedure.

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.
4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **Available** to **Upgrading**, and then changes to **Active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **Unavailable**. You can't recover the snapshot from this state.

   > **Note**
   >
   > If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, run the AWS CLI modify-db-snapshot command.

Options

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `--engine-version` – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
```

```
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier my_db_snapshot ^
    --engine-version new_version
```

Amazon RDS API

To upgrade a DB snapshot to a new database engine version, call the RDS API ModifyDBSnapshot operation.

Parameters

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

Upgrade options for DB snapshots with unsupported engine versions for RDS for MariaDB

The following table shows which engine versions you can upgrade to from an unsupported engine version for RDS for MariaDB DB snapshots.

> **Note**
>
> You might have to upgrade your DB snapshot more than once to upgrade to your chosen engine version.

DB snapshot engine version	Engine versions available for upgrade
10.0.17, 10.0.24, 10.0.28, 10.0.31, 10.0.32, 10.0.34, 10.0.35	10.0.38, 10.1.48, 10.6.19, 10.6.20, 10.11.9, 10.11.10, 11.4.3, 11.4.4, 11.8.3
10.1.14, 10.1.16, 10.1.19, 10.1.23, 10.1.26, 10.1.31, 10.1.34	10.1.48, 10.2.44, 10.6.19, 10.6.20, 10.11.9, 10.11.10, 11.4.3, 11.4.4, 11.8.3
10.2.11, 10.2.12, 10.2.15, 10.2.21, 10.2.32, 10.2.37, 10.2.39, 10.2.40, 10.2.41, 10.2.43	10.2.44, 10.3.39, 10.6.19, 10.6.20, 10.6.21, 10.11.9, 10.11.10, 10.11.11, 11.4.3, 11.4.4, 11.8.3
10.3.8, 10.3.13, 10.3.20, 10.3.23, 10.3.28, 10.3.31, 10.3.32	10.3.39, 10.4.34, 10.6.19, 10.6.20 10.6.21, 10.11.9, 10.11.10, 10.11.11, 11.4.3, 11.4.4, 11.8.3
10.4.8	10.4.34, 10.5.16, 10.5.17, 10.5.18, 10.5.20, 10.5.21, 10.5.22, 10.5.23, 10.5.24, 10.5.25, 10.5.26, 10.5.27, 10.5.28, 10.6.8, 10.6.10, 10.6.11, 10.6.13, 10.6.14, 10.6.15, 10.6.16, 10.6.18, 10.6.19, 10.6.20, 10.6.21, 10.11.4, 10.6.17, 10.11.5, 10.11.6, 10.11.7, 10.11.8, 10.11.9, 10.11.10, 10.11.11

Importing data into an Amazon RDS for MariaDB DB instance

You can use several different techniques to import data into an RDS for MariaDB DB instance. The best approach depends on a number of factors:

- Source of the data
- Amount of data
- One-time import or ongoing
- Amount of downtime

If you are also migrating an application with the data, the amount of downtime is important to consider.

The following table lists techniques to importing data into an RDS for MariaDB DB instance:

> **Note**
>
> Amazon RDS doesn't support `mariadb-backup` or importing from Amazon S3 for MariaDB.

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MariaDB database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MariaDB database as the replication source. You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or higher, or using binary log coordinates for MariaDB instances on earlier versions than 10.0.24. MariaDB GTIDs are implemented differently than	Configuri ng binary log file position replicati on with an external source instance

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
				MySQL GTIDs, which aren't supported by Amazon RDS.	Importing data to an Amazon RDS for MariaDB DB instance with reduced downtime

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	What is AWS Database Migration Service and Using a MySQL-com patible database as a target for AWS DMS in the *AWS Database Migration Service User Guide*
Existing MariaDB DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	Working with DB instance read replicas

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MariaDB database	Small	One time	Some	Copy the data directly to your MariaDB DB instance using a command-line utility.	Importing data from an external MariaDB database to an Amazon RDS for MariaDB DB instance
Data not stored in an existing database	Medium	One time	Some	Create flat files and import them using MariaDB `LOAD DATA LOCAL INFILE` statements.	Importing data from any source to an Amazon RDS for MariaDB DB instance

Note

The `mysql` system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the `mysql` database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI restore-db-instance-

from-db-snapshot command. You can recover the DB instance using restore-db-instance-to-point-in-time command.

Importing data considerations for MariaDB

The following content contains technical information related to loading data into MariaDB. This content is aimed at users who are familiar with the MariaDB server architecture.

Binary logging

Enabling binary logging reduces data load performance and requires up to four times additional disk space compared to disabled logging. The transaction size used to load the data directly affects system performance and disk space needs—larger transactions require more resources.

Transaction size

Transaction size influences the following aspects of MariaDB data loads:

- Resource consumption
- Disk space utilization
- Resume process
- Time to recover
- Input format (flat files or SQL)

This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. You can enable and disable binary logging by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. For more information, see Backup retention period.

This section also describes the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part on the following factors:

- Upload rate
- Other database activity taking place during the load
- Capacity of your Amazon RDS DB instance

The binary logs also consume disk space roughly equal to the amount of data loaded until the logs are backed up and removed. Amazon RDS minimizes this by frequently backing up and removing binary logs.

Large transactions

For large transactions, binary logging triples IOPS and disk usage for the following reasons:

- The binary log cache stores transaction data temporarily on disk.
- This cache grows with the transaction size, which consumes disk space.
- When the transaction (commit or rollback) completes, the system copies the cache to the binary log.

This process creates three copies of the data:

- The original data
- The cache on disk
- The final binary log entry

Each write operation incurs additional IO, further impacting performance.

Because of this, binary logging requires triple the disk space compared to disabled logging. For example, loading 10 GiB of data as a single transaction creates three copies:

- 10 GiB for the table data
- 10 GiB for the binary log cache
- 10 GiB for the binary log file

The total temporary disk space required is 30 GiB.

Important disk space considerations:

- The cache file persists until either the session ends or a new transaction creates another cache.
- The binary log remains until it's backed up, potentially holding 20 GiB (cache and log) for an extended period.

If you use `LOAD DATA LOCAL INFILE` to load the data, data recovery creates a fourth copy in case the database has to be recovered from a backup made before the load. During recovery, MariaDB extracts the data from the binary log into a flat file. MariaDB then runs `LOAD DATA LOCAL INFILE`. Building on the preceding example, this recovery requires a total temporary disk space of 40 GiB, or 10 GiB each for table, cache, log, and local file. Without at least 40 GiB of free disk space, recovery fails.

Optimizing large data loads

For large data loads, disable binary logging to reduce overhead and disk space requirements. You can disable binary logging by setting the backup retention period to 0. After loading completes, restore the backup retention period to the appropriate non-zero value. For more information, see Modifying an Amazon RDS DB instance and Backup retention period in the settings table.

> **Note**
>
> If the DB instance is a source DB instance for read replicas, then you can't set the backup retention period to 0.

Before loading the data, we recommend that you create a DB snapshot. For more information, see Managing manual backups.

InnoDB

The following information about undo logging and recovery options supports keeping InnoDB transactions small to optimize database performance.

Understanding InnoDB undo logging

Undo is a logging mechanism that enables transaction rollback and supports multi-version concurrency control (MVCC).

For MariaDB 10.11 and lower versions, undo logs are stored in the InnoDB system tablespace (usually ibdata1) and are retained until the purge thread removes them. As a result, large data load

transactions can cause the system tablespace to become quite large and consume disk space that you can't reclaim unless you recreate the database.

For all MariaDB versions, the purge thread must wait to remove any undo logs until the oldest active transaction either commits or rolls back. If the database is processing other transactions during the load, their undo logs also accumulate and can't be removed, even if the transactions commit and no other transaction needs the undo logs for MVCC. In this situation, all transactions—including read-only transactions—slow down. This slowdown occurs because all transactions access all rows that any transaction—not just the load transaction—changes. In effect, transactions must scan through undo logs that long-running load transactions prevented from being purged during an undo log cleanup. This affects performance for any operation accessing modified rows.

InnoDB transaction recovery options

Although InnoDB optimizes commit operations, large transaction rollbacks are slow. For faster recovery, perform a point-in-time recovery or restore a DB snapshot. For more information, see Point-in-time recovery and Restoring to a DB instance.

Data import formats

MariaDB supports two data import formats: flat files and SQL. Review the information about each format to determine the best option for your needs.

Flat files

For small transactions, load flat files with `LOAD DATA LOCAL INFILE`. This data import format can provide the following benefits over using SQL:

- Less network traffic
- Lower data transmission costs
- Decreased database processing overhead
- Faster processing

`LOAD DATA LOCAL INFILE` loads the entire flat file as one transaction. Keep the size of the individual files small for the following advantages:

- **Resume capability** – You can keep track of which files have been loaded. If a problem arises during the load, you can pick up where you left off. You might need to retransmit some data to Amazon RDS, but with small files, the amount retransmitted is minimal.

- **Parallel data loading** – If you have sufficient IOPS and network bandwidth for a single file load, loading in parallel could save time.
- **Load rate control** – If your data load has a negative impact on other processes, you can control the load rate by increasing the interval between files.

Large transactions reduce the benefits of using `LOAD DATA LOCAL INFILE` to import data. When you can't break a large amount of data into smaller files, consider using SQL.

SQL

SQL has one main advantage over flat files: you can easily keep transaction sizes small. However, SQL can take significantly longer to load than flat files. Also, after a failure, it can be difficult to determine where to resume—you can't restart mariadb-dump files. If a failure occurs while loading mariadb-dump file, you must modify or replace the file before the load can resume. Or, alternatively, after you correct the cause of the failure, you can restore to the point in time before the load and resend the file. For more information, see Point-in-time recovery.

Using Amazon RDS DB snapshots for database checkpoints

If you load data over long durations—such as hours or days—without binary logging, use DB snapshots to provide periodic checkpoints for data safety. Each DB snapshot creates a consistent copy of your database instance that serves as a recovery point during system failures or data corruption events. Because DB snapshots are fast, frequent checkpointing has minimal impact on load performance. You can delete previous DB snapshots without impacting database durability or recovery capabilities. For more information about DB snapshots, see Managing manual backups.

Reducing database load times

The following items are additional tips to reduce load times:

- Create all secondary indexes before loading data into MariaDB databases. Unlike other database systems, MariaDB rebuilds the entire table when adding or modifying secondary indexes. This process creates a new table with index changes, copies all data, and drops the original table.
- Load data in primary key order. For InnoDB tables, this can reduce load times by 75%–80% and reduce data file size by 50%.
- Disable foreign key constraints by setting `foreign_key_checks` to `0`. This is often required for flat files loaded with `LOAD DATA LOCAL INFILE`. For any load, disabling foreign key

checks accelerates data loading. After loading completes, re-enable constraints by setting `foreign_key_checks` to 1 and verify the data.

- Load data in parallel unless approaching a resource limit. To enable concurrent loading across multiple table segments, use partitioned tables when appropriate.
- To reduce SQL execution overhead, combine multiple `INSERT` statements into single multi-value `INSERT` operations. `mariadb-dump` implements this optimization automatically.
- Reduce InnoDB log IO operations by setting `innodb_flush_log_at_trx_commit` to `0`. After loading completes, restore `innodb_flush_log_at_trx_commit` to 1.

> **Warning**
>
> Setting `innodb_flush_log_at_trx_commit` to `0` causes InnoDB to flush its logs every second instead of at each commit. This setting increases performance but can risk transaction loss during system failures.

- If you are loading data into a DB instance that doesn't have read replicas, set `sync_binlog` to `0`. After loading completes, restore `sync_binlog parameter`to 1.
- Load data into a Single-AZ DB instance before converting the DB instance to a Multi-AZ deployment. If the DB instance already uses a Multi-AZ deployment, we don't recommend switching to a Single-AZ deployment for data loading. Doing so only provides marginal improvements

Importing data from an external MariaDB database to an Amazon RDS for MariaDB DB instance

You can import data from an existing MariaDB database to an RDS for MariaDB DB instance. You do so by copying the database with mysqldump or mariadb-dump, and piping the database directly into the RDS for MariaDB DB instance. The `mysqldump` or `mariadb-dump` command line utility is commonly used to make backups and transfer data from one MariaDB server to another. It's included with MariaDB client software.

Starting with MariaDB 11.0.1, you must use `mariadb-dump` instead of `mysqldump`.

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following example. Replace values with your own information. For MariaDB 11.0.1 and higher versions, replace `mysqldump` with `mariadb-dump`.

```
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary  \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocal_password | mariadb -u RDS_user \
        --port=port_number \
        --host=host_name \
        -pRDS_password
```

Important

Make sure not to leave a space between the `-p` option and the entered password. As a security best practice, specify credentials other than the prompts shown in this example.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file:
  - `sys`
  - `performance_schema`
  - `information_schema`

  The `mysqldump` and `mariadb-dump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups.

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, specify the name of a user account on the local MariaDB database that you identify with the `--databases` parameter.

- `--databases` *database_name* – Use to specify the name of the database on the local MariaDB instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` or `mariadb-dump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `--routines` – Use if routines such as stored procedures or functions exist in the database that you are copying. Set the parameter to `0`, which excludes the routines during the import process. Then later manually recreate the routines in the Amazon RDS database.
- `--triggers` – Use if triggers exist in the database that you are copying. Set the parameter to `0`, which excludes the triggers during the import process. Then later manually recreate the triggers in the Amazon RDS database.
- `--events` – Use if events exist in the database that you are copying. Set the parameter to `0`, which excludes the events during the import process. Then later manually recreate the events in the Amazon RDS database.
- `-p`*local_password* – Use to specify a password. In the first usage of this parameter, specify the password for the user account that you identify with the first `-u` parameter.
- `-u` *RDS_user* – Use to specify a user name. In the second usage of this parameter, specify the name of a user account on the default database for the MariaDB DB instance that you identify with the `--host` parameter.
- `--port` *port_number* – Use to specify the port for your MariaDB DB instance. By default, this is 3306 unless you changed the value when creating the DB instance.
- `--host` *host_name* – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the DB instance details in the Amazon RDS console.
- `-p`*RDS_password* – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude

them when you run `mysqldump` or `mariadb-dump`. To do so, include the following parameters with your `mysqldump` or `mariadb-dump` command:

- `--routines=0`
- `--triggers=0`
- `--events=0`

Example

The following example copies the `world` sample database on the local host to an RDS for MariaDB DB instance. Replace values with your own information.

For Linux, macOS, or Unix:

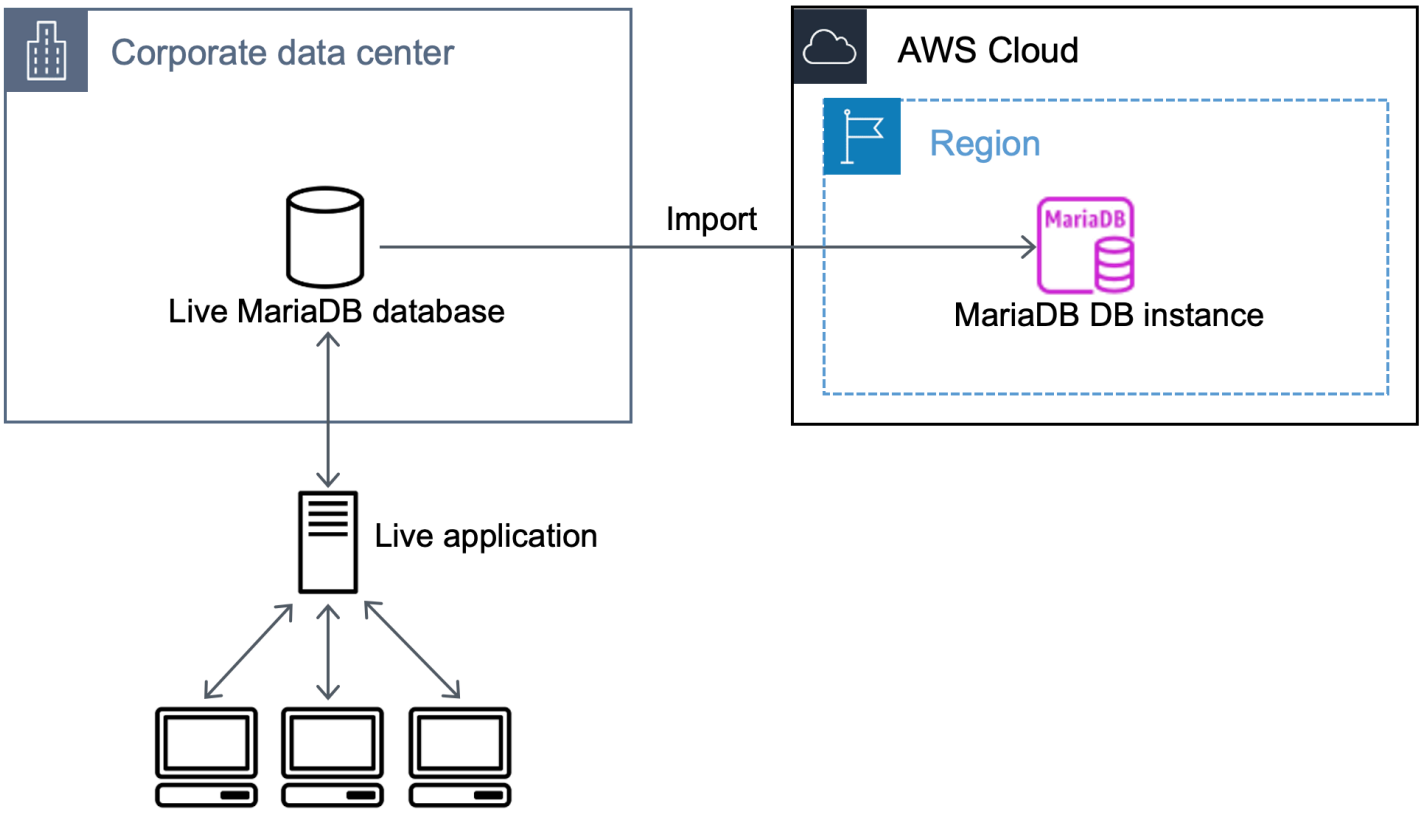
```
sudo mariadb-dump -u local_user \
    --databases world \
    --single-transaction \
    --compress \
    --order-by-primary  \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocal_password | mariadb -u rds_user \
        --port=3306 \
        --host=my_instance.123456789012.us-east-1.rds.amazonaws.com \
        -pRDS_password
```

For Windows:

Run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**. Replace values with your own information.

```
mariadb-dump -u local_user ^
    --databases world ^
    --single-transaction ^
    --compress ^
    --order-by-primary  ^
    --routines=0 ^
    --triggers=0 ^
```

```
    --events=0 ^
    -plocal_password | mariadb -u RDS_user ^
        --port=3306 ^
        --host=my_instance.123456789012.us-east-1.rds.amazonaws.com ^
        -pRDS_password
```

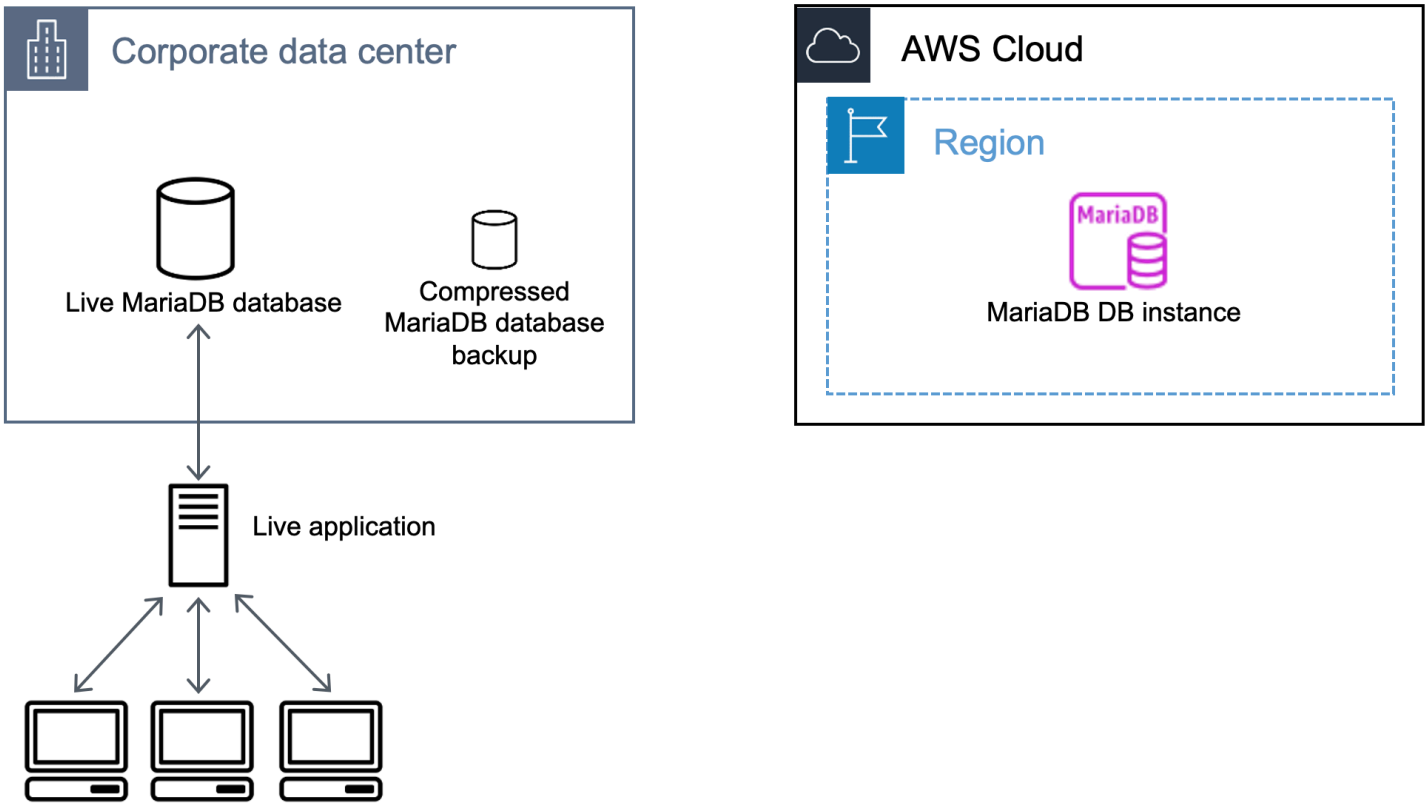


> **Note**
>
> As a security best practice, specify credentials other than the prompts shown in the example.

Importing data to an Amazon RDS for MariaDB DB instance with reduced downtime

In some cases, you might need to import data from an external MariaDB database that supports a live application to an RDS for MariaDB DB instance. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. If the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB, configure MariaDB replication based on global transaction identifiers (GTIDs). Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see Global transaction ID in the MariaDB documentation.



The following diagram shows importing an external MariaDB database into a MariaDB database on Amazon RDS.

Task 1: Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB database with minimal downtime is to create a copy of the source data.

The following diagram shows creating a backup of the MariaDB database.

You can use the `mysqldump` or `mariadb-dump` utility to create a database backup in either SQL or delimited-text format. In MariaDB 10.5, the client is called mariadb-dump. Starting with MariaDB 11.0.1, you must use `mariadb-dump` instead of `mysqldump`. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that `mysqldump` or `mariadb-dump` runs.

We also recommend that you weigh `mysqldump` or `mariadb-dump` performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information, see Step 5: Load the data in the Importing data from any source procedure.

Before you start the backup operation, make sure to set the replication options on the MariaDB database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

Make sure that you're aware of the following recommendations and considerations:

- Use the `--single-transaction` option with `mysqldump` or `mariadb-dump` because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while `mysqldump` or `mariadb-dump` is running. You can schedule a maintenance window for these operations.
- Exclude the following schemas from the dump file:
  - `sys`
  - `performance_schema`
  - `information_schema`

  The `mysqldump` and `mariadb-dump` utilities exclude these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.

To set replication options

1. Edit the `my.cnf` file. This file is usually located under `/etc`.

   ```
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   The following example shows the updated `[mariadb]` section of a `my.cnf` file:

   ```
   [mariadb]
   log-bin
   server-id=1
   log-basename=master1
   binlog-format=mixed
   ```

   For more information, see Setting the Replication Source Configuration in the MariaDB documentation.
2. For replication with a Multi-AZ DB cluster, enable `gtid_strict_mode`. For more information, see gtid_strict_mode in the MariaDB documentation.

   Enabling `gtid_strict_mode` isn't required for replication with a DB instance.

3. Restart the `mariadb` service.

```
sudo service mariadb restart
```

To create a backup copy of your existing database

1. Create a backup of your data using the `mysqldump` or `mariadb-dump` utility, specifying either SQL or delimited-text format.

   To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options for `mysqldump` and `mariadb-dump`.

   To avoid including the MySQL system database in the backup, don't use the `--all-databases` option with `mysqldump` or `mariadb-dump`. For more information, see Creating a Data Snapshot Using mysqldump in the MySQL documentation.

   Use chmod, if necessary, to make sure that the directory where the backup file is being created is writeable.

   > **Important**
   >
   > On Windows, run the command window as an administrator.

   - To produce SQL output, use the following command. For MariaDB 10.11 versions and lower, replace `mariadb-dump` with `mysqldump`.

     For Linux, macOS, or Unix:

     ```
     sudo mariadb-dump \
         --databases database_name \
         --master-data=2  \
         --single-transaction \
         --order-by-primary \
         -r backup.sql \
         -u local_user \
         -ppassword
     ```

> **Note**
>
> As a security best practice, specify credentials other than the prompts shown in the example.

For Windows:

```
mariadb-dump ^
    --databases database_name ^
    --master-data=2  ^
    --single-transaction ^
    --order-by-primary ^
    -r backup.sql ^
    -u local_user ^
    -ppassword
```

> **Note**
>
> As a security best practice, specify credentials other than the prompts shown in the example.

- To produce delimited-text output, use the following command. For MariaDB 11.01 and higher versions, replace `mysqldump` with `mariadb-dump`.

  For Linux, macOS, or Unix:

```
sudo mysqldump \
    --tab=target_directory \
    --fields-terminated-by ',' \
    --fields-enclosed-by '"' \
    --lines-terminated-by 0x0d0a \
    database_name \
    --master-data=2 \
    --single-transaction \
    --order-by-primary \
    -ppassword
```

  For Windows:

```
mysqldump ^
    --tab=target_directory ^
    --fields-terminated-by "," ^
    --fields-enclosed-by """ ^
    --lines-terminated-by 0x0d0a ^
    database_name ^
    --master-data=2 ^
    --single-transaction ^
    --order-by-primary ^
    -ppassword
```

Note

As a security best practice, specify credentials other than the prompts shown in the example.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump` or `mariadb-dump`. To do so, include the following arguments with your `mysqldump` or `mariadb-dump` command:

- `--routines=0`
- `--triggers=0`
- `--events=0`

When you run `mysqldump` and specify the delimited-text format, a `CHANGE MASTER TO` comment is returned. This comment contains the master log file name and position. If the external instance is a MariaDB 10.0.23 or lower version, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

The following output is returned for MariaDB versions.

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
 MASTER_LOG_POS=107;
```

2. If the external instance you are using is MariaDB version 10.0.24 or higher, use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, and then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

   ```
   SELECT BINLOG_GTID_POS('binary_log_file_name', binary_log_file_position);
   ```

   Note the GTID returned. You need the GTID to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

   - To compress SQL output, use the following command:

     ```
     gzip backup.sql
     ```

   - To compress delimited-text output, use the following command:

     ```
     tar -zcvf backup.tar.gz target_directory
     ```

Task 2: Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.

The following diagram shows copying the database backup to an Amazon EC2 instance.

To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the Amazon RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses—for example, `203.0.113.0/24`—or another VPC security group. You can use the Amazon VPC console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the *Amazon Virtual Private Cloud User Guide*.
2. Open the Amazon EC2 console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 in the *Amazon Elastic Compute Cloud User Guide*.
3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console

window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Security group rules in the *Amazon Virtual Private Cloud User Guide*.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod`, if necessary, to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or a Secure Shell (SSH) client to copy the file. The following command is an example `scp` command:

```
scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

> **Important**
>
> When copying sensitive data, be sure to use a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MariaDB client tools using the following commands:

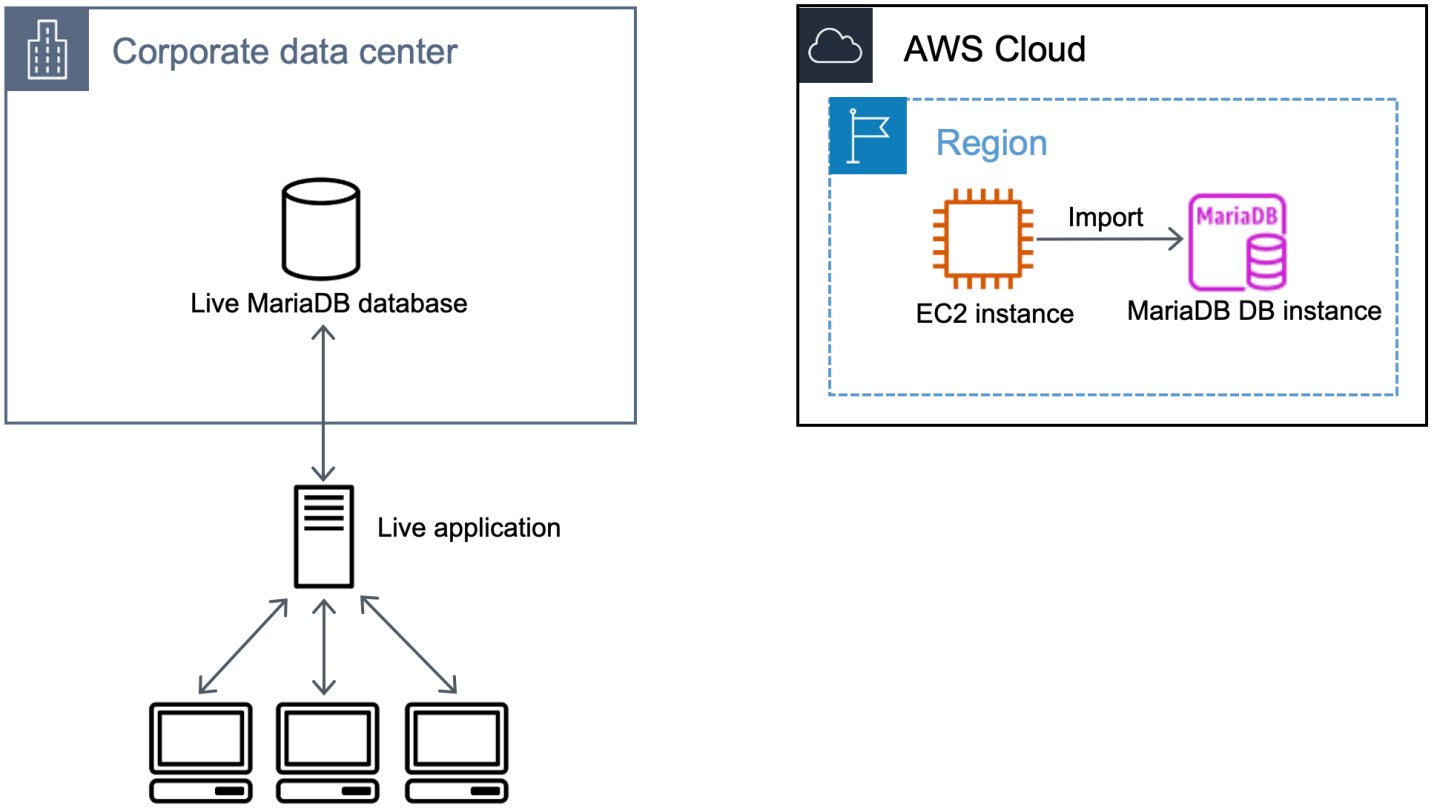
```
sudo yum update -y
sudo yum install mariadb1011-client-utils -y
```

For more information, see Connect to your instance for Linux instances in the *Amazon Elastic Compute Cloud User Guide* and MariaDB Connectors in the MariaDB documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following commands are examples.

- To decompress SQL output, use the following command:

```
gzip backup.sql.gz -d
```



- To decompress delimited-text output, use the following command:

```
tar xzvf backup.tar.gz
```

Task 3: Create a MariaDB database and import data from your Amazon EC2 instance

By creating an RDS for MariaDB DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from Amazon EC2 faster than over the internet.

The following diagram shows importing the backup from an Amazon EC2 instance into a MariaDB database.

To create a MariaDB database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also, decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB database. For more information, see DB instance classes.
2. Create a DB instance in the AWS Region that contains your Amazon EC2 instance. Follow the instructions in Creating an Amazon RDS DB instance and use the following guidelines:
   - Specify a DB engine version that is compatible with your source DB instance.

- Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described in a following section, your DB instance must be publicly accessible.
- Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.

3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information about creating a parameter group, see Parameter groups for Amazon RDS.
4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the DB instance. The hostname for the Amazon RDS database is the **Endpoint** value for this DB instance without the port number, for example, `mysampledb.123456789012.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the database details in the Amazon RDS console.
5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance for Linux instances in the *Amazon Elastic Compute Cloud User Guide*.
6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following command is an example:

   ```
   mysql -h host_name -P 3306 -u db_master_user -p
   ```

   The *host_name* is the Amazon RDS database endpoint.
7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file. This command loads the data into the Amazon RDS DB instance.

   - For SQL format, use the following command:

     ```
     MariaDB [(none)]> source backup.sql;
     ```

   - For delimited-text format, first create the database, if it isn't the default database that you created when setting up the Amazon RDS database.

```
MariaDB [(none)]> create database database_name;
MariaDB [(none)]> use database_name;
```

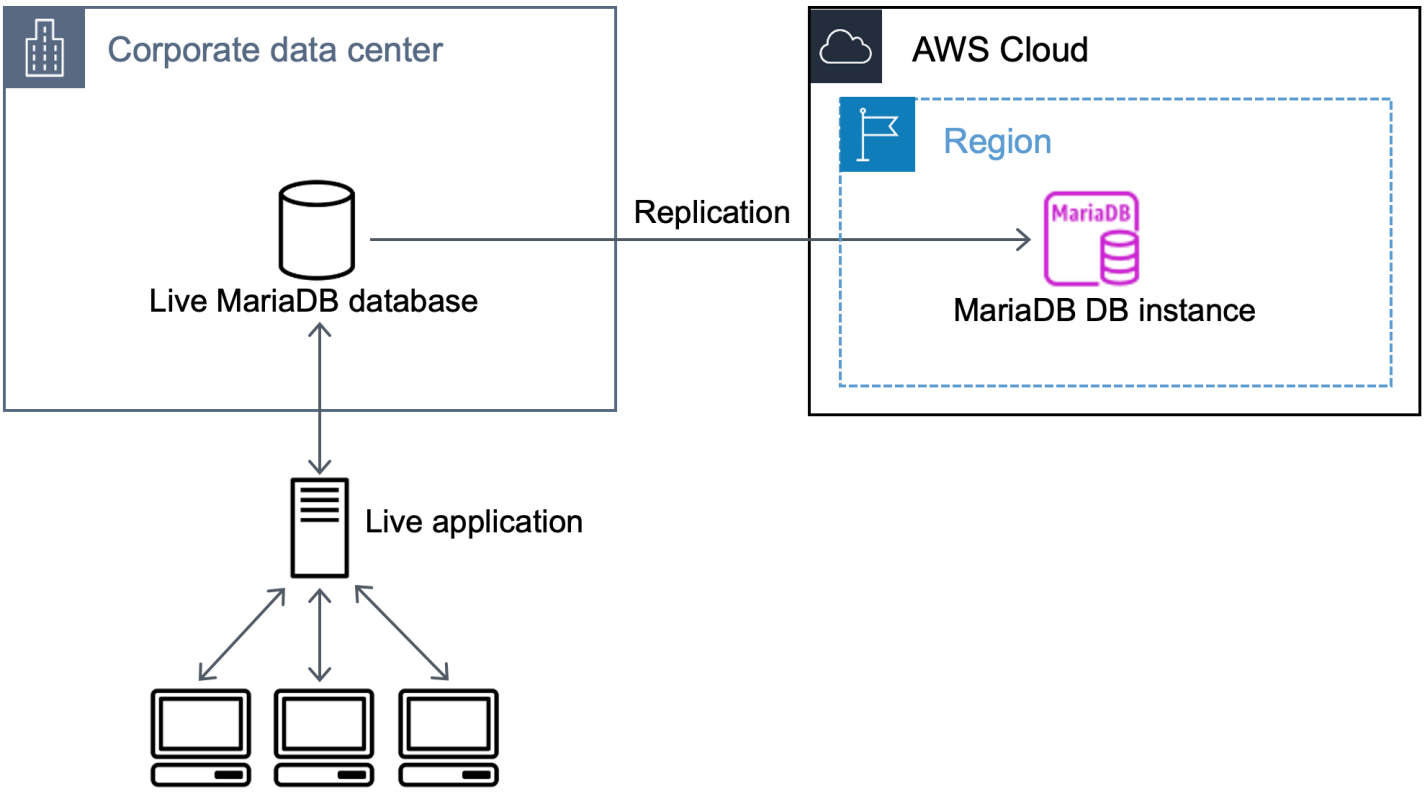
Then create the tables.

```
MariaDB [(none)]> source table1.sql
MariaDB [(none)]> source table2.sql
etc...
```

Then import the data.

```
MariaDB [(none)]> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS
 TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
MariaDB [(none)]> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS
 TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.



> **Note**
>
> If you used any data-formatting options with `mysqldump` or `mariadb-dump` when you initially dumped the table, make sure to use the same options with `LOAD DATA LOCAL INFILE` to ensure proper interpretation of the data file contents.

8. Run a simple `SELECT` query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminate an instance in the *Amazon Elastic Compute Cloud User Guide*.

Task 4: Replicate data from your external database to your new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB database. You can use replication to bring the copied database up-to-date with the source database.

The permissions required to start replication on an Amazon RDS database are restricted and aren't available to your Amazon RDS master user. Because of this, use the appropriate Amazon RDS stored procedure:

- mysql.rds_set_external_master
- mysql.rds_set_external_master_gtid to configure replication and mysql.rds_start_replication to start replication

To start replication

In Task 1, when you set replication options, you turned on binary logging and set a unique server ID for your source database. Now, you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on configuring a VPC security group, see Configure security group rules in the *Amazon Virtual Private Cloud User Guide*.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the `host` command:

   ```
   host host_name
   ```

   The *host_name* is the DNS name from the Amazon RDS database endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the DB instance details in the Amazon RDS console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following command is an example:

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   > **Note**
   >
   > Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command:

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

4. If you used SQL format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, look at the contents of that file by running the following command:

   ```
   cat backup.sql
   ```

The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with `mysqldump`. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

```
--
-- Position to start replication or point-in-time recovery from
--

-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from Step 1 in Task 1 when you created a backup copy of your existing database.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from Step 2 in Task 1 when you created a backup copy of your existing database.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master stored procedure.

   If you have a SQL format backup file, use the master log file name and master log position that you determined in Step 4. If you used delimited-text format, use the name and position that you determined when creating the backup files. The following command is an example:

   ```
   CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,
       'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
   ```

   > **Note**
   >
   > Specify credentials other than the prompts shown here as a security best practice.

   If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master_gtid stored procedure. Use the GTID that you determined in Step

2 in Task 1 when you created a backup copy of your existing database. The following command is an example:

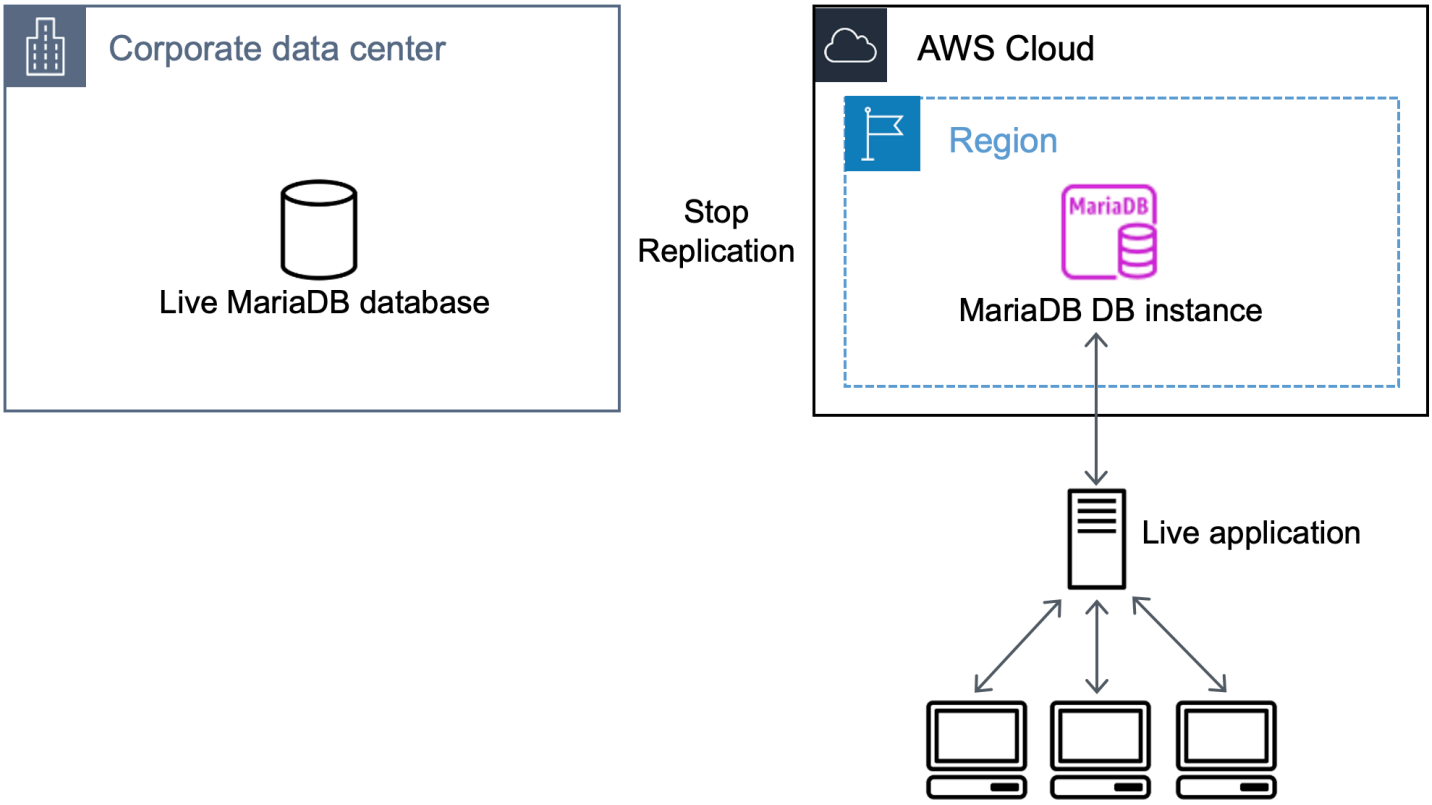
```
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306,
 'ReplicationUser', 'password', 'GTID', 1);
```

The *source_server_ip_address* is the IP address of source replication instance. An EC2 private DNS address isn't currently supported.

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

6. On the Amazon RDS database, to start replication, run the following command that uses the mysql.rds_start_replication stored procedure:

```
CALL mysql.rds_start_replication;
```



7. On the Amazon RDS database, to determine when the replica is up-to-date with the source replication instance, run the SHOW REPLICA STATUS command. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

   For a MariaDB 10.5, 10.6, 10.11, 11.4, or 11.8 DB instance, use the mysql.rds_replica_status stored procedure instead of running the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database by using the Amazon RDS console. For more information, see Introduction to backups.

Task 5: Redirect your live application to your Amazon RDS instance

After the MariaDB database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.

To redirect your live application to your MariaDB database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Configure security group rules in the *Amazon Virtual Private Cloud User Guide*.
2. Verify that the `Seconds_Behind_Master` field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   ```
   SHOW REPLICA STATUS;
   ```

   For a MariaDB 10.5, 10.6, 10.11, 11.4, or 11.8 DB instance, use the mysql.rds_replica_status procedure instead of running the MySQL command.
3. Close all connections to the source when their transactions complete.
4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.
5. Connect to the DB instance.

6. Stop replication for the Amazon RDS instance by running the following command that uses the mysql.rds_stop_replication stored procedure:

```
CALL mysql.rds_stop_replication;
```

7. Reset the replication configuration so this instance is no longer identified as a replica by running the following command that uses the mysql.rds_reset_external_master stored procedure on your Amazon RDS database:

```
CALL mysql.rds_reset_external_master;
```

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS and Working with DB instance read replicas.

Importing data from any source to an Amazon RDS for MariaDB DB instance

With Amazon RDS, you can migrate existing MariaDB data from any source to an RDS for MariaDB DB instance. You can transfer data from on-premises databases, other cloud providers, or existing RDS for MariaDB DB instances to your target RDS for MariaDB DB instance. With this functionality, you can consolidate databases, implement disaster recovery solutions, or transition from self-managed databases. Common scenarios include moving from self-hosted MariaDB servers to fully managed Amazon RDS DB instances, consolidating multiple MariaDB databases into a single DB instance, or creating test environments with production data. The following sections provide step-by-step instructions for importing your MariaDB data using methods such as `mariadb-dump`, backup files, or replication.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file—you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name could be `sales.csv` or `sales.txt`.

If possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The names of the new files include ascending numerical suffixes. The following command produces files with names such as `sales.part_00` and `sales.part_01`.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

You can store the flat files anywhere. However, when you load the data in Step 5, you must invoke the `mysql` shell from the same location where the files exist, or use the absolute path for the files when you run `LOAD DATA LOCAL INFILE`.

Step 2: Stop any applications from accessing the target DB instance

Before starting a large load, stop all application activity from accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, we recommend that you create DB snapshots of the target Amazon RDS DB instance both before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that you can use to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use DB snapshots after the load to import data into new database instances.

The following example runs the AWS CLI create-db-snapshot command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2" is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2. For more information, see restore-db-instance-from-db-snapshot.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS-2 \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS-2 ^
    --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier. For more information, see delete-db-instance.

The following example also takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier AcmeRDS \
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

Step 4 (Optional): Turn off Amazon RDS automated backups

> **Warning**
>
> Don't turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups is a performance optimization and isn't required for data loads. Turning off automated backups erases all existing backups. As a result, after you turn off

automated backups, point-in-time recovery isn't possible. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and then restarts it to turn MariaDB logging on or off.

Run the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding. For more information, see modify-db-instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --apply-immediately \
    --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --apply-immediately ^
    --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the `AcmeRDS` DB instance:

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[].
{DBInstanceStatus:DBInstanceStatus}"
```

When the DB instance status is `available`, you're ready to proceed to the next step.

Step 5: Load the data

To read rows from your flat files into the database tables, use the MariaDB `LOAD DATA LOCAL INFILE` statement.

> **Note**
>
> You must invoke the `mariadb` shell from the same location where your flat files exist, or use the absolute path for the files when you run `LOAD DATA LOCAL INFILE`.

The following example shows how to load data from a file named `sales.txt` into a table named `Sales` in the database:

```
MariaDB [(none)]> LOAD DATA LOCAL INFILE 'sales.txt' INTO TABLE Sales FIELDS TERMINATED
 BY ' ' ENCLOSED BY '' ESCAPED BY '\\';
Query OK, 1 row affected (0.01 sec)
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

For more information about the `LOAD DATA` statement, see LOAD DATA INFILE in the MariaDB documentation.

Step 6: Turn back on Amazon RDS automated backups

If you turned off Amazon RDS automated backups in Step 4, after the load is finished, turn automated backups on by setting the backup retention period back to its preload value. As noted in Step 4, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example runs the AWS CLI modify-db-instance command to turn on automated backups for the `AcmeRDS` DB instance and set the retention period to one day:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --backup-retention-period 1 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --backup-retention-period 1 ^
    --apply-immediately
```

Working with MariaDB replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas. For specific information about working with read replicas on Amazon RDS for MariaDB, see Working with MariaDB read replicas.

You can also configure replication based on binary log coordinates for a MariaDB DB instance. For MariaDB instances, you can also configure replication based on global transaction IDs (GTIDs), which provides better crash safety. For more information, see Configuring GTID-based replication with an external source instance.

The following are other replication options available with RDS for MariaDB:

- You can set up replication between an RDS for MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance.
- You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS for MariaDB DB instance with reduced downtime and Exporting data from a MySQL DB instance by using replication.

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Configuring MariaDB binary logging.

For information about replication compatibility between MariaDB versions, see Replication Compatibility in the MariaDB documentation.

- Configuring binary log file position replication with an external source instance

Working with MariaDB read replicas

Following, you can find specific information about working with read replicas on Amazon RDS for MariaDB. For general information about read replicas and instructions for using them, see Working with DB instance read replicas.

- Configuring replication filters with MariaDB
- Configuring delayed replication with MariaDB
- Updating read replicas with MariaDB
- Working with Multi-AZ read replica deployments with MariaDB
- Using cascading read replicas with RDS for MariaDB
- Monitoring MariaDB read replicas
- Starting and stopping replication with MariaDB read replicas
- Troubleshooting a MariaDB read replica problem

Configuring read replicas with MariaDB

Before a MariaDB DB instance can serve as a replication source, make sure to turn on automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have as the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MariaDB supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MariaDB.

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

Configuring replication filters with MariaDB

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

> **Note**
>
> You can also use replication filters to specify which databases and tables are replicated with a primary MariaDB DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance.

- Setting replication filtering parameters for RDS for MariaDB
- Replication filtering limitations for RDS for MariaDB
- Replication filtering examples for RDS for MariaDB
- Viewing the replication filters for a read replica

Setting replication filtering parameters for RDS for MariaDB

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, the database that includes the specified tables must be included in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and _ wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and _ wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MariaDB documentation.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and _ wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see Configuring MariaDB binary logging.

> **Note**
>
> All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for RDS for MariaDB

The following limitations apply to replication filtering for RDS for MariaDB:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MariaDB `binlog_do_db` and `binlog_ignore_db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

  For more information, see Restrictions on XA Transactions in the MySQL documentation.
- Replication filtering isn't supported for RDS for MariaDB version 10.2.

Replication filtering examples for RDS for MariaDB

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

> **Note**
>
> You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Parameter groups for Amazon RDS.

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS. When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Escaping wildcard characters in names
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication. When you set `replicate-do-db` for a read replica, only the databases specified in the parameter are replicated.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
 "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
 "ApplyMethod":"immediate"}]"
```

Example Including tables in replication

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-do-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-do-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

Example Escaping wildcard characters in names

The following example shows you how to use the escape character \ to escape a wildcard character that is part of a name.

Assume that you have several table names in database `mydb1` that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my
\_table%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my
\_table%", "ApplyMethod":"immediate"}]"
```

Example Excluding databases from replication

The following example excludes the `mydb1` and `mydb2` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue":
 "mydb1,mydb2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue":
 "mydb1,mydb2", "ApplyMethod":"immediate"}]"
```

Example Excluding tables from replication

The following example excludes tables `table1` and `table2` in database `mydb1` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
```

```
  --parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue":
 "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `orders` and `returns` in database `mydb` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue":
 "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see Viewing parameter values for a DB parameter group in Amazon RDS.
- In a MariaDB client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

  In the output, the following fields show the replication filters for the read replica:
  - `Replicate_Do_DB`

- `Replicate_Ignore_DB`
- `Replicate_Do_Table`
- `Replicate_Ignore_Table`
- `Replicate_Wild_Do_Table`
- `Replicate_Wild_Ignore_Table`

For more information about these fields, see Checking Replication Status in the MySQL documentation.

> **Note**
>
> Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5, then use `SHOW SLAVE STATUS`.

Configuring delayed replication with MariaDB

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

  To stop replication, use the mysql.rds_stop_replication stored procedure.
- Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

> **Note**
>
> - Delayed replication is supported for MariaDB 10.6 and higher.
> - Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
> - You can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration.

Topics

- Configuring delayed replication during read replica creation
- Modifying delayed replication for an existing read replica
- Promoting a read replica

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

To configure delayed replication during read replica creation

1. Using a MariaDB client, connect to the MariaDB DB instance to be the source for read replicas as the master user.
2. Run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   > **Note**
   >
   > After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the mysql.rds_set_source_delay stored procedure.

To modify delayed replication for an existing read replica

1. Using a MariaDB client, connect to the read replica as the master user.
2. Use the mysql.rds_stop_replication stored procedure to stop replication.
3. Run the mysql.rds_set_source_delay stored procedure.

For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

```
call mysql.rds_set_source_delay(3600);
```

4. Use the mysql.rds_start_replication stored procedure to start replication.

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance.

Updating read replicas with MariaDB

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to speed the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to **0** in the DB parameter group for the read replica.

Working with Multi-AZ read replica deployments with MariaDB

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS.

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for MariaDB

RDS for MariaDB supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for MariaDB DB instance.

With cascading read replicas, your RDS for MariaDB DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MariaDB DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MariaDB DB instance. For example, suppose that you have an RDS for MariaDB DB instance, `mariadb-main`. You can do the following:

- Starting with `mariadb-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mariadb-main`. A complete series of instances from an RDS for MariaDB source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MariaDB DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica, and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mariadb-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `mariadb-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

Monitoring MariaDB read replicas

For MariaDB read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command.

> **Note**
>
> Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5, then use `SHOW SLAVE STATUS`.

Common causes for replication lag for MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MariaDB.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag` = -1 is equivalent to `Seconds_Behind_Master` = `NULL`.

Starting and stopping replication with MariaDB read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures mysql.rds_stop_replication and mysql.rds_start_replication. You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS for MariaDB DB instance with reduced downtime and Exporting data from a MySQL DB instance by using replication.

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS ends replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary

logs required by the read replica are deleted from the source DB instance after replication is ended. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MariaDB read replica problem

The replication technologies for MariaDB are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MariaDB documentation, go to Replication overview.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MariaDB engine by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0047. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MariaDB error message is returned, review the error in the MariaDB error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group that is used to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` parameter value in the DB parameter group associated with a source DB instance is smaller than

the `max_allowed_packet` parameter value in the DB parameter group associated with the source's read replica. In these cases, the replication process can throw an error (Packet bigger than 'max_allowed_packet' bytes) and stop replication. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. If you are creating indexes on a read replica, you need to have the `read_only` parameter set to **0** to create the indexes. If you are writing to tables on the read replica, it might break replication.
- Using a non-transactional storage engine such as MyISAM. read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MariaDB.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in Skipping the current replication error for RDS for MySQL. Otherwise, you can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

For MariaDB DB instances, in some cases read replicas can't be switched to the secondary if some binary log (binlog) events aren't flushed during the failure. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

Configuring GTID-based replication with an external source instance

You can set up replication based on global transaction identifiers (GTIDs) from an external MariaDB instance of version 10.0.24 or higher into an RDS for MariaDB DB instance. Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the RDS for MariaDB DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.

- Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance ensures that you can restore your source instance in the event of a failure.
- Turn on automated backups on your MariaDB DB instance on Amazon RDS. Turning on automated backups ensures that you can restore your replica to a particular point in time if you need to resynchronize your source instance and replica. For information on backups and Point-In-Time Restore, see Backing up, restoring, and exporting data.

> **Note**
>
> The permissions required to start replication on a MariaDB DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS mysql.rds_set_external_master_gtid and mysql.rds_start_replication commands to set up replication between your live database and your RDS for MariaDB database.

To start replication between an external source instance and a MariaDB DB instance on Amazon RDS, use the following procedure.

To start replication

1. Make the source MariaDB instance read-only:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Get the current GTID of the external MariaDB instance. You can do this by using `mysql` or the query editor of your choice to run `SELECT @@gtid_current_pos;`.

   The GTID is formatted as `<domain-id>-<server-id>-<sequence-id>`. A typical GTID looks something like **`0-1234510749-1728`**. For more information about GTIDs and their component parts, see Global transaction ID in the MariaDB documentation.

3. Copy the database from the external MariaDB instance to the MariaDB DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS for MariaDB DB instance with reduced downtime.

   For Linux, macOS, or Unix:

```
mysqldump \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

For Windows:

```
mysqldump ^
    --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

> **Note**
>
> Make sure that there isn't a space between the `-p` option and the entered password. Specify a password other than the prompt shown here as a security best practice.

Use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command to specify the host name, user name, port, and password to connect to your MariaDB DB instance. The host name is the DNS name from the MariaDB DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

4. Make the source MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the external MariaDB database to the VPC security group for the MariaDB DB instance. For more information on modifying a VPC security group, go to Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

   The IP address can change when the following conditions are met:

   - You are using a public IP address for communication between the external source instance and the DB instance.
   - The external source instance was stopped and restarted.

   If these conditions are met, verify the IP address before adding it.

   You might also need to configure your local network to permit connections from the IP address of your MariaDB DB instance, so that it can communicate with your external MariaDB instance. To find the IP address of the MariaDB DB instance, use the `host` command.

   ```
   host db_instance_endpoint
   ```

   The host name is the DNS name from the MariaDB DB instance endpoint.

6. Using the client of your choice, connect to the external MariaDB instance and create a MariaDB user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

7. For the external MariaDB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the MariaDB DB instance the replica. Connect to the MariaDB DB instance as the master user and identify the external MariaDB database as the replication source instance by using the mysql.rds_set_external_master_gtid command. Use the GTID that you determined in Step 2. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('mymasterserver.mydomain.com', 3306,
 'repl_user', 'password', 'GTID', 1);
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

9. On the MariaDB DB instance, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

Topics

- Before you begin
- Configuring binary log file position replication with an external source instance

Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon

RDS mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) or mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher), and mysql.rds_start_replication commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify the `binlog_format` parameter. In MariaDB and MySQL 8.0 and lower versions, `binlog_format` defaults to `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect. In MySQL 8.4 and higher versions, `binlog_format` defaults to `ROW`.

For information about setting the `binlog_format` parameter, see Configuring RDS for MySQL binary logging for Single-AZ databases. For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up, restoring, and exporting data.

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;
```

```
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

```
File                        Position
-------------------------------------
 mysql-bin-changelog.000031      107
-------------------------------------
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS for MySQL database with reduced downtime].

   For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

   For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

> **Note**
>
> Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

   The IP address can change when the following conditions are met:

   - You are using a public IP address for communication between the external source instance and the DB instance.
   - The external source instance was stopped and restarted.

   If these conditions are met, verify the IP address before adding it.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher) or mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) command. Use the master log file name and master log position that you determined in step 2. The following commands are examples.

MySQL 8.4

```
CALL mysql.rds_set_external_source ('mysourceserver.mydomain.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
```

MariaDB and MySQL 8.0 and 5.7

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
```

> **Note**
>
> On RDS for MySQL, you can choose to use delayed replication by running the mysql.rds_set_external_source_with_delay (RDS for MySQL major versions 8.4 and higher) or mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the mysql.rds_start_replication_until stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

Options for MariaDB database engine

Following, you can find descriptions for options, or additional features, that are available for Amazon RDS instances running the MariaDB DB engine. To turn on these options, you add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for MariaDB:

Option ID	Engine versions
MARIADB_AUDIT_PLUGIN	MariaDB 10.3 and higher

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MariaDB database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

> **Note**
>
> If you don't configure an option setting in the RDS console, RDS uses the default setting.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_PATH	/rdsdbdata/log/audit/	/rdsdbdata/log/audit/	The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS . For more information, see Viewing and listing database log files and MariaDB database log files.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_ROTATE_SIZE	1–1000000000	1000000	The size in bytes that when reached, causes the file to rotate. For more information, see Log rotation and retention for MariaDB.
SERVER_AUDIT_FILE_ROTATIONS	0–100	9	The number of log rotations to save when `server_audit_output_type=file` . If set to 0, then the log file never rotates. For more information, see Log rotation and retention for MariaDB and Downloading a database log file.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_EVENTS	CONNECT, QUERY, TABLE, QUERY_DDL , QUERY_DML , QUERY_DML_NO_SELECT , QUERY_DCL	CONNECT, QUERY	The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged. • CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database. • QUERY: Log the text of all queries run against the database. • TABLE: Log tables affected by queries when the queries are run against the database. • QUERY_DDL : Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on). • QUERY_DML : Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT). • QUERY_DML_NO_SELECT : Similar to the QUERY_DML event, but doesn't log SELECT queries. • QUERY_DCL : Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).
SERVER_AUDIT_INCL_USERS	Multiple comma-separated values	None	Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS , make sure no values are added to SERVER_AUDIT_EXCL_USERS .

Option setting	Valid values	Default value	Description
SERVER_AUDIT_EXCL_USERS	Multiple comma-separated values	None	Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS. The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list. **Note** CONNECT activity is always recorded for all users, even if the user is specified for this option setting.
SERVER_AUDIT_LOGGING	ON	ON	Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin.
SERVER_AUDIT_QUERY_LOG_LIMIT	0–2147483647	1024	The limit on the length of the query string in a record.

Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose **mariadb** for **Engine**, and choose **10.3** or higher for **Major engine version**. For more information, see Creating an option group.
2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see Audit Plugin option settings.
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the DB instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see Viewing and listing database log files. For information about downloading the log file, see Downloading a database log file.

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify settings for the plugin. For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see Audit Plugin option settings.

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For information about working with parameter groups and setting parameters, see Parameter groups for Amazon RDS.

Viewing MariaDB parameters

RDS for MariaDB parameters are set to the default values of the storage engine that you have selected. For more information about MariaDB parameters, see the MariaDB documentation. For more information about MariaDB storage engines, see Supported storage engines for MariaDB on Amazon RDS.

You can view the parameters available for a specific RDS for MariaDB version using the RDS console or the AWS CLI. For information about viewing the parameters in a MariaDB parameter group in the RDS console, see Viewing parameter values for a DB parameter group in Amazon RDS.

Using the AWS CLI, you can view the parameters for an RDS for MariaDB version by running the `describe-engine-default-parameters` command. Specify one of the following values for the `--db-parameter-group-family` option:

- `mariadb11.8`
- `mariadb11.4`
- `mariadb10.11`
- `mariadb10.6`
- `mariadb10.5`
- `mariadb10.4`
- `mariadb10.3`

For example, to view the parameters for RDS for MariaDB version 10.6, run the following command.

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6
```

Your output looks similar to the following.

```
{
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "alter_algorithm",
                "Description": "Specify the alter table algorithm.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "string",
                "AllowedValues": "DEFAULT,COPY,INPLACE,NOCOPY,INSTANT",
                "IsModifiable": true
            },
            {
                "ParameterName": "analyze_sample_percentage",
                "Description": "Percentage of rows from the table ANALYZE TABLE will
 sample to collect table statistics.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "float",
                "AllowedValues": "0-100",
                "IsModifiable": true
            },
            {
                "ParameterName": "aria_block_size",
                "Description": "Block size to be used for Aria index pages.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "integer",
                "AllowedValues": "1024-32768",
                "IsModifiable": false
            },
            {
                "ParameterName": "aria_checkpoint_interval",
                "Description": "Interval in seconds between automatic checkpoints.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "integer",
                "AllowedValues": "0-4294967295",
                "IsModifiable": true
            },
        ...
```

To list only the modifiable parameters for RDS for MariaDB version 10.6, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6 \
   --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mariadb10.6 ^
   --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```

MySQL parameters that aren't available

The following MySQL parameters are not available in MariaDB-specific DB parameter groups:

- bind_address
- binlog_error_action
- binlog_gtid_simple_recovery
- binlog_max_flush_queue_time
- binlog_order_commits
- binlog_row_image
- binlog_rows_query_log_events
- binlogging_impossible_mode
- block_encryption_mode
- core_file
- default_tmp_storage_engine
- div_precision_increment
- end_markers_in_json
- enforce_gtid_consistency
- eq_range_index_dive_limit
- explicit_defaults_for_timestamp
- gtid_executed

- gtid-mode
- gtid_next
- gtid_owned
- gtid_purged
- log_bin_basename
- log_bin_index
- log_bin_use_v1_row_events
- log_slow_admin_statements
- log_slow_slave_statements
- log_throttle_queries_not_using_indexes
- master-info-repository
- optimizer_trace
- optimizer_trace_features
- optimizer_trace_limit
- optimizer_trace_max_mem_size
- optimizer_trace_offset
- relay_log_info_repository
- rpl_stop_slave_timeout
- slave_parallel_workers
- slave_pending_jobs_size_max
- slave_rows_search_algorithms
- storage_engine
- table_open_cache_instances
- timed_mutexes
- transaction_allow_batching
- validate-password
- validate_password_dictionary_file
- validate_password_length
- validate_password_mixed_case_count
- validate_password_number_count

- validate_password_policy
- validate_password_special_char_count

For more information on MySQL parameters, see the MySQL documentation.

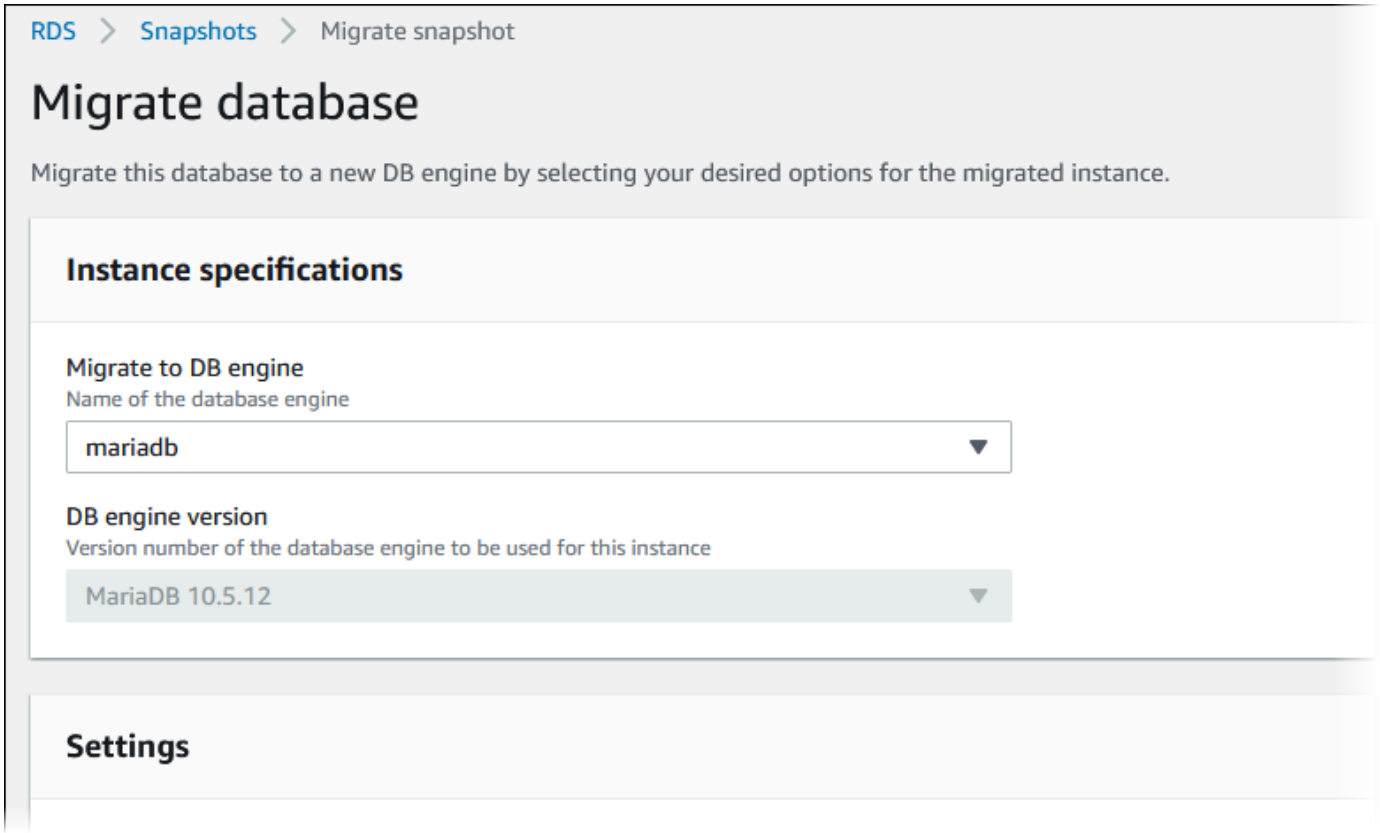
Migrating data from a MySQL DB snapshot to a MariaDB DB instance

You can migrate an RDS for MySQL DB snapshot to a new DB instance running MariaDB using the AWS Management Console, the AWS CLI, or Amazon RDS API. You must use a DB snapshot that was created from an Amazon RDS DB instance running MySQL 5.6 or 5.7. To learn how to create an RDS for MySQL DB snapshot, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

Migrating the snapshot doesn't affect the original DB instance from which the snapshot was taken. You can test and validate the new DB instance before diverting traffic to it as a replacement for the original DB instance.

After you migrate from MySQL to MariaDB, the MariaDB DB instance is associated with the default DB parameter group and option group. After you restore the DB snapshot, you can associate a custom DB parameter group with the new DB instance. However, a MariaDB parameter group has a different set of configurable system variables. For information about the differences between MySQL and MariaDB system variables, see System Variable Differences between MariaDB and MySQL. To learn about DB parameter groups, see Parameter groups for Amazon RDS. To learn about option groups, see Working with option groups.

Performing the migration



You can migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To migrate a MySQL DB snapshot to a MariaDB DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**, and then select the MySQL DB snapshot you want to migrate.
3. For **Actions**, choose **Migrate snapshot**. The **Migrate database** page appears.
4. For **Migrate to DB Engine**, choose **mariadb**.

   Amazon RDS selects the **DB engine version** automatically. You can't change the DB engine version.

5. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.
6. Choose **Migrate**.

AWS CLI

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, run the AWS CLI `restore-db-instance-from-db-snapshot` command with the following options:

- --db-instance-identifier – Name of the DB instance to create from the DB snapshot.
- --db-snapshot-identifier – The identifier for the DB snapshot to restore from.
- --engine – The database engine to use for the new instance.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier newmariadbinstance \
```

```
    --db-snapshot-identifier mysqlsnapshot \
    --engine mariadb
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier newmariadbinstance ^
    --db-snapshot-identifier mysqlsnapshot ^
    --engine mariadb
```

API

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, call the Amazon RDS API operation `RestoreDBInstanceFromDBSnapshot`.

Incompatibilities between MariaDB and MySQL

Incompatibilities between MySQL and MariaDB include the following:

- You can't migrate a DB snapshot created with MySQL 8.0 to MariaDB.
- If the source MySQL database uses a SHA256 password hash, make sure to reset user passwords that are SHA256 hashed before you connect to the MariaDB database. The following code shows how to reset a password that is SHA256 hashed.

  ```
  SET old_passwords = 0;
  UPDATE mysql.user SET plugin = 'mysql_native_password',
  Password = PASSWORD('new_password')
  WHERE (User, Host) = ('master_user_name', %);
  FLUSH PRIVILEGES;
  ```

- If your RDS master user account uses the SHA-256 password hash, make sure to reset the password using the AWS Management Console, the `modify-db-instance` AWS CLI command, or the ModifyDBInstance RDS API operation. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.
- MariaDB doesn't support the Memcached plugin. However, the data used by the Memcached plugin is stored as InnoDB tables. After you migrate a MySQL DB snapshot, you can access the data used by the Memcached plugin using SQL. For more information about the innodb_memcache database, see InnoDB memcached Plugin Internals.

MariaDB on Amazon RDS SQL reference

Following, you can find descriptions of system stored procedures that are available for Amazon RDS instances running the MariaDB DB engine.

You can use the system stored procedures that are available for MySQL DB instances and MariaDB DB instances. These stored procedures are documented at RDS for MySQL stored procedure reference. MariaDB DB instances support all of the stored procedures, except for `mysql.rds_start_replication_until` and `mysql.rds_start_replication_until_gtid`.

Additionally, the following system stored procedures are supported only for Amazon RDS DB instances running MariaDB:

- mysql.rds_replica_status
- mysql.rds_set_external_master_gtid
- mysql.rds_kill_query_id
- mysql.rds_execute_operation

mysql.rds_replica_status

Shows the replication status of a MariaDB read replica.

Call this procedure on the read replica to show status information on essential parameters of the replica threads.

Syntax

```
CALL mysql.rds_replica_status;
```

Usage notes

This procedure is only supported for MariaDB DB instances running MariaDB version 10.5 and higher.

This procedure is the equivalent of the `SHOW REPLICA STATUS` command. This command isn't supported for MariaDB version 10.5 and higher DB instances.

In prior versions of MariaDB, the equivalent `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5 and higher, it requires the `REPLICATION REPLICA ADMIN` privilege. To protect the RDS management of MariaDB 10.5 and higher DB instances, this new privilege isn't granted to the RDS master user.

Examples

The following example shows the status of a MariaDB read replica:

```
call mysql.rds_replica_status;
```

The response is similar to the following:

```
*************************** 1. row ***************************
               Replica_IO_State: Waiting for master to send event
                    Source_Host: XX.XX.XX.XXX
                    Source_User: rdsrepladmin
                    Source_Port: 3306
                  Connect_Retry: 60

mysql.rds_set_external_master_gtid

Configures GTID-based replication from a MariaDB instance running external to Amazon RDS to a MariaDB DB instance. This stored procedure is supported only where the external MariaDB instance is version 10.0.24 or higher. When setting up replication where one or both instances do not support MariaDB global transaction identifiers (GTIDs), use mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower).

Using GTIDs for replication provides crash-safety features not offered by binary log replication, so we recommend it in cases where the replicating instances support it.

Syntax

```
CALL mysql.rds_set_external_master_gtid(
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , gtid
  , ssl_encryption
);
```

Parameters

host_name

String. The host name or IP address of the MariaDB instance running external to Amazon RDS that will become the source instance.

host_port

Integer. The port used by the MariaDB instance running external to Amazon RDS to be configured as the source instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

String. The ID of a user with `REPLICATION SLAVE` permissions in the MariaDB DB instance to be configured as the read replica.

replication_user_password

String. The password of the user ID specified in `replication_user_name`.

gtid

String. The global transaction ID on the source instance that replication should start from.

You can use `@@gtid_current_pos` to get the current GTID if the source instance has been locked while you are configuring replication, so the binary log doesn't change between the points when you get the GTID and when replication starts.

Otherwise, if you are using `mysqldump` version 10.0.13 or greater to populate the replica instance prior to starting replication, you can get the GTID position in the output by using the `--master-data` or `--dump-slave` options. If you are not using `mysqldump` version

10.0.13 or greater, you can run the `SHOW MASTER STATUS` or use those same `mysqldump` options to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance:

```
SELECT BINLOG_GTID_POS('<binary log file name>', <binary log file position>);
```

For more information about the MariaDB implementation of GTIDs, go to Global transaction ID in the MariaDB documentation.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The `mysql.rds_set_external_master_gtid` procedure must be run by the master user. It must be run on the MariaDB DB instance that you are configuring as the replica of a MariaDB instance running external to Amazon RDS. Before running `mysql.rds_set_external_master_gtid`, you must have configured the instance of MariaDB running external to Amazon RDS as a source instance. For more information, see Importing data into an Amazon RDS for MariaDB DB instance.

> **Warning**
>
> Do not use `mysql.rds_set_external_master_gtid` to manage replication between two Amazon RDS DB instances. Use it only when replicating with a MariaDB instance running external to RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_master_gtid` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the replica to start the

replication process. You can call mysql.rds_reset_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) to remove the read replica configuration.

When `mysql.rds_set_external_master_gtid` is called, Amazon RDS records the time, user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MariaDB DB instance, the following example configures it as the replica of an instance of MariaDB running external to Amazon RDS.

```
call mysql.rds_set_external_master_gtid
 ('Sourcedb.some.com',3306,'ReplicationUser','SomePassW0rd','0-123-456',0);
```

mysql.rds_kill_query_id

Ends a query running against the MariaDB server in order to terminate long-running or problematic queries. You can identify the query ID and effectively stop a specific query to address performance issues and maintain optimal database operation.

Syntax

```
CALL mysql.rds_kill_query_id(queryID);
```

Parameters

queryID

Integer. The identity of the query to be ended.

Usage notes

To stop a query running against the MariaDB server, use the `mysql.rds_kill_query_id` procedure and pass in the ID of that query. To obtain the query ID, query the MariaDB Information schema PROCESSLIST table, as shown following:

```
SELECT USER, HOST, COMMAND, TIME, STATE, INFO, QUERY_ID FROM
                INFORMATION_SCHEMA.PROCESSLIST WHERE USER = '<user name>';
```

The connection to the MariaDB server is retained.

Examples

The following example ends a query with a query ID of 230040:

```
call mysql.rds_kill_query_id(230040);
```

mysql.rds_execute_operation

Executes InnoDB operations to manage buffer pool states and temporary tablespace. This procedure can be used to dynamically control InnoDB operations such as dumping and loading buffer pool states or truncating temporary tablespace.

Syntax

```
CALL mysql.rds_execute_operation(operation);
```

Parameters

operation

String. The InnoDB operations to execute. Valid values are:

- *innodb_buffer_pool_dump_now* - Operation that dumps the current state of the buffer pool.
- *innodb_buffer_pool_load_now* - Operation that loads the saved buffer pool state.
- *innodb_buffer_pool_load_abort* - Operation that aborts a buffer pool load operation.
- *innodb_truncate_temporary_tablespace_now* - Operation that truncates the temporary tablespace.

Usage notes

This procedure is only supported for MariaDB DB instances running MariaDB version 11.8 and higher.

During execution, binary logging is temporarily disabled to prevent replication of these administrative commands.

The procedure maintains an audit trail by logging all operations in the `mysql.rds_history` table.

Examples

The following example demonstrates temporary tablespace shrinking using `mysql.rds_execute_operation`:

To check current temporary tablespace size, run the following query:

```
SELECT FILE_SIZE FROM information_schema.innodb_sys_tablespaces WHERE name LIKE
 'innodb_temporary';
+------------+
| FILE_SIZE  |
+------------+
| 6723469312 |  -- 6.3 GB
+------------+
```

When you drop temporary tables, it doesn't reduce storage usage in the global tablespace. To reduce the size of the global tablespace, run the `mysql.rds_execute_operation` command to shrink the temporary tablespace.

```
CALL mysql.rds_execute_operation('innodb_truncate_temporary_tablespace_now');
Query OK, 2 rows affected (0.004 sec)
```

After you run the procedure, verify that the space was reclaimed.

```
SELECT FILE_SIZE FROM information_schema.innodb_sys_tablespaces WHERE name LIKE
 'innodb_temporary';
+-----------+
| FILE_SIZE |
+-----------+
|  12582912 |  -- 12 MB
+-----------+
```

> **Note**
>
> The shrink operation might take time, depending on the temporary tablespace size and current workload.

Important

The temporary tablespace shrinks only when all temporary tables that contributed to its size are no longer in use. We recommend that you run this procedure when there are no active temporary tablespaces on the instance.

Local time zone for MariaDB DB instances

By default, the time zone for a MariaDB DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Parameter groups for Amazon RDS.

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of MariaDB, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MariaDB versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the mysql_tzinfo_to_sql tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Asuncion, America/Bogota, America/Buenos_Aires, America/Caracas, America/Chihuahua, America/Cuiaba, America/Denver, America/Fortaleza, America/Guatemala, America/Halifax, America/Manaus, America/Matamoros, America/Monterrey, America/Montevideo, America/Phoenix, America/Santiago, America/Tijuana
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Irkutsk, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Krasnoyarsk, Asia/Magadan, Asia/Muscat, Asia/Novosibirsk, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Hobart, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan, Canada/Yukon
Europe	Europe/Amsterdam, Europe/Athens, Europe/Dublin, Europe/Helsinki, Europe/Istanbul, Europe/Kaliningrad Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Sarajevo
Pacific	Pacific/Auckland, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Samoa
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Known issues and limitations for RDS for MariaDB

The following items are known issues and limitations when using RDS for MariaDB.

> **Note**
>
> This list is not exhaustive.

- MariaDB file size limits in Amazon RDS
- InnoDB reserved word
- Custom ports
- Performance Insights

MariaDB file size limits in Amazon RDS

For MariaDB DB instances, the maximum size of a table is 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) are set by default for MariaDB DB instances. This limit isn't related to the maximum storage limit for MariaDB DB instances. For more information about the storage limit, see Amazon RDS DB instance storage.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. *Partitioning* distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

To determine the size of all InnoDB tablespaces

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

> **Note**
>
> For MariaDB 10.6 and higher, this query also returns the size of the InnoDB system tablespace.
> For MariaDB versions earlier than 10.6, you can't determine the size of the InnoDB system tablespace by querying the system tables. We recommend that you upgrade to a later version.

```
SELECT SPACE,NAME,ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH+DATA_FREE)
/ 1024 / 1024/ 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema')
and ENGINE<>'InnoDB';
```

To enable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to `0` in the parameter group for the DB instance.

For information on updating a parameter group, see Parameter groups for Amazon RDS.

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command. You can use this command to move a table from the global tablespace to its own tablespace. Or you can move a table from its own tablespace to the global tablespace. Following is an example.

```
ALTER TABLE table_name ENGINE=InnoDB, ALGORITHM=COPY;
```

InnoDB reserved word

InnoDB is a reserved word for RDS for MariaDB. You can't use this name for a MariaDB database.

Custom ports

Amazon RDS blocks connections to custom port 33060 for the MariaDB engine. Choose a different port for your MariaDB engine.

Performance Insights

InnoDB counters are not visible in Performance Insights for RDS for MariaDB version 10.11 because the MariaDB community no longer supports them.

Amazon RDS for Microsoft SQL Server

Amazon RDS supports several versions and editions of Microsoft SQL Server. The following table shows the most recent supported minor version of each major version. For the full list of supported versions, editions, and RDS engine versions, see Microsoft SQL Server versions on Amazon RDS.

Major version	Service Pack / GDR	Cumulative Update	Minor version	Knowledge Base Article	Release Date
SQL Server 2022	Not applicable	CU23	16.0.4236.2	KB5078297	January 29, 2026
SQL Server 2019	GDR	CU32 GDR	15.0.4455.2	KB5068404	November 11, 2025
SQL Server 2017	GDR	CU31 GDR	14.0.3515.1	KB5068402	November 11, 2025
SQL Server 2016	SP3 GDR	Not applicable	13.0.6475.1	KB5068401	November 11, 2025

For information about licensing for SQL Server, see Licensing Microsoft SQL Server on Amazon RDS. For information about SQL Server builds, see this Microsoft support article about Where to find information about the latest SQL Server builds.

With Amazon RDS, you can create DB instances and DB snapshots, point-in-time restores, and automated or manual backups. DB instances running SQL Server can be used inside a VPC. You can also use Secure Sockets Layer (SSL) to connect to a DB instance running SQL Server, and you can use transparent data encryption (TDE) to encrypt data at rest. Amazon RDS currently supports Multi-AZ deployments for SQL Server using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs) as a high-availability, failover solution.

To deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio. Amazon RDS does not allow

direct host access to a DB instance via Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, the master user is assigned to the *db_owner* role for all user databases on that instance, and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see Setting up your Amazon RDS environment.

Common management tasks for Microsoft SQL Server on Amazon RDS

The following are the common management tasks you perform with an Amazon RDS for SQL Server DB instance, with links to relevant documentation for each task.

Task area	Description	Relevant documentation
Instance classes, storage, and PIOPS	If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance class support for Microsoft SQL Server Amazon RDS storage types
Multi-AZ deployments	A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. Multi-AZ deployments for SQL Server are implemented using SQL Server's native DBM or AGs technology.	Configuring and managing a Multi-AZ deployment for Amazon RDS Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups
Amazon Virtual Private Cloud (VPC)	If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. If your account does	Working with a DB instance in a VPC

Task area	Description	Relevant documentation
	not have a default VPC, and you want the DB instance in a VPC, you must create the VPC and subnet groups before you create the DB instance.	
Security groups	By default, DB instances are created with a firewall that prevents access to them. You therefore must create a security group with the correct IP addresses and network configuration to access the DB instance.	Controlling access with security groups
Parameter groups	If your DB instance is going to require specific database parameters, you should create a parameter group before you create the DB instance.	Parameter groups for Amazon RDS
Option groups	If your DB instance is going to require specific database options, you should create an option group before you create the DB instance.	Options for the Microsoft SQL Server database engine
Connecting to your DB instance	After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio.	Connecting to your Microsoft SQL Server DB instance

Task area	Description	Relevant documentation
Backup and restore	When you create your DB instance, you can configure it to take automated backups. You can also back up and restore your databases manually by using full backup files (.bak files).	Introduction to backups Importing and exporting SQL Server databases using native backup and restore
Monitoring	You can monitor your SQL Server DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing metrics in the Amazon RDS console Viewing Amazon RDS events
Log files	You can access the log files for your SQL Server DB instance.	Monitoring Amazon RDS log files Amazon RDS for Microsoft SQL Server database log files

There are also advanced administrative tasks for working with SQL Server DB instances. For more information, see the following documentation:

- Common DBA tasks for Amazon RDS for Microsoft SQL Server.
- Working with AWS Managed Active Directory with RDS for SQL Server
- Accessing the tempdb database

Limitations for Microsoft SQL Server DB instances

The Amazon RDS implementation of Microsoft SQL Server on a DB instance has some limitations that you should be aware of:

- The maximum number of databases supported on a DB instance depends on the instance class type and the availability mode—Single-AZ, Multi-AZ Database Mirroring (DBM), or Multi-AZ

Availability Groups (AGs). The Microsoft SQL Server system databases don't count toward this limit.

The following table shows the maximum number of supported databases for each instance class type and availability mode. Use this table to help you decide if you can move from one instance class type to another, or from one availability mode to another. If your source DB instance has more databases than the target instance class type or availability mode can support, modifying the DB instance fails. You can see the status of your request in the **Events** pane.

Instance class type	Allowed vCPU range	Single-AZ	Multi-AZ with DBM	Multi-AZ with Always On AGs
db.*.micro to db.*.medium	N/A	30	N/A	N/A
db.*.large	N/A	30	30	30
db.*.xlarge to db.*.16xlarge	4 vCPUs - 64 vCPUs	100	50	75
db.*.24xlarge to db.*.32xlarge	4 vCPUs - 64 vCPUs	100	50	100
db.*.24xlarge to db.*.32xlarge	96 vCPUs - 128 vCPUs	100	50	100

* Represents the different instance class types.

For example, let's say that your DB instance runs on a db.*.16xlarge with Single-AZ and that it has 76 databases. You modify the DB instance to upgrade to using Multi-AZ Always On AGs. This upgrade fails, because your DB instance contains more databases than your target configuration can support. If you upgrade your instance class type to db.*.24xlarge instead, the modification succeeds.

If the upgrade fails, you see events and messages similar to the following:

- Unable to modify database instance class. The instance has 76 databases, but after conversion it would only support 75.

- Unable to convert the DB instance to Multi-AZ: The instance has 76 databases, but after conversion it would only support 75.

  If the point-in-time restore or snapshot restore fails, you see events and messages similar to the following:

  - Database instance put into incompatible-restore. The instance has 76 databases, but after conversion it would only support 75.
- The following ports are reserved for Amazon RDS, and you can't use them when you create a DB instance: `1234, 1434, 3260, 3343, 3389, 47001,` and `49152-49156`.
- Client connections from IP addresses within the range 169.254.0.0/16 are not permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.
- SQL Server Standard Edition uses only a subset of the available processors if the DB instance has more processors than the software limits (24 cores, 4 sockets, and 128GB RAM). Examples of this are the db.m5.24xlarge and db.r5.24xlarge instance classes.

  For more information, see the table of scale limits under Editions and supported features of SQL Server 2019 (15.x) in the Microsoft documentation.
- Amazon RDS for SQL Server doesn't support importing data into the msdb database.
- You can't rename databases on a DB instance in a SQL Server Multi-AZ deployment.
- Make sure that you use these guidelines when setting the following DB parameters on RDS for SQL Server:
  - `max server memory (mb)` >= 256 MB
  - `max worker threads` >= (number of logical CPUs * 7)

  For more information on setting DB parameters, see Parameter groups for Amazon RDS.
- The maximum storage size for SQL Server DB instances is the following:
  - General Purpose (SSD) storage – 16 TiB for all editions
  - Provisioned IOPS storage – 64 TiB for all editions
  - Magnetic storage – 1 TiB for all editions

  If you have a scenario that requires a larger amount of storage, you can use sharding across multiple DB instances to get around the limit. This approach requires data-dependent routing logic in applications that connect to the sharded system. You can use an existing sharding framework, or you can write custom code to enable sharding. If you use an existing framework, the framework can't install any components on the same server as the DB instance.

- The minimum storage size for SQL Server DB instances is the following:
  - General Purpose (SSD) storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Provisioned IOPS storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
  - Magnetic storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
- Amazon RDS doesn't support running these services on the same server as your RDS DB instance:
  - Data Quality Services
  - Master Data Services

  To use these features, we recommend that you install SQL Server on an Amazon EC2 instance, or use an on-premises SQL Server instance. In these cases, the EC2 or SQL Server instance acts as the Master Data Services server for your SQL Server DB instance on Amazon RDS. You can install SQL Server on an Amazon EC2 instance with Amazon EBS storage, pursuant to Microsoft licensing policies.
- Because of limitations in Microsoft SQL Server, restoring to a point in time before successfully running `DROP DATABASE` might not reflect the state of that database at that point in time. For example, the dropped database is typically restored to its state up to 5 minutes before the `DROP DATABASE` command was issued. This type of restore means that you can't restore the transactions made during those few minutes on your dropped database. To work around this, you can reissue the `DROP DATABASE` command after the restore operation is completed. Dropping a database removes the transaction logs for that database.
- For SQL Server, you create your databases after you create your DB instance. Database names follow the usual SQL Server naming rules with the following differences:
  - Database names can't start with `rdsadmin`.
  - They can't start or end with a space or a tab.
  - They can't contain any of the characters that create a new line.
  - They can't contain a single quote (`'`).
- SQL Server Web Edition only allows you to use the **Dev/Test** template when creating a new RDS for SQL Server DB instance.
- SQL Server Web Edition is designed for web hosters and web VAPs to host public and internet-accessible web pages, websites, web applications, and web services. For more information, see Licensing Microsoft SQL Server on Amazon RDS.

DB instance class support for Microsoft SQL Server

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements. For more information, see DB instance classes.

The following list of DB instance classes supported for Microsoft SQL Server is provided here for your convenience. For the most current list, see the RDS console: https://console.aws.amazon.com/rds/.

Not all DB instance classes are available on all supported SQL Server minor versions. For example, some newer DB instance classes such as db.r6i aren't available on older minor versions. You can use the describe-orderable-db-instance-options AWS CLI command to find out which DB instance classes are available for your SQL Server edition and version.

SQL Server edition	2022 support range	2019 support range	2017 and 2016 support range
Enterprise Edition	db.t3.xlarge –db.t3.2xlarge	db.t3.xlarge –db.t3.2xlarge	db.t3.xlarge –db.t3.2xlarge
	db.r5.xlarge –db.r5.24xlarge	db.r5.xlarge –db.r5.24xlarge	db.r5.xlarge –db.r5.24xlarge
	db.r5b.xlarge –db.r5b.24xlarge	db.r5b.xlarge –db.r5b.24xlarge	db.r5b.xlarge –db.r5b.24xlarge

Note

- Starting with the 7th generation instance class, hyper-threading is disabled on RDS SQL Server for instance sizes 2xlarge and above. This results in the total number of vCPUs available being half of that supported by the corresponding EC2 instance. For example, the EC2 instance type `m7i.2xlarge` by default supports 4 cores and 2 threadsPerCore, resulting in a total of 8 vCPUs. In contrast, the RDS for SQL Server `db.m7i.2xlarge` instance, with hyper-threading disabled, results in 4 cores and 1 threadsPerCore, overall 4 vCPUs.
- Starting with the 7th generation instances, your billing provides a detailed breakdown of RDS DB instance and third-party licensing fees. For more details, refer to RDS SQL Server pricing.

Optimize CPUs for RDS for SQL Server license-included instances

With RDS for SQL Server, you can use Optimize CPU by specifying processor features to configure the vCPU count on your DB instance while maintaining the same memory and IOPS. You can achieve desired memory-to-CPU ratios for specific database workload requirements and reduce licensing costs for Microsoft Windows OS and SQL Server, which are based on vCPU count.

To specify processor feature, use the following parameters:

```
--processor-features "Name=coreCount,Value=value" \
 "Name=threadsPerCore,Value=value"
```

- **coreCount** – Specify the number of CPU cores for the DB instance, to optimize licensing costs for DB instances. See DB instance classes that support Optimize CPU to find the allowed values for core count for a selected instance type.
- **threadsPerCore** – Specify the threads per core to define the number of threads per CPU core. See DB instance classes that support Optimize CPU to find the allowed values for threads per core for a selected instance type.

Sample command to create an RDS for SQL Server instance with Optimize CPU settings:

```
aws rds create-db-instance \
    --engine sqlserver-ee \
    --engine-version 16.00 \
    --license-model license-included \
    --allocated-storage 300 \
    --master-username myuser \
    --master-user-password xxxxx \
    --no-multi-az \
    --vpc-security-group-ids myvpcsecuritygroup \
    --db-subnet-group-name mydbsubnetgroup \
    --db-instance-identifier my-rds-instance \
    --db-instance-class db.m7i.8xlarge \
    --processor-features "Name=coreCount,Value=8" "Name=threadsPerCore,Value=1"
```

In this example, you create a `db.m7i.8xlarge` instance, which by default has a coreCount of 16. By using Optimize CPU, you opt for a coreCount of 8, resulting in an effective vCPU count of 8.

If you create the instance without the `--processor-features` parameter, core count is set to 16 and threads per core is set to 1 by default, resulting in a default vCPU count of 16.

Some considerations to keep in mind while specifying processor features:

- **Create** – Specify both the `coreCount` and `threadsPerCore` for the `processor-features` parameter from the allowed values. See DB instance classes that support Optimize CPU.
- **Modify** – When modifying from one instance class configured with Optimize CPU settings to another one that supports Optimize CPU settings, you must specify the default processor

settings using the `--use-default-processor-features` parameter or explicitly define the options during the modify request.

> **Note**
>
> Changing the vCPU count can have implications for the licensing fee cost associated with the DB instance.

- **Snapshot restore** – When restoring a snapshot to the same instance type as source, the restored DB instance inherits the Optimize CPU settings from the snapshot. If restoring to a different instance type, you need to define the Optimize CPU settings for the target instance or specify the `--use-default-processor-features` parameter.
- **Point-in-time restore** – Point-in-time restore (PITR) involves restoring a specific snapshot based on the designated time for PITR and subsequently applying all transactional log backups to that snapshot, thereby bringing the instance to the specified point in time. For PITR, the Optimize CPU settings, `coreCount` and `threadsPerCore`, are derived from the source snapshot (not the point in time) unless custom values are specified during the PITR request. If the source snapshot being used is enabled with Optimize CPU settings and you are using a different instance type for PITR, you must define the Optimize CPU settings for the target instance or specify the `—-use-default-processor-features` parameter.

Limitations

The following limitations apply when using Optimize CPU:

- Optimize CPU is supported with Enterprise, Standard, and Web Editions only.
- Optimize CPU is available on select instances. See DB instance classes that support Optimize CPU.
- Customizing the number of CPU cores is supported on instance sizes of `2xlarge` and above. With these instance types, the minimum number of vCPCU supported for Optimize CPU is 4.
- Optimize CPU allows only 1 thread per core since Hyper-Threading is disabled for instances starting from 7th generation that support Optimize CPU.

DB instance classes that support Optimize CPU

RDS for SQL Server supports Optimize CPU beginning with the 7th Generation instance class type. Additionally, RDS provides a detailed billing breakdown of RDS DB instance and third-party licensing fees, starting from the 7th Generation instance class type, regardless of whether the Optimize CPU feature is enabled.

RDS for SQL Server provides support for Optimize CPU on specific instance sizes, with the smallest instance size supported being `2xlarge`. The minimum configuration supported is 4 vCPUs. The table below outlines the DB instance classes that support the Optimize CPU, including their default and valid values for CPU cores, CPU threads per core and vCPUs:

General purpose instances

Instan type	Default vCPUs	Default CPU cores	Valid CPU cores	Valid threads per core
m7i.l	2	1	1	2
m7i.x e	4	2	2	2
m7i.2 ge	4	4	1,2,3,4	1
m7i.4 ge	8	8	1,2,3,4,5,6,7,8	1
m7i.8 ge	16	16	1,2,3,4,5,6,7,8,9, 10,11,12,13,14,15, 16	1
m7i.1 rge	24	24	1,2,3,4,5,6,7,8,9, 10,11,12,13,14,15, 16,17,18,19,20,21, 22,23,24	1
m7i.1 rge	32	32	1,2,3,4,5,6,7,8,9, 10,11,12,13,14,15,	1

Instan type	Default vCPUs	Default CPU cores	Valid CPU cores	Valid threads per core
			16,17,18,19,20,21, 22,23,24,25,26,27, 28,29,30,31,32	

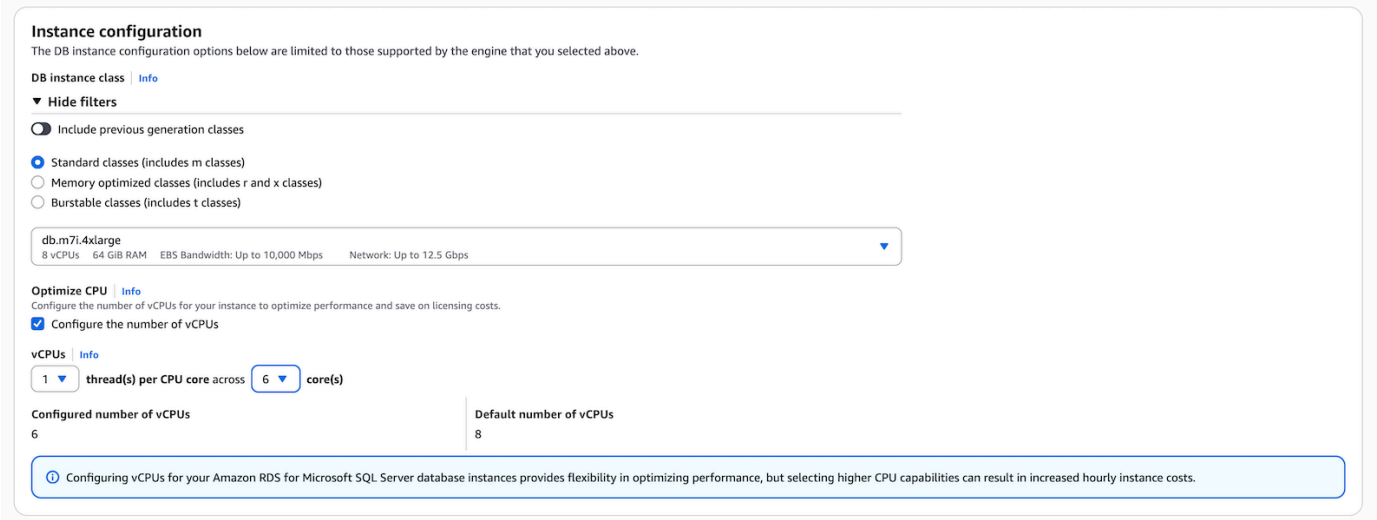
Memory optimized instances

Instan type	Default vCPUs	Default CPU cores	Valid CPU cores	Valid threads per core
r7i.l	2	1	1	2
r7i.x e	4	2	2	2
r7i.2 ge	4	4	1,2,3,4	1
r7i.4 ge	8	8	1,2,3,4,5,6,7,8	1
r7i.8 ge	16	16	1,2,3,4,5,6,7,8,9, 10,11,12,13,14,15, 16	1
r7i.1 rge	24	24	1,2,3,4,5,6,7,8,9, 10,11,12,13,14,15, 16,17,18,19,20,21, 22,23,24	1
r7i.1 rge	32	32	1,2,3,4,5,6,7,8,9, 10,11,12,13,14,15, 16,17,18,19,20,21, 22,23,24,25,26,27, 28,29,30,31,32	1

Setting the CPU cores and threads per CPU core for a DB instance class

You can configure the number of CPU cores and threads per core for the DB instance class when you perform the following operations:

- Creating an Amazon RDS DB instance
- Modifying an Amazon RDS DB instance
- Restoring to a DB instance
- Restoring a DB instance to a specified time for Amazon RDS



> **Note**
>
> When you modify a DB instance to configure the number of CPU cores or threads per core, there is a brief outage similar to when you modify the instance class.

Set the CPU cores by using the AWS Management Console, AWS CLI or the RDS API.

Console

To set the cores

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Create database**.
3. When setting the **Instance configuration** options:
    a. Choose the **Optimize CPU** option.
    b. Set your **vCPU** option by choosing the number of cores.

4. After completing other selections, select **Create database**.

AWS CLI

To set the cores

1. To configure Optimize CPU using the AWS CLI, include the `--processor-features` option in the command. Specify the number of CPU cores with the `coreCount` and `threadsPerCore` as 1.
2. Use the following syntax:

```
aws rds create-db-instance \
    --engine sqlserver-ee \
    --engine-version 16.00 \
    --license-model license-included \
    --allocated-storage 300 \
    --master-username myuser \
    --master-user-password xxxxx \
    --no-multi-az \
    --vpc-security-group-ids myvpcsecuritygroup \
    --db-subnet-group-name mydbsubnetgroup \
    --db-instance-identifier my-rds-instance \
    --db-instance-class db.m7i.4xlarge \
    --processor-features "Name=coreCount,Value=6" "Name=threadsPerCore,Value=1"
```

Example of viewing valid processor values for a DB instance class

Use the `describe-orderable-db-instance-options` command to show the default vCPUs, cores, and threads per core. For example, the output for the following command shows the processor options for the db.r7i.2xlarge instance class.

```
aws rds describe-orderable-db-instance-options --engine sqlserver-ee \
--db-instance-class db.r7i.2xlarge

Sample output:
-------------------------------------------------------------
|            DescribeOrderableDBInstanceOptions             |
+-----------------------------------------------------------+
||               OrderableDBInstanceOptions                ||
|+-----------------------------------+--------------------+|
||  DBInstanceClass                  |  db.r7i.2xlarge    ||
||  Engine                           |  sqlserver-ee      ||
||  EngineVersion                    |  13.00.6300.2.v1   ||
||  LicenseModel                     |  license-included  ||
||  MaxIopsPerDbInstance             |                    ||

||  SupportsPerformanceInsights      |  True              ||
||  SupportsStorageAutoscaling       |  True              ||
||  SupportsStorageEncryption        |  True              ||
||  SupportsStorageThroughput        |  False             ||
||  Vpc                              |  True              ||
|+-----------------------------------+--------------------+|
|||                  AvailabilityZones                    |||
```

```
||+-----------------------------------------------------+||
|||                        Name                         |||
||+-----------------------------------------------------+||
|||  us-west-2a                                         |||
|||  us-west-2b                                         |||
|||  us-west-2c                                         |||
||+-----------------------------------------------------+||
|||             AvailableProcessorFeatures              |||
||+-----------------+-----------------+-----------------+||
|||  AllowedValues  |  DefaultValue   |       Name      |||
||+-----------------+-----------------+-----------------+||
|||  1,2,3,4        |  4              |  coreCount      |||
|||  1              |  1              |  threadsPerCore |||
||+-----------------+-----------------+-----------------+||
```

In addition, you can run the following commands for DB instance class processor information:

- `describe-db-instances` – Shows the processor information for the specified DB instance
- `describe-db-snapshots` – Shows the processor information for the specified DB snapshot
- `describe-valid-db-instance-modifications` – Shows the valid modifications to the processor for the specified DB instance

In the output of the preceding command, the values for the processor features are `null` if Optimize CPU is not configured.

Example of setting the number of CPU cores for a DB instance

The following example modifies *`mydbinstance`* by setting the number of CPU cores to 4 threadsPerCore as 1. Apply the changes immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit `--apply-immediately option`.

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.r7i.8xlarge \
    --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" \
    --apply-immediately
```

Example of returning to default processor settings for a DB instance

The following example modifies *mydbinstance* by returning it to the default processor values for it.

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.r7i.8xlarge \
    --use-default-processor-features \
    --apply-immediately
```

Microsoft SQL Server security

The Microsoft SQL Server database engine uses role-based security. The master user name that you specify when you create a DB instance is a SQL Server Authentication login that is a member of the `processadmin`, `public`, and `setupadmin` fixed server roles.

Any user who creates a database is assigned to the db_owner role for that database and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

The following server-level roles aren't available in Amazon RDS for SQL Server:

- bulkadmin
- dbcreator
- diskadmin
- securityadmin
- serveradmin
- sysadmin

The following server-level permissions aren't available on RDS for SQL Server DB instances:

- ALTER ANY DATABASE
- ALTER ANY EVENT NOTIFICATION
- ALTER RESOURCES
- ALTER SETTINGS (you can use the DB parameter group API operations to modify parameters; for more information, see Parameter groups for Amazon RDS)

- AUTHENTICATE SERVER
- CONTROL_SERVER
- CREATE DDL EVENT NOTIFICATION
- CREATE ENDPOINT
- CREATE SERVER ROLE
- CREATE TRACE EVENT NOTIFICATION
- DROP ANY DATABASE
- EXTERNAL ACCESS ASSEMBLY
- SHUTDOWN (You can use the RDS reboot option instead)
- UNSAFE ASSEMBLY
- ALTER ANY AVAILABILITY GROUP
- CREATE ANY AVAILABILITY GROUP

SSL support for Microsoft SQL Server DB instances

You can use SSL to encrypt connections between your applications and your Amazon RDS DB instances running Microsoft SQL Server. You can also force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

SSL is supported in all AWS Regions and for all supported SQL Server editions. For more information, see Using SSL with a Microsoft SQL Server DB instance.

Using SSL with a Microsoft SQL Server DB instance

You can use Secure Sockets Layer (SSL) to encrypt connections between your client applications and your Amazon RDS DB instances running Microsoft SQL Server. SSL support is available in all AWS regions for all supported SQL Server editions.

When you create a SQL Server DB instance, Amazon RDS creates an SSL certificate for it. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

There are 2 ways to use SSL to connect to your SQL Server DB instance:

- Force SSL for all connections — this happens transparently to the client, and the client doesn't have to do any work to use SSL.

  > **Note**
  >
  > When you set `rds.force_ssl` to 1 and use SSMS version 19.3, 20.0, and 20.2, check for the following:
  >
  > - Enable **Trust Server Certificate** in SSMS.
  > - Import the certificate in your system.

- Encrypt specific connections — this sets up an SSL connection from a specific client computer, and you must do work on the client to encrypt connections.

For information about Transport Layer Security (TLS) support for SQL Server, see TLS 1.2 support for Microsoft SQL Server.

Forcing connections to your DB instance to use SSL

You can force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

If you want to force SSL, use the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to `0 (off)`. Set the `rds.force_ssl` parameter to `1 (on)` to force connections to use SSL. The `rds.force_ssl` parameter is static, so after you change the value, you must reboot your DB instance for the change to take effect.

To force all connections to your DB instance to use SSL

1. Determine the parameter group that is attached to your DB instance:

   a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   b. In the top right corner of the Amazon RDS console, choose the AWS Region of your DB instance.

   c. In the navigation pane, choose **Databases**, and then choose the name of your DB instance to show its details.

   d. Choose the **Configuration** tab. Find the **Parameter group** in the section.

2. If necessary, create a new parameter group. If your DB instance uses the default parameter group, you must create a new parameter group. If your DB instance uses a nondefault parameter group, you can choose to edit the existing parameter group or to create a new parameter group. If you edit an existing parameter group, the change affects all DB instances that use that parameter group.

   To create a new parameter group, follow the instructions in Creating a DB parameter group in Amazon RDS.

3. Edit your new or existing parameter group to set the `rds.force_ssl` parameter to `true`. To edit the parameter group, follow the instructions in Modifying parameters in a DB parameter group in Amazon RDS.

4. If you created a new parameter group, modify your DB instance to attach the new parameter group. Modify the **DB Parameter Group** setting of the DB instance. For more information, see Modifying an Amazon RDS DB instance.

5. Reboot your DB instance. For more information, see Rebooting a DB instance.

Encrypting specific connections

You can force all connections to your DB instance to use SSL, or you can encrypt connections from specific client computers only. To use SSL from a specific client, you must obtain certificates for the client computer, import certificates on the client computer, and then encrypt the connections from the client computer.

> **Note**
>
> All SQL Server instances created after August 5, 2014, use the DB instance endpoint in the Common Name (CN) field of the SSL certificate. Prior to August 5, 2014, SSL certificate verification was not available for VPC-based SQL Server instances. If you have a VPC-based SQL Server DB instance that was created before August 5, 2014, and you want to use SSL certificate verification and ensure that the instance endpoint is included as the CN for the SSL certificate for that DB instance, then rename the instance. When you rename a DB instance, a new certificate is deployed and the instance is rebooted to enable the new certificate.

Obtaining certificates for client computers

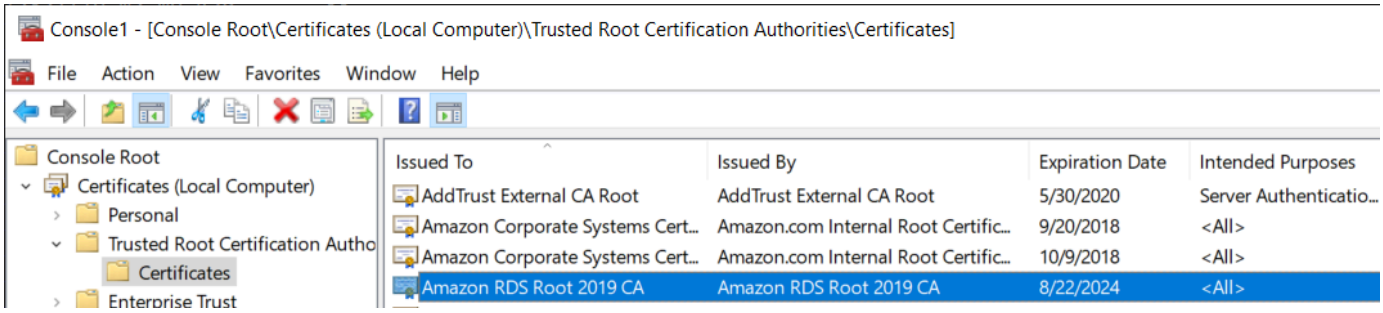
To encrypt connections from a client computer to an Amazon RDS DB instance running Microsoft SQL Server, you need a certificate on your client computer.

To obtain that certificate, download the certificate to your client computer. You can download a root certificate that works for all regions. You can also download a certificate bundle that contains both the old and new root certificate. In addition, you can download region-specific intermediate certificates. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

After you have downloaded the appropriate certificate, import the certificate into your Microsoft Windows operating system by following the procedure in the section following.

Importing certificates on client computers

You can use the following procedure to import your certificate into the Microsoft Windows operating system on your client computer.



To import the certificate into your Windows operating system:

1. On the **Start** menu, type **Run** in the search box and press **Enter**.
2. In the **Open** box, type **`MMC`** and then choose **OK**.
3. In the MMC console, on the **File** menu, choose **Add/Remove Snap-in**.
4. In the **Add or Remove Snap-ins** dialog box, for **Available snap-ins**, select **`Certificates`**, and then choose **Add**.

5. In the **Certificates snap-in** dialog box, choose **Computer account**, and then choose **Next**.
6. In the **Select computer** dialog box, choose **Finish**.
7. In the **Add or Remove Snap-ins** dialog box, choose **OK**.
8. In the MMC console, expand **Certificates**, open the context (right-click) menu for **Trusted Root Certification Authorities**, choose **All Tasks**, and then choose **Import**.
9. On the first page of the Certificate Import Wizard, choose **Next**.
10. On the second page of the Certificate Import Wizard, choose **Browse**. In the browse window, change the file type to **All files (*.*)** because .pem is not a standard certificate extension. Locate the .pem file that you downloaded previously.

> **Note**
>
> When connecting from Windows clients such as SQL Server Management Studio (SSMS), we recommend using the PKCS#7 (.p7b) certificate format instead of the global-bundle.pem file. The .p7b format ensures the complete certificate chain — including Root and Intermediate Certificate Authorities (CAs) — is correctly imported into the Windows Certificate Store. This prevents connection failures that can occur when mandatory encryption is enabled, as .pem imports may not install the full chain properly.

11. Choose **Open** to select the certificate file, and then choose **Next**.
12. On the third page of the Certificate Import Wizard, choose **Next**.
13. On the fourth page of the Certificate Import Wizard, choose **Finish**. A dialog box appears indicating that the import was successful.
14. In the MMC console, expand **Certificates**, expand **Trusted Root Certification Authorities**, and then choose **Certificates**. Locate the certificate to confirm it exists, as shown here.

Encrypting connections to an Amazon RDS DB instance running Microsoft SQL Server

After you have imported a certificate into your client computer, you can encrypt connections from the client computer to an Amazon RDS DB instance running Microsoft SQL Server.

For SQL Server Management Studio, use the following procedure. For more information about SQL Server Management Studio, see Use SQL Server management studio.

To encrypt connections from SQL Server Management Studio

1. Launch SQL Server Management Studio.
2. For **Connect to server**, type the server information, login user name, and password.
3. Choose **Options**.
4. Select **Encrypt connection**.
5. Choose **Connect**.
6. Confirm that your connection is encrypted by running the following query. Verify that the query returns `true` for `encrypt_option`.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

For any other SQL client, use the following procedure.

To encrypt connections from other SQL clients

1. Append `encrypt=true` to your connection string. This string might be available as an option, or as a property on the connection page in GUI tools.

> **Note**
>
> To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS SQL certificate to the Java CA certificate (cacerts) store. You can do this by using the keytool utility.

2. Confirm that your connection is encrypted by running the following query. Verify that the query returns `true` for `encrypt_option`.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

Configuring SQL Server security protocols and ciphers

You can turn certain security protocols and ciphers on and off using DB parameters. The security parameters that you can configure (except for TLS version 1.2) are shown in the following table.

DB parameter	Allowed values (default in bold)	Description
rds.tls10	**default**, enabled, disabled	TLS 1.0.
rds.tls11	**default**, enabled, disabled	TLS 1.1.
rds.tls12	**default**	TLS 1.2. You can't modify this value.
rds.fips	**0**, 1	When you set the parameter to 1, RDS forces the use of modules that are compliant with the Federal Information Processing Standard (FIPS) 140-2 standard. For more information, see Use SQL Server 2016 in FIPS 140-2-compliant mode in the Microsoft documentation.
rds.rc4	**default**, enabled, disabled	RC4 stream cipher.
rds.diffie-hellman	**default**, enabled, disabled	Diffie-Hellman key-exchange encryption.
rds.diffie-hellman-min-key-bit-length	**default**, 1024, 2048, 3072, 4096	Minimum bit length for Diffie-Hellman keys.
rds.curve25519	**default**, enabled, disabled	Curve25519 elliptic-curve encryption cipher. This parameter isn't supported for all engine versions.

DB parameter	Allowed values (default in bold)	Description
rds.3des168	**default**, enabled, disabled	Triple Data Encryption Standard (DES) encryption cipher with a 168-bit key length.

Note

For minor engine versions after 16.00.4120.1, 15.00.4365.2, 14.00.3465.1, 13.00.6435.1, and 12.00.6449.1, the default setting for the DB parameters `rds.tls10`, `rds.tls11`, `rds.rc4`, `rds.curve25519`, and `rds.3des168` is *disabled*. Otherwise the default setting is *enabled*.

For minor engine versions after 16.00.4120.1, 15.00.4365.2, 14.00.3465.1, 13.00.6435.1, and 12.00.6449.1, the default setting for `rds.diffie-hellman-min-key-bit-lengthis` 3072. Otherwise the default setting is 2048.

Use the following process to configure the security protocols and ciphers:

1. Create a custom DB parameter group.
2. Modify the parameters in the parameter group.
3. Associate the DB parameter group with your DB instance.

For more information on DB parameter groups, see Parameter groups for Amazon RDS.

Creating the security-related parameter group

Create a parameter group for your security-related parameters that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`sqlserver-ciphers-se-13`**.
   c. For **Description**, enter **`Parameter group for security protocols and ciphers`**.
5. Choose **Create**.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "Parameter group for security protocols and ciphers"
```

  For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "Parameter group for security protocols and ciphers"
```

Modifying security-related parameters

Modify the security-related parameters in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **sqlserver-ciphers-se-13**.
4. Under **Parameters**, filter the parameter list for **rds**.
5. Choose **Edit parameters**.
6. Choose **rds.tls10**.
7. For **Values**, choose **disabled**.
8. Choose **Save changes**.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --parameters
 "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --parameters
 "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

Associating the security-related parameter group with your DB instance

To associate the parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

Console

You can associate the parameter group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the parameter group with a new or existing DB instance.

To create a DB instance with the parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
```

```
    --allocated-storage 100 \
    --master-user-password secret123 \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --db-parameter-group-name sqlserver-ciphers-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --master-user-password secret123 ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --db-parameter-group-name sqlserver-ciphers-se-13
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

To modify a DB instance and associate the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --apply-immediately
```

Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

> **Note**
>
> Some applications are configured to connect to SQL Server DB instances only if they can successfully verify the certificate on the server.
> For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For information about using SSL/TLS with Microsoft SQL Server DB instances, see Using SSL with a Microsoft SQL Server DB instance.

Topics

- Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL
- Determining whether a client requires certificate verification in order to connect
- Updating your application trust store

Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Parameter groups for Amazon RDS.

Run the following query to get the current encryption option for all the open connections to a DB instance. The column `ENCRYPT_OPTION` returns `TRUE` if the connection is encrypted.

```
select SESSION_ID,
    ENCRYPT_OPTION,
    NET_TRANSPORT,
    AUTH_SCHEME
    from SYS.DM_EXEC_CONNECTIONS
```

This query shows only the current connections. It doesn't show whether applications that have connected and disconnected in the past have used SSL.

Determining whether a client requires certificate verification in order to connect

You can check whether different types of clients require certificate verification to connect.

> **Note**
>
> If you use connectors other than the ones listed, see the specific connector's documentation for information about how it enforces encrypted connections. For more information, see Connection modules for Microsoft SQL databases in the Microsoft SQL Server documentation.

SQL Server Management Studio

Check whether encryption is enforced for SQL Server Management Studio connections:

1. Launch SQL Server Management Studio.
2. For **Connect to server**, enter the server information, login user name, and password.

3. Choose **Options**.
4. Check if **Encrypt connection** is selected in the connect page.

For more information about SQL Server Management Studio, see Use SQL Server Management Studio.

Sqlcmd

The following example with the `sqlcmd` client shows how to check a script's SQL Server connection to determine whether successful connections require a valid certificate. For more information, see Connecting with sqlcmd in the Microsoft SQL Server documentation.

When using `sqlcmd`, an SSL connection requires verification against the server certificate if you use the `-N` command argument to encrypt connections, as in the following example.

```
$ sqlcmd -N -S dbinstance.rds.amazon.com -d ExampleDB
```

> **Note**
>
> If `sqlcmd` is invoked with the `-C` option, it trusts the server certificate, even if that doesn't match the client-side trust store.

ADO.NET

In the following example, the application connects using SSL, and the server certificate must be verified.

```
using SQLC = Microsoft.Data.SqlClient;

...

    static public void Main()
    {
        using (var connection = new SQLC.SqlConnection(
            "Server=tcp:dbinstance.rds.amazon.com;" +
            "Database=ExampleDB;User ID=LOGIN_NAME;" +
```

```
            "Password=YOUR_PASSWORD;" +
            "Encrypt=True;TrustServerCertificate=False;"
            ))
        {
            connection.Open();
            ...
        }
```

Java

In the following example, the application connects using SSL, and the server certificate must be verified.

```
String connectionUrl =
    "jdbc:sqlserver://dbinstance.rds.amazon.com;" +
    "databaseName=ExampleDB;integratedSecurity=true;" +
    "encrypt=true;trustServerCertificate=false";
```

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS certificate to the Java CA certificate store. For instructions, see Configuring the client for encryption in the Microsoft SQL Server documentation. You can also provide the trusted CA certificate file name directly by appending `trustStore=`*`path-to-certificate-trust-store-file`* to the connection string.

> **Note**
>
> If you use `TrustServerCertificate=true` (or its equivalent) in the connection string, the connection process skips the trust chain validation. In this case, the application connects even if the certificate can't be verified. Using `TrustServerCertificate=false` enforces certificate validation and is a best practice.

Updating your application trust store

You can update the trust store for applications that use Microsoft SQL Server. For instructions, see Encrypting specific connections. Also, see Configuring the client for encryption in the Microsoft SQL Server documentation.

If you are using an operating system other than Microsoft Windows, see the software distribution documentation for SSL/TLS implementation for information about adding a new root CA certificate. For example, OpenSSL and GnuTLS are popular options. Use the implementation method to add trust to the RDS root CA certificate. Microsoft provides instructions for configuring certificates on some systems.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Compliance program support for Microsoft SQL Server DB instances

AWS Services in scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see AWS services in scope by compliance program.

HIPAA support for Microsoft SQL Server DB instances

You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see HIPAA compliance.

Amazon RDS for SQL Server supports HIPAA for the following versions and editions:

- SQL Server 2022 Enterprise, Standard, and Web Editions
- SQL Server 2019 Enterprise, Standard, and Web Editions
- SQL Server 2017 Enterprise, Standard, and Web Editions

- SQL Server 2016 Enterprise, Standard, and Web Editions

To enable HIPAA support on your DB instance, set up the following three components.

Component	Details
Auditing	To set up auditing, set the parameter `rds.sqlserver_audit` to the value `fedramp_hipaa`. If your DB instance is not already using a custom DB parameter group, you must create a custom parameter group and attach it to your DB instance before you can modify the `rds.sqlserver_audit` parameter. For more information, see Parameter groups for Amazon RDS.
Transport encryption	To set up transport encryption, force all connections to your DB instance to use Secure Sockets Layer (SSL). For more information, see Forcing connections to your DB instance to use SSL.
Encryption at rest	To set up encryption at rest, you have two options: 1. If you're running SQL Server 2016–2022 Enterprise Edition or 2022 Standard Edition, you can use Transparent Data Encryption (TDE) to achieve encryption at rest. For more information, see Support for Transparent Data Encryption in SQL Server. 2. You can set up encryption at rest by using AWS Key Management Service (AWS KMS) encryption keys. For more information, see Encrypting Amazon RDS resources.

Microsoft SQL Server versions on Amazon RDS

You can specify any currently supported Microsoft SQL Server version when creating a new DB instance. You can specify the Microsoft SQL Server major version (such as Microsoft SQL Server 14.00), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is

specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

The following table shows the supported SQL Server versions for all editions and all AWS Regions, except where noted.

> **Note**
>
> You can also use the describe-db-engine-versions AWS CLI command to see a list of supported versions, as well as defaults for newly created DB instances. You can view the major versions of your SQL Server databases by running the describe-db-major-engine-versions AWS CLI command or by using the DescribeDBMajorEngineVersions RDS API operation.

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
SQL Server 2022	16.00.4236.2 (CU23)	`16.00.4236.2.v1`
	16.00.4230.2 (CU22 GDR)	`16.00.4230.2.v1`
	16.00.4225.2 (CU22)	`16.00.4225.2.v1`
	16.00.4215.2 (CU21)	`16.00.4215.2.v1`
	16.00.4210.1 (CU20 GDR)	`16.00.4210.1.v1`
	16.00.4205.1 (CU20)	`16.00.4205.1.v1`
	16.00.4195.2 (CU19)	`16.00.4195.2.v1`
	16.00.4185.3 (CU18)	`16.00.4185.3.v1`
	16.00.4175.1 (CU17)	`16.00.4175.1.v1`
	16.00.4165.4 (CU16)	`16.00.4165.4.v1`
	16.00.4150.1 (CU15)	`16.00.4150.1.v1`
	16.00.4140.3 (CU14 GDR)	`16.00.4140.3.v1`

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
	16.00.4135.4 (CU14)	`16.00.4135.4.v1`
	16.00.4131.2 (CU13)	`16.00.4131.2.v1`
	16.00.4125.3 (CU13)	`16.00.4125.3.v1`
	16.00.4120.1 (CU12 GDR)	`16.00.4120.1.v1`
	16.00.4115.5 (CU12)	`16.00.4115.5.v1`
	16.00.4105.2 (CU11)	`16.00.4105.2.v1`
	16.00.4095.4 (CU10)	`16.00.4095.4.v1`
	16.00.4085.2 (CU9)	`16.00.4085.2.v1`

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
SQL Server 2019	15.00.4455.2 (CU32 GDR)	`15.00.4455.2.v1`
	15.00.4445.1 (CU32 GDR)	`15.00.4445.1.v1`
	15.00.4440.1 (CU32 GDR)	`15.00.4440.1.v1`
	15.00.4435.7 (CU32)	`15.00.4435.7.v1`
	15.00.4430.1 (CU32)	`15.00.4430.1.v1`
	15.00.4420.2 (CU31)	`15.00.4420.2.v1`
	15.00.4415.2 (CU30)	`15.00.4415.2.v1`
	15.00.4410.1 (CU29 GDR)	`15.00.4410.1.v1`
	15.00.4395.2 (CU28)	`15.00.4395.2.v1`
	15.00.4390.2 (CU28)	`15.00.4390.2.v1`
	15.00.4385.2 (CU28)	`15.00.4385.2.v1`
	15.00.4382.1 (CU27)	`15.00.4382.1.v1`
	15.00.4375.4 (CU27)	`15.00.4375.4.v1`
	15.00.4365.2 (CU26)	`15.00.4365.2.v1`
	15.00.4355.3 (CU25)	`15.00.4355.3.v1`
	15.00.4345.5 (CU24)	`15.00.4345.5.v1`
	15.00.4335.1 (CU23)	`15.00.4335.1.v1`
	15.00.4322.2 (CU22)	`15.00.4322.2.v1`
	15.00.4316.3 (CU21)	`15.00.4316.3.v1`
	15.00.4312.2 (CU20)	`15.00.4312.2.v1`

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
	15.00.4236.7 (CU16)	`15.00.4236.7.v1`
	15.00.4198.2 (CU15)	`15.00.4198.2.v1`
	15.00.4153.1 (CU12)	`15.00.4153.1.v1`
	15.00.4073.23 (CU8)	`15.00.4073.23.v1`
	15.00.4043.16 (CU5)	`15.00.4043.16.v1`

Major version	Minor version	RDS API EngineVersion and CLI engine-version
SQL Server 2017	14.00.3515.1 (CU31 GDR)	14.00.3515.1.v1
	14.00.3505.1 (CU31 GDR)	14.00.3505.1.v1
	14.00.3500.1.(CU31 GDR)	14.00.3500.1.v1
	14.00.3495.9 (CU31 GDR)	14.00.3495.9.v1
	14.00.3485.1 (CU31 GDR)	14.00.3485.1.v1
	14.00.3480.1 (CU31)	14.00.3480.1.v1
	14.00.3475.1 (CU31)	14.00.3475.1.v1
	14.00.3471.2 (CU31)	14.00.3471.2.v1
	14.00.3465.1 (CU31)	14.00.3465.1.v1
	14.00.3460.9 (CU31)	14.00.3460.9.v1
	14.00.3451.2 (CU30)	14.00.3451.2.v1
	14.00.3421.10 (CU27)	14.00.3421.10.v1
	14.00.3401.7 (CU25)	14.00.3401.7.v1
	14.00.3381.3 (CU23)	14.00.3381.3.v1

	14.00.3281.6 (CU19)	14.00.3281.6.v1

Major version	Minor version	RDS API `EngineVersion` and CLI `engine-version`
SQL Server 2016	13.00.6475.1 (GDR)	`14.00.6475.1.v1`
	13.00.6470.1 (GDR)	`14.00.6470.1.v1`
	13.00.6465.1 (GDR)	`13.00.6465.1.v1`
	13.00.6460.7 (GDR)	`13.00.6460.7.v1`
	13.00.6455.2 (GDR)	`13.00.6455.2.v1`
	13.00.6450.1 (GDR)	`13.00.6450.1.v1`
	13.00.6445.1 (GDR)	`13.00.6445.1.v1`
	13.00.6441.1 (GDR)	`13.00.6441.1.v1`
	13.00.6435.1 (GDR)	`13.00.6435.1.v1`
	13.00.6430.49 (GDR)	`13.00.6430.49.v1`
	13.00.6419.1 (SP3 + Hotfix)	`13.00.6419.1.v1`
	13.00.6300.2 (SP3)	`13.00.6300.2.v1`

Version management in Amazon RDS

Amazon RDS includes flexible version management that enables you to control when and how your DB instance is patched or upgraded. This enables you to do the following for your DB engine:

- Maintain compatibility with database engine patch versions.
- Test new patch versions to verify that they work with your application before you deploy them in production.
- Plan and perform version upgrades to meet your service level agreements and timing requirements.

Microsoft SQL Server engine patching in Amazon RDS

Amazon RDS periodically aggregates official Microsoft SQL Server database patches into a DB instance engine version that's specific to Amazon RDS. For more information about the Microsoft SQL Server patches in each engine version, see Version and feature support on Amazon RDS.

Currently, you manually perform all engine upgrades on your DB instance. For more information, see Upgrades of the Microsoft SQL Server DB engine.

Deprecation schedule for major engine versions of Microsoft SQL Server on Amazon RDS

The following table displays the planned schedule of deprecations for major engine versions of Microsoft SQL Server.

Date	Information
July 14, 2026	Microsoft will stop critical patch updates for SQL Server 2016. For more informatio Server 2016 in the Microsoft documentation.
July 14, 2026	Amazon RDS plans to end support of Microsoft SQL Server 2016 on RDS for SQL Se remaining instances will be scheduled to migrate to SQL Server 2017 (latest minor more information, see Announcement: Amazon RDS for SQL Server ending suppor Server 2016. To avoid an automatic upgrade from Microsoft SQL Server 2016, you can upgrade a nient to you. For more information, see Upgrading a DB instance engine version.
January 15, 2026	Amazon RDS is starting to disable the creation of new RDS for SQL Server DB instar SQL Server 2016. For more information, see Announcement: Amazon RDS for SQL for Microsoft SQL Server 2016.
July 9, 2024	Microsoft will stop critical patch updates for SQL Server 2014. For more informatio Server 2014 in the Microsoft documentation.
June 1, 2024	Amazon RDS plans to end support of Microsoft SQL Server 2014 on RDS for SQL Se remaining instances will be scheduled to migrate to SQL Server 2016 (latest minor

Date	Information
	more information, see Announcement: Amazon RDS for SQL Server ending suppor major versions. To avoid an automatic upgrade from Microsoft SQL Server 2014, you can upgrade a nient to you. For more information, see Upgrading a DB instance engine version.
July 12, 2022	Microsoft will stop critical patch updates for SQL Server 2012. For more informatio Server 2012 in the Microsoft documentation.
June 1, 2022	Amazon RDS plans to end support of Microsoft SQL Server 2012 on RDS for SQL Se remaining instances will be scheduled to migrate to SQL Server 2014 (latest minor more information, see Announcement: Amazon RDS for SQL Server ending suppor major versions. To avoid an automatic upgrade from Microsoft SQL Server 2012, you can upgrade a nient to you. For more information, see Upgrading a DB instance engine version.
September 1, 2021	Amazon RDS is starting to disable the creation of new RDS for SQL Server DB instar SQL Server 2012. For more information, see Announcement: Amazon RDS for SQL for SQL Server 2012 major versions.
July 12, 2019	The Amazon RDS team deprecated support for Microsoft SQL Server 2008 R2 in Ju instances of Microsoft SQL Server 2008 R2 are migrating to SQL Server 2012 (lates available). To avoid an automatic upgrade from Microsoft SQL Server 2008 R2, you can upgrad convenient to you. For more information, see Upgrading a DB instance engine vers
April 25, 2019	Before the end of April 2019, you will no longer be able to create new Amazon RDS database instances using Microsoft SQL Server 2008R2.

Microsoft SQL Server features on Amazon RDS

The supported SQL Server versions on Amazon RDS include the following features. In general, a version also includes features from the previous versions, unless otherwise noted in the Microsoft documentation.

Topics

- Microsoft SQL Server 2022 features
- Microsoft SQL Server 2019 features
- Microsoft SQL Server 2017 features
- Microsoft SQL Server 2016 features
- Microsoft SQL Server 2014 end of support on Amazon RDS
- Microsoft SQL Server 2012 end of support on Amazon RDS
- Microsoft SQL Server 2008 R2 end of support on Amazon RDS
- Change data capture support for Microsoft SQL Server DB instances
- Features not supported and features with limited support

Microsoft SQL Server 2022 features

SQL Server 2022 includes many new features, such as the following:

- Parameter Sensitive Plan Optimization – allows multiple cached plans for a single parameterized statement, potentially reducing issues with parameter sniffing.
- SQL Server Ledger – provides the ability to cryptographically prove that your data hasn't been altered without authorization.
- Instant file initialization for transaction log file growth events – results in faster execution of log growth events up to 64MB, including for databases with TDE enabled.
- System page latch concurrency enhancements – reduces page latch contention while allocating and deallocating data pages and extents, providing significant performance enhancements to `tempdb` heavy workloads.

For the full list of SQL Server 2022 features, see What's new in SQL Server 2022 (16.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support.

Microsoft SQL Server 2019 features

SQL Server 2019 includes many new features, such as the following:

- Accelerated database recovery (ADR) – Reduces crash recovery time after a restart or a long-running transaction rollback.
- Intelligent Query Processing (IQP):
  - Row mode memory grant feedback – Corrects excessive grants automatically, that would otherwise result in wasted memory and reduced concurrency.
  - Batch mode on rowstore – Enables batch mode execution for analytic workloads without requiring columnstore indexes.
  - Table variable deferred compilation – Improves plan quality and overall performance for queries that reference table variables.
- Intelligent performance:
  - `OPTIMIZE_FOR_SEQUENTIAL_KEY` index option – Improves throughput for high-concurrency inserts into indexes.
  - Improved indirect checkpoint scalability – Helps databases with heavy DML workloads.
  - Concurrent Page Free Space (PFS) updates – Enables handling as a shared latch rather than an exclusive latch.
- Monitoring improvements:
  - `WAIT_ON_SYNC_STATISTICS_REFRESH` wait type – Shows accumulated instance-level time spent on synchronous statistics refresh operations.
  - Database-scoped configurations – Include `LIGHTWEIGHT_QUERY_PROFILING` and `LAST_QUERY_PLAN_STATS`.
  - Dynamic management functions (DMFs) – Include `sys.dm_exec_query_plan_stats` and `sys.dm_db_page_info`.
- Verbose truncation warnings – The data truncation error message defaults to include table and column names and the truncated value.
- Resumable online index creation – In SQL Server 2017, only resumable online index rebuild is supported.

For the full list of SQL Server 2019 features, see What's new in SQL Server 2019 (15.x) in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support.

Microsoft SQL Server 2017 features

SQL Server 2017 includes many new features, such as the following:

- Adaptive query processing
- Automatic plan correction (an automatic tuning feature)
- GraphDB
- Resumable index rebuilds

For the full list of SQL Server 2017 features, see What's new in SQL Server 2017 in the Microsoft documentation.

For a list of unsupported features, see Features not supported and features with limited support.

Microsoft SQL Server 2016 features

Amazon RDS supports the following features of SQL Server 2016:

- Always Encrypted
- JSON Support
- Operational Analytics
- Query Store
- Temporal Tables

For the full list of SQL Server 2016 features, see What's new in SQL Server 2016 in the Microsoft documentation.

Microsoft SQL Server 2014 end of support on Amazon RDS

SQL Server 2014 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2014 to the latest minor version of SQL Server 2016. For more information, see Version management in Amazon RDS.

Microsoft SQL Server 2012 end of support on Amazon RDS

SQL Server 2012 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2012 to the latest minor version of SQL Server 2016. For more information, see Version management in Amazon RDS.

Microsoft SQL Server 2008 R2 end of support on Amazon RDS

SQL Server 2008 R2 has reached its end of support on Amazon RDS.

RDS is upgrading all existing DB instances that are still using SQL Server 2008 R2 to the latest minor version of SQL Server 2012. For more information, see Version management in Amazon RDS.

Change data capture support for Microsoft SQL Server DB instances

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables, and stores metadata about each change that you can access later. For more information, see Change data capture in the Microsoft documentation.

Amazon RDS supports CDC for the following SQL Server editions and versions:

- Microsoft SQL Server Enterprise Edition (All versions)
- Microsoft SQL Server Standard Edition:
  - 2022
  - 2019
  - 2017
  - 2016 version 13.00.4422.0 SP1 CU2 and later

To use CDC with your Amazon RDS DB instances, first enable or disable CDC at the database level by using RDS-provided stored procedures. After that, any user that has the `db_owner` role for that database can use the native Microsoft stored procedures to control CDC on that database. For more information, see Using change data capture for Amazon RDS for SQL Server.

You can use CDC and AWS Database Migration Service to enable ongoing replication from SQL Server DB instances.

Features not supported and features with limited support

The following Microsoft SQL Server features aren't supported on Amazon RDS:

- Backing up to Microsoft Azure Blob Storage
- Buffer pool extension
- Custom password policies
- Data Quality Services
- Database Log Shipping
- Database snapshots (Amazon RDS supports only DB instance snapshots)
- Extended stored procedures, including xp_cmdshell
- FILESTREAM support
- File tables
- Machine Learning and R Services (requires OS access to install it)
- Maintenance plans
- Performance Data Collector
- Policy-Based Management
- PolyBase
- Replication
- Server-level triggers
- Service Broker endpoints
- Stretch database
- TRUSTWORTHY database property (requires sysadmin role)
- T-SQL endpoints (all operations using CREATE ENDPOINT are unavailable)
- WCF Data Services

The following Microsoft SQL Server features have limited support on Amazon RDS:

- Distributed queries/linked servers. For more information, see Implement linked servers with Amazon RDS for Microsoft SQL Server.
- Common Runtime Language (CLR). On RDS for SQL Server 2016 and lower versions, CLR is supported in SAFE mode and using assembly bits only. CLR isn't supported on RDS for SQL

Server 2017 and higher versions. For more information, see Common Runtime Language Integration in the Microsoft documentation.

- Link servers with Oracle OLEDB in Amazon RDS for SQL Server. For more information, see Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server.

The following features aren't supported on Amazon RDS with SQL Server 2022:

- Suspend database for snapshot
- External Data Source
- Backup and restore to S3 compatible object storage
- Object store integration
- TLS 1.3 and MS-TDS 8.0
- Backup compression offloading with QAT
- SQL Server Analysis Services (SSAS)
- Database mirroring with Multi-AZ deployments. SQL Server Always On is the only supported method with Multi-AZ deployments.

Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary replica so database operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the passive secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS manages failover by actively monitoring your Multi-AZ deployment and initiating a failover when a problem with your primary occurs. Failover doesn't occur unless the standby and primary are fully in sync. Amazon RDS actively maintains your Multi-AZ deployment by automatically repairing unhealthy DB instances and re-establishing synchronous replication. You don't have to manage anything. Amazon RDS handles the primary, the witness, and the

standby instance for you. When you set up SQL Server Multi-AZ, RDS configures passive secondary instances for all of the databases on the instance.

For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.

Using Transparent Data Encryption to encrypt data at rest

Amazon RDS supports Microsoft SQL Server Transparent Data Encryption (TDE), which transparently encrypts stored data. Amazon RDS uses option groups to enable and configure these features. For more information about the TDE option, see Support for Transparent Data Encryption in SQL Server.

Functions and stored procedures for Amazon RDS for Microsoft SQL Server

Following, you can find a list of the Amazon RDS functions and stored procedures that help automate SQL Server tasks.

Task type	Procedure or function	Where it's used
Administrative tasks	`rds_drop_database`	Dropping a database in an Amazon RDS for Microsoft SQL Server DB instance
	`rds_failover_time`	Determining the last failover time for Amazon RDS for SQL Server
	`rds_manage_view_db_permission`	Deny or allow viewing database names for Amazon RDS for SQL Server
	`rds_modify_db_name`	Renaming a Amazon RDS for Microsoft SQL Server database in a Multi-AZ deployment

Task type	Procedure or function	Where it's used
	`rds_read_error_log`	Viewing error and agent logs
	`rds_set_configuration`	This operation is used to set various DB instance configurations: • Change data capture for Multi-AZ instances • Setting the retention period for trace and dump files • Compressing backup files
	`rds_set_database_online`	Transitioning a Amazon RDS for SQL Server database from OFFLINE to ONLINE

	`rds_set_system_database_sync_objects`
	
	`rds_fn_get_system_database_sync_objects`
	
	`rds_fn_server_object_last_sync_time`
		Turning on SQL Server Agent job replication

Task type	Procedure or function	Where it's used
	`rds_show_configuration`	To see the values that are set using `rds_set_configuration`, see these topics: • Change data capture for Multi-AZ instances • Setting the retention period for trace and dump files
	`rds_shrink_tempdbfile`	Shrinking the tempdb database
Change data capture (CDC)	`rds_cdc_disable_db`	Disabling CDC
	`rds_cdc_enable_db`	Enabling CDC
Database Mail	`rds_fn_sysmail_allitems`	Viewing messages, logs, and attachments
	`rds_fn_sysmail_event_log`	Viewing messages, logs, and attachments
	`rds_fn_sysmail_mailattachments`	Viewing messages, logs, and attachments
	`rds_sysmail_control`	This operation is used in starting and stopping the mail queue: • Starting the mail queue • Stopping the mail queue

Task type	Procedure or function	Where it's used
	`rds_sysmail_delete_mailitems_sp`	Deleting messages
Native backup and restore	`rds_backup_database`	Backing up a database
	`rds_cancel_task`	Canceling a task
	`rds_finish_restore`	Finishing a database restore
	`rds_restore_database`	Restoring a database
	`rds_restore_log`	Restoring a log
Amazon S3 file transfer	`rds_delete_from_filesystem`	Deleting files on the RDS DB instance
	`rds_download_from_s3`	Downloading files from an Amazon S3 bucket to a SQL Server DB instance
	`rds_gather_file_details`	Listing files on the RDS DB instance

Task type	Procedure or function	Where it's used
	`rds_upload_to_s3`	Uploading files from a SQL Server DB instance to an Amazon S3 bucket
Microsoft Distributed Transaction Coordinator (MSDTC)	`rds_msdtc_transaction_tracing`	Using transaction tracing
SQL Server Audit	`rds_fn_get_audit_file`	Viewing audit logs

Transparent Data Encryption	`rds_backup_tde_certificate`
	`rds_drop_tde_certificate`
	`rds_restore_tde_certificate`
	`rds_fn_list_user_tde_certificates`
		Support for Transparent Data Encryption in SQL Server

Task type	Procedure or function	Where it's used
Microsoft Business Intelligence (MSBI)	`rds_msbi_task`	This operation is used with SQL Server Analysis Services (SSAS): • Deploying SSAS projects on Amazon RDS • Adding a domain user as a database administrator • Backing up an SSAS database • Restoring an SSAS database This operation is also used with SQL Server Integration Services (SSIS): • Administrative permissions on SSISDB • Deploying an SSIS project This operation is also used with SQL Server Reporting Services (SSRS): • Granting access to domain users • Revoking system-level permissions
	`rds_fn_task_status`	This operation shows the status of MSBI tasks: • SSAS: Monitoring the status of a deployment task • SSIS: Monitoring the status of a deployment task • SSRS: Monitoring the status of a task
SSIS	`rds_drop_ssis_database`	Dropping the SSISDB database
	`rds_sqlagent_proxy`	Creating an SSIS proxy

Task type	Procedure or function	Where it's used
SSRS	`rds_drop_ssrs_databases`	Deleting the SSRS databases
Resource Governor	`rds_create_resource_pool`	Create resource Pool
	`rds_alter_resource_pool`	Alter resource pool
	`rds_drop_resource_pool`	Drop resource pool
	`rds_create_workload_group`	Create workload group
	`rds_alter_workload_group`	Alter workload group
	`rds_drop_workload_group`	Drop workload group
	`rds_create_classifier_function`	Create and register classifier function

Task type	Procedure or function	Where it's used
	`rds_drop_classifier_function`	Drop classifier function
	`rds_alter_resource_governor_configuration`	Resource governor configuration changes
	`rds_bind_tempdb_metadata_to_resource_pool`	Bind TempDB to a resource pool
	`rds_unbind_tempdb_metadata_from_resource_pool`	Unbind TempDB from a resource pool
	`rds_cleanup_resource_governor`	Cleanup resource governor

Local time zone for Microsoft SQL Server DB instances

The time zone of an Amazon RDS DB instance running Microsoft SQL Server is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the AWS Management Console, the Amazon RDS API CreateDBInstance action, or the AWS CLI create-db-instance command.

If your DB instance is part of a Multi-AZ deployment (using SQL Server DBM or AGs), then when you fail over, your time zone remains the local time zone that you set. For more information, see Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups.

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see Restoring a DB instance to a specified time for Amazon RDS.

The following are limitations to setting the local time zone on your DB instance:

- You can't modify the time zone of an existing SQL Server DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Supported time zones

You can set your local time zone to one of the values listed in the following table.

Time zone	Standard time offset	Description	Notes
Afghanistan Standard Time	(UTC+04:30)	Kabul	This time zone doesn't observe daylight saving time.
Alaskan Standard Time	(UTC–09:00)	Alaska	
Aleutian Standard Time	(UTC–10:00)	Aleutian Islands	

Time zone	Standard time offset	Description	Notes
Altai Standard Time	(UTC+07:00)	Barnaul, Gorno-Altaysk	
Arab Standard Time	(UTC+03:00)	Kuwait, Riyadh	This time zone doesn't observe daylight saving time.
Arabian Standard Time	(UTC+04:00)	Abu Dhabi, Muscat	
Arabic Standard Time	(UTC+03:00)	Baghdad	This time zone doesn't observe daylight saving time.
Argentina Standard Time	(UTC–03:00)	City of Buenos Aires	This time zone doesn't observe daylight saving time.
Astrakhan Standard Time	(UTC+04:00)	Astrakhan, Ulyanovsk	
Atlantic Standard Time	(UTC–04:00)	Atlantic Time (Canada)	
AUS Central Standard Time	(UTC+09:30)	Darwin	This time zone doesn't observe daylight saving time.
Aus Central W. Standard Time	(UTC+08:45)	Eucla	
AUS Eastern Standard Time	(UTC+10:00)	Canberra, Melbourne, Sydney	

Time zone	Standard time offset	Description	Notes
Azerbaijan Standard Time	(UTC+04:00)	Baku	
Azores Standard Time	(UTC–01:00)	Azores	
Bahia Standard Time	(UTC–03:00)	Salvador	
Bangladesh Standard Time	(UTC+06:00)	Dhaka	This time zone doesn't observe daylight saving time.
Belarus Standard Time	(UTC+03:00)	Minsk	This time zone doesn't observe daylight saving time.
Bougainville Standard Time	(UTC+11:00)	Bougainville Island	
Canada Central Standard Time	(UTC–06:00)	Saskatchewan	This time zone doesn't observe daylight saving time.
Cape Verde Standard Time	(UTC–01:00)	Cabo Verde Is.	This time zone doesn't observe daylight saving time.
Caucasus Standard Time	(UTC+04:00)	Yerevan	
Cen. Australia Standard Time	(UTC+09:30)	Adelaide	
Central America Standard Time	(UTC–06:00)	Central America	This time zone doesn't observe daylight saving time.

Time zone	Standard time offset	Description	Notes
Central Asia Standard Time	(UTC+06:00)	Astana	This time zone doesn't observe daylight saving time.
Central Brazilian Standard Time	(UTC–04:00)	Cuiaba	
Central Europe Standard Time	(UTC+01:00)	Belgrade, Bratislava, Budapest, Ljubljana, Prague	
Central European Standard Time	(UTC+01:00)	Sarajevo, Skopje, Warsaw, Zagreb	
Central Pacific Standard Time	(UTC+11:00)	Solomon Islands, New Caledonia	This time zone doesn't observe daylight saving time.
Central Standard Time	(UTC–06:00)	Central Time (US and Canada)	
Central Standard Time (Mexico)	(UTC–06:00)	Guadalajara, Mexico City, Monterrey	
Chatham Islands Standard Time	(UTC+12:45)	Chatham Islands	
China Standard Time	(UTC+08:00)	Beijing, Chongqing, Hong Kong, Urumqi	This time zone doesn't observe daylight saving time.
Cuba Standard Time	(UTC–05:00)	Havana	

Time zone	Standard time offset	Description	Notes
Dateline Standard Time	(UTC–12:00)	International Date Line West	This time zone doesn't observe daylight saving time.
E. Africa Standard Time	(UTC+03:00)	Nairobi	This time zone doesn't observe daylight saving time.
E. Australia Standard Time	(UTC+10:00)	Brisbane	This time zone doesn't observe daylight saving time.
E. Europe Standard Time	(UTC+02:00)	Chisinau	
E. South America Standard Time	(UTC–03:00)	Brasilia	
Easter Island Standard Time	(UTC–06:00)	Easter Island	
Eastern Standard Time	(UTC–05:00)	Eastern Time (US and Canada)	
Eastern Standard Time (Mexico)	(UTC–05:00)	Chetumal	
Egypt Standard Time	(UTC+02:00)	Cairo	
Ekaterinburg Standard Time	(UTC+05:00)	Ekaterinburg	
Fiji Standard Time	(UTC+12:00)	Fiji	

Time zone	Standard time offset	Description	Notes
FLE Standard Time	(UTC+02:00)	Helsinki, Kyiv, Riga, Sofia, Tallinn, Vilnius	
Georgian Standard Time	(UTC+04:00)	Tbilisi	This time zone doesn't observe daylight saving time.
GMT Standard Time	(UTC)	Dublin, Edinburgh, Lisbon, London	This time zone isn't the same as Greenwich Mean Time. This time zone does observe daylight saving time.
Greenland Standard Time	(UTC–03:00)	Greenland	
Greenwich Standard Time	(UTC)	Monrovia, Reykjavik	This time zone doesn't observe daylight saving time.
GTB Standard Time	(UTC+02:00)	Athens, Bucharest	
Haiti Standard Time	(UTC–05:00)	Haiti	
Hawaiian Standard Time	(UTC–10:00)	Hawaii	
India Standard Time	(UTC+05:30)	Chennai, Kolkata, Mumbai, New Delhi	This time zone doesn't observe daylight saving time.
Iran Standard Time	(UTC+03:30)	Tehran	

Time zone	Standard time offset	Description	Notes
Israel Standard Time	(UTC+02:00)	Jerusalem	
Jordan Standard Time	(UTC+02:00)	Amman	
Kaliningrad Standard Time	(UTC+02:00)	Kaliningrad	
Kamchatka Standard Time	(UTC+12:00)	Petropavlovsk-Kamchatsky – Old	
Korea Standard Time	(UTC+09:00)	Seoul	This time zone doesn't observe daylight saving time.
Libya Standard Time	(UTC+02:00)	Tripoli	
Line Islands Standard Time	(UTC+14:00)	Kiritimati Island	
Lord Howe Standard Time	(UTC+10:30)	Lord Howe Island	
Magadan Standard Time	(UTC+11:00)	Magadan	This time zone doesn't observe daylight saving time.
Magallanes Standard Time	(UTC–03:00)	Punta Arenas	
Marquesas Standard Time	(UTC–09:30)	Marquesas Islands	
Mauritius Standard Time	(UTC+04:00)	Port Louis	This time zone doesn't observe daylight saving time.
Middle East Standard Time	(UTC+02:00)	Beirut	
Montevideo Standard Time	(UTC–03:00)	Montevideo	

Time zone	Standard time offset	Description	Notes
Morocco Standard Time	(UTC+01:00)	Casablanca	
Mountain Standard Time	(UTC–07:00)	Mountain Time (US and Canada)	
Mountain Standard Time (Mexico)	(UTC–07:00)	Chihuahua, La Paz, Mazatlan	
Myanmar Standard Time	(UTC+06:30)	Yangon (Rangoon)	This time zone doesn't observe daylight saving time.
N. Central Asia Standard Time	(UTC+07:00)	Novosibirsk	
Namibia Standard Time	(UTC+02:00)	Windhoek	
Nepal Standard Time	(UTC+05:45)	Kathmandu	This time zone doesn't observe daylight saving time.
New Zealand Standard Time	(UTC+12:00)	Auckland, Wellington	
Newfoundland Standard Time	(UTC–03:30)	Newfoundland	
Norfolk Standard Time	(UTC+11:00)	Norfolk Island	
North Asia East Standard Time	(UTC+08:00)	Irkutsk	
North Asia Standard Time	(UTC+07:00)	Krasnoyarsk	
North Korea Standard Time	(UTC+09:00)	Pyongyang	

Time zone	Standard time offset	Description	Notes

Licensing Microsoft SQL Server on Amazon RDS

When you set up an Amazon RDS DB instance for Microsoft SQL Server, the software license is included.

This means that you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software. Amazon RDS pricing includes the software license, underlying hardware resources, and Amazon RDS management capabilities.

Amazon RDS supports the following Microsoft SQL Server editions:

- Enterprise
- Standard
- Web
- Express

> **Note**
>
> SQL Server Web Edition is designed for Web hosters and Web VAPs to host public and internet-accessible web pages, websites, web applications, and web services. This level of support is required for compliance with Microsoft's usage rights. For more information, see AWS service terms.

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM), Always On Availability Groups (AGs), and block level replication for SQL Server Web Edition. There are no additional licensing requirements for Multi-AZ deployments. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.

Restoring license-terminated DB instances

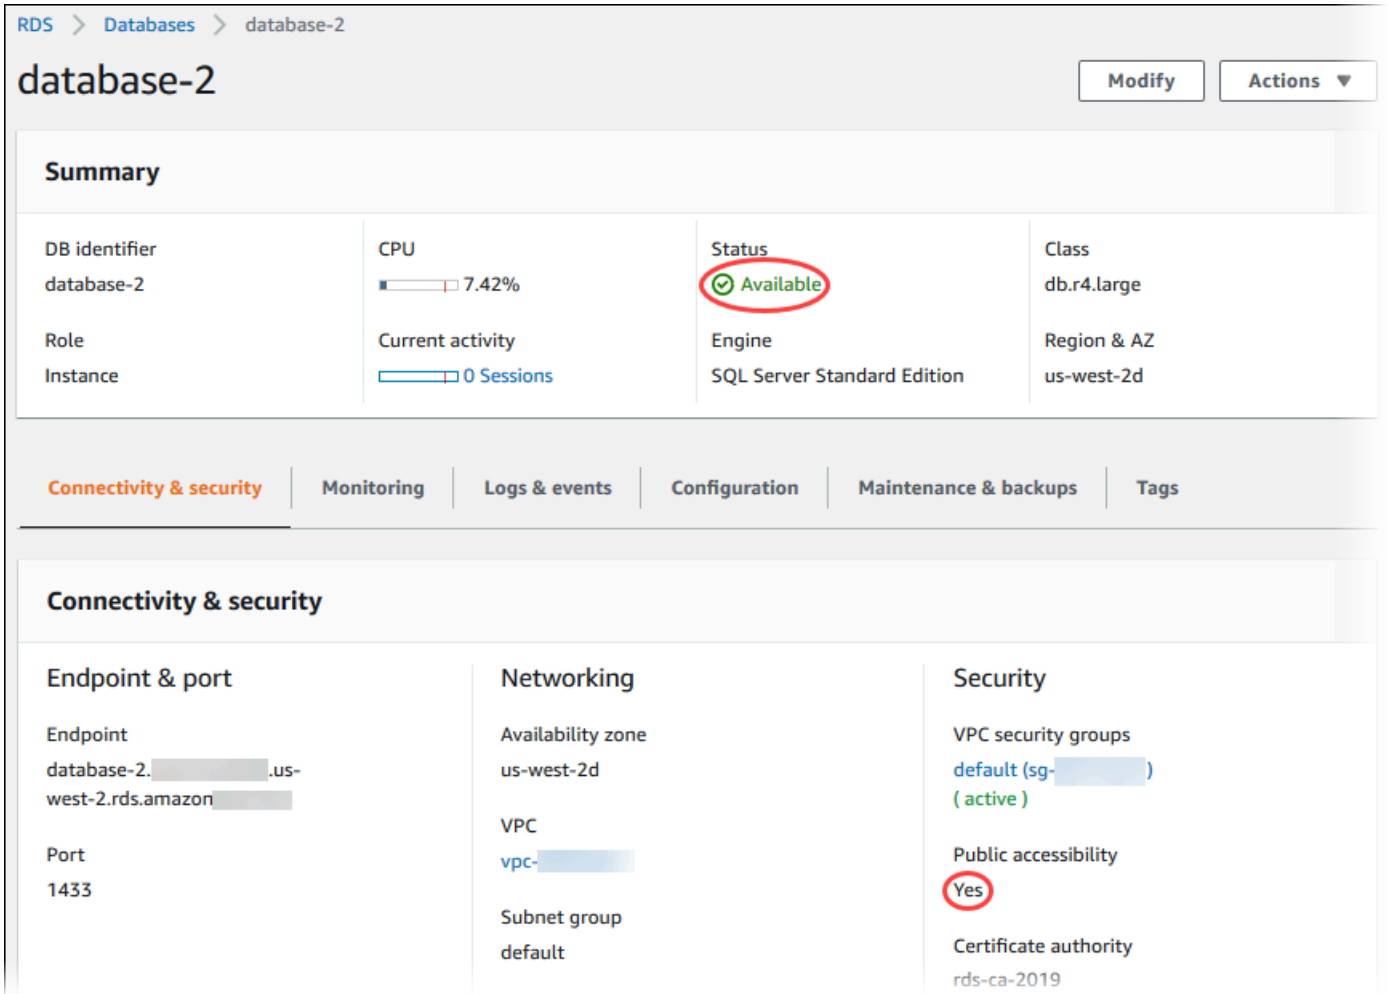
Amazon RDS takes snapshots of license-terminated DB instances. If your instance is terminated for licensing issues, you can restore it from the snapshot to a new DB instance. New DB instances have a license included.

For more information, see Restoring license-terminated DB instances for Amazon RDS for SQL Server.

Development and test

For development and testing scenarios, you can use Express Edition for many development, testing, and other non-production needs. You can also use Developer Edition, which includes all SQL Server Enterprise Edition features but is licensed only for non-production use. You can download and install SQL Server Developer Edition on RDS for SQL Server. For more information, see Working with SQL Server Developer Edition on RDS for SQL Server using a Custom Engine Version (CEV) with Bring Your Own Media (BYOM).You can also download and install SQL Server Developer Edition on RDS Custom for SQL Server using the same approach. For more information, see Preparing a CEV using Bring Your Own Media (BYOM). For more information on the difference between SQL Server editions, see Editions and supported features of SQL Server 2019 in the Microsoft documentation.

Connecting to your Microsoft SQL Server DB instance



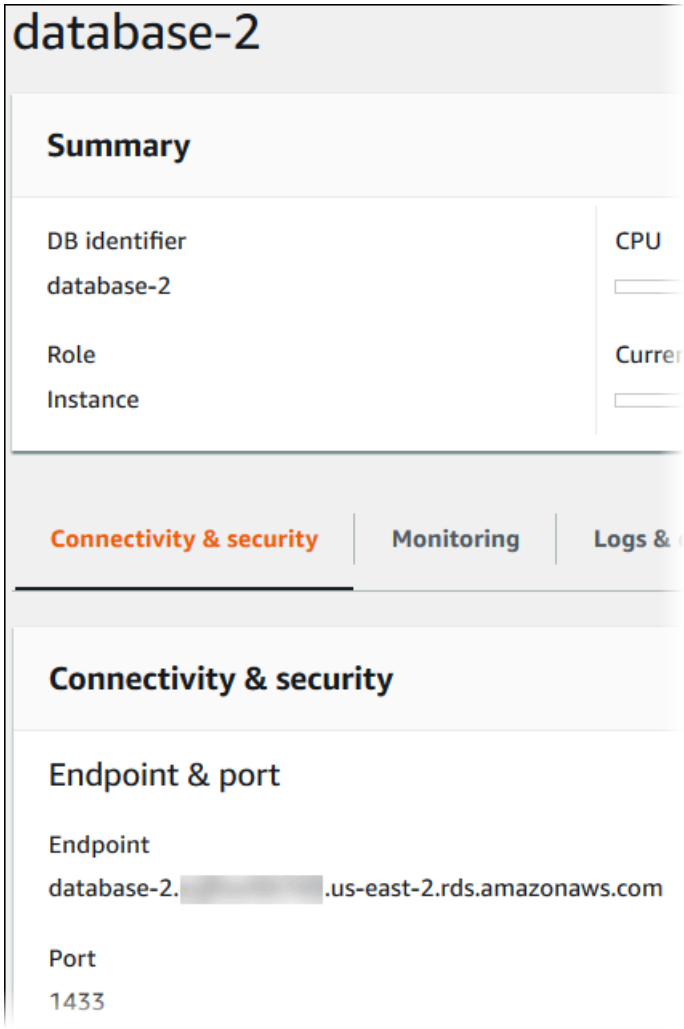
After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to your DB instance by using either Microsoft SQL Server Management Studio (SSMS) or SQL Workbench/J.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to a Microsoft SQL Server DB instance.

Before you connect

Before you can connect to your DB instance, it has to be available and accessible.

1. Make sure that its status is `available`. You can check this on the details page for your instance in the AWS Management Console or by using the describe-db-instances AWS CLI command.



2. Make sure that it is accessible to your source. Depending on your scenario, it may not need to be publicly accessible. For more information, see Amazon VPC and Amazon RDS.
3. Make sure that the inbound rules of your VPC security group allow access to your DB instance. For more information, see Can't connect to Amazon RDS DB instance.

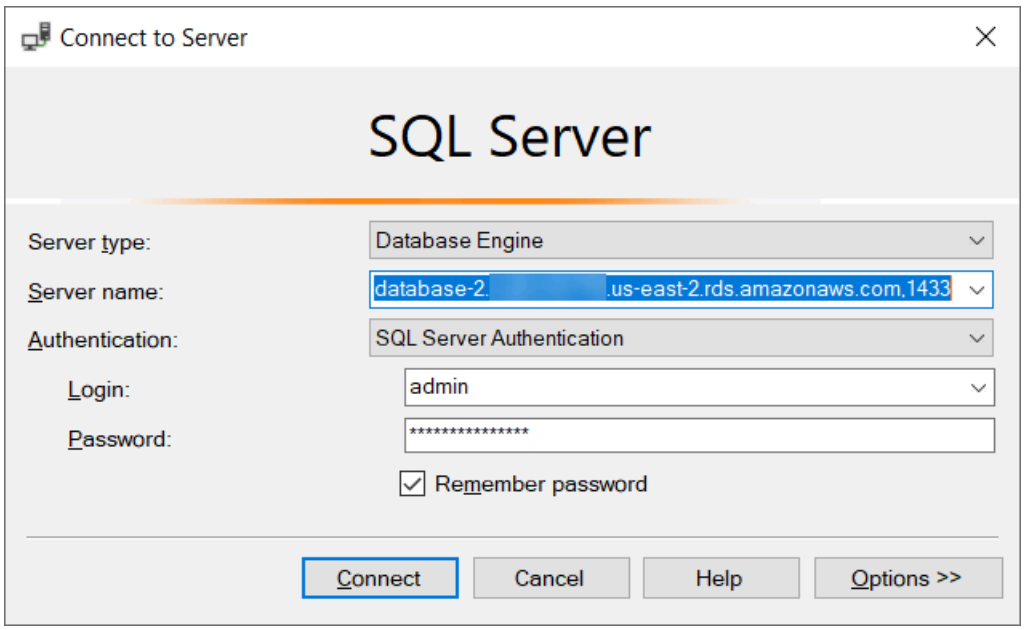
Finding the DB instance endpoint and port number

You need both the endpoint and the port number to connect to the DB instance.

To find the endpoint and port

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the Domain Name System (DNS) name (endpoint) and port number for your DB instance:
    a. Open the RDS console and choose **Databases** to display a list of your DB instances.
    b. Choose the SQL Server DB instance name to display its details.
    c. On the **Connectivity & security** tab, copy the endpoint.

d. Note the port number.



Connecting to your DB instance with Microsoft SQL Server Management Studio

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS). To download a standalone version of this utility, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Start SQL Server Management Studio.

   The **Connect to Server** dialog box appears.

2. Provide the information for your DB instance:

   a. For **Server type**, choose **Database Engine**.

   b. For **Server name**, enter the DNS name (endpoint) and port number of your DB instance, separated by a comma.

   > **Important**
   >
   > Change the colon between the endpoint and port number to a comma.

   Your server name should look like the following example.

   ```
   database-2.cg034itsfake.us-east-1.rds.amazonaws.com,1433
   ```

   c. For **Authentication**, choose **SQL Server Authentication**.

   d. For **Login**, enter the master user name for your DB instance.

   e. For **Password**, enter the password for your DB instance.

3. Choose **Connect**.

   After a few moments, SSMS connects to your DB instance.

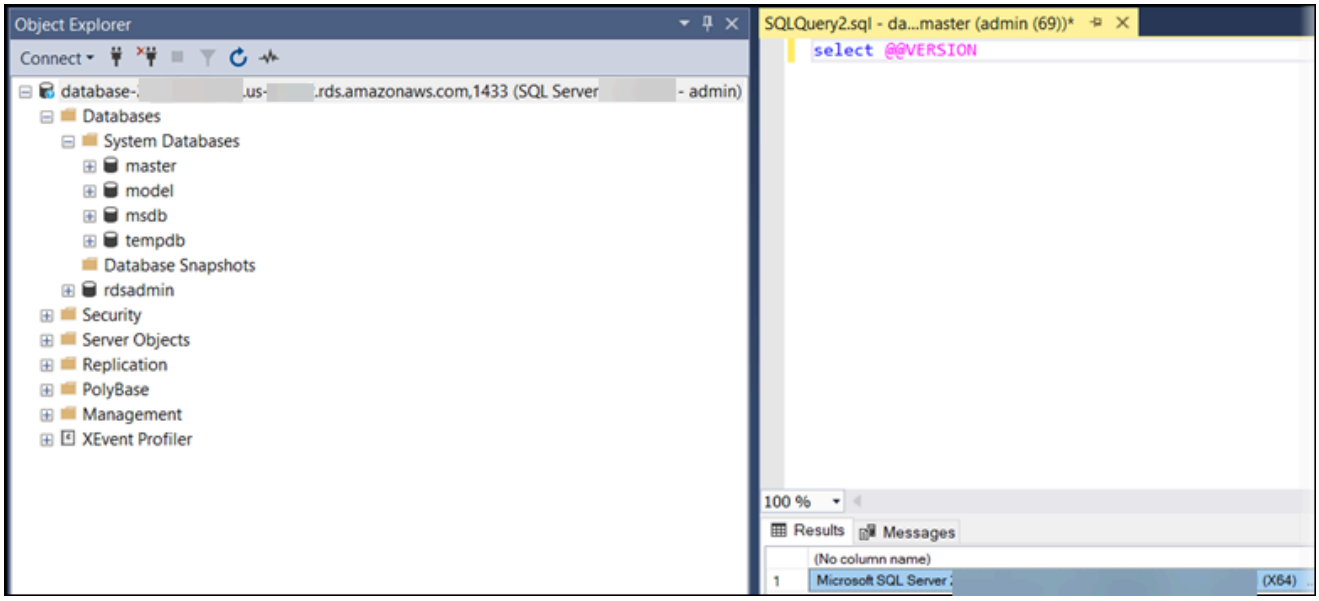
   If you can't connect to your DB instance, see Security group considerations and Troubleshooting connections to your SQL Server DB instance.

4. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (`master`, `model`, `msdb`, and `tempdb`). To explore the system databases, do the following:

   a. In SSMS, on the **View** menu, choose **Object Explorer**.

   b. Expand your DB instance, expand **Databases**, and then expand **System Databases**.

5. Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks. For more information, see Common DBA tasks for Amazon RDS for Microsoft SQL Server.



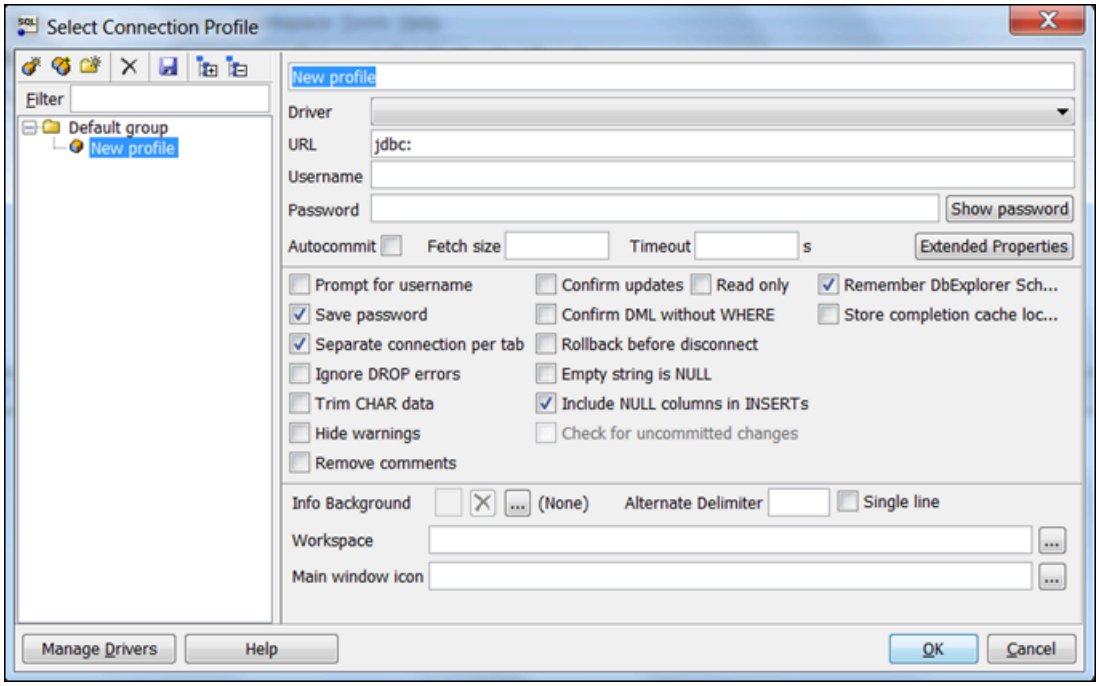
6. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In SSMS, on the **File** menu point to **New** and then choose **Query with Current Connection**.

   b. Enter the following SQL query.

```
select @@VERSION
```

   c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.

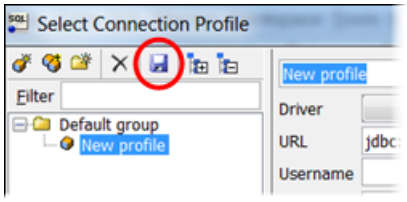


Connecting to your DB instance with SQL Workbench/J

This example shows how to connect to a DB instance running the Microsoft SQL Server database engine by using the SQL Workbench/J database tool. To download SQL Workbench/J, see SQL Workbench/J.

SQL Workbench/J uses JDBC to connect to your DB instance. You also need the JDBC driver for SQL Server. To download this driver, see Download Microsoft JDBC Driver for SQL Server.

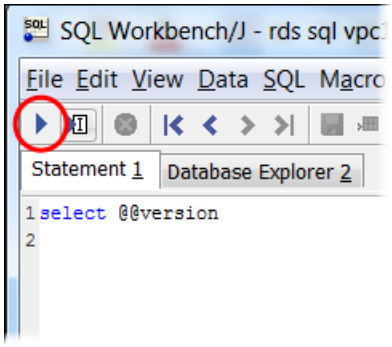
To connect to a DB instance using SQL Workbench/J



1. Open SQL Workbench/J. The **Select Connection Profile** dialog box appears, as shown following.

2. In the first box at the top of the dialog box, enter a name for the profile.
3. For **Driver**, choose **`SQL JDBC 4.0`**.
4. For **URL**, enter **`jdbc:sqlserver://`**, then enter the endpoint of your DB instance. For example, the URL value might be the following.

```
jdbc:sqlserver://sqlsvr-pdz.abcd12340.us-west-2.rds.amazonaws.com:1433
```



5. For **Username**, enter the master user name for the DB instance.
6. For **Password**, enter the password for the master user.
7. Choose the save icon in the dialog toolbar, as shown following.

8. Choose **OK**. After a few moments, SQL Workbench/J connects to your DB instance. If you can't connect to your DB instance, see Security group considerations and Troubleshooting connections to your SQL Server DB instance.
9. In the query pane, enter the following SQL query.

```
select @@VERSION
```

10. Choose the `Execute` icon in the toolbar, as shown following.

The query returns the version information for your DB instance, similar to the following.

```
Microsoft SQL Server 2017 (RTM-CU22) (KB4577467) - 14.0.3356.20 (X64)
```

Security group considerations

To connect to your DB instance, your DB instance must be associated with a security group. This security group contains the IP addresses and network configuration that you use to access the DB instance. You might have associated your DB instance with an appropriate security group when you created your DB instance. If you assigned a default, no-configured security group when you created your DB instance, your DB instance firewall prevents connections.

In some cases, you might need to create a new security group to make access possible. For instructions on creating a new security group, see Controlling access with security groups. For a topic that walks you through the process of setting up rules for your VPC security group, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

After you have created the new security group, modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance.

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Using SSL with a Microsoft SQL Server DB instance.

Troubleshooting connections to your SQL Server DB instance

The following table shows error messages that you might encounter when you attempt to connect to your SQL Server DB instance.

Issue	Troubleshooting suggestions
Could not open a connection to SQL Server – Microsoft SQL Server, Error: 53	Make sure that you specified the server name correctly. For **Server name**, enter the DNS name and port number of your sample DB instance, separated by a comma. **Important** If you have a colon between the DNS name and port number, change the colon to a comma. Your server name should look like the following example. `sample-instance.cg034itsfake.us-east-1.rds.amazonaws.com,1433`
No connection could be made because the target machine actively refused it – Microsoft SQL Server, Error: 10061	You were able to reach the DB instance but the connection was refused. This issue is usually caused by specifying the user name or password incorrectly. Verify the user name and password, then retry.
A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible... The wait operation timed out – Microsoft SQL Server, Error: 258	The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group. For more information, see Security in Amazon RDS . Your database instance must be publicly accessible. To connect to it from outside of the VPC, the instance must have a public IP address assigned.

Note

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Working with SQL Server Developer Edition on RDS for SQL Server

RDS for SQL Server supports SQL Server Developer Edition. Developer Edition includes all SQL Server Enterprise Edition features but is licensed only for non-production use. You can create RDS for SQL Server Developer Edition instances using your own installation media through the custom engine version (CEV) feature.

Benefits

You can use RDS for SQL Server Developer Edition to:

- Lower costs in development and test environments while maintaining feature parity with production databases.
- Access Enterprise Edition capabilities in non-production environments without Enterprise licensing fees.
- Use Amazon RDS-automated management features, including backups, patching, and monitoring.

> **Note**
>
> SQL Server Developer Edition is licensed for development and testing purposes only and cannot be used in production environments.

Region availability

RDS for SQL Server Developer Edition is available in the following AWS Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- US West (N. California)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)

- Asia Pacific (Singapore)
- Asia Pacific (Osaka)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Ireland)
- Europe (Frankfurt)
- Europe (London)
- Europe (Stockholm)
- Europe (Paris)
- Canada (Central)
- South America (São Paulo)
- Africa (Cape Town)

Licensing and usage

SQL Server Developer Edition is licensed by Microsoft for development and test environments only. You cannot use Developer Edition as a production server. When you use SQL Server Developer Edition on Amazon RDS, you are responsible for complying with Microsoft's SQL Server Developer Edition licensing terms. You pay only for the AWS infrastructure costs - there is no additional SQL Server licensing fee. For pricing details, see RDS for SQL Server pricing.

Prerequisites

Before using SQL Server Developer Edition on RDS for SQL Server, ensure you have the following requirements:

- You must obtain the installation binaries directly from Microsoft and ensure compliance with Microsoft's licensing terms.
- You must have access to use the following resources to create a Developer Edition DB instance:
  - AWS account with `AmazonRDSFullAccess` and `s3:GetObject` permissions.
- An Amazon S3 bucket is required for storing installation media. You will need an ISO and cumulative update file to upload to the Amazon S3 bucket as part of CEV creation. For more information, see Uploading installation media to an Amazon S3 bucket.

- All installation media files must reside within the same Amazon S3 bucket and the same folder path within that Amazon S3 bucket in the same Region where the custom engine version is created.

Supported versions

Developer Edition on RDS for SQL Server supports the following versions:

- SQL Server 2022 CU 21 (16.00.4215.2)
- SQL Server 2019 CU 32 GDR (15.00.4455.2)

To list all supported engine versions for Developer Edition CEV creation, use the following AWS CLI command:

```
aws rds describe-db-engine-versions --engine sqlserver-dev-ee --output json --
query "{DBEngineVersions: DBEngineVersions[?Status=='requires-custom-engine-
version'].{Engine: Engine, EngineVersion: EngineVersion, Status: Status,
 DBEngineVersionDescription: DBEngineVersionDescription}}"
```

The command returns output similar to the following example:

```
{
    "DBEngineVersions": [
        {
            "Engine": "sqlserver-dev-ee",
            "EngineVersion": "16.00.4215.2.v1",
            "Status": "requires-custom-engine-version",
            "DBEngineDescription": "Microsoft SQL Server Enterprise Developer Edition",
            "DBEngineVersionDescription": "SQL Server 2022 16.00.4215.2.v1"
        }
    ]
}
```

The engine version status as `requires_custom_engine_version` identifies template engine versions that are supported. These templates show which SQL Server versions you can import.

Limitations

The following limitations apply to SQL Server Developer Edition on Amazon RDS:

- Currently only supported on M6i and R6i instance classes.
- Multi-AZ deployments and read replicas are not supported.
- You must provide and manage your own SQL Server installation media.
- Custom engine versions for SQL Server Developer Edition (sqlserver-dev-ee) cannot be shared cross-Region or cross-account.

Preparing a CEV for RDS for SQL Server

Prerequisites

Before creating a custom engine version, make sure you have completed the following prerequisites:

Prepare SQL Server Developer Edition installation media

You must obtain the SQL Server Developer Edition installation media from Microsoft and prepare it for upload to S3.

To download installation media from Microsoft

1. **Option A:** Use your Visual Studio subscription to download the Developer Edition ISO. Only the English version is supported.
2. **Option B: Using SQL Server Installer**
    a. Download the SQL Server Developer Edition installer.
    b. Run the installer and choose **Download Media** to download the full ISO.
    c. Choose **English** as the preferred language.
    d. Choose **ISO** as the media type.
    e. Choose **Download**.

To download cumulative updates

1. Visit the Microsoft Catalog Update page.
2. Find a SQL Server Developer Edition supported by RDS for SQL Server, for example "SQL Server 2022 Cumulative Update".
3. Download the latest supported CU executable file and save it to your machine.

4. Example files: `SQLServer2022-KB5065865-x64.exe` (CU21 for SQL Server 2022)

> **Important**
>
> RDS for SQL Server only supports specific Cumulative Update (CU) versions. You must use the exact version listed in the table below. Do not use newer CU versions even if available from Microsoft, as they may not be compatible with RDS.

Alternatively, you can also download the required Cumulative Update (CU) file directly from the following:

The following table lists the supported SQL Server Developer Edition version and its corresponding Cumulative Update for use with RDS:

SQL Server Version	Supported CU	KB Article	Download File Name
SQL Server 2022	CU21	KB5065865	SQLServer2022-KB5065865-x64.exe
SQL Server 2019	CU32 GDR	KB5068404	SQLServer2019-KB5068404-x64.exe

Creating a custom engine version for RDS for SQL Server

A custom engine version (CEV) for RDS for SQL Server consists of your SQL Server Developer Edition installation media imported into Amazon RDS. It is necessary to upload the base ISO installer and cumulative update files (.exe) to your Amazon S3 bucket. Once uploaded, you should provide the Amazon S3 location to RDS for it to download, validate, and subsequently create your CEV.

Naming limitations

When creating a CEV, you must follow specific naming conventions:

- CEV name must follow the pattern `major-version.minor-version.customized-string`.

- `customized-string` can contain 1-50 alphanumeric characters, underscores, dashes, and periods. For example: `16.00.4215.2.my-dev-cev` for SQL Server 2022.

To list all supported engine versions, use the following command:

```
aws rds describe-db-engine-versions --engine sqlserver-dev-ee --output json --
query "{DBEngineVersions: DBEngineVersions[?Status=='requires-custom-engine-
version'].{Engine: Engine, EngineVersion: EngineVersion, Status: Status,
 DBEngineVersionDescription: DBEngineVersionDescription}}"

{
    "DBEngineVersions": [
        {
            "Engine": "sqlserver-dev-ee",
            "EngineVersion": "16.00.4215.2.v1",
            "Status": "requires-custom-engine-version",
            "DBEngineDescription": "Microsoft SQL Server Enterprise Developer Edition",
            "DBEngineVersionDescription": "SQL Server 2022 16.00.4215.2.v1"
        }
    ]
}
```

AWS CLI

To create the custom engine version

- Use the create-custom-db-engine-version command.

  The following options are required:

  - `--engine`
  - `--engine-version`
  - `--database-installation-files-s3-bucket-name`
  - `--database-installation-files`
  - `--region`

  You can also specify the following options:

  - `--database-installation-files-s3-prefix`

- `--description`
- `--tags`

```
aws rds create-custom-db-engine-version \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.cev-dev-ss2022-cu21 \
--region us-west-2 \
--database-installation-files-s3-bucket-name my-s3-installation-media-bucket \
--database-installation-files-s3-prefix sqlserver-dev-media \
--database-installation-files "SQLServer2022-x64-ENU-Dev.iso" "SQLServer2022-
KB5065865-x64.exe"
```

CEV creation typically takes 15-30 minutes. To monitor the CEV creation progress, use the following command:

```
# Check CEV status
aws rds describe-db-engine-versions \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.my-dev-cev \
--region us-west-2
```

Lifecycle of an RDS for SQL Server CEV

When working with SQL Server Developer Edition on RDS for SQL Server, your custom engine versions transition through various lifecycle states.

Lifecycle State	Description	When It Occurs	Available Actions
pending-validation	Initial state when CEV is created	This is the initial state after creation with the `create-custom-db-engine-version` command.	Monitor status via `describe-db-engine-version` .

Lifecycle State	Description	When It Occurs	Available Actions
validating	CEV Validation state	Amazon RDS is validating your custom engine version (CEV). This asynchronous process may take some time to complete.	Monitor the status until validation is complete.
available	The custom engine version (CEV) validation completed successfully.	Custom Engine Version (CEV) is now available. Amazon RDS successfully validated your SQL Server ISO and cumulative update files. You can now create DB instances using this CEV.	Create DB instances using this CEV
failed	RDS for SQL Server can't create the custom engine version (CEV) because the validation check failed.	ISO and cumulativ e media validation failed.	ISO validation failed. Check the failure reason in `describe-db-engine-version`, fix any file issues such as hash mismatches or corrupted content, and then recreate your custom engine version (CEV).

Lifecycle State	Description	When It Occurs	Available Actions
deleting	The custom engine version (CEV) is deleting	After customer calls `delete-custom-db-engine-version` until deletion workflow completes.	Monitor status via `describe-db-engine-version` .
incompatible-installation-media	Amazon RDS was unable to validate the installation media provided for the custom engine version (CEV)	The custom engine version (CEV) validation has failed. This is a terminal state.	See failureReason via `describe-db-engine-versions` for info on why validation failed; delete CEV.

Describe CEV Status

You can see the state of your CEVs using the AWS CLI:

```
aws rds describe-db-engine-versions \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.my-dev-cev \
--region us-west-2 \
--query 'DBEngineVersions[0].{Version:EngineVersion,Status:Status}'
```

Sample output

```
| DescribeDBEngineVersions                    |
+------------+--------------------------------+
| Status | Version                            |
+------------+--------------------------------+
| available | 16.00.4215.2.cev-dev-ss2022-cu21    |
+------------+--------------------------------+
```

When a CEV shows `failed` status, you can determine the reason using the following command:

```
aws rds describe-db-engine-versions \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.my-dev-cev \
```

```
--region us-west-2 \
--query 'DBEngineVersions[0].
{Version:EngineVersion,Status:Status,FailureReason:FailureReason}'
```

Creating an RDS for SQL Server Developer Edition DB instance

Launching Developer Edition instance on RDS for SQL Server follows a two-step process: first create a CEV with `create-custom-db-engine-version`, Once your custom engine version is in the available state, you can create Amazon RDS database instances using the CEV.

Key differences for Developer Edition instance creation

Parameter	Developer Edition
`--engine`	sqlserver-dev-ee
`--engine-version`	Custom engine version (e.g., 16.00.4215.2.cev-dev-ss2022-cu21)
`--license-model`	bring-your-own-license

AWS CLI

To create a SQL Server Developer Edition DB instance, use the create-db-instance command with the following parameters:

The following options are required:

- `--db-instance-identifier`
- `--db-instance-class`
- `--engine` – `sqlserver-dev-ee`
- `--region`

Examples:

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier my-dev-sqlserver \
```

```
--db-instance-class db.m6i.xlarge \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.my-dev-cev \
--allocated-storage 200 \
--master-username admin \
--master-user-password changeThisPassword \
--license-model bring-your-own-license \
--no-multi-az \
--vpc-security-group-ids sg-xxxxxxxxx \
--db-subnet-group-name my-db-subnet-group \
--backup-retention-period 7 \
--region us-west-2
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier my-dev-sqlserver ^
--db-instance-class db.m6i.xlarge ^
--engine sqlserver-dev-ee ^
--engine-version 16.00.4215.2.cev-dev-ss2022-cu21 ^
--allocated-storage 200 ^
--master-username admin ^
--master-user-password master_user_password ^
--license-model bring-your-own-license ^
--no-multi-az ^
--vpc-security-group-ids sg-xxxxxxxxx ^
--db-subnet-group-name my-db-subnet-group ^
--backup-retention-period 7 ^
--region us-west-2
```

Refer to Creating a DB instance to create using the AWS console.

Applying database minor version upgrades

RDS for SQL Server Developer Edition requires creating a new custom engine version (CEV) with latest cumulative update to apply database minor version upgrade. Database minor version upgrades for SQL Server Developer Edition involve the following steps:

1. Before upgrading, verify current engine version on the instance, identify the target database engine version from Amazon RDS supported versions. For information about what SQL Server versions are available on Amazon RDS, see Working with SQL Server Developer Edition on RDS for SQL Server.

2. Obtain and upload installation media (ISO and CU), then create a new custom engine version.
3. Apply database minor version upgrade by using Amazon RDS `modify-db-instance` with the new CEV.

```
aws rds modify-db-instance \
--db-instance-identifier <instance-id> \
--engine-version <new-cev-version> \
--no-apply-immediately ## use --apply-immediately for immediate update
```

> **Note**
>
> `--no-apply-immediately` (the default) to apply the changes during the next maintenance window.

Viewing and managing custom engine versions

To view all your RDS for SQL Server Developer Edition CEVs, use the `describe-db-engine-versions` command with the `--engine` input as `sqlserver-dev-ee`.

```
aws rds describe-db-engine-versions \
--engine sqlserver-dev-ee \
--include-all \
--region us-west-2
```

To view the details of a specific CEV, use the following command:

```
aws rds describe-db-engine-versions \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.cev-dev-ss2022-cu21 \
--region us-west-2
```

> **Note**
>
> This command only returns CEVs with an `available` status. To view CEVs in validating or other states, include the `--include-all` flag.

Deleting custom engine versions

Before deleting a CEV, make sure it isn't being used by any of the following:

- An Amazon RDS DB instance
- A snapshot of an Amazon RDS DB instance
- An automated backup of an Amazon RDS DB instance

> **Note**
>
> You can't delete a CEV if there are any resources associated with it.

To delete a custom engine version, use the delete-custom-db-engine-version command.

- `--engine`: Specify `sqlserver-dev-ee` for Developer Edition
- `--engine-version`: The exact CEV version identifier to delete
- `--region`: AWS Region where the CEV exists

```
aws rds delete-custom-db-engine-version \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.my-dev-cev \
--region us-west-2
```

To monitor the CEV deletion process, use the `describe-db-engine-versions` command and specify your RDS for SQL Server CEV engine version

```
aws rds describe-db-engine-versions \
--engine sqlserver-dev-ee \
--engine-version 16.00.4215.2.my-dev-cev \
--region us-west-2
```

Status Values:

- `deleting`: CEV deletion in progress
- No results returned: CEV successfully deleted

Troubleshooting SQL Server Developer Edition for RDS for SQL Server

The following table lists some common errors and corresponding solutions when working with SQL Server Developer Edition for RDS for SQL Server

Common Errors and Solutions

Error Code	Description	Solution
InvalidParameterValue	Invalid CEV parameters or file references	Verify file names, paths, and parameter syntax
DBSubnetGroupNotFound	Subnet group doesn't exist	Create subnet group or verify name
InvalidVPCNetworkState	VPC configuration issue	Check VPC, subnets, and routing tables
InvalidEngineVersion	CEV not available or invalid	Verify CEV status and name
InvalidDBInstanceClass	Instance class not supported	Choose supported instance class
CustomDBEngineVersionQuotaExceededFault	You have reached the maximum number of custom engine versions	If required increase service quota, alternatively Delete unused CEVs if required
CreateCustomDBEngineVersionFault	Amazon RDS was unable to access the specified installer file in the Amazon S3 bucket.	Amazon RDS cannot access the SQL Server installation files in the specified Amazon S3 location. Grant the Amazon RDS service principal (rds.amazonaws.com) s3:GetObject permission in your Amazon S3 bucket policy. Validate that the Amazon S3 bucket Region is the same as the Region where you are creating the CEV.

Working with Active Directory with RDS for SQL Server

You can join an RDS for SQL Server DB instance to a Microsoft Active Directory (AD) domain. Your AD domain can be hosted on AWS Managed AD within AWS, or on a self-managed AD in a location of your choice, including your corporate data centers, on AWS EC2, or with other cloud providers.

You can authenticate domain users using NTLM authentication and Kerberos authentication with self-managed Active Directory and AWS Managed Microsoft AD.

In the following sections, you can find information about working with self-managed Active Directory and AWS Managed Active Directory for Microsoft SQL Server on Amazon RDS.

Topics

- Working with self-managed Active Directory with an Amazon RDS for SQL Server DB instance
- Working with AWS Managed Active Directory with RDS for SQL Server

Working with self-managed Active Directory with an Amazon RDS for SQL Server DB instance

Amazon RDS for SQL Server seamlessly integrates with your self-managed Active Directory (AD) domain, regardless of where your AD is hosted - whether in your data center, on Amazon EC2, or with other cloud providers. This integration enables direct user authentication through NTLM or Kerberos protocols, eliminating the need for complex intermediary domains or forest trusts. When you connect to your RDS SQL Server DB instance, authentication requests are securely forwarded to your designated AD domain, maintaining your existing identity management structure while leveraging Amazon RDS's managed database capabilities.

Topics

- Region and version availability
- Requirements
- Considerations
- Setting up self-managed Active Directory
- Joining your DB instance to self-managed Active Directory
- Managing a DB instance in a self-managed Active Directory Domain
- Understanding self-managed Active Directory Domain membership
- Troubleshooting self-managed Active Directory
- Restoring a SQL Server DB instance and then adding it to a self-managed Active Directory domain

Region and version availability

Amazon RDS supports self-managed AD for SQL Server using NTLM and Kerberos in all commercial AWS Regions and AWS GovCloud (US) Regions.

Requirements

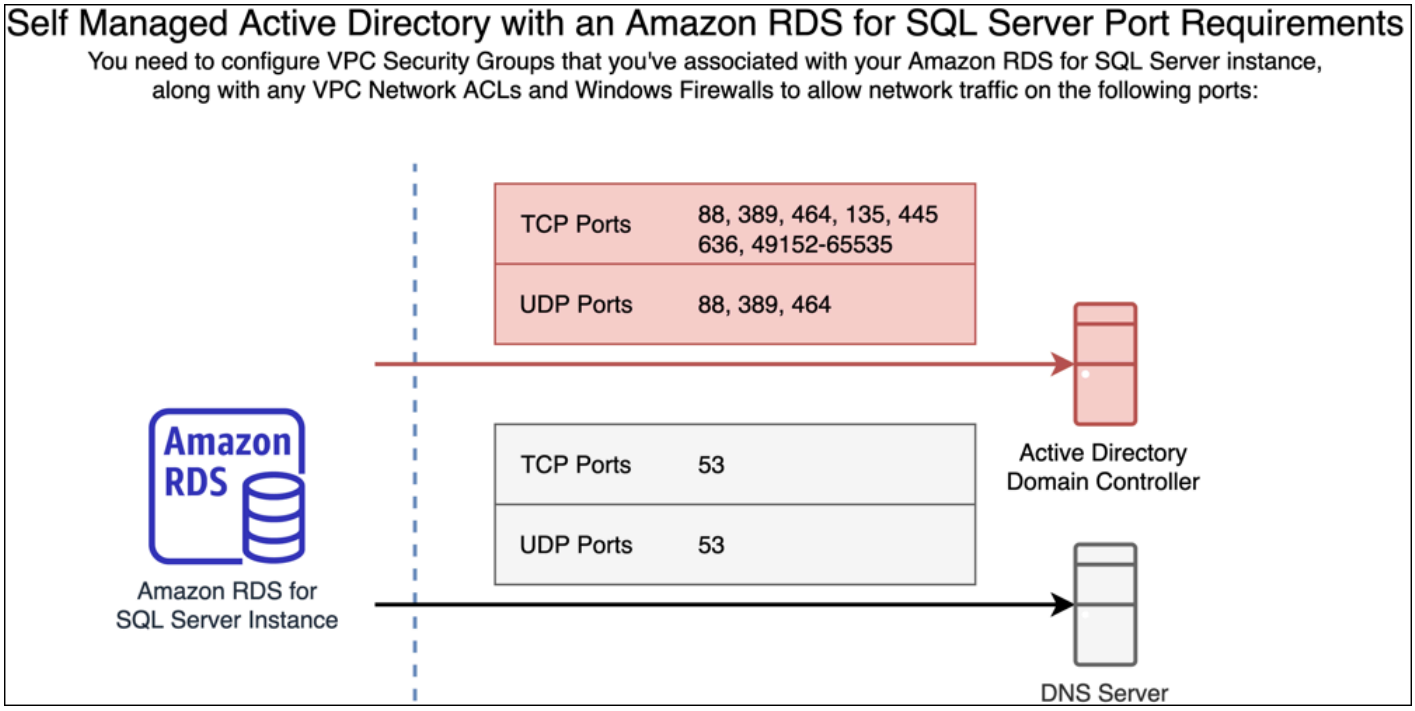
Make sure you've met the following requirements before joining an RDS for SQL Server DB instance to your self-managed AD domain.

Topics

- Configure your on-premises AD

- Configure your network connectivity
- Configure your AD domain service account
- Configuring secure communication over LDAPS

Configure your on-premises AD



Make sure that you have an on-premises or other self-managed Microsoft AD that you can join the Amazon RDS for SQL Server instance to. Your on-premises AD should have the following configuration:

- If you have AD sites defined, make sure the subnets in the VPC associated with your RDS for SQL Server DB instance are defined in your AD site. Confirm there aren't any conflicts between the subnets in your VPC and the subnets in your other AD sites.
- Your AD domain controller has a domain functional level of Windows Server 2008 R2 or higher.
- Your AD domain name can't be in Single Label Domain (SLD) format. RDS for SQL Server does not support SLD domains.
- The fully qualified domain name (FQDN) for your AD can't exceed 47 characters.

Configure your network connectivity

Make sure that you have met the following network configurations:

- Configure connectivity between the Amazon VPC where you want to create the RDS for SQL Server DB instance and your self-managed AD. You can set up connectivity using AWS Direct Connect, AWS VPN, VPC peering, or AWS Transit Gateway.
- For VPC security groups, the default security group for your default Amazon VPC is already added to your RDS for SQL Server DB instance in the console. Ensure that the security group and the VPC network ACLs for the subnet(s) where you're creating your RDS for SQL Server DB instance allow traffic on the ports and in the directions shown in the following diagram.

The following table identifies the role of each port.

Protocol	Ports	Role
TCP/UDP	53	Domain Name System (DNS)
TCP/UDP	88	Kerberos authentication
TCP/UDP	464	Change/Set password
TCP/UDP	389	Lightweight Directory Access Protocol (LDAP)
TCP	135	Distributed Computing Environment / End Point Mapper (DCE / EPMAP)
TCP	445	Directory Services SMB file sharing

Protocol	Ports	Role
TCP	636	Lightweight Directory Access Protocol over TLS/SSL (LDAPS)
TCP	49152 - 65535	Ephemeral ports for RPC

- Generally, the domain DNS servers are located in the AD domain controllers. You do not need to configure the VPC DHCP option set to use this feature. For more information, see DHCP option sets in the *Amazon VPC User Guide*.

> **Important**
>
> If you're using VPC network ACLs, you must also allow outbound traffic on dynamic ports (49152-65535) from your RDS for SQL Server DB instance. Ensure that these traffic rules are also mirrored on the firewalls that apply to each of the AD domain controllers, DNS servers, and RDS for SQL Server DB instances.
> While VPC security groups require ports to be opened only in the direction that network traffic is initiated, most Windows firewalls and VPC network ACLs require ports to be open in both directions.

Configure your AD domain service account

Make sure that you have met the following requirements for an AD domain service account:

- Make sure that you have a domain service account in your self-managed AD domain with delegated permissions to join computers to the domain. A domain service account is a user account in your self-managed AD that has been delegated permission to perform certain tasks.
- The domain service account needs to be delegated the following permissions in the Organizational Unit (OU) that you're joining your RDS for SQL Server DB instance to:
  - Validated ability to write to the DNS host name
  - Validated ability to write to the service principal name
  - Create and delete computer objects

These represent the minimum set of permissions that are required to join computer objects to your self-managed AD. For more information, see Errors when attempting to join computers to a domain in the Microsoft Windows Server documentation.

- To use Kerberos authentication, you need to provide Service Principal Names (SPNs) and DNS permissions to your AD domain service account:
  - **Write SPN**: Delegate the **Write SPN** permission to the AD domain service account in the OU where you need to join the RDS for SQL Server DB instance. This permissions is different from the validated write SPN.
  - **DNS permissions**: Provide the following permissions to the AD domain service account in the DNS manager at the server level for your domain controller:
    - List contents
    - Read all properties
    - Read permissions

> **Important**
>
> Do not move computer objects that RDS for SQL Server creates in the Organizational Unit after your DB instance is created. Moving the associated objects will cause your RDS for SQL Server DB instance to become misconfigured. If you need to move the computer objects created by Amazon RDS, use the ModifyDBInstance RDS API operation to modify the domain parameters with the desired location of the computer objects.

Configuring secure communication over LDAPS

Communication over LDAPS is recommended for RDS to query and access computer objects as well as SPNs in the domain controller. To use secure LDAP, use a valid SSL certificate on your domain controller that meets the requirements for secure LDAPS. If a valid SSL certificate does not exist on the domain controller, the RDS for SQL Server DB instance defaults to using LDAP. For more information on certificate validity, see Requirements for an LDAPS certificate.

Considerations

When adding an RDS for SQL Server DB instance to a self-managed AD, keep the consider the following:

- Your DB instances sync with AWS's NTP service and not the AD domain's time server. For database connections between linked SQL Server instances within your AD domain, you can only SQL authentication and not Windows authentication.
- Group Policy Object settings from your self-managed AD domain are not propagated to your RDS for SQL Server instances.

Setting up self-managed Active Directory

To set up a self-managed AD, take the following steps.

Topics

- Step 1: Create an Organizational Unit in your AD
- Step 2: Create an AD domain service account in your AD
- Step 3: Delegate control to the AD domain service account
- Step 4: Create an AWS KMS key
- Step 5: Create an AWS secret

Step 1: Create an Organizational Unit in your AD

> **Important**
>
> We recommend creating a dedicated OU and service credential scoped to that OU for any AWS account that owns an RDS for SQL Server DB instance joined your self-managed AD domain. By dedicating an OU and service credential, you can avoid conflicting permissions and follow the principal of least privilege.

To create an OU in your AD

1. Connect to your AD domain as a domain administrator.
2. Open **Active Directory Users and Computers** and select the domain where you want to create your OU.
3. Right-click the domain and choose **New**, then **Organizational Unit**.
4. Enter a name for the OU.
5. Keep the box selected for **Protect container from accidental deletion**.

6. Click **OK**. Your new OU will appear under your domain.

Step 2: Create an AD domain service account in your AD

The domain service account credentials will be used for the secret in AWS Secrets Manager.

To create an AD domain service account in your AD

1. Open **Active Directory Users and Computers** and select the domain and OU where you want to create your user.
2. Right-click the **Users** object and choose **New**, then **User**.
3. Enter a first name, last name, and logon name for the user. Click **Next**.
4. Enter a password for the user. Don't select **"User must change password at next login"**. Don't select **"Account is disabled"**. Click **Next**.
5. Click **OK**. Your new user will appear under your domain.

Step 3: Delegate control to the AD domain service account

To delegate control to the AD domain service account in your domain

1. Open **Active Directory Users and Computers** MMC snap-in and select the domain where you want to create your user.
2. Right-click the OU that you created earlier and choose **Delegate Control**.
3. On the **Delegation of Control Wizard**, click **Next**.
4. On the **Users or Groups** section, click **Add**.
5. On the **Select Users, Computers, or Groups** section, enter the AD domain service account you created and click **Check Names**. If your AD domain service account check is successful, click **OK**.
6. On the **Users or Groups** section, confirm your AD domain service account was added and click **Next**.
7. On the **Tasks to Delegate** section, choose **Create a custom task to delegate** and click **Next**.
8. On the **Active Directory Object Type** section:
    a. Choose **Only the following objects in the folder**.
    b. Select **Computer Objects**.

c. Select **Create selected objects in this folder**.

d. Select **Delete selected objects in this folder** and click **Next**.

9. On the **Permissions** section:

   a. Keep **General** selected.

   b. Select **Validated write to DNS host name**.

   c. Select **Validated write to service principal name** and click **Next**.

   d. To enable Kerberos authentication, keep **Property-specific** selected and select **Write servicePrincipalName** from the list.

10. For **Completing the Delegation of Control Wizard**, review and confirm your settings and click **Finish**.

11. For Kerberos authentication, open the DNS Manager and open **Server** properties.

    a. In the Windows dialog box, type `dnsmgmt.msc`.

    b. Add the AD domain service account under the **Security** tab.

    c. Select the **Read** permission and apply your changes.

Step 4: Create an AWS KMS key

The KMS key is used to encrypt your AWS secret.

To create an AWS KMS key

> **Note**
>
> For **Encryption Key**, don't use the AWS default KMS key. Be sure to create the AWS KMS key in the same AWS account that contains the RDS for SQL Server DB instance that you want to join to your self-managed AD.

1. In the AWS KMS console, choose **Create key**.
2. For **Key Type**, choose **Symmetric**.
3. For **Key Usage**, choose **Encrypt and decrypt**.
4. For **Advanced options**:

   a. For **Key material origin**, choose **KMS**.

b. For **Regionality**, choose **Single-Region key** and click **Next**.

5. For **Alias**, provide a name for the KMS key.
6. (Optional) For **Description**, provide a description of the KMS key.
7. (Optional) For **Tags**, provide a tag the KMS key and click **Next**.
8. For **Key administrators**, provide the name of an IAM user and select it.
9. For **Key deletion**, keep the box selected for **Allow key administrators to delete this key** and click **Next**.
10. For **Key users**, provide the same IAM user from the previous step and select it. Click **Next**.
11. Review the configuration.
12. For **Key policy**, include the following to the policy **Statement**:

```
{
    "Sid": "Allow use of the KMS key on behalf of RDS",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "rds.amazonaws.com"
        ]
    },
    "Action": "kms:Decrypt",
    "Resource": "*"
}
```

13. Click **Finish**.

Step 5: Create an AWS secret

To create a secret

> **Note**
>
> Be sure to create the secret in the same AWS account that contains the RDS for SQL Server DB instance that you want to join to your self-managed AD.

1. In AWS Secrets Manager, choose **Store a new secret**.
2. For **Secret type**, choose **Other type of secret**.

3. For **Key/value pairs**, add your two keys:

   a. For the first key, enter `SELF_MANAGED_ACTIVE_DIRECTORY_USERNAME`.

   b. For the value of the first key, enter only the username (without the domain prefix) of the AD user. Do not include the domain name as this causes instance creation to fail.

   c. For the second key, enter `SELF_MANAGED_ACTIVE_DIRECTORY_PASSWORD`.

   d. For the value of the second key, enter the password that you created for the AD user on your domain.

4. For **Encryption key**, enter the KMS key that you created in a previous step and click **Next**.
5. For **Secret name**, enter a descriptive name that helps you find your secret later.
6. (Optional) For **Description**, enter a description for the secret name.
7. For **Resource permission**, click **Edit**.
8. Add the following policy to the permission policy:

> **Note**
>
> We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the *confused deputy* problem. Use your AWS account for `aws:sourceAccount` and the RDS for SQL Server DB instance ARN for `aws:sourceArn`. For more information, see Preventing cross-service confused deputy problems.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":
    [
        {
            "Effect": "Allow",
            "Principal":
            {
                "Service": "rds.amazonaws.com"
            },
            "Action": "secretsmanager:GetSecretValue",
            "Resource": "*",
```

```
            "Condition":
            {
                "StringEquals":
                {
                    "aws:sourceAccount": "123456789012"
                },
                "ArnLike":
                {
                    "aws:sourceArn": "arn:aws:rds:us-
west-2:123456789012:db:*"
                }
            }
        }
    ]
}
```

9. Click **Save** then click **Next**.
10. For **Configure rotation settings**, keep the default values and choose **Next**.
11. Review the settings for the secret and click **Store**.
12. Choose the secret you created and copy the value for the **Secret ARN**. This will be used in the next step to set up self-managed Active Directory.

Joining your DB instance to self-managed Active Directory

To join your RDS for SQL Server DB instance to your self-managed AD, follow these steps:

Step 1: Create or modify a SQL Server DB instance

You can use the console, CLI, or RDS API to associate an RDS for SQL Server DB instance with a self-managed AD domain. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.

- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.

- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the self-managed AD domain that you created:

- For the `--domain-fqdn` parameter, use the fully qualified domain name (FQDN) of your self-managed AD.
- For the `--domain-ou` parameter, use the OU that you created in your self-managed AD.
- For the `--domain-auth-secret-arn` parameter, use the value of the **Secret ARN** that you created in a previous step.
- For the `--domain-dns-ips` parameter, use the primary and secondary IPv4 addresses of the DNS servers for your self-managed AD. If you don't have a secondary DNS server IP address, enter the primary IP address twice.

The following example CLI commands show how to create, modify, and remove an RDS for SQL Server DB instance with a self-managed AD domain.

> **Important**
>
> If you modify a DB instance to join it to or remove it from a self-managed AD domain, a reboot of the DB instance is required for the modification to take effect. You can choose to apply the changes immediately or wait until the next maintenance window. Choosing the **Apply Immediately** option will cause downtime for a single-AZ DB instance. A multi-AZ DB instance will perform a failover before completing a reboot. For more information, see Using the schedule modifications setting.

The following CLI command creates a new RDS for SQL Server DB instance and joins it to a self-managed AD domain.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier my-DB-instance \
    --db-instance-class db.m5.xlarge \
    --allocated-storage 50 \
    --engine sqlserver-se \
    --engine-version 15.00.4043.16.v1 \
    --license-model license-included \
    --master-username my-master-username \
    --master-user-password my-master-password \
    --domain-fqdn my_AD_domain.my_AD.my_domain \
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain \
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" \
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier my-DB-instance ^
    --db-instance-class db.m5.xlarge ^
    --allocated-storage 50 ^
    --engine sqlserver-se ^
    --engine-version 15.00.4043.16.v1 ^
    --license-model license-included ^
    --master-username my-master-username ^
    --master-user-password my-master-password ^
    --domain-fqdn my-AD-test.my-AD.mydomain ^
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain ^
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" \ ^
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

The following CLI command modifies an existing RDS for SQL Server DB instance to use a self-managed AD domain.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-DB-instance \
    --domain-fqdn my_AD_domain.my_AD.my_domain \
```

```
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain \
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" \
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-DBinstance ^
    --domain-fqdn my_AD_domain.my_AD.my_domain ^
    --domain-ou OU=my-AD-test-OU,DC=my-AD-test,DC=my-AD,DC=my-domain ^
    --domain-auth-secret-arn "arn:aws:secretsmanager:region:account-number:secret:my-
AD-test-secret-123456" ^
    --domain-dns-ips "10.11.12.13" "10.11.12.14"
```

The following CLI command removes an RDS for SQL Server DB instance from a self-managed AD domain.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-DB-instance \
    --disable-domain
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-DB-instance ^
    --disable-domain
```

Step 2: Using Kerberos or NTLM Authentication

NTLM authentication

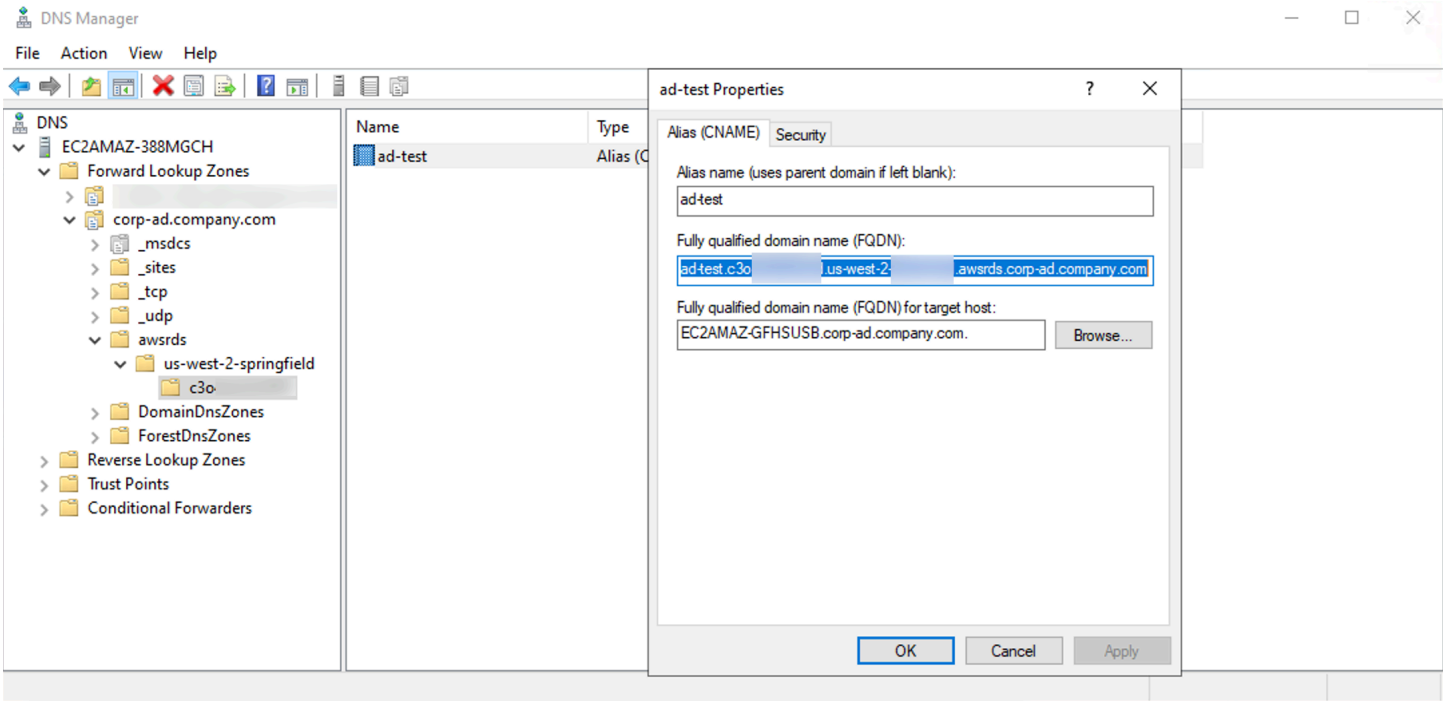
Each Amazon RDS DB instance has an endpoint and each endpoint has a DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance. To authenticate using NTLM authentication, you must connect to the RDS endpoint or the listener endpoint if you are using a Multi-AZ deployment.

During planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary database so operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the secondary as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Kerberos authentication

Kerberos-based authentication for RDS for SQL Server requires connections be made to a specific Service Principal Name (SPN). However, after a failover event, the application might not be aware of the new SPN. To address this, RDS for SQL Server offers a Kerberos-based endpoint.

The Kerberos-based endpoint follows a specific format. If your RDS endpoint is *`rds-instance-name`*`.`*`account-region-hash`*`.`*`aws-region`*`.rds.amazonaws.com`, the corresponding Kerberos-based endpoint would be *`rds-instance-name`*`.`*`account-region-hash`*`.`*`aws-region`*`.awsrds.`*`fully qualified domain name (FQDN)`*.



For example, if the RDS endpoint is `ad-test.cocv6zwtircu.us-east-1.rds.amazonaws.com` and the domain name is `corp-ad.company.com`, the Kerberos-based endpoint would be `ad-test.cocv6zwtircu.us-east-1.awsrds.corp-ad.company.com`.

This Kerberos-based endpoint can be used to authenticate with the SQL Server instance using Kerberos, even after a failover event, as the endpoint is automatically updated to point to the new SPN of the primary SQL Server instance.

Finding your CNAME

To find your CNAME, connect to your domain controller and open **DNS Manager**. Navigate to **Forward Lookup Zones** and your FQDN.

Navigate through **awsrds**, **aws-region**, and **account and region specific hash**.

If after connecting CNAME from remote client, an NTLM connection is returned, check if required ports are allowlisted.

To check if your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
    FROM sys.dm_exec_connections
    WHERE session_id = @@SSPID;
```

If your instance returns an NTLM connection when you connect to a Kerberos endpoint, verify your network configuration and user configurations. See Configure your network connectivity.

Step 3: Create Windows Authentication SQL Server logins

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do for any other DB instance. Because the DB instance is joined to the self-managed AD domain, you can provision SQL Server logins and users. You do this from the AD users and groups utility in your self-managed AD domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

In order for a self-managed AD domain service account to authenticate with SQL Server, a SQL Server Windows login must exist for the self-managed AD domain service account or a self-

managed AD group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A self-managed AD domain service account that doesn't have a SQL Server login or belong to a self-managed AD group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create a self-managed AD SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication and create your self-managed AD SQL Server logins under the context of the master user.

You can run a data definition language (DDL) command such as the following to create a SQL Server login for an self-managed AD domain service account or group.

> **Note**
>
> Specify users and groups using the pre-Windows 2000 login name in the format *my_AD_domain**my_AD_domain_user*. You can't use a user principal name (UPN) in the format *my_AD_domain_user*@*my_AD_domain*.

```
USE [master]
GO
CREATE LOGIN [my_AD_domain\my_AD_domain_user] FROM WINDOWS WITH DEFAULT_DATABASE =
 [master], DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see CREATE LOGIN (Transact-SQL) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a self-managed AD domain-joined client machine using Windows authentication.

Managing a DB instance in a self-managed Active Directory Domain

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your self-managed AD domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a self-managed domain join for a failed membership, use the ModifyDBInstance API operation and specify the same set of parameters:
  - `--domain-fqdn`
  - `--domain-dns-ips`
  - `--domain-ou`
  - `--domain-auth-secret-arn`
- To remove a DB instance from a self-managed domain, use the `ModifyDBInstance` API operation and specify `--disable-domain` for the domain parameter.
- To move a DB instance from one self-managed domain to another, use the `ModifyDBInstance` API operation and specify the domain parameters for the new domain:
  - `--domain-fqdn`
  - `--domain-dns-ips`
  - `--domain-ou`
  - `--domain-auth-secret-arn`
- To list self-managed AD domain membership for each DB instance, use the DescribeDBInstances API operation.

Understanding self-managed Active Directory Domain membership

After you create or modify your DB instance while specifying AD details, the instance becomes a member of the self-managed AD domain. The AWS console indicates the status of the self-managed Active Directory domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the AD domain.
- **joining** – The instance is in the process of becoming a member of the AD domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the AD domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the AD domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the AD domain during the next scheduled maintenance window.

- **failed** – A configuration problem has prevented the instance from joining the AD domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the self-managed AD domain.

> **Important**
>
> A request to become a member of a self-managed AD domain can fail because of a network connectivity issue. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a self-managed AD domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the self-managed AD domain.

Troubleshooting self-managed Active Directory

The following are issues you might encounter when you set up or modify self-managed AD.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 2 / 0x2	The system cannot find the file specified.	The format or location for the Organizational Unit (OU) specified with the `–domain-ou` parameter is invalid. The domain service account specified via AWS Secrets Manager lack the permissions required to join the OU.	Review the `–domain-ou` parameter. Ensure the domain service account has the correct permissions to the OU. For more information, see Configure your AD domain service account.
Error 5 / 0x5	Access is denied.	Misconfigured permissions for the domain service account, or the computer account already exists in the domain.	Review the domain service account permissions in the domain, and verify that the RDS computer account is not duplicated in the domain. You can verify the name

Error Code	Description	Common causes	Troubleshooting suggestions
			of the RDS computer account by running `SELECT @@SERVERNAME` on your RDS for SQL Server DB instance. If you are using Multi-AZ, try rebooting with failover and then verify that the RDS computer account again. For more information, see Rebooting a DB instance.
Error 87 / 0x57	The parameter is incorrect.	The domain service account specified via AWS Secrets Manager doesn't have the correct permissions. The user profile may also be corrupted.	Review the requirements for the domain service account. For more information, see Configure your AD domain service account.
Error 234 / 0xEA	Specified Organizational Unit (OU) does not exist.	The OU specified with the `–domain-ou` parameter doesn't exist in your self-managed AD.	Review the `–domain-ou` parameter and ensure the specified OU exists in your self-managed AD.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 1326 / 0x52E	The user name or password is incorrect.	The domain service account credentials provided in AWS Secrets Manager contains an unknown username or bad password. The domain account may also be disabled in your self-managed AD.	Ensure the credentials provided in AWS Secrets Manager are correct and the domain account is enabled in your self-managed AD.
Error 1355 / 0x54B	The specified domain either does not exist or could not be contacted.	The domain is down, the specified set of DNS IPs are unreachable, or the specified FQDN is unreachable.	Review the `–domain-dns-ips` and `–domain-fqdn` parameters to ensure they're correct. Review the networking configuration of your RDS for SQL Server DB instance and ensure your self-managed AD is reachable. For more information, see Configure your network connectivity.
Error 1722 / 0x6BA	The RPC server is unavailable.	There was an issue reaching the RPC service of your AD domain. This might be a service or network issue.	Validate that the RPC service is running on your domain controllers and that the TCP ports 135 and `49152-65535` are reachable on your domain from your RDS for SQL Server DB instance.

Error Code	Description	Common causes	Troubleshooting suggestions
Error 1727 / 0x6BF	The remote procedure call failed and did not execute.	Network connectivity issue or firewall restriction blocking RPC communication to the domain controller.	If using Cross VPC domain join, validate Cross VPC communication is setup correctly with either VPC peering or Transit Gateway. Ensure TCP high ports 49152-65535 are reachable on your domain from your RDS for SQL Server DB instance, including any possible firewall restrictions.
Error 2224 / 0x8B0	The user account already exists.	The computer account that's attempting to be added to your self-managed AD already exists.	Identify the computer account by running `SELECT @@SERVERNAME` on your RDS for SQL Server DB instance and then carefully remove it from your self-managed AD.
Error 2242 / 0x8c2	The password of this user has expired.	The password for the domain service account specified via AWS Secrets Manager has expired.	Update the password for the domain service account used to join your RDS for SQL Server DB instance to your self-managed AD.

After joining your DB instance to a self-managed Active Directory domain, you might receive RDS events related to your domain health.

```
Unhealthy domain state detected while attempt to verify or
```

```
configure your Kerberos endpoint in your domain on
node node_n. message
```

For Multi-AZ instances, you might notice the error reporting for both node1 and node2, which indicates your instance's Kerberos configuration is not ready for failover. In the event of a failover, you might experience authentication difficulties using Kerberos. Resolve the configuration issues to ensure Kerberos setup is valid and up to date. For Multi-AZ instances, no actions are required to use Kerberos authentication on the new primary host given all network and permission configurations are in place.

For Single-AZ instances, node1 is the primary node. If your Kerberos authentication is not working as expected, check the instance events and resolve the configuration issues to ensure Kerberos setup is valid and up to date.

Restoring a SQL Server DB instance and then adding it to a self-managed Active Directory domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a self-managed Active Directory domain. Once the DB instance is restored, modify the instance using the process explained in Step 1: Create or modify a SQL Server DB instance to add the DB instance to a self-managed AD domain.

Working with AWS Managed Active Directory with RDS for SQL Server

You can use AWS Managed Microsoft AD to authenticate users with Windows Authentication when they connect to your RDS for SQL Server DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to enable Windows Authentication. When users authenticate with a SQL Server DB instance joined to the trusting domain, authentication requests are forwarded to the domain directory that you create with Directory Service.

Region and version availability

Amazon RDS supports using only AWS Managed Microsoft AD for Windows Authentication. RDS doesn't support using AD Connector. For more information, see the following:

- Application compatibility policy for AWS Managed Microsoft AD
- Application compatibility policy for AD Connector

For information on version and Region availability, see Kerberos authentication with RDS for SQL Server.

Overview of setting up Windows authentication

Amazon RDS uses mixed mode for Windows Authentication. This approach means that the *master user* (the name and password used to create your SQL Server DB instance) uses SQL Authentication. Because the master user account is a privileged credential, you should restrict access to this account.

To get Windows Authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust. The trust can be one-way or two-way. For more information on setting up forest trusts using Directory Service, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

To set up Windows authentication for a SQL Server DB instance, do the following steps, explained in greater detail in Setting up Windows Authentication for SQL Server DB instances:

1. Use AWS Managed Microsoft AD, either from the AWS Management Console or Directory Service API, to create an AWS Managed Microsoft AD directory.
2. If you use the AWS CLI or Amazon RDS API to create your SQL Server DB instance, create an AWS Identity and Access Management (IAM) role. This role uses the managed IAM policy

`AmazonRDSDirectoryServiceAccess` and allows Amazon RDS to make calls to your directory. If you use the console to create your SQL Server DB instance, AWS creates the IAM role for you.

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Managing AWS STS in an AWS Region in the *IAM User Guide*.

3. Create and configure users and groups in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users and groups in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different VPCs, enable cross-VPC traffic.
5. Use Amazon RDS to create a new SQL Server DB instance either from the console, AWS CLI, or Amazon RDS API. In the create request, you provide the domain identifier ("`d-*`" identifier) that was generated when you created your directory and the name of the role you created. You can also modify an existing SQL Server DB instance to use Windows Authentication by setting the domain and IAM role parameters for the DB instance.
6. Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users from the Active Directory users and groups in their domain. (These are known as SQL Server "Windows" logins.) Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

When you create a domain-connected RDS for SQL Server DB instance using the Amazon RDS console, AWS automatically creates the `rds-directoryservice-access-role` IAM role. This role is essential for managing domain-connected instances and is required for the following operations:

- Making configuration changes to domain-connected SQL Server instances
- Managing Active Directory integration settings
- Performing maintenance operations on domain-joined instances

Important

If you delete the `rds-directoryservice-access-role` IAM role, you can't make changes to your domain-connected SQL Server instance through the Amazon RDS console or API. Attempting to modify the instance results in an error message stating: You don't have permission to iam:CreateRole. To request access, copy the following text and send it to your AWS administrator.
This error occurs because Amazon RDS needs to recreate the role to manage the domain connection, but lacks the necessary permissions. Additionally, this error is not logged in CloudTrail, which can make troubleshooting more difficult.

If you accidentally delete the `rds-directoryservice-access-role`, you must have `iam:CreateRole` permissions to recreate it before you can make any changes to your domain-connected SQL Server instance. To recreate the role manually, ensure it has the `AmazonRDSDirectoryServiceAccess` managed policy attached and the appropriate trust relationship that allows the RDS service to assume the role.

Creating the endpoint for Kerberos authentication

Kerberos-based authentication requires that the endpoint be the customer-specified host name, a period, and then the fully qualified domain name (FQDN). For example, the following is an example of an endpoint you might use with Kerberos-based authentication. In this example, the SQL Server DB instance host name is `ad-test` and the domain name is `corp-ad.company.com`.

```
ad-test.corp-ad.company.com
```

If you want to make sure your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
  FROM sys.dm_exec_connections
 WHERE session_id = @@SPID;
```

Setting up Windows Authentication for SQL Server DB instances

You use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Windows Authentication for a SQL Server DB instance. To set up Windows Authentication, take the following steps.

Step 1: Create a directory using the AWS Directory Service for Microsoft Active Directory

Directory Service creates a fully managed, Microsoft Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, Directory Service creates two domain controllers and Domain Name Service (DNS) servers on your behalf. The directory servers are created in two subnets in two different Availability Zones within a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, Directory Service performs the following tasks on your behalf:

- Sets up a Microsoft Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
- Creates a security group for the directory controllers.

When you launch an AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all your directory's objects. This OU, which has the NetBIOS name that you typed when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The *admin* account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users, groups, and computers.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users and groups in your OU.
- Create additional OUs and containers.
- Delegate authority.
- Create and link group policies.
- Restore deleted objects from the Active Directory Recycle Bin.
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service.

The admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders).

- View DNS event logs.
- View security event logs.

To create a directory with AWS Managed Microsoft AD

1. In the Directory Service console navigation pane, choose **Directories** and choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. This is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

   Edition

   Choose the edition that meets your requirements.

   Directory DNS name

   The fully qualified name for the directory, such as `corp.example.com`. Names longer than 47 characters aren't supported by SQL Server.

   Directory NetBIOS name

   An optional short name for the directory, such as `CORP`.

   Directory description

   An optional description for the directory.

   Admin password

   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password can't include the word `admin`. The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

   - Lowercase letters (a-z)
   - Uppercase letters (A-Z)
   - Numbers (0-9)

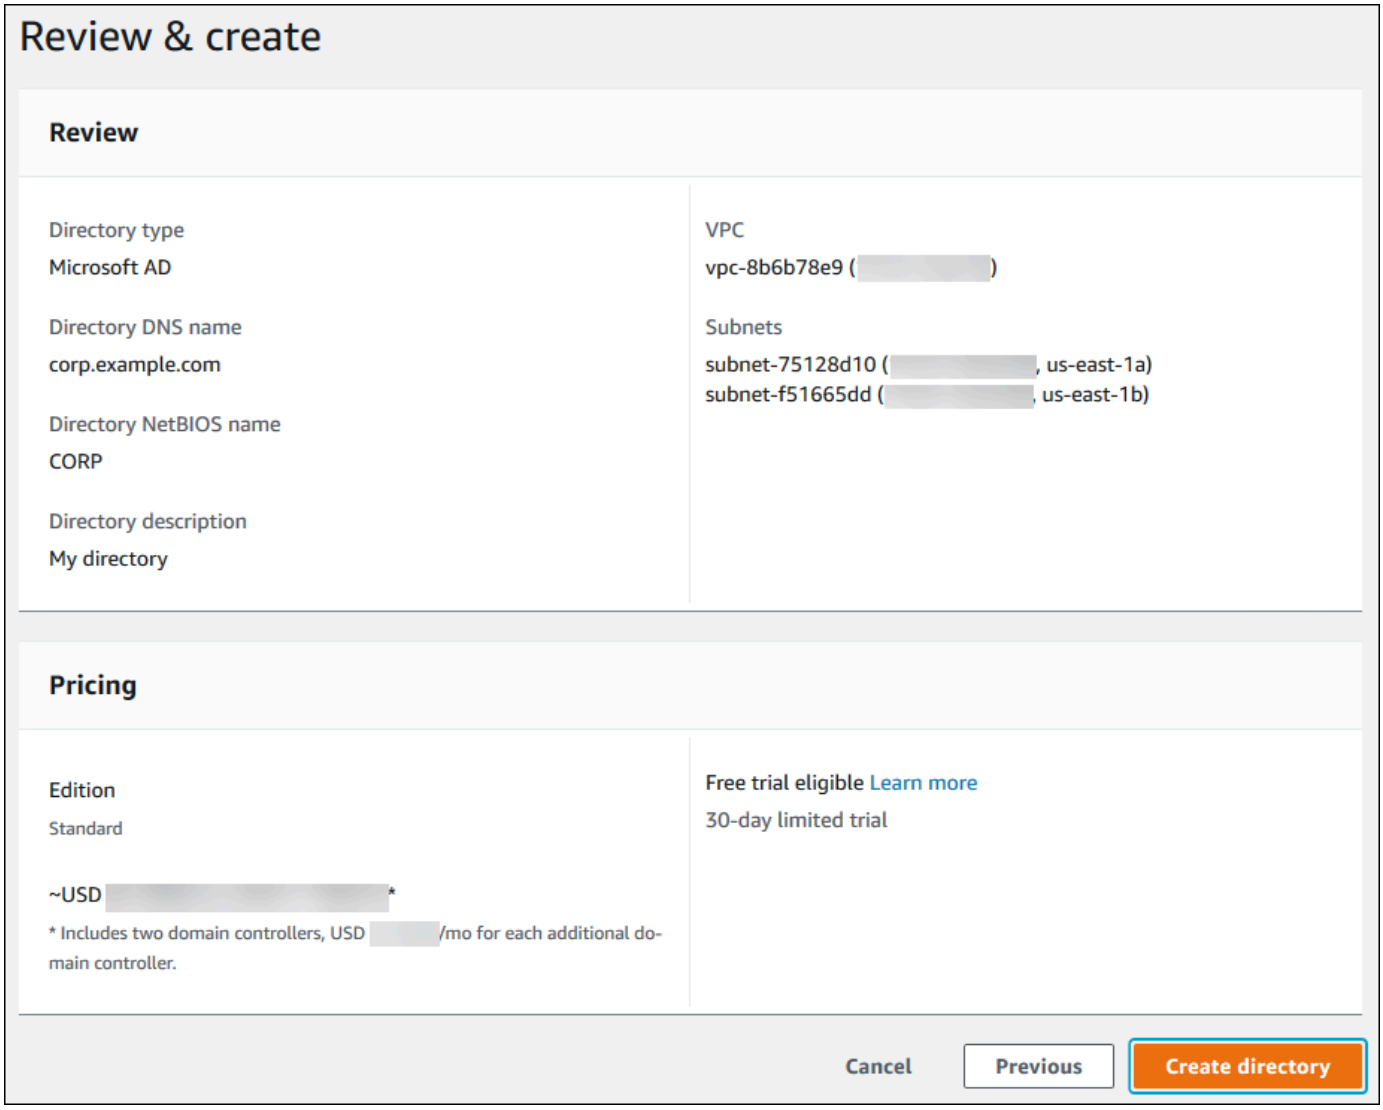
- Non-alphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

Retype the administrator password.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

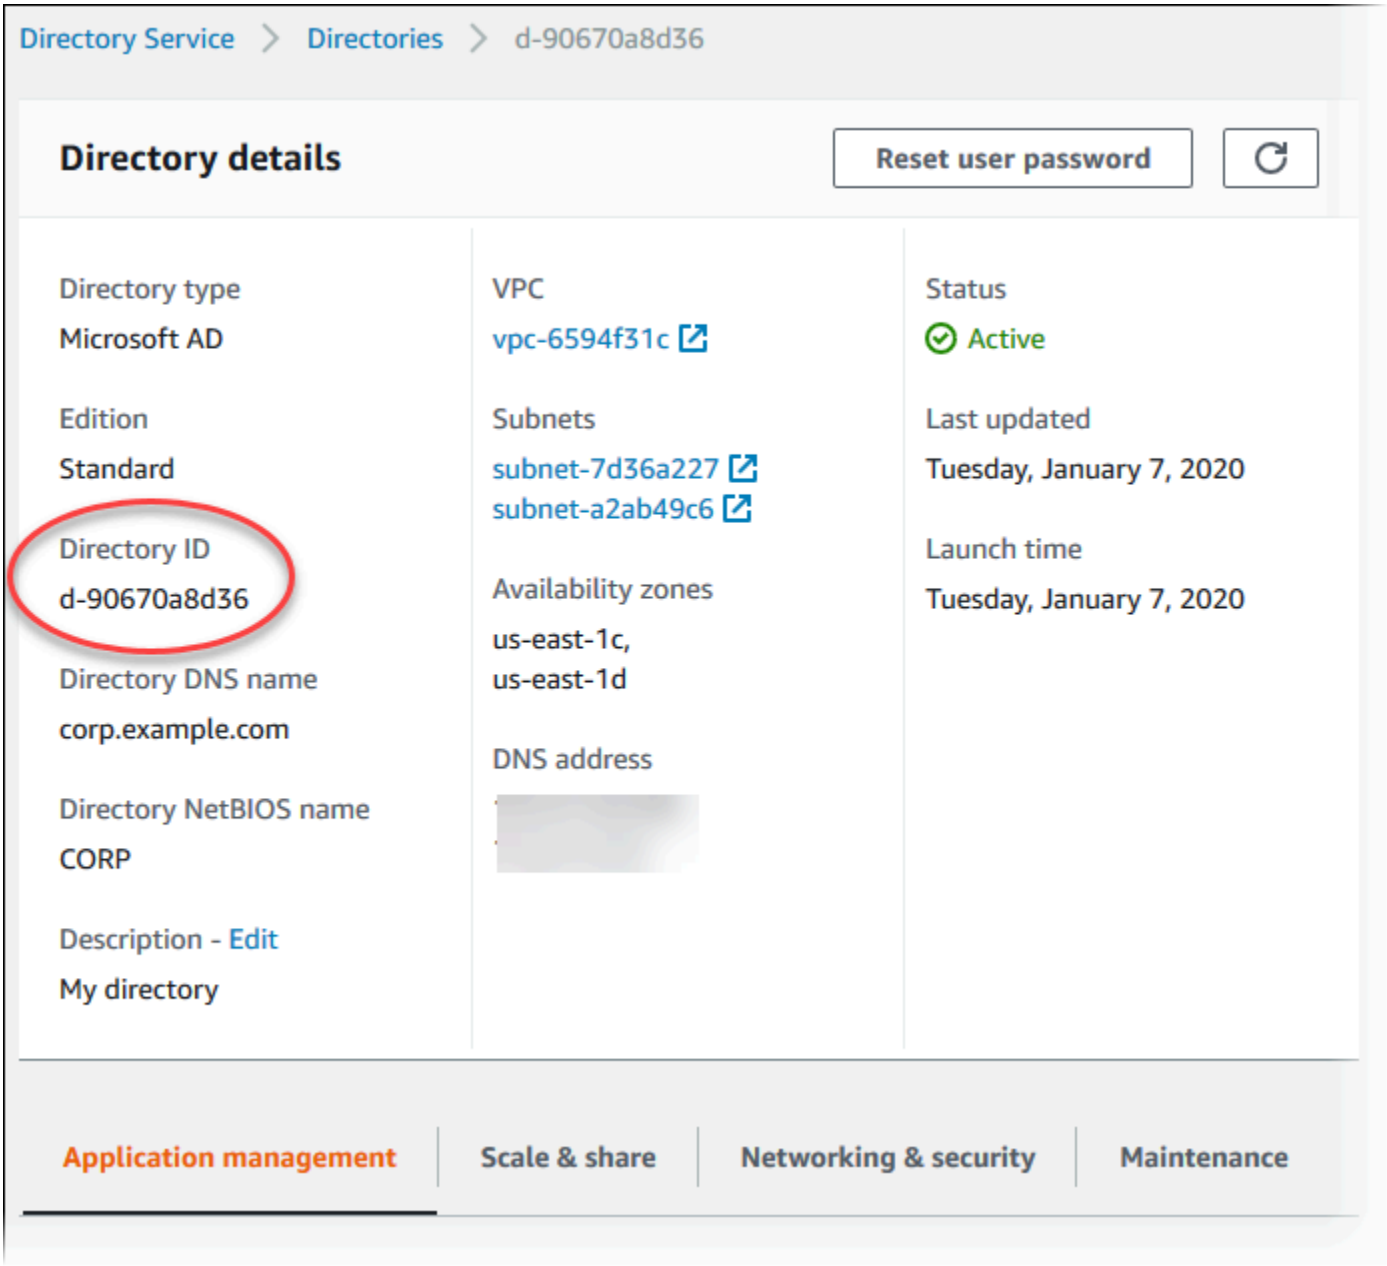
VPC



Choose the VPC for the directory.

> **Note**
>
> You can locate the directory and the DB instance in different VPCs, but if you do so, make sure to enable cross-VPC traffic. For more information, see Step 4: Enable cross-VPC traffic between the directory and the DB instance.

Subnets



Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous**. When the information is correct, choose **Create directory**.

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID**. You need this value when you create or modify your SQL Server DB instance.

Step 2: Create the IAM role for use by Amazon RDS

If you use the console to create your SQL Server DB instance, you can skip this step. If you use the CLI or RDS API to create your SQL Server DB instance, you must create an IAM role that uses the `AmazonRDSDirectoryServiceAccess` managed IAM policy. This role allows Amazon RDS to make calls to the Directory Service for you.

If you are using a custom policy for joining a domain, rather than using the AWS-managed `AmazonRDSDirectoryServiceAccess` policy, make sure that you allow the

`ds:GetAuthorizedApplicationDetails` action. This requirement is effective starting July 2019, due to a change in the Directory Service API.

The following IAM policy, `AmazonRDSDirectoryServiceAccess`, provides access to Directory Service.

Example IAM policy for providing access to Directory Service

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
            "ds:DescribeDirectories",
            "ds:AuthorizeApplication",
            "ds:UnauthorizeApplication",
            "ds:GetAuthorizedApplicationDetails"
        ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For Windows Authentication, make sure to include the DB instances, as shown in the following example.

Example trust relationship with global condition context key for Windows Authentication

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [

 "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    ]
                }
            }
        }
    ]
}
```

Create an IAM role using this IAM policy and trust relationship. For more information about creating IAM roles, see Creating customer managed policies in the *IAM User Guide*.

Step 3: Create and configure users and groups

You can create users and groups with the Active Directory Users and Computers tool. This tool is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory. Groups are very useful for giving or denying privileges to groups of users, rather than having to apply those privileges to each individual user.

To create users and groups in an Directory Service directory, you must be connected to a Windows EC2 instance that is a member of the Directory Service directory. You must also be logged in as a user that has privileges to create users and groups. For more information, see Add users and groups (Simple AD and AWS Managed Microsoft AD) in the *AWS Directory Service Administration Guide*.

Step 4: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 5: Create or modify a SQL Server DB instance.

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join in the *Directory Service Administration Guide*.
2. Sign in to the Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 5: Create or modify a SQL Server DB instance

Create or modify a SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.
- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.
- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

Windows Authentication is only supported for SQL Server DB instances in a VPC.

For the DB instance to be able to use the domain directory that you created, the following is required:

- For **Directory**, you must choose the domain identifier (d-*ID*) generated when you created the directory.
- Make sure that the VPC security group has an outbound rule that lets the DB instance communicate with the directory.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier (`d-`*`ID`*) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role that you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 6: Create Windows Authentication SQL Server logins

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users. You do this from the Active Directory users and groups in your domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

For an Active Directory user to authenticate with SQL Server, a SQL Server Windows login must exist for the user or a group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A user that doesn't have a SQL Server login or belong to a group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create an Active Directory SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication.

Run a data definition language (DDL) command such as the following example to create a SQL Server login for an Active Directory user or group.

Note

Specify users and groups using the pre-Windows 2000 login name in the format *domainName**login_name*. You can't use a user principal name (UPN) in the format *login_name*@*DomainName*.
You can only create a Windows Authentication login on an RDS for SQL Server instance by using T-SQL statements. You can't use the SQL Server Management studio to create a Windows Authentication login.

```
USE [master]
GO
```

```
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
 DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see CREATE LOGIN (Transact-SQL) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a domain-joined client machine using Windows authentication.

Managing a DB instance in a Domain

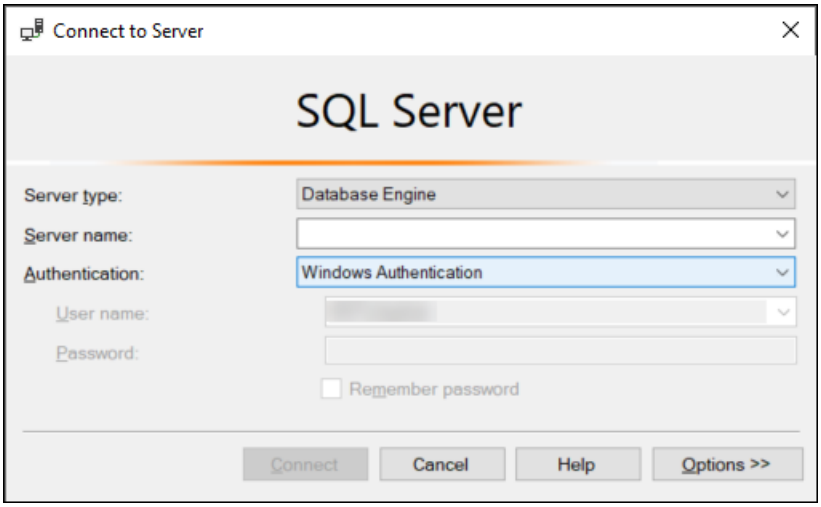
You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the `ModifyDBInstance` API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the DescribeDBInstances API operation.

Understanding Domain membership

After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:



- **joined** – The instance is a member of the domain.
- **joining** – The instance is in the process of becoming a member of the domain.
- **pending-join** – The instance membership is pending.

- **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

Connecting to SQL Server with Windows authentication

To connect to SQL Server with Windows Authentication, you must be logged into a domain-joined computer as a domain user. After launching SQL Server Management Studio, choose **Windows Authentication** as the authentication type, as shown following.

Restoring a SQL Server DB instance and then adding it to a domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a domain. Once the DB instance is restored, modify the instance using the process explained in Step 5: Create or modify a SQL Server DB instance to add the DB instance to a domain.

Upgrades of the Microsoft SQL Server DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for SQL Server DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must *manually* perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you test the upgrade by following the steps described in Testing an RDS for SQL Server upgrade.

Minor version upgrades contain only changes that are backward-compatible with existing applications. You can upgrade the minor version for your DB instance in two ways:

- *Manually* – Modify your DB instance to initiate the upgrade
- *Automatically* – Enable automatic minor version upgrades for your DB instance

When you enable automatic minor version upgrades, RDS for SQL Server automatically upgrades your database instance during scheduled maintenance windows when critical security updates are available in a newer minor version.

For minor engine versions after `16.00.4120.1`, `15.00.4365.2`, `14.00.3465.1`, `13.00.6435.1`, the following security protocols are disabled by default:

- `rds.tls10` (TLS 1.0 protocol)
- `rds.tls11` (TLS 1.1 protocol)
- `rds.rc4` (RC4 cipher)
- `rds.curve25519` (Curve25519 encryption)
- `rds.3des168` (Triple DES encryption)

For earlier engine versions, Amazon RDS enables these security protocols by default.

```
...

"ValidUpgradeTarget": [
    {
```

```
        "Engine": "sqlserver-se",
        "EngineVersion": "14.00.3281.6.v1",
        "Description": "SQL Server 2017 14.00.3281.6.v1",
        "AutoUpgrade": false,
        "IsMajorVersionUpgrade": false
    }
...
```

For more information about performing upgrades, see Upgrading a SQL Server DB instance. For information about what SQL Server versions are available on Amazon RDS, see Amazon RDS for Microsoft SQL Server.

Amazon RDS also supports upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

Major version upgrades for RDS for SQL Server

Amazon RDS currently supports the following major version upgrades to a Microsoft SQL Server DB instance.

You can upgrade your existing DB instance to SQL Server 2017 or 2019 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions.

Current version	Supported upgrade versions
SQL Server 2019	SQL Server 2022
SQL Server 2017	SQL Server 2022 SQL Server 2019

Current version	Supported upgrade versions
SQL Server 2016	SQL Server 2022
	SQL Server 2019
	SQL Server 2017

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
    --engine sqlserver-se \
    --engine-version 14.00.3281.6.v1 \
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
    --output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
    --engine sqlserver-se ^
    --engine-version 14.00.3281.6.v1 ^
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
    --output table
```

The output shows that you can upgrade version 14.00.3281.6 to the latest available SQL Server 2017 or 2019 versions.

```
-------------------------
|DescribeDBEngineVersions|
+------------------------+
|      EngineVersion     |
+------------------------+
|  14.00.3294.2.v1       |
|  14.00.3356.20.v1      |
|  14.00.3381.3.v1       |
```

```
|  14.00.3401.7.v1       |
|  14.00.3421.10.v1      |
|  14.00.3451.2.v1       |
|  15.00.4043.16.v1      |
|  15.00.4073.23.v1      |
|  15.00.4153.1.v1       |
|  15.00.4198.2.v1       |
|  15.00.4236.7.v1       |
+------------------------+
```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see Compatibility level in the Microsoft documentation. When you upgrade your DB instance, all existing databases remain at their original compatibility level.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named `customeracct` to be compatible with SQL Server 2016, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 130
```

Considerations for SQL Server upgrades

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. The second DB snapshot is taken after the upgrade finishes.

> **Note**
>
> Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance.

After an upgrade is completed, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore from the DB snapshot that was taken before the upgrade to create a new DB instance.

During a minor or major version upgrade of SQL Server, the **Free Storage Space** and **Disk Queue Depth** metrics will display -1. After the upgrade is completed, both metrics will return to normal.

Before you upgrade your SQL Server instance, review the following information.

Topics

- Best practices before initiating an upgrade
- Multi-AZ considerations
- Read replica considerations
- Option group considerations
- Parameter group considerations

Best practices before initiating an upgrade

Before starting the upgrade process, implement the following preparatory stpes to allow optimal upgrade performance and minimize potential issues:

Timing and workload management

- Schedule upgrades during low transaction volume periods.
- Minimize write operations during the upgrade window.

  This allows Amazon RDS to complete upgrades faster by reducing the number of transaction log backup files that RDS needs to restore during secondary-to-primary pairing.

Transaction management

- Identify and monitor long-running transactions.
- Ensure all critical transactions are commited before starting the upgrade.
- Prevent long-running transactions during the upgrade window.

Log file optimization

Review and optimize transaction log files:

- Shrink oversized log files.
- Reduce high log consumption patterns.
- Manage Virtual Log Files (VLFs).

- Maintain adequate free space for normal operations.

Multi-AZ considerations

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.

In a Multi-AZ deployment (Mirroring/AlwaysOn), when an upgrade is requested, RDS follows a rolling upgrade strategy for the primary and secondary instances. Rolling upgrades ensure at least one instance is available for transactions while the secondary instance is upgraded. The outage is expected to only last the duration of a failover.

During the upgrade, RDS removes the secondary instance from the Multi-AZ configuration, performs an upgrade of the secondary instance, and restores any transaction log backups from the primary taken during the time it was disconnected. After all the log backups are restored, RDS joins the upgraded secondary to the primary. When all the databases are in a synchronized state, RDS performs a failover to the upgraded secondary instance. Once the failover is completed, RDS proceeds with upgrading the old primary instance, restores any transaction log backups, and pairs it with the new primary.

To minimize this failover duration, we recommend using AlwaysOn AGs availability group listener endpoint when using client libraries that support the `MultiSubnetFailover` connection option in the connection string. When using the availability group listener endpoint, failover times are typically less than 10 seconds, however, this duration does not include any additional crash recovery time.

Read replica considerations

During a database version upgrade, Amazon RDS upgrades all of your read replicas along with the primary DB instance. Amazon RDS does not support database version upgrades on the read replicas separately. For more information on read replicas, see Working with read replicas for Microsoft SQL Server in Amazon RDS.

When you perform a database version upgrade of the primary DB instance, all its read-replicas are also automatically upgraded. Amazon RDS will upgrade all of the read replicas simultaneously before upgrading the primary DB instance. Read replicas may not be available until the database version upgrade on the primary DB instance is complete.

Option group considerations

If your DB instance uses a custom DB option group, in some cases Amazon RDS can't automatically assign your DB instance a new option group. For example, when you upgrade to a new major version, you must specify a new option group. We recommend that you create a new option group, and add the same options to it as your existing custom option group.

For more information, see Creating an option group or Copying an option group.

Parameter group considerations

If your DB instance uses a custom DB parameter group:

- Amazon RDS automatically reboots the DB instance after an upgrade.
- In some cases, RDS can't automatically assign a new parameter group to your DB instance.

  For example, when you upgrade to a new major version, you must specify a new parameter group. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group in Amazon RDS or Copying a DB parameter group in Amazon RDS.

Testing an RDS for SQL Server upgrade

Before you perform a major version upgrade on your DB instance, you should thoroughly test your database, and all applications that access the database, for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review Upgrade SQL Server in the Microsoft documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations.
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations.

4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring to a DB instance.
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console
   - AWS CLI
   - RDS API
7. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
8. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
9. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you do not allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a SQL Server DB instance

For information about manually or automatically upgrading a SQL Server DB instance, see the following:

- Upgrading a DB instance engine version
- Best practices for upgrading SQL Server 2008 R2 to SQL Server 2016 on Amazon RDS for SQL Server

> **Important**
>
> If you have any snapshots that are encrypted using AWS KMS, we recommend that you initiate an upgrade before support ends.

Upgrading deprecated DB instances before support ends

After a major version is deprecated, you can't install it on new DB instances. RDS will try to automatically upgrade all existing DB instances.

If you need to restore a deprecated DB instance, you can do point-in-time recovery (PITR) or restore a snapshot. Doing this gives you temporary access a DB instance that uses the version that is being deprecated. However, after a major version is fully deprecated, these DB instances will also be automatically upgraded to a supported version.

Working with storage in RDS for SQL Server

With RDS for SQL Server, you can attach up to three additional volumes to your RDS for SQL Server instance, each mapped to a unique Windows drive letter. This allows you to distribute database files across multiple volumes beyond the default `D:` drive. When you add a storage volume, you get enhanced flexibility for database file management and storage optimization.

Benefits include:

- **Flexible file distribution** – Distribute database data files and log files across multiple volumes for improved I/O performance.
- **Storage optimization** – Use different storage types and configurations for different workload requirements.
- **Scalability** – Add storage capacity without modifying existing volumes.

On this page

- Considerations for using additional storage volumes with RDS for SQL Server
- Add, remove, or modify storage volumes with RDS for SQL Server
- Restore operations for additional storage volumes with RDS for SQL Server
- Use cases for additional storage volumes with RDS for SQL Server

Considerations for using additional storage volumes with RDS for SQL Server

Take note of the following features and limitations when using additional storage volumes with RDS for SQL Server:

- You can only add storage volumes on SQL Server Standard Edition (SE), Enterprise Edition (EE), and Developer Edition (DEV-EE).
- You can add up to 3 additional storage volumes per instance.
- Volume names are automatically mapped to Windows drive letters as follows:
  - `rdsdbdata2` – `H:` drive
  - `rdsdbdata3` – `I:` drive
  - `rdsdbdata4` – `J:` drive

- TempDB files continue to use the `T:` drive when using NVMe instance storage. SQL Server Audit files and Microsoft Business Intelligence (MSBI) files remain on the `D:` drive.
- You can only add General Purpose SSD (gp3) and Provisioned IOPS SSD (io2) storage types.
- The minimum storage size of additional storage volumes is the same as the limit set for the default `D:` drive. The maximum storage size for your DB instance is 256 TiB total across all volumes.
- Adding storage volumes to instances with read replicas or to read replica instances isn't supported.
- Adding storage volumes to instances enabled for cross-region automated backup isn't supported.
- Configuring additional storage volumes for storage autoscaling isn't supported.
- Moving files between volumes after creation isn't supported.
- You can't delete the `D:` volume, but you can delete other storage volumes as long as they're empty.
- Modifying the size of existing volumes during snapshot restore or point-in-time recovery (PITR) isn't supported. However, you can add new storage volumes during restore operations.

Add, remove, or modify storage volumes with RDS for SQL Server

You can add, modify, and remove additional storage volumes using the AWS CLI or AWS Management Console. All operations use the `modify-db-instance` API operation with the `additional-storage-volumes` parameter.

> **Important**
>
> Adding or removing additional storage volumes creates a backup pending action and a point-in-time restore blackout window. This window closes when the backup workflow completes.

Topics

- Adding storage volumes
- Scaling additional storage volumes
- Removing additional storage volumes

Adding storage volumes

You can add up to three storage volumes beyond the default `D:` drive. To add a new storage volume to your RDS for SQL Server instance, use the `modify-db-instance` command with the `additional-storage-volumes` parameter.

The following example adds a new 4,000 GiB General Purpose SSD (gp3) volume named `rdsdbdata4`.

```
aws rds modify-db-instance \
  --db-instance-identifier my-sql-server-instance \
  --region us-east-1 \
  --additional-storage-volumes
 '[{"VolumeName":"rdsdbdata4","StorageType":"gp3","AllocatedStorage":4000}]' \
  --apply-immediately
```

Scaling additional storage volumes

You can modify any storage setting for your additional volumes except for storage size. The following example modifies the IOPS setting for the `rdsdbdata2` volume.

```
aws rds modify-db-instance \
  --db-instance-identifier my-sql-server-instance \
  --region us-east-1 \
  --additional-storage-volumes '[{"VolumeName":"rdsdbdata2","IOPS":4000}]' \
  --apply-immediately
```

Removing additional storage volumes

You can't delete the `D:` volume, but you can delete other storage volumes when they're empty.

> **Warning**
>
> Before you remove an additional storage volume, make sure that no database files are stored on the volume.

The following example removes the `rdsdbdata4` volume.

```
aws rds modify-db-instance \
  --db-instance-identifier my-sql-server-instance \
```

```
  --region us-east-1 \
  --additional-storage-volumes '[{"VolumeName":"rdsdbdata4","SetForDelete":true}]' \
  --apply-immediately
```

Restore operations for additional storage volumes with RDS for SQL Server

When you restore your database, you can add storage volumes. You can also modify the storage settings of existing volumes.

Topics

- Snapshot restore
- Point-in-time recovery
- Native database restore

Snapshot restore

When restoring from a snapshot, you can add new additional storage volumes or modify the IOPS, throughput, and storage type settings of existing volumes.

The following example restores a DB instance from a snapshot and modifies the IOPS setting for the `rdsdbdata2` volume:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier my-restored-instance \
  --db-snapshot-identifier my-snapshot \
  --region us-east-1 \
  --additional-storage-volumes '[{"VolumeName":"rdsdbdata2","IOPS":5000}]'
```

Point-in-time recovery

During point-in-time recovery (PITR), you can add new additional storage volumes with custom configurations.

The following example performs PITR and adds a new 5,000 GiB General Purpose SSD (gp3) volume:

```
aws rds restore-db-instance-to-point-in-time \
  --source-db-instance-identifier my-source-instance \
```

```
  --target-db-instance my-pitr-instance \
  --use-latest-restorable-time \
  --region us-east-1 \
  --additional-storage-volumes
'[{"VolumeName":"rdsdbdata4","StorageType":"gp3","AllocatedStorage":5000,"IOPS":5000,"StorageT
```

Native database restore

You can use the `rds_restore_database` stored procedure to restore databases to specific additional storage volumes. Two new parameters support volume selection:

`data_file_volume`

Specifies the drive letter for database data files

`log_file_volume`

Specifies the drive letter for database log files

The following example restores a database with data files on the `H:` drive and log files on the `I:` drive:

```
EXEC msdb.dbo.rds_restore_database
    @restore_db_name='my_database',
    @s3_arn_to_restore_from='arn:aws:s3:::my-bucket/backup-file.bak',
    @data_file_volume='H:',
    @log_file_volume='I:';
```

If you don't specify volume parameters, or if you specify the `D:` drive for both parameters, the database files are restored to the default `D:` drive:

```
EXEC msdb.dbo.rds_restore_database
    @restore_db_name='my_database',
    @s3_arn_to_restore_from='arn:aws:s3:::my-bucket/backup-file.bak';
```

Use cases for additional storage volumes with RDS for SQL Server

Additional storage volumes support various database management scenarios. The following sections describe common use cases and implementation approaches.

Topics

- Creating databases on additional storage volumes
- Extending storage capacity
- Moving databases between volumes
- Archiving data to cost-effective storage

Creating databases on additional storage volumes

You can create new databases directly on additional storage volumes using standard SQL Server `CREATE DATABASE` statements.

The following example creates a database with data files on the `H:` drive and log files on the `I:` drive:

```
CREATE DATABASE MyDatabase
ON (
    NAME = 'MyDatabase_Data',
    FILENAME = 'H:\rdsdbdata\data\MyDatabase_Data.mdf',
    SIZE = 100MB,
    FILEGROWTH = 10MB
)
LOG ON (
    NAME = 'MyDatabase_Log',
    FILENAME = 'I:\rdsdbdata\data\MyDatabase_Log.ldf',
    SIZE = 10MB,
    FILEGROWTH = 10%
);
```

Extending storage capacity

When the default `D:` drive reaches its maximum capacity, you can add additional storage volumes, scale existing volumes, and create new data files or log files on the new volumes.

To extend storage capacity

1. Add a storage volume to your instance using the `modify-db-instance` command.
2. Add a new data file to the additional storage volume:

```
ALTER DATABASE MyDatabase
ADD FILE (
```

```
    NAME = 'MyDatabase_Data2',
    FILENAME = 'H:\rdsdbdata\data\MyDatabase_Data2.ndf',
    SIZE = 500MB,
    FILEGROWTH = 50MB
);
```

Moving databases between volumes

To move a database to a different volume, use the backup and restore approach with the `rds_backup_database` and `rds_restore_database` stored procedures. For more information, see Using native backup and restore.

To move a database to a different volume

1. Back up the database using `rds_backup_database`:

```
EXEC msdb.dbo.rds_backup_database
    @source_db_name='MyDatabase',
    @s3_arn_to_backup_to='arn:aws:s3:::my-bucket/database-backup.bak';
```

2. Restore the database to the target volume:

```
EXEC msdb.dbo.rds_restore_database
    @restore_db_name='MyDatabase_New',
    @s3_arn_to_restore_from='arn:aws:s3:::my-bucket/database-backup.bak',
    @data_file_volume='H:',
    @log_file_volume='I:';
```

3. Drop the database from your old drive to release the space. For more information, see Dropping a database in an Amazon RDS for Microsoft SQL Server DB instance.

Archiving data to cost-effective storage

For partitioned tables, you can archive older data to additional storage volumes with different performance characteristics.

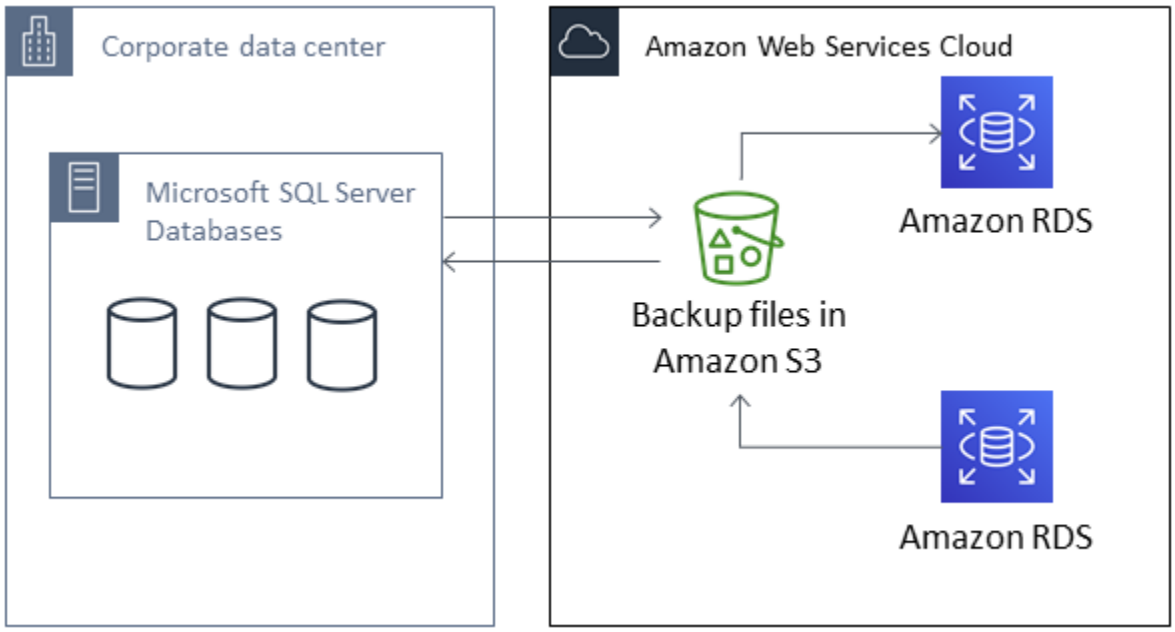
To archive partitioned data

1. Add a storage volume with appropriate storage type and capacity.
2. Create a new filegroup on the additional storage volume:

```
ALTER DATABASE MyDatabase
ADD FILEGROUP ArchiveFileGroup;

ALTER DATABASE MyDatabase
ADD FILE (
    NAME = 'Archive_Data',
    FILENAME = 'H:\rdsdbdata\data\Archive_Data.ndf',
    SIZE = 1GB,
    FILEGROWTH = 100MB
) TO FILEGROUP ArchiveFileGroup;
```

3. Move partitions to the new filegroup using SQL Server partition management commands.



Importing and exporting SQL Server databases using native backup and restore

Amazon RDS supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). When you use RDS, you access files stored in Amazon S3 rather than using the local file system on the database server.

For example, you can create a full backup from your local server, store it on S3, and then restore it onto an existing Amazon RDS DB instance. You can also make backups from RDS, store them on S3, and then restore them wherever you want.

Native backup and restore is available in all AWS Regions for Single-AZ and Multi-AZ DB instances, including Multi-AZ DB instances with read replicas. Native backup and restore is available for all editions of Microsoft SQL Server supported on Amazon RDS.

The following diagram shows the supported scenarios.

Using native .bak files to back up and restore databases is usually the fastest way to back up and restore databases. There are many additional advantages to using native backup and restore. For example, you can do the following:

- Migrate databases to or from Amazon RDS.
- Move databases between RDS for SQL Server DB instances.
- Migrate data, schemas, stored procedures, triggers, and other database code inside .bak files.

- Backup and restore single databases, instead of entire DB instances.
- Create copies of databases for development, testing, training, and demonstrations.
- Store and transfer backup files with Amazon S3, for an added layer of protection for disaster recovery.
- Create native backups of databases that have Transparent Data Encryption (TDE) turned on, and restore those backups to on-premises databases. For more information, see Support for Transparent Data Encryption in SQL Server.
- Restore native backups of on-premises databases that have TDE turned on to RDS for SQL Server DB instances. For more information, see Support for Transparent Data Encryption in SQL Server.

Limitations and recommendations

The following are some limitations to using native backup and restore:

- You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance.
- You can't restore a database with the same name as an existing database. Database names are unique.
- We strongly recommend that you don't restore backups from one time zone to a different time zone. If you restore backups from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change.
- RDS for Microsoft SQL Server has a size limit of 5 TB per file. For native backups of larger databases, you can use multifile backup.
- The maximum database size that can be backed up to S3 depends on the available memory, CPU, I/O, and network resources on the DB instance. The larger the database, the more memory the backup agent consumes.
- You can't back up to or restore from more than 10 backup files at the same time.
- A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a manual or automated snapshot exists, then do another full backup before proceeding with the differential backup.
- Differential and log restores aren't supported for databases with files that have their file_guid (unique identifier) set to `NULL`.
- You can run up to two backup or restore tasks at the same time.
- You can't perform native log backups from SQL Server on Amazon RDS.
- RDS supports native restores of databases up to 64 TiB. Native restores of databases on SQL Server Express Edition are limited to 10 GB.
- You can't do a native backup during the maintenance window, or any time Amazon RDS is in the process of taking a snapshot of the database. If a native backup task overlaps with the RDS daily backup window, the native backup task is canceled.
- On Multi-AZ DB instances, you can only natively restore databases that are backed up in the full recovery model.
- Calling the RDS procedures for native backup and restore within a transaction isn't supported.
- Use a symmetric encryption AWS KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

- Native backup files are encrypted with the specified KMS key using the "Encryption-Only" crypto mode. When you are restoring encrypted backup files, be aware that they were encrypted with the "Encryption-Only" crypto mode.
- You can't restore a database that contains a FILESTREAM file group.
- Amazon S3 server-side encryption with AWS KMS (SSE-KMS) is supported through your S3 bucket's default encryption configuration when you pass `@enable_bucket_default_encryption=1` to the backup stored procedure. By default, the restore supports the S3 object's server-side encryption.

  When you provide a KMS key to a stored procedure, any native backup and restores are encrypted and decrypted on the client-side with the KMS key. AWS stores the backups in the S3 bucket with SSE-S3 when `@enable_bucket_default_encryption=0` or with your S3 bucket's configured default encryption key when `@enable_bucket_default_encryption=1`.
- When using S3 Access Points, the access point cannot be configured to use an RDS internal VPC.
- For highest performance, we recommend using directory buckets or access points for directory buckets if they are available in your region.

If your database can be offline while the backup file is created, copied, and restored, we recommend that you use native backup and restore to migrate it to RDS. If your on-premises database can't be offline, we recommend that you use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Native backup and restore isn't intended to replace the data recovery capabilities of the cross-region snapshot copy feature. We recommend that you use snapshot copy to copy your database snapshot to another AWS Region for cross-region disaster recovery in Amazon RDS. For more information, see Copying a DB snapshot for Amazon RDS.

Setting up for native backup and restore

To set up for native backup and restore, you need three components:

1. An Amazon S3 bucket to store your backup files.

   You must have an S3 bucket to use for your backup files and then upload backups you want to migrate to RDS. If you already have an Amazon S3 bucket, you can use that. If you don't, you can

create a bucket. Alternatively, you can choose to have a new bucket created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console.

For information on using S3, see the Amazon Simple Storage Service User Guide

2. An AWS Identity and Access Management (IAM) role to access the bucket.

   If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the SQLSERVER_BACKUP_RESTORE option by using the AWS Management Console. Alternatively, you can create a new one manually.

   If you want to create a new IAM role manually, take the approach discussed in the next section. Do the same if you want to attach trust relationships and permissions policies to an existing IAM role.

3. The SQLSERVER_BACKUP_RESTORE option added to an option group on your DB instance.

   To enable native backup and restore on your DB instance, you add the SQLSERVER_BACKUP_RESTORE option to an option group on your DB instance. For more information and instructions, see Support for native backup and restore in SQL Server.

Manually creating an IAM role for native backup and restore

If you want to manually create a new IAM role to use with native backup and restore, you can do so. In this case, you create a role to delegate permissions from the Amazon RDS service to your Amazon S3 bucket. When you create an IAM role, you attach a trust relationship and a permissions policy. The trust relationship allows RDS to assume this role. The permissions policy defines the actions this role can perform. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

For the native backup and restore feature, use trust relationships and permissions policies similar to the examples in this section. In the following example, we use the service principal name `rds.amazonaws.com` as an alias for all service accounts. In the other examples, we specify an Amazon Resource Name (ARN) to identify another account, user, or role that we're granting access to in the trust policy.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full ARN of the resources accessing the role. For native backup and restore, make sure to include both the DB option group and the DB instances, as shown in the following example.

Example of trust relationship with global condition context key for native backup and restore

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {

                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Example permissions policy for native backup and restore with encryption support

If you want to encrypt your backup files, include an encryption key in your permissions policy. For more information about encryption keys, see Getting started in the *AWS Key Management Service Developer Guide*.

Note

You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.
The IAM role must also be a key user and key administrator for the KMS key, that is, it must be specified in the key policy. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToKey",
      "Effect": "Allow",

        "s3:GetObjectAttributes",
```

```
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
    }
  ]
}
```

Example permissions policy for native backup and restore using access points without encryption support

The actions required to use S3 access points are the same as for S3 buckets. The resource path is updated to match the S3 access point ARN pattern.

> **Note**
>
> Access points must be configured to use **Network origin: Internet** as RDS does not publish private VPCs. S3 traffic from RDS instances does not go through the public internet since it goes through private VPCs.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketLocation"
                ],
            "Resource": [
            "arn:aws:s3:us-east-1:111122223333:accesspoint/amzn-s3-demo-ap",
            "arn:aws:s3:::underlying-bucket"
            ]
        },
```

```
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectAttributes",
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
                ],
                "Resource": [
                "arn:aws:s3:us-east-1:111122223333:accesspoint/amzn-s3-demo-ap/
*",
                    "arn:aws:s3:::underlying-bucket/*"
                    ]
                }
            ]
}
```

Example permissions policy for native backup and restore using access points for directory buckets without encryption support

Directory buckets use a different, session-based authorization mechanism than general purpose buckets, so the only required permission for native backup restore is the bucket-level “s3express:CreateSession” permission. To configure object-level access, you must use access points for directory buckets.

> **Note**
>
> Access points must be configured to use **Network origin: Internet** as RDS does not publish private VPCs. S3 traffic from RDS instances does not go through the public internet since it goes through private VPCs.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":
    [
        {
```

```
        "Effect": "Allow",
        "Action": "s3express:CreateSession",
        "Resource":
            [
                "arn:aws:s3express:us-east-1:111122223333:accesspoint/amzn-s3-
demo-accesspoint--use1-az6--xa-s3",
                "arn:aws:s3express:us-east-1:111122223333:bucket/amzn-s3-demo-
bucket--use1-az6--x-s3"
            ]
        }
    ]
}
```

Using native backup and restore

After you have enabled and configured native backup and restore, you can start using it. First, you connect to your Microsoft SQL Server database, and then you call an Amazon RDS stored procedure to do the work. For instructions on connecting to your database, see Connecting to your Microsoft SQL Server DB instance.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your Amazon S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name.extension`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

If you also provide an optional KMS key, the format for the ARN of the key is `arn:aws:kms:region:account-id:key/key-id`. For more information, see Amazon resource names (ARNs) and AWS service namespaces. You must use a symmetric encryption KMS key to encrypt your backups. Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.

> **Note**
>
> Whether or not you use a KMS key, the native backup and restore tasks enable server-side Advanced Encryption Standard (AES) 256-bit encryption through SSE-S3 by default for files uploaded to S3. Passing in `@enable_bucket_default_encryption=1` to the backup stored procedure uses your S3 bucket's configured default encryption key.

For instructions on how to call each stored procedure, see the following topics:

- Backing up a database
- Restoring a database
- Restoring a log
- Finishing a database restore
- Working with partially restored databases
- Canceling a task
- Tracking the status of tasks

Backing up a database

To back up your database, use the `rds_backup_database` stored procedure.

> **Note**
>
> You can't back up a database during the maintenance window, or while Amazon RDS is taking a snapshot.

Usage

```
exec msdb.dbo.rds_backup_database
 @source_db_name='database_name',
 @s3_arn_to_backup_to='arn:aws:s3:::bucket_name/file_name.extension',
 [@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
 [@overwrite_s3_backup_file=0|1],
 [@block_size=512|1024|2048|4096|8192|16384|32768|65536],
        [@max_transfer_size=n],
        [@buffer_count=n],
 [@type='DIFFERENTIAL|FULL'],
 [@number_of_files=n],
 [@enable_bucket_default_encryption=0|1];
```

The following parameters are required:

- `@source_db_name` – The name of the database to back up.
- `@s3_arn_to_backup_to` – The ARN indicating the Amazon S3 bucket, access point, directory bucket, or access point for directory bucket to use for the backup, plus the name of the backup file.

  The file can have any extension, but `.bak` is usually used. Note that access point ARNs must be of the format `arn:aws:s3:us-east-1:111122223333:access-point-name/object/key`.

The following parameters are optional:

- `@kms_master_key_arn` – The ARN for the symmetric encryption KMS key to use to encrypt the item.
  - You can't use the default encryption key. If you use the default key, the database won't be backed up.

  - If you don't specify a KMS key identifier, the backup file won't be encrypted. For more information, see Encrypting Amazon RDS resources.
  - When you specify a KMS key, client-side encryption is used.
  - Amazon RDS doesn't support asymmetric KMS keys. For more information, see Creating symmetric encryption KMS keys in the *AWS Key Management Service Developer Guide*.
- `@overwrite_s3_backup_file` – A value that indicates whether to overwrite an existing backup file.
  - `0` – Doesn't overwrite an existing file. This value is the default.

    Setting `@overwrite_s3_backup_file` to 0 returns an error if the file already exists.
  - `1` – Overwrites an existing file that has the specified name, even if it isn't a backup file.
- `@type` – The type of backup.
  - `DIFFERENTIAL` – Makes a differential backup.
  - `FULL` – Makes a full backup. This value is the default.

  A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a snapshot exists, then do another full backup before proceeding with the differential backup.

  You can look for the last full backup or snapshot using the following example SQL query:

```
select top 1
database_name
,  backup_start_date
,  backup_finish_date
from    msdb.dbo.backupset
where   database_name='mydatabase'
and     type = 'D'
order by backup_start_date desc;
```

- `@number_of_files` – The number of files into which the backup will be divided (chunked). The maximum number is 10.
  - Multifile backup is supported for both full and differential backups.
  - If you enter a value of 1 or omit the parameter, a single backup file is created.

Provide the prefix that the files have in common, then suffix that with an asterisk (*). The asterisk can be anywhere in the *file_name* part of the S3 ARN. The asterisk is replaced by a series of alphanumeric strings in the generated files, starting with 1-of-*number_of_files*.

For example, if the file names in the S3 ARN are backup*.bak and you set @number_of_files=4, the backup files generated are backup1-of-4.bak, backup2-of-4.bak, backup3-of-4.bak, and backup4-of-4.bak.

- If any of the file names already exists, and @overwrite_s3_backup_file is 0, an error is returned.
- Multifile backups can only have one asterisk in the *file_name* part of the S3 ARN.
- Single-file backups can have any number of asterisks in the *file_name* part of the S3 ARN. Asterisks aren't removed from the generated file name.

- @block_size – Block size (in bytes) specifying the physical block size for backup operations. Valid values are 512, 1024, 2048, 4096, 8192, 16384, 32768, and 65536
- @max_transfer_size – Maximum transfer size denotes the upper limit of data volume (in bytes) transmitted per I/O operation during the backup process. Valid values are multiples of 65536 bytes (64 KB) up to 4194304 bytes (4 MB).
- @buffer_count – Total number of I/O buffers to be use for the backup process.
- @enable_bucket_default_encryption – A value that indicates whether to use the S3 bucket's default encryption configuration for server-side encryption in S3. Directory buckets always use the bucket's default encryption configuration regardless of this setting.
  - 0 – Server-side encryption uses Advanced Encryption Standard (AES) 256-bit encryption through SSE-S3.
  - 1 – Server-side encryption uses your S3 bucket's configured default encryption.

Examples

Example of differential backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@overwrite_s3_backup_file=1,
@type='DIFFERENTIAL';
```

Example of full backup with client-side encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@overwrite_s3_backup_file=1,
@type='FULL';
```

Example of multifile backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=4;
```

Example of multifile differential backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@type='DIFFERENTIAL',
@number_of_files=4;
```

Example of multifile backup with encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@number_of_files=4;
```

Example of multifile backup with S3 overwrite

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@overwrite_s3_backup_file=1,
@number_of_files=4;
```

Example of backup with block size

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@block_size=512;
```

Example of multifile backup with `@max_transfer_size` and `@buffer_count`

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=4,
@max_transfer_size=4194304,
@buffer_count=10;
```

Example of single-file backup with the @number_of_files parameter

This example generates a backup file named `backup*.bak`.

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=1;
```

Example of full backup with server-side encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@overwrite_s3_backup_file=1,
@type='FULL',
@enable_bucket_default_encryption=1;
```

Example of full backup using an access point

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point/
object/backup1.bak',
```

```
@overwrite_s3_backup_file=1,
@type='FULL';
```

Example of full backup using an access point for a directory bucket

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3express:us-east-1:123456789012:accesspoint/my-access-point--use1-az6--xa-s3/object/backup1.bak',
@overwrite_s3_backup_file=1,
@type='FULL';
```

Restoring a database

To restore your database, call the `rds_restore_database` stored procedure. Amazon RDS creates an initial snapshot of the database after the restore task is complete and the database is open.

Usage

```
exec msdb.dbo.rds_restore_database
 @restore_db_name='database_name',
 @s3_arn_to_restore_from='arn:aws:s3:::bucket_name/file_name.extension',
 @with_norecovery=0|1,
 [@keep_cdc=0|1],
 [@data_file_volume='D:|H:|I:|J:'],
 [@log_file_volume='D:|H:|I:|J:'],
 [@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
        [@block_size=512|1024|2048|4096|8192|16384|32768|65536],
        [@max_transfer_size=n],
        [@buffer_count=n],
 [@type='DIFFERENTIAL|FULL'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database to restore. Database names are unique. You can't restore a database with the same name as an existing database.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and names of the backup files used to restore the database.
  - For a single-file backup, provide the entire file name.

- For a multifile backup, provide the prefix that the files have in common, then suffix that with an asterisk (*).
  - If using a directory bucket, the ARN must end with `/*` due to differences for directory buckets.
- If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameter is required for differential restores, but optional for full restores:

- `@with_norecovery` – The recovery clause to use for the restore operation.
  - Set it to `0` to restore with RECOVERY. In this case, the database is online after the restore.
  - Set it to `1` to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later differential restores.
  - For DIFFERENTIAL restores, specify `0` or `1`.
  - For `FULL` restores, this value defaults to `0`.

The following parameters are optional:

- `@keep_cdc` – Indicates whether to retain Change Data Capture (CDC) configuration on the restored database. Set to `1` to enable KEEP_CDC, `0` to disable. The default value is `0`.
- `@data_file_volume` – Specifies the drive letter for database data files. The default value is `D:`.
- `@log_file_volume` – Specifies the drive letter for database log files The default value is `D:`.
- `@kms_master_key_arn` – If you encrypted the backup file, the KMS key to use to decrypt the file.

  When you specify a KMS key, client-side encryption is used.
- `@type` – The type of restore. Valid types are `DIFFERENTIAL` and `FULL`. The default value is `FULL`.
- `@block_size` – Block size (in bytes) specifying the physical block size for backup operations. Valid values are 512, 1024, 2048, 4096, 8192, 16384, 32768, and 65536
- `@max_transfer_size` – Maximum transfer size denotes the upper limit of data volume (in bytes) transmitted per I/O operation during the backup process. Valid values are multiples of 65536 bytes (64 KB) up to 4194304 bytes (4 MB).
- `@buffer_count` – Total number of I/O buffers to be use for the backup process.

Note

For differential restores, either the database must be in the RESTORING state or a task must already exist that restores with NORECOVERY.
You can't restore later differential backups while the database is online.
You can't submit a restore task for a database that already has a pending restore task with RECOVERY.
Full restores with both NORECOVERY and KEEP_CDC aren't supported.
All native restores aren't supported on instances that have cross-region read replicas.
For supported configurations, restoring a database on a Multi-AZ instance with read replicas is similar to restoring a database on a Multi-AZ instance. You don't have to take any additional actions to restore a database on a replica.

Examples

Example of single-file restore

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

Example of multifile restore

To avoid errors when restoring multiple files, make sure that all the backup files have the same prefix, and that no other files use that prefix.

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*';
```

Example of full database restore with RECOVERY

The following three examples perform the same task, full restore with RECOVERY.

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
[@type='DIFFERENTIAL|FULL'];
```

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=0;
```

Example of full database restore with encryption

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of restore with block size

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@block_size=512;
```

Example of multifile restore with @max_transfer_size and @buffer_count

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*',
@max_transfer_size=4194304,
@buffer_count=10;
```

Example of full database restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
```

```
@with_norecovery=1;
```

Example of differential restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=1;
```

Example of differential restore with RECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=0;
```

Example of full database restore with RECOVERY using an access point

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:us-east-1:111122223333:accesspoint/my-access-point/
object/backup1.bak',
@with_norecovery=0;
```

Example of full database restore with KEEP_CDC

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@keep_cdc=1;
```

Restoring a log

To restore your log, call the `rds_restore_log` stored procedure.

Usage

```
exec msdb.dbo.rds_restore_log
```

```
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/log_file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@with_norecovery=0|1],
[@keep_cdc=0|1],
[@stopat='datetime'],
[@block_size=512|1024|2048|4096|8192|16384|32768|65536],
       [@max_transfer_size=n],
       [@buffer_count=n];
```

The following parameters are required:

- `@restore_db_name` – The name of the database whose log to restore.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and name of the log file used to restore the log. The file can have any extension, but `.trn` is usually used.

  If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameters are optional:

- `@keep_cdc` – Indicates whether to retain Change Data Capture (CDC) configuration on the restored database. Set to 1 to enable KEEP_CDC, 0 to disable. The default value is 0.
- `@kms_master_key_arn` – If you encrypted the log, the KMS key to use to decrypt the log.
- `@with_norecovery` – The recovery clause to use for the restore operation. This value defaults to 1.
  - Set it to `0` to restore with RECOVERY. In this case, the database is online after the restore. You can't restore further log backups while the database is online.
  - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later log restores.
- `@stopat` – A value that specifies that the database is restored to its state at the date and time specified (in datetime format). Only transaction log records written before the specified date and time are applied to the database.

  If this parameter isn't specified (it is NULL), the complete log is restored.
- `@block_size` – Block size (in bytes) specifying the physical block size for backup operations. Valid values are 512, 1024, 2048, 4096, 8192, 16384, 32768, and 65536

- `@max_transfer_size` – Maximum transfer size denotes the upper limit of data volume (in bytes) transmitted per I/O operation during the backup process. Valid values are multiples of 65536 bytes (64 KB) up to 4194304 bytes (4 MB).
- `@buffer_count` – Total number of I/O buffers to be use for the backup process.

> **Note**
>
> For log restores, either the database must be in a state of restoring or a task must already exist that restores with NORECOVERY.
> You can't restore log backups while the database is online.
> You can't submit a log restore task on a database that already has a pending restore task with RECOVERY.

Examples

Example of log restore

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of log restore with encryption

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of log restore with NORECOVERY

The following two examples perform the same task, log restore with NORECOVERY.

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=1;
```

```
exec msdb.dbo.rds_restore_log
```

```
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of restore with block size

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@block_size=512;
```

Example of log restore with RECOVERY

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0;
```

Example of log restore with STOPAT clause

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0,
@stopat='2019-12-01 03:57:09';
```

Example of log restore with KEEP_CDC

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@keep_cdc=1;
```

Finishing a database restore

If the last restore task on the database was performed using `@with_norecovery=1`, the database is now in the RESTORING state. Open this database for normal operation by using the `rds_finish_restore` stored procedure.

Usage

```
exec msdb.dbo.rds_finish_restore @db_name='database_name';
```

> **Note**
>
> To use this approach, the database must be in the RESTORING state without any pending restore tasks.
> To finish restoring the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Working with partially restored databases

Dropping a partially restored database

To drop a partially restored database (left in the RESTORING state), use the `rds_drop_database` stored procedure.

```
exec msdb.dbo.rds_drop_database @db_name='database_name';
```

> **Note**
>
> You can't submit a DROP database request for a database that already has a pending restore or finish restore task.
> To drop the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Snapshot restore and point-in-time recovery behavior for partially restored databases

Partially restored databases in the source instance (left in the RESTORING state) are dropped from the target instance during snapshot restore and point-in-time recovery.

Canceling a task

To cancel a backup or restore task, call the `rds_cancel_task` stored procedure.

> **Note**
>
> You can't cancel a FINISH_RESTORE task.

Usage

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can get the task ID by calling `rds_task_status`.

Tracking the status of tasks

To track the status of your backup and restore tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks. The status for tasks is updated approximately every two minutes. Task history is retained for 36 days.

Usage

```
exec msdb.dbo.rds_task_status
 [@db_name='database_name'],
 [@task_id=ID_number];
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
- `@task_id` – The ID of the task to show the task status for.

Examples

Example of listing the status for a specific task

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task

```
exec msdb.dbo.rds_task_status
@db_name='my_database',
@task_id=5;
```

Example of listing all tasks and their statuses on a specific database

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their statuses on the current instance

```
exec msdb.dbo.rds_task_status;
```

Response

The `rds_task_status` stored procedure returns the following columns.

Column	Description
`task_id`	The ID of the task.

`task_type`	Task type depending on the input parameters, as follows:
	• For backup tasks:
	  • BACKUP_DB – Full database backup
	  • BACKUP_DB_DIFFERENTIAL – Differential database backup
	• For restore tasks:
	  • RESTORE_DB – Full database restore with RECOVERY
	  • RESTORE_DB_NORECOVERY – Full database restore with NORECOVERY
	  • RESTORE_DB_DIFFERENTIAL – Differential database restore with R ECOVERY
	  • RESTORE_DB_DIFFERENTIAL_NORECOVERY – Differential database restore with NORECOVERY
	  • RESTORE_DB_LOG – Log restore with RECOVERY
	  •

Column	Description
	RESTORE_DB_LOG_NORECOVERY – Log restore with NORECOVERY • For tasks that finish a restore: • FINISH_RESTORE – Finish restore and open database Amazon RDS creates an initial snapshot of the database after it is open on completion of the following restore tasks: • RESTORE_DB • RESTORE_DB_DIFFERENTIAL • RESTORE_DB_LOG • FINISH_RESTORE
`database_name`	The name of the database that the task is associated with.
`% complete`	The progress of the task as a percent value.
`duration (mins)`	The amount of time spent on the task, in minutes.

Column	Description
lifecycle	The status of the task. The possible statuses are the following: • CREATED – As soon as you call rds_backup_database or rds_restore_database , a task is created and the status is set to CREATED. • IN_PROGRESS – After a backup or restore task starts, the status is set to IN_PROGRESS . It can take up to 5 minutes for the status to change from CREATED to IN_PROGRESS . • SUCCESS – After a backup or restore task completes, the status is set to SUCCESS. • ERROR – If a backup or restore task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – As soon as you call rds_cancel_task , the status of the task is set to CANCEL_REQUESTED . • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED .
task_info	Additional information about the task. If an error occurs while backing up or restoring a database, this column contains information about the error. For a list of possible errors, and mitigation strategies, see Troubleshooting.
last_updated	The date and time that the task status was last updated. The status is updated after every 5 percent of progress.
created_at	The date and time that the task was created.
S3_object_arn	The ARN indicating the Amazon S3 prefix and the name of the file that is being backed up or restored.

Column	Description
`overwrite_s3_backup_file`	The value of the `@overwrite_s3_backup_file` parameter specified when calling a backup task. For more information, see Backing up a database.
`KMS_master_key_arn`	The ARN for the KMS key used for encryption (for backup) and decryption (for restore).
`filepath`	Not applicable to native backup and restore tasks.
`overwrite_file`	Not applicable to native backup and restore tasks.

Compressing backup files

To save space in your Amazon S3 bucket, you can compress your backup files. For more information about compressing backup files, see Backup compression in the Microsoft documentation.

Compressing your backup files is supported for the following database editions:

- Microsoft SQL Server Enterprise Edition
- Microsoft SQL Server Standard Edition

To verify the compression option for your backup files, run the following code:

```
exec rdsadmin.dbo.rds_show_configuration 'S3 backup compression';
```

To turn on compression for your backup files, run the following code:

```
exec rdsadmin.dbo.rds_set_configuration 'S3 backup compression', 'true';
```

To turn off compression for your backup files, run the following code:

```
exec rdsadmin.dbo.rds_set_configuration 'S3 backup compression', 'false';
```

Troubleshooting

The following are issues you might encounter when you use native backup and restore.

Issue	Troubleshooting suggestions
Database backup/restore option is not enabled yet or is in the process of being enabled. Please try again later.	Make sure that you have added the SQLSERVER_BACKUP_RESTORE option to the DB option group associated with your DB instance. For more information, see Adding the native backup and restore option.
The EXECUTE permission was denied on the object '*rds_backup_database* ', database 'msdb', schema 'dbo'.	Make sure that you are using the master user when executing the stored procedure. If you encounter this error even after being logged in as the master user, it might be due to the admin user permissions being misaligned. To reset the master user, use the AWS Management Console. See Resetting the db_owner role membership for master user for Amazon RDS for SQL Server.
The EXECUTE permission was denied on the object '*rds_restore_database* ', database 'msdb', schema 'dbo'.	Make sure that you are using the master user when executing the stored procedure. If you encounter this error even after being logged in as the master user, it might be due to the admin user permissions being misaligned. To reset the master user, use the AWS Management Console. See Resetting the db_owner role membership for master user for Amazon RDS for SQL Server.
Access Denied	The backup or restore process can't access the backup file. This is usually caused by issues like the following: • Referencing the incorrect bucket. Referencing the bucket using an incorrect format. Referencing a file name without using the ARN. • Incorrect permissions on the bucket file. For example, if it is created by a different account that is trying to access it now, add the correct permissions. •

Issue	Troubleshooting suggestions
	An IAM policy that is incorrect or incomplete. Your IAM role must include all the necessary elements, including, for example, the correct version. These are highlighted in Importing and exporting SQL Server databases using native backup and restore.
BACKUP DATABASE WITH COMPRESSION isn't supported on <edition_name> Edition	Compressing your backup files is only supported for Microsoft SQL Server Enterprise Edition and Standard Edition. For more information, see Compressing backup files.
Key <ARN> does not exist	You attempted to restore an encrypted backup, but didn't provide a valid encryption key. Check your encryption key and retry. For more information, see Restoring a database.
Please reissue task with correct type and overwrite property	If you attempt to back up your database and provide the name of a file that already exists, but set the overwrite property to false, the save operation fails. To fix this error, either provide the name of a file that doesn't already exist, or set the overwrite property to true. For more information, see Backing up a database. It's also possible that you intended to restore your database, but called the `rds_backup_database` stored procedure accidentally. In that case, call the `rds_restore_database` stored procedure instead. For more information, see Restoring a database. If you intended to restore your database and called the `rds_restore_database` stored procedure, make sure that you provided the name of a valid backup file. For more information, see Using native backup and restore.

Issue	Troubleshooting suggestions
Please specify a bucket that is in the same region as RDS instance	You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance. You can use Amazon S3 replication to copy the backup file to the correct AWS Region. For more information, see Cross-Region replication in the Amazon S3 documentation.
The specified bucket does not exist	Verify that you have provided the correct ARN for your bucket and file, in the correct format. For more information, see Using native backup and restore.
User <ARN> is not authorized to perform <kms action> on resource <ARN>	You requested an encrypted operation, but didn't provide correct AWS KMS permissions. Verify that you have the correct permissio ns, or add them. For more information, see Setting up for native backup and restore.
The Restore task is unable to restore from more than 10 backup file(s). Please reduce the number of files matched and try again.	Reduce the number of files that you're trying to restore from. You can make each individual file larger if necessary.
Database '*database_name* ' already exists. Two databases that differ only by case or accent are not allowed. Choose a different database name.	You can't restore a database with the same name as an existing database. Database names are unique.

Importing and exporting SQL Server data using other methods

Following, you can find information about using snapshots to import your Microsoft SQL Server data to Amazon RDS. You can also find information about using snapshots to export your data from an RDS DB instance running SQL Server.

If your scenario supports it, it's easier to move data in and out of Amazon RDS by using the native backup and restore functionality. For more information, see Importing and exporting SQL Server databases using native backup and restore.

> **Note**
>
> Amazon RDS for Microsoft SQL Server doesn't support importing data into the `msdb` database.

Importing data into RDS for SQL Server by using a snapshot

To import data into a SQL Server DB instance by using a snapshot

1. Create a DB instance. For more information, see Creating an Amazon RDS DB instance.
2. Stop applications from accessing the destination DB instance.

   If you prevent access to your DB instance while you are importing data, data transfer is faster. Additionally, you don't need to worry about conflicts while data is being loaded if other applications cannot write to the DB instance at the same time. If something goes wrong and you have to roll back to an earlier database snapshot, the only changes that you lose are the imported data. You can import this data again after you resolve the issue.

   For information about controlling access to your DB instance, see Controlling access with security groups.
3. Create a snapshot of the target database.

   If the target database is already populated with data, we recommend that you take a snapshot of the database before you import the data. If something goes wrong with the data import or you want to discard the changes, you can restore the database to its previous state by using the snapshot. For information about database snapshots, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

> **Note**
>
> When you take a database snapshot, I/O operations to the database are suspended for a moment (milliseconds) while the backup is in progress.

4. Disable automated backups on the target database.

   Disabling automated backups on the target DB instance improves performance while you are importing your data because Amazon RDS doesn't log transactions when automatic backups are disabled. However, there are some things to consider. Automated backups are required to perform a point-in-time recovery. Thus, you can't restore the database to a specific point in time while you are importing data. Additionally, any automated backups that were created on the DB instance are erased unless you choose to retain them.

   Choosing to retain the automated backups can help protect you against accidental deletion of data. Amazon RDS also saves the database instance properties along with each automated backup to make it easy to recover. Using this option lets you restore a deleted database instance to a specified point in time within the backup retention period even after deleting it. Automated backups are automatically deleted at the end of the specified backup window, just as they are for an active database instance.

   You can also use previous snapshots to recover the database, and any snapshots that you have taken remain available. For information about automated backups, see Introduction to backups.

5. Disable foreign key constraints, if applicable.

   If you need to disable foreign key constraints, you can do so with the following script.

```
--Disable foreign keys on all tables
    DECLARE @table_name SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

    OPEN table_cursor;
    FETCH NEXT FROM table_cursor INTO @table_name;

    WHILE @@FETCH_STATUS = 0 BEGIN
      SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' NOCHECK CONSTRAINT
 ALL';
```

```
      EXEC (@cmd);
      FETCH NEXT FROM table_cursor INTO @table_name;
    END

    CLOSE table_cursor;
    DEALLOCATE table_cursor;

    GO
```

6. Drop indexes, if applicable.
7. Disable triggers, if applicable.

   If you need to disable triggers, you can do so with the following script.

```
--Disable triggers on all tables
    DECLARE @enable BIT = 0;
    DECLARE @trigger SYSNAME;
    DECLARE @table SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
     table_object.name table_name
    FROM sysobjects trigger_object
    JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
    WHERE trigger_object.type = 'TR';

    OPEN trigger_cursor;
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

    WHILE @@FETCH_STATUS = 0 BEGIN
      IF @enable = 1
         SET @cmd = 'ENABLE ';
      ELSE
         SET @cmd = 'DISABLE ';

      SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
 dbo.'+QUOTENAME(@table)+' ';
      EXEC (@cmd);
      FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
    END

    CLOSE trigger_cursor;
    DEALLOCATE trigger_cursor;
```

```
    GO
```

8. Query the source SQL Server instance for any logins that you want to import to the destination DB instance.

   SQL Server stores logins and passwords in the `master` database. Because Amazon RDS doesn't grant access to the `master` database, you cannot directly import logins and passwords into your destination DB instance. Instead, you must query the `master` database on the source SQL Server instance to generate a data definition language (DDL) file. This file should include all logins and passwords that you want to add to the destination DB instance. This file also should include role memberships and permissions that you want to transfer.

   For information about querying the `master` database, see Transfer logins and passwords between instances of SQL Server in the Microsoft Knowledge Base.

   The output of the script is another script that you can run on the destination DB instance. The script in the Knowledge Base article has the following code:

   ```
   p.type IN
   ```

   Every place `p.type` appears, use the following code instead:

   ```
   p.type = 'S'
   ```

9. Import the data using the method in Import the data.
10. Grant applications access to the target DB instance.

    When your data import is complete, you can grant access to the DB instance to those applications that you blocked during the import. For information about controlling access to your DB instance, see Controlling access with security groups.

11. Enable automated backups on the target DB instance.

    For information about automated backups, see Introduction to backups.

12. Enable foreign key constraints.

    If you disabled foreign key constraints earlier, you can now enable them with the following script.

    ```
    --Enable foreign keys on all tables
    ```

```
    DECLARE @table_name SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

    OPEN table_cursor;
    FETCH NEXT FROM table_cursor INTO @table_name;

    WHILE @@FETCH_STATUS = 0 BEGIN
      SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' CHECK CONSTRAINT ALL';
      EXEC (@cmd);
      FETCH NEXT FROM table_cursor INTO @table_name;
    END

    CLOSE table_cursor;
    DEALLOCATE table_cursor;
```

13. Enable indexes, if applicable.
14. Enable triggers, if applicable.

    If you disabled triggers earlier, you can now enable them with the following script.

```
--Enable triggers on all tables
    DECLARE @enable BIT = 1;
    DECLARE @trigger SYSNAME;
    DECLARE @table SYSNAME;
    DECLARE @cmd NVARCHAR(MAX);
    DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
     table_object.name table_name
    FROM sysobjects trigger_object
    JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
    WHERE trigger_object.type = 'TR';

    OPEN trigger_cursor;
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

    WHILE @@FETCH_STATUS = 0 BEGIN
      IF @enable = 1
         SET @cmd = 'ENABLE ';
      ELSE
         SET @cmd = 'DISABLE ';

      SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
 dbo.'+QUOTENAME(@table)+' ';
```

```
    EXEC (@cmd);
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END

CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;
```

Import the data

Microsoft SQL Server Management Studio is a graphical SQL Server client that is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

> **Note**
>
> SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio includes the following tools, which are useful in importing data to a SQL Server DB instance:

- Generate and Publish Scripts Wizard
- Import and Export Wizard
- Bulk copy

Generate and Publish Scripts Wizard

The Generate and Publish Scripts Wizard creates a script that contains the schema of a database, the data itself, or both. You can generate a script for a database in your local SQL Server deployment. You can then run the script to transfer the information that it contains to an Amazon RDS DB instance.

> **Note**
>
> For databases of 1 GiB or larger, it's more efficient to script only the database schema. You then use the Import and Export Wizard or the bulk copy feature of SQL Server to transfer the data.

For detailed information about the Generate and Publish Scripts Wizard, see the Microsoft SQL Server documentation.

In the wizard, pay particular attention to the advanced options on the **Set Scripting Options** page to ensure that everything you want your script to include is selected. For example, by default, database triggers are not included in the script.

When the script is generated and saved, you can use SQL Server Management Studio to connect to your DB instance and then run the script.

Import and Export Wizard

The Import and Export Wizard creates a special Integration Services package, which you can use to copy data from your local SQL Server database to the destination DB instance. The wizard can filter which tables and even which tuples within a table are copied to the destination DB instance.

> **Note**
>
> The Import and Export Wizard works well for large datasets, but it might not be the fastest way to remotely export data from your local deployment. For an even faster way, consider the SQL Server bulk copy feature.

For detailed information about the Import and Export Wizard, see the Microsoft SQL Server documentation.

In the wizard, on the **Choose a Destination** page, do the following:

- For **Server Name**, type the name of the endpoint for your DB instance.
- For the server authentication mode, choose **Use SQL Server Authentication**.
- For **User name** and **Password**, type the credentials for the master user that you created for the DB instance.

Bulk copy

The SQL Server bulk copy feature is an efficient means of copying data from a source database to your DB instance. Bulk copy writes the data that you specify to a data file, such as an ASCII file. You can then run bulk copy again to write the contents of the file to the destination DB instance.

This section uses the **bcp** utility, which is included with all editions of SQL Server. For detailed information about bulk import and export operations, see the Microsoft SQL Server documentation.

> **Note**
>
> Before you use bulk copy, you must first import your database schema to the destination DB instance. The Generate and Publish Scripts Wizard, described earlier in this topic, is an excellent tool for this purpose.

The following command connects to the local SQL Server instance. It generates a tab-delimited file of a specified table in the C:\ root directory of your existing SQL Server deployment. The table is specified by its fully qualified name, and the text file has the same name as the table that is being copied.

```
bcp dbname.schema_name.table_name out C:\table_name.txt -n -S localhost -U username -
P password -b 10000
```

The preceding code includes the following options:

- `-n` specifies that the bulk copy uses the native data types of the data to be copied.
- `-S` specifies the SQL Server instance that the *bcp* utility connects to.
- `-U` specifies the user name of the account to log in to the SQL Server instance.
- `-P` specifies the password for the user specified by `-U`.
- `-b` specifies the number of rows per batch of imported data.

> **Note**
>
> There might be other parameters that are important to your import situation. For example, you might need the `-E` parameter that pertains to identity values. For more information; see the full description of the command line syntax for the **bcp** utility in the Microsoft SQL Server documentation.

For example, suppose that a database named `store` that uses the default schema, dbo, contains a table named `customers`. The user account `admin`, with the password `insecure`, copies 10,000 rows of the `customers` table to a file named `customers.txt`.

```
bcp store.dbo.customers out C:\customers.txt -n -S localhost -U admin -P insecure -b
 10000
```

After you generate the data file, you can upload the data to your DB instance by using a similar command. Beforehand, create the database and schema on the target DB instance. Then use the `in` argument to specify an input file instead of `out` to specify an output file. Instead of using localhost to specify the local SQL Server instance, specify the endpoint of your DB instance. If you use a port other than 1433, specify that too. The user name and password are the master user and password for your DB instance. The syntax is as follows.

```
bcp dbname.schema_name.table_name
     in C:\table_name.txt -n -S endpoint,port -U master_user_name -
P master_user_password -b 10000
```

To continue the previous example, suppose that the master user name is `admin`, and the password is `insecure`. The endpoint for the DB instance is `rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com`, and you use port 4080. The command is as follows.

```
bcp store.dbo.customers in C:\customers.txt -n -S rds.ckz2kqd4qsn1.us-
east-1.rds.amazonaws.com,4080 -U admin -P insecure -b 10000
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Exporting data from RDS for SQL Server

You can choose one of the following options to export data from an RDS for SQL Server DB instance:

- **Native database backup using a full backup file (.bak)** – Using .bak files to backup databases is heavily optimized, and is usually the fastest way to export data. For more information, see Importing and exporting SQL Server databases using native backup and restore.

- **SQL Server Import and Export Wizard** – For more information, see SQL Server Import and Export Wizard.
- **SQL Server Generate and Publish Scripts Wizard and bcp utility** – For more information, see SQL Server Generate and Publish Scripts Wizard and bcp utility.

SQL Server Import and Export Wizard

You can use the SQL Server Import and Export Wizard to copy one or more tables, views, or queries from your RDS for SQL Server DB instance to another data store. This choice is best if the target data store is not SQL Server. For more information, see SQL Server Import and Export Wizard in the SQL Server documentation.

The SQL Server Import and Export Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see the Microsoft website.

To use the SQL Server Import and Export Wizard to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to your Microsoft SQL Server DB instance.
2. In **Object Explorer**, expand **Databases**, open the context (right-click) menu for the source database, choose **Tasks**, and then choose **Export Data**. The wizard appears.
3. On the **Choose a Data Source** page, do the following:
    a. For **Data source**, choose **`SQL Server Native Client 11.0`**.
    b. Verify that the **Server name** box shows the endpoint of your RDS for SQL Server DB instance.
    c. Select **Use SQL Server Authentication**. For **User name** and **Password**, type the master user name and password of your DB instance.
    d. Verify that the **Database** box shows the database from which you want to export data.
    e. Choose **Next**.
4. On the **Choose a Destination** page, do the following:
    a. For **Destination**, choose **`SQL Server Native Client 11.0`**.

> **Note**
>
> Other target data sources are available. These include .NET Framework data providers, OLE DB providers, SQL Server Native Client providers, ADO.NET providers, Microsoft Office Excel, Microsoft Office Access, and the Flat File source. If you choose to target one of these data sources, skip the remainder of step 4. For details on the connection information to provide next, see Choose a destination in the SQL Server documentation.

b. For **Server name**, type the server name of the target SQL Server DB instance.

c. Choose the appropriate authentication type. Type a user name and password if necessary.

d. For **Database**, choose the name of the target database, or choose **New** to create a new database to contain the exported data.

If you choose **New**, see Create database in the SQL Server documentation for details on the database information to provide.

e. Choose **Next**.

5. On the **Table Copy or Query** page, choose **Copy data from one or more tables or views** or **Write a query to specify the data to transfer**. Choose **Next**.
6. If you chose **Write a query to specify the data to transfer**, you see the **Provide a Source Query** page. Type or paste in a SQL query, and then choose **Parse** to verify it. Once the query validates, choose **Next**.
7. On the **Select Source Tables and Views** page, do the following:

a. Select the tables and views that you want to export, or verify that the query you provided is selected.

b. Choose **Edit Mappings** and specify database and column mapping information. For more information, see Column mappings in the SQL Server documentation.

c. (Optional) To see a preview of data to be exported, select the table, view, or query, and then choose **Preview**.

d. Choose **Next**.

8. On the **Run Package** page, verify that **Run immediately** is selected. Choose **Next**.
9. On the **Complete the Wizard** page, verify that the data export details are as you expect. Choose **Finish**.

10. On the **The execution was successful** page, choose **Close**.

SQL Server Generate and Publish Scripts Wizard and bcp utility

You can use the SQL Server Generate and Publish Scripts Wizard to create scripts for an entire database or just selected objects. You can run these scripts on a target SQL Server DB instance to recreate the scripted objects. You can then use the bcp utility to bulk export the data for the selected objects to the target DB instance. This choice is best if you want to move a whole database (including objects other than tables) or large quantities of data between two SQL Server DB instances. For a full description of the bcp command-line syntax, see bcp utility in the Microsoft SQL Server documentation.

The SQL Server Generate and Publish Scripts Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a free download.

To use the SQL Server Generate and Publish Scripts Wizard and the bcp utility to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see Connecting to your Microsoft SQL Server DB instance.
2. In **Object Explorer**, expand the **Databases** node and select the database you want to script.
3. Follow the instructions in Generate and publish scripts Wizard in the SQL Server documentation to create a script file.
4. In SQL Server Management Studio, connect to your target SQL Server DB instance.
5. With the target SQL Server DB instance selected in **Object Explorer**, choose **Open** on the **File** menu, choose **File**, and then open the script file.
6. If you have scripted the entire database, review the CREATE DATABASE statement in the script. Make sure that the database is being created in the location and with the parameters that you want. For more information, see CREATE DATABASE in the SQL Server documentation.
7. If you are creating database users in the script, check to see if server logins exist on the target DB instance for those users. If not, create logins for those users; the scripted commands to create the database users fail otherwise. For more information, see Create a login in the SQL Server documentation.

8. Choose **!Execute** on the SQL Editor menu to run the script file and create the database objects. When the script finishes, verify that all database objects exist as expected.
9. Use the bcp utility to export data from the RDS for SQL Server DB instance into files. Open a command prompt and type the following command.

   ```
   bcp database_name.schema_name.table_name out data_file -n -S aws_rds_sql_endpoint -
   U username -P password
   ```

   The preceding code includes the following options:

   - *table_name* is the name of one of the tables that you've recreated in the target database and now want to populate with data.
   - *data_file* is the full path and name of the data file to be created.
   - `-n` specifies that the bulk copy uses the native data types of the data to be copied.
   - `-S` specifies the SQL Server DB instance to export from.
   - `-U` specifies the user name to use when connecting to the SQL Server DB instance.
   - `-P` specifies the password for the user specified by `-U`.

   The following shows an example command.

   ```
   bcp world.dbo.city out C:\Users\JohnDoe\city.dat -n -S sql-jdoe.1234abcd.us-
   west-2.rds.amazonaws.com,1433 -U JohnDoe -P ClearTextPassword
   ```

   Repeat this step until you have data files for all of the tables you want to export.
10. Prepare your target DB instance for bulk import of data by following the instructions at Basic guidelines for bulk importing data in the SQL Server documentation.
11. Decide on a bulk import method to use after considering performance and other concerns discussed in About bulk import and bulk export operations in the SQL Server documentation.
12. Bulk import the data from the data files that you created using the bcp utility. To do so, follow the instructions at either Import and export bulk data by using the bcp utility or Import bulk data by using BULK INSERT or OPENROWSET(BULK...) in the SQL Server documentation, depending on what you decided in step 11.

Using BCP utility from Linux to import and export data

The BCP (Bulk Copy Program) utility provides an efficient way to transfer large amounts of data between your RDS for SQL Server DB instance and data files. You can use BCP from Linux environments to perform bulk data operations, making it useful for data migration, ETL processes, and regular data transfers.

BCP supports both importing data from files into SQL Server tables and exporting data from SQL Server tables to files. This is particularly effective for transferring structured data in various formats including delimited text files.

Prerequisites

Before using BCP with your RDS for SQL Server DB instance from Linux, ensure you have the following:

- A Linux environment with network connectivity to your RDS for SQL Server DB instance
- Microsoft SQL Server command-line tools installed on your Linux system, including:
  - sqlcmd - SQL Server command-line query tool
  - bcp - Bulk Copy Program utility
- Valid credentials for your RDS for SQL Server DB instance
- Network access configured through security groups to allow connections on the SQL Server port (typically 1433)
- Appropriate database permissions for the operations you want to perform

Installing SQL Server command-line tools on Linux

To use BCP from Linux, you need to install the Microsoft SQL Server command-line tools. For detailed installation instructions for your specific Linux distribution, see the following Microsoft documentation:

- Install sqlcmd and bcp the SQL Server command-line tools on Linux
- bcp utility - Complete reference for the BCP utility

After installation, ensure the tools are available in your PATH by running:

```
bcp -v
```

```
sqlcmd -?
```

Exporting data from RDS for SQL Server

You can use BCP to export data from your RDS for SQL Server DB instance to files on your Linux system. This is useful for creating backups, data analysis, or preparing data for migration.

Basic export syntax

The basic syntax for exporting data using BCP is:

```
bcp database.schema.table out output_file -S server_name -U username -P password
 [options]
```

Where:

- `database.schema.table` - The fully qualified table name
- `output_file` - The path and name of the output file
- `server_name` - Your RDS for SQL Server endpoint
- `username` - Your database username
- `password` - Your database password

Export example

The following example exports data from a table named `customers` in the `sales` database:

```
bcp sales.dbo.customers out /home/user/customers.txt \
    -S mydb.cluster-abc123.us-east-1.rds.amazonaws.com \
    -U admin \
    -P mypassword \
    -c \
    -t "|" \
    -r "\n"
```

This command:

- Exports data from the `customers` table
- Saves the output to `/home/user/customers.txt`

- Uses character format (`-c`)
- Uses pipe (|) as the field delimiter (`-t "|"`)
- Uses newline as the row delimiter (`-r "\n"`)

Importing data to RDS for SQL Server

You can use BCP to import data from files on your Linux system into your RDS for SQL Server DB instance. This is useful for data migration, loading test data, or regular data updates.

Basic import syntax

The basic syntax for importing data using BCP is:

```
bcp database.schema.table in input_file -S server_name -U username -P password
 [options]
```

Where:

- `database.schema.table` - The fully qualified destination table name
- `input_file` - The path and name of the input file
- `server_name` - Your RDS for SQL Server endpoint
- `username` - Your database username
- `password` - Your database password

Import example

The following example imports data from a file into a table named `customers`:

```
bcp sales.dbo.customers in /home/user/customers.txt \
    -S mydb.cluster-abc123.us-east-1.rds.amazonaws.com \
    -U admin \
    -P mypassword \
    -c \
    -t "|" \
    -r "\n" \
    -b 1000
```

This command:

- Imports data into the `customers` table
- Reads data from `/home/user/customers.txt`
- Uses character format (`-c`)
- Uses pipe (|) as the field delimiter (`-t "|"`)
- Uses newline as the row delimiter (`-r "\n"`)
- Processes data in batches of 1000 rows (`-b 1000`)

Common BCP options

BCP provides numerous options to control data formatting and transfer behavior. The following table describes commonly used options:

Option	Description
`-c`	Uses character data type for all columns
`-n`	Uses native database data types
`-t`	Specifies the field delimiter (default is tab)
`-r`	Specifies the row delimiter (default is newline)
`-b`	Specifies the batch size for bulk operations
`-F`	Specifies the first row to export or import
`-L`	Specifies the last row to export or import
`-e`	Specifies an error file to capture rejected rows
`-f`	Specifies a format file for data formatting
`-q`	Uses quoted identifiers for object names

Best practices and considerations

When using BCP with RDS for SQL Server from Linux, consider the following best practices:

- **Use batch processing** – For large datasets, use the `-b` option to process data in batches. T his improves performance and allows for better error recovery.
- **Handle errors gracefully** – Use the `-e` option to capture error information and rejected rows in a separate file for analysis.
- **Choose appropriate data formats** – Use character format (`-c`) for cross-platform compatibility or native format (`-n`) for better performance when both source and destination are SQL Server.
- **Secure your credentials** – Avoid putting passwords directly in command lines. Consider using environment variables or configuration files with appropriate permissions.
- **Test with small datasets** – Before processing large amounts of data, test your BCP commands with smaller datasets to verify formatting and connectivity.
- **Monitor network connectivity** – Ensure stable network connections, especially for large data transfers. Consider using tools like `screen` or `tmux` for long-running operations.
- **Validate data integrity** – After data transfer, verify row counts and sample data to ensure the operation completed successfully.

Troubleshooting common issues

The following table describes common issues you might encounter when using BCP from Linux and their solutions:

Issue	Solution
Connection timeout or network errors	Verify your Amazon RDS endpoint, security group settings, and network connectivity. Make sure the SQL Server port (typically 1433) is accessible from your Linux system.
Authentication failures	Verify your username and password. Make sure the database user has appropriate permissions for the operations you're performing.
Data format errors	Check your field and row delimiters. Make sure the data format matches what BCP expects. Use format files for complex data structures.

Issue	Solution
Permission denied errors	Make sure your database user has `INSERT` permissions for imports or `SELECT` permissions for exports on the target tables.
Large file handling issues	Use batch processing with the `-b` option. Consider splitting large files into smaller chunks for better performance and error recovery.
Character encoding problems	Ensure your data files use compatible character encoding. Use the `-c` option for character format or specify appropriate code pages.

Working with read replicas for Microsoft SQL Server in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas.

In this section, you can find specific information about working with read replicas on Amazon RDS for SQL Server.

- Synchronizing database users and objects with a SQL Server read replica
- Troubleshooting a SQL Server read replica problem

Configuring read replicas for SQL Server

Before a DB instance can serve as a source instance for replication, you must enable automatic backups on the source DB instance. To do so, you set the backup retention period to a value other than 0. Setting this type of deployment also enforces that automatic backups are enabled.

Creating a SQL Server read replica doesn't require an outage for the primary DB instance. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without any service interruption. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to 15 read replicas from one source DB instance. For replication to operate effectively, we recommend that you configure each read replica with the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

The SQL Server DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS upgrades the primary immediately after upgrading the read replicas, regardless of the maintenance window. For more information about upgrading the DB engine version, see Upgrades of the Microsoft SQL Server DB engine.

For a read replica to receive and apply changes from the source, it should have sufficient compute and storage resources. If a read replica reaches compute, network, or storage resource capacity, the read replica stops receiving or applying changes from its source. You can modify the storage and CPU resources of a read replica independently from its source and other read replicas.

For more information about how to create a read replica, see Creating a read replica.

Read replica limitations with SQL Server

The following limitations apply to SQL Server read replicas on Amazon RDS:

- Read replicas are only available on the SQL Server Enterprise Edition (EE) engine.
- Read replicas are available for SQL Server versions 2016–2022.
- You can create up to 15 read replicas from one source DB instance. Replication might lag when your source DB instance has more than 5 read replicas.
- Read replicas are only available for DB instances running on DB instance classes with four or more vCPUs.
- A read replica supports up to 100 databases depending on the instance class type and availability mode. You must create databases on the source DB instance to automatically replicate them to the read replicas. You can't choose individual databases to replicate. For more information, see Limitations for Microsoft SQL Server DB instances.
- You can't drop a database from a read replica. To drop a database, drop it from the source DB instance with the `rds_drop_database` stored procedure. For more information, see Dropping a database in an Amazon RDS for Microsoft SQL Server DB instance.
- If the source DB instance uses Transparent Data Encryption (TDE) to encrypt data, the read replica also automatically configures TDE.

  If the source DB instance uses a KMS key to encrypt data, read replicas in the same region use the same KMS key. For cross-region read replicas, you must specify a KMS key from the read replica's region when creating the read replica. You can't change the KMS key for a read replica.
- Read replicas have the same time zone and collation as the source DB instance, regardless of Availabilty Zone they're created in.
- The following aren't supported on Amazon RDS for SQL Server:
  - Backup retention of read replicas
  - Point-in-time recovery from read replicas
  - Manual snapshots of read replicas
  - Multi-AZ read replicas
  - Creating read replicas of read replicas
  - Synchronization of user logins to read replicas

- Amazon RDS for SQL Server doesn't intervene to mitigate high replica lag between a source DB instance and its read replicas. Make sure that the source DB instance and its read replicas are sized properly, in terms of computing power and storage, to suit their operational load.
- You can replicate between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, but not into or out of AWS GovCloud (US) Regions.

Option considerations for RDS for SQL Server replicas

Before you create an RDS for SQL Server replica, consider the following requirements, restrictions, and recommendations:

- If your SQL Server replica is in the same Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

  For more information about option groups, see Working with option groups.
- When you create a SQL Server cross-Region replica, Amazon RDS creates a dedicated option group for it.

  You can't remove an SQL Server cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for a SQL Server cross-Region replica.

  The following options are replicated options. To add replicated options to a SQL Server cross-Region replica, add it to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas.

  - `TDE`

  The following options are non-replicated options. You can add or remove non-replicated options from a dedicated option group.

  - `MSDTC`
  - `SQLSERVER_AUDIT`
  - To enable the `SQLSERVER_AUDIT` option on cross-Region read replica, add the `SQLSERVER_AUDIT` option on the dedicated option group on the cross-region read replica and the source instance's option group. By adding the `SQLSERVER_AUDIT` option on the source instance of SQL Server cross-Region read replica, you can create Server Level Audit Object

and Server Level Audit Specifications on each of the cross-Region read replicas of the source instance. To allow the cross-Region read replicas access to upload the completed audit logs to an Amazon S3 bucket, add the `SQLSERVER_AUDIT` option to the dedicated option group and configure the option settings. The Amazon S3 bucket that you use as a target for audit files must be in the same Region as the cross-Region read replica. You can modify the option setting of the `SQLSERVER_AUDIT` option for each cross region read replica independently so each can access an Amazon S3 bucket in their respective Region.

The following options are not supported for read replicas.

- `SSRS`
- `SSAS`
- `SSIS`

The following options are partially supported for cross-Region read replicas.

- `SQLSERVER_BACKUP_RESTORE`
- The source DB instance of a SQL Server cross-Region replica can have the `SQLSERVER_BACKUP_RESTORE` option, but you can not perform native restores on the source DB instance until you delete all its cross-Region replicas. Any existing native restore tasks will be cancelled during the creation of a cross-Region replica. You can't add the `SQLSERVER_BACKUP_RESTORE` option to a dedicated option group.

  For more information on native backup and restore, see Importing and exporting SQL Server databases using native backup and restore

When you promote a SQL Server cross-Region read replica, the promoted replica behaves the same as other SQL Server DB instances, including the management of its options. For more information about option groups, see Working with option groups.

Synchronizing database users and objects with a SQL Server read replica

Any logins, custom server roles, SQL agent jobs, or other server-level objects that exist in the primary DB instance at the time of creating a read replica are expected to be present in the newly created read replica. However, any server-level objects that are created in the primary DB instance after the creation of the read replica will not be automatically replicated, and you must create them manually in the read replica.

The database users are automatically replicated from the primary DB instance to the read replica. As the read replica database is in read-only mode, the security identifier (SID) of the database user cannot be updated in the database. Therefore, when creating SQL logins in the read replica, it's essential to ensure that the SID of that login matches the SID of the corresponding SQL login in the primary DB instance. If you don't synchronize the SIDs of the SQL logins, they won't be able to access the database in the read replica. Windows Active Directory (AD) Authenticated Logins do not experience this issue because the SQL Server obtains the SID from the Active Directory.

To synchronize a SQL login from the primary DB instance to the read replica

1. Connect to the primary DB instance.
2. Create a new SQL login in the primary DB instance.

```
USE [master]
GO
CREATE LOGIN TestLogin1
WITH PASSWORD = 'REPLACE WITH PASSWORD';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

3. Create a new database user for the SQL login in the database.

```
USE [REPLACE WITH YOUR DB NAME]
GO
CREATE USER TestLogin1 FOR LOGIN TestLogin1;
GO
```

4. Check the SID of the newly created SQL login in primary DB instance.

```
SELECT name, sid FROM sys.server_principals WHERE name =  'TestLogin1';
```

5. Connect to the read replica. Create the new SQL login.

```
CREATE LOGIN TestLogin1 WITH PASSWORD = 'REPLACE WITH PASSWORD', SID=REPLACE WITH
 sid FROM STEP #4;
```

Alternately, if you have access to the read replica database, you can fix the orphaned user as follows:

1. Connect to the read replica.
2. Identify the orphaned users in the database.

```
USE [REPLACE WITH YOUR DB NAME]
GO
EXEC sp_change_users_login 'Report';
GO
```

3. Create a new SQL login for the orphaned database user.

```
CREATE LOGIN TestLogin1 WITH PASSWORD = 'REPLACE WITH PASSWORD', SID=REPLACE WITH
 sid FROM STEP #2;
```

Example:

```
CREATE LOGIN TestLogin1 WITH PASSWORD = 'TestPa$$word#1',
 SID=0x1A2B3C4D5E6F7G8H9I0J1K2L3M4N5O6P;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Troubleshooting a SQL Server read replica problem

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. For information about replication lag time, see Monitoring read replication.

If replication lag is too long, you can use the following query to get information about the lag.

```
SELECT AR.replica_server_name
     , DB_NAME (ARS.database_id) 'database_name'
     , AR.availability_mode_desc
     , ARS.synchronization_health_desc
     , ARS.last_hardened_lsn
     , ARS.last_redone_lsn
     , ARS.secondary_lag_seconds
```

```
FROM sys.dm_hadr_database_replica_states ARS
INNER JOIN sys.availability_replicas AR ON ARS.replica_id = AR.replica_id
--WHERE DB_NAME(ARS.database_id) = 'database_name'
ORDER BY AR.replica_server_name;
```

Multi-AZ deployments for Amazon RDS for Microsoft SQL Server

Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS supports Multi-AZ deployments for Microsoft SQL Server by using either SQL Server Database Mirroring (DBM), Always On Availability Groups (AGs), or block level replication. Amazon RDS monitors and maintains the health of your Multi-AZ deployment. If problems occur, RDS automatically repairs unhealthy DB instances, reestablishes synchronization, and initiates failovers. Failover only occurs if the standby and primary are fully in sync. You don't have to manage anything.

When you set up SQL Server Multi-AZ, RDS automatically configures all databases on the instance to use DBM, AGs, or block level replication. Amazon RDS handles the primary, the witness, and the secondary DB instance for you when you configure DBM or AGs. For block level replication, RDS handles the primary and the secondary DB instances. Because configuration is automatic, RDS selects DBM, Always On AGs, or block level replication based on the version of SQL Server that you deploy.

Amazon RDS supports Multi-AZ with Always On AGs for the following SQL Server versions and editions:

- SQL Server 2022:
  - Standard Edition
  - Enterprise Edition
- SQL Server 2019:
  - Standard Edition 15.00.4073.23 and higher
  - Enterprise Edition
- SQL Server 2017:
  - Standard Edition 14.00.3401.7 and higher

  - Enterprise Edition 14.00.3049.1 and higher
- SQL Server 2016: Enterprise Edition 13.00.5216.0 and higher

Amazon RDS supports Multi-AZ with DBM for the following SQL Server versions and editions, except for the versions noted previously:

- SQL Server 2019: Standard Edition 15.00.4043.16
- SQL Server 2017: Standard and Enterprise Editions
- SQL Server 2016: Standard and Enterprise Editions

Amazon RDS supports Multi-AZ with block level replication for SQL Server 2022 Web Edition 16.00.4215.2 and above.

> **Note**
>
> Only new DB instances created with 16.00.4215.2 or higher support Multi-AZ deployments with block level replication. The following restrictions apply for existing SQL Server 2022 Web Edition instances:
>
> - For existing instances on version 16.00.4215.2, you must restore a snapshot to a new instance with the same or higher minor version to enable block level replication.
> - SQL Server 2022 Web instances with an older minor version can be upgraded to minor version 16.00.4215.2 or higher to enable block level replication.

You can use the following SQL query to determine whether your SQL Server DB instance is Single-AZ, Multi-AZ with DBM, or Multi-AZ with Always On AGs. This query does not apply for Multi-AZ deployments on SQL Server Web Edition.

```
SELECT CASE WHEN dm.mirroring_state_desc IS NOT NULL THEN 'Multi-AZ (Mirroring)'
    WHEN dhdrs.group_database_id IS NOT NULL THEN 'Multi-AZ (AlwaysOn)'
    ELSE 'Single-AZ'
    END 'high_availability'
FROM sys.databases sd
LEFT JOIN sys.database_mirroring dm ON sd.database_id = dm.database_id
LEFT JOIN sys.dm_hadr_database_replica_states dhdrs ON sd.database_id =
 dhdrs.database_id AND dhdrs.is_local = 1
```

```
WHERE DB_NAME(sd.database_id) = 'rdsadmin';
```

The output resembles the following:

```
high_availability
Multi-AZ (AlwaysOn)
```

Adding Multi-AZ to a Microsoft SQL Server DB instance

When you create a new SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with Database Mirroring (DBM), Always On AGs or block level replication. You do so by choosing **Yes (Mirroring / Always On / Block Level Replication)** from **Multi-AZ deployment**. For more information, see Creating an Amazon RDS DB instance.

When you modify an existing SQL Server DB instance using the console, you can add Multi-AZ with DBM, AGs, or block level replication by choosing **Yes (Mirroring / Always On / Block Level Replication)** from **Multi-AZ deployment** on the **Modify DB instance** page. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If your DB instance is running Database Mirroring (DBM)—not Always On Availability Groups (AGs)—you might need to disable in-memory optimization before you add Multi-AZ. Disable in-memory optimization with DBM before you add Multi-AZ if your DB instance runs SQL Server 2016 or 2017 Enterprise Edition and has in-memory optimization enabled. If your DB instance is running AGs or block level replication for SQL Server Web Editions, it doesn't require this step.

Removing Multi-AZ from a Microsoft SQL Server DB instance

When you modify an existing SQL Server DB instance using the AWS Management Console, you can remove Multi-AZ with DBM, AGs, or block level replication. You can do this by choosing **No (Mirroring / Always On / Block Level Replication)** from **Multi-AZ deployment** on the **Modify DB instance** page. For more information, see Modifying an Amazon RDS DB instance.

Microsoft SQL Server Multi-AZ deployment limitations, notes, and recommendations

The following are some limitations when working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Cross-Region Multi-AZ isn't supported.
- Stopping an RDS for SQL Server DB instance in a multi-AZ deployment isn't supported.
- You can't configure the secondary DB instance to accept database read activity.
- Multi-AZ with Always On Availability Groups (AGs) supports in-memory optimization.
- Multi-AZ with Always On Availability Groups (AGs) doesn't support Kerberos authentication for the availability group listener. This is because the listener has no Service Principal Name (SPN).
- Multi-AZ with block level replication is currently only supported for SQL Server Web Edition instances.
- You can't rename a database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment. If you need to rename a database on such an instance, first turn off Multi-AZ for the DB instance, then rename the database. Finally, turn Multi-AZ back on for the DB instance.
- You can only restore Multi-AZ DB instances that are backed up using the full recovery model.
- Multi-AZ deployments have a limit of 10,000 SQL Server Agent jobs.

  If you need a higher limit, request an increase by contacting Support. Open the AWS Support Center page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.
- You can't have an offline database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment.
- RDS for SQL Server doesn't replicate MSDB database permissions to the secondary instance. If you need these permissions on the secondary instance, you must recreate them manually.
- Volume metrics are not available for the secondary host of the instance using block level replication.

The following are some notes about working with Multi-AZ deployments on RDS for SQL Server DB instances:

- Amazon RDS exposes the Always On AGs availability group listener endpoint. The endpoint is visible in the console, and is returned by the `DescribeDBInstances` API operation as an entry in the endpoints field.
- Amazon RDS supports availability group multisubnet failovers.
- To use SQL Server Multi-AZ with a SQL Server DB instance in a virtual private cloud (VPC), first create a DB subnet group that has subnets in at least two distinct Availability Zones. Then assign the DB subnet group to the primary replica of the SQL Server DB instance.
- When a DB instance is modified to be a Multi-AZ deployment, during the modification it has a status of **modifying**. Amazon RDS creates the standby, and makes a backup of the primary DB instance. After the process is complete, the status of the primary DB instance becomes **available**.
- Multi-AZ deployments maintain all databases on the same node. If a database on the primary host fails over, all your SQL Server databases fail over as one atomic unit to your standby host. Amazon RDS provisions a new healthy host, and replaces the unhealthy host.
- Multi-AZ with DBM, AGs, or block level replication supports a single standby replica.
- Users, logins, and permissions are automatically replicated for you on the secondary. You don't need to recreate them. User-defined server roles are replicated in DB instances that use Always On AGs or block level replication for Multi-AZ deployments.
- In Multi-AZ deployments, RDS for SQL Server creates SQL Server logins to allow Always On AGs or Database Mirroring. RDS creates logins with the following pattern, `db_<dbiResourceId>_node1_login`, `db_<dbiResourceId>_node2_login`, and `db_<dbiResourceId>_witness_login`.
- RDS for SQL Server creates a SQL Server login to allow access to read replicas. RDS creates a login with the following pattern, `db_<readreplica_dbiResourceId>_node_login`.
- In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see Turning on SQL Server Agent job replication.
- You might observe elevated latencies compared to a standard DB instance deployment (in a single Availability Zone) because of the synchronous data replication.
- Failover times are affected by the time it takes to complete the recovery process. Large transactions increase the failover time.
- In SQL Server Multi-AZ deployments, reboot with failover reboots only the primary DB instance. After the failover, the primary DB instance becomes the new secondary DB instance. Parameters might not be updated for Multi-AZ instances. For reboot without failover, both the primary and

secondary DB instances reboot, and parameters are updated after the reboot. If the DB instance is unresponsive, we recommend reboot without failover.

The following are some recommendations for working with Multi-AZ deployments on RDS for Microsoft SQL Server DB instances:

- For databases used in production or preproduction, we recommend the following options:
  - Multi-AZ deployments for high availability
  - "Provisioned IOPS" for fast, consistent performance
  - "Memory optimized" rather than "General purpose"
- You can't select the Availability Zone (AZ) for the secondary instance, so when you deploy application hosts, take this into account. Your database might fail over to another AZ, and the application hosts might not be in the same AZ as the database. For this reason, we recommend that you balance your application hosts across all AZs in the given AWS Region.
- For best performance, don't enable Database Mirroring, Always On AGs, or block level replication during a large data load operation. If you want your data load to be as fast as possible, finish loading data before you convert your DB instance to a Multi-AZ deployment.
- Applications that access the SQL Server databases should have exception handling that catches connection errors. The following code sample shows a try/catch block that catches a communication error. In this example, the `break` statement exits the `while` loop if the connection is successful, but retries up to 10 times if an exception is thrown.

```
int RetryMaxAttempts = 10;
int RetryIntervalPeriodInSeconds = 1;
int iRetryCount = 0;
while (iRetryCount < RetryMaxAttempts)
{
   using (SqlConnection connection = new SqlConnection(DatabaseConnString))
   {
      using (SqlCommand command = connection.CreateCommand())
      {
         command.CommandText = "INSERT INTO SOME_TABLE VALUES ('SomeValue');";
         try
         {
            connection.Open();
            command.ExecuteNonQuery();
            break;
         }
```

```
         catch (Exception ex)
         {
            Logger(ex.Message);
            iRetryCount++;
         }
         finally {
            connection.Close();
         }
      }
   }
   Thread.Sleep(RetryIntervalPeriodInSeconds * 1000);
}
```

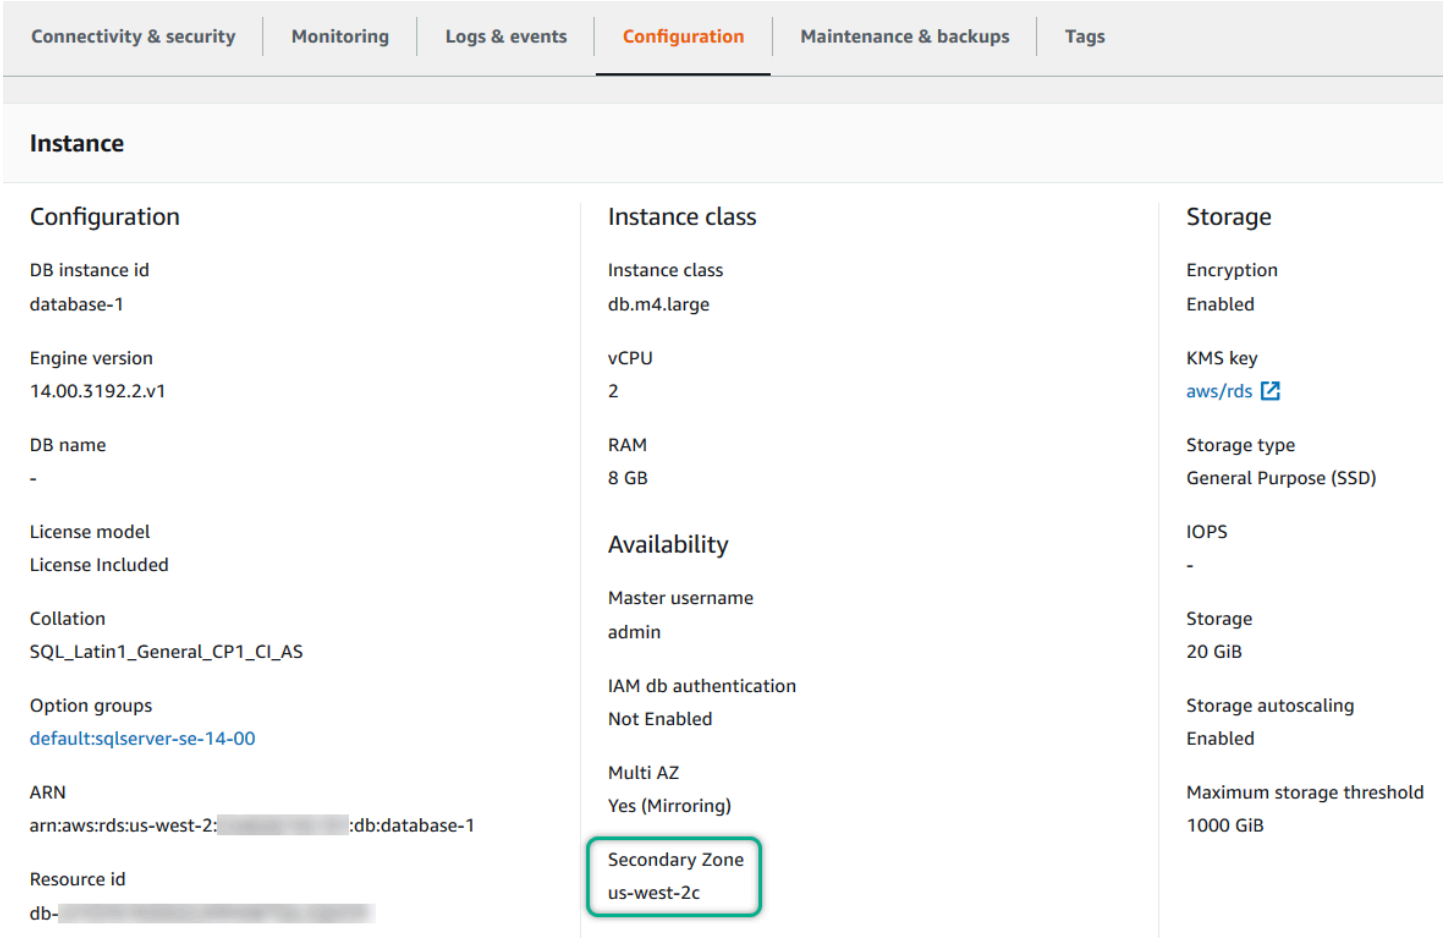
- Don't use the `Set Partner Off` command when working with Multi-AZ instances using DBM or AGs. This command is not supported on instances using block level replication. For example, don't do the following.

```
--Don't do this
ALTER DATABASE db1 SET PARTNER off
```

- Don't set the recovery mode to `simple`. For example, don't do the following.

```
--Don't do this
ALTER DATABASE db1 SET RECOVERY simple
```

- Don't use the DEFAULT_DATABASE parameter when creating new logins on Multi-AZ DB instances unless using block level replication for high availability, because these settings can't be applied to the standby mirror. For example, don't do the following.



```
--Don't do this
CREATE LOGIN [test_dba] WITH PASSWORD=foo, DEFAULT_DATABASE=[db2]
```

  Also, don't do the following.

```
--Don't do this
ALTER LOGIN [test_dba] WITH DEFAULT_DATABASE=[db3]
```

Determining the location of the secondary

You can determine the location of the secondary replica by using the AWS Management Console. You need to know the location of the secondary if you are setting up your primary DB instance in a VPC.

You can also view the Availability Zone of the secondary using the AWS CLI command `describe-db-instances` or RDS API operation `DescribeDBInstances`. The output shows the secondary AZ where the standby mirror is located.

Migrating from Database Mirroring to Always On Availability Groups

In version 14.00.3049.1 of Microsoft SQL Server Enterprise Edition, Always On Availability Groups (AGs) are enabled by default.

To migrate from Database Mirroring (DBM) to AGs, first check your version. If you are using a DB instance with a version prior to Enterprise Edition 13.00.5216.0, modify the instance to patch it

to 13.00.5216.0 or later. If you are using a DB instance with a version prior to Enterprise Edition 14.00.3049.1, modify the instance to patch it to 14.00.3049.1 or later.

If you want to upgrade a mirrored DB instance to use AGs, run the upgrade first, modify the instance to remove Multi-AZ, and then modify it again to add Multi-AZ. This converts your instance to use Always On AGs.

Additional features for Microsoft SQL Server on Amazon RDS

In the following sections, you can find information about augmenting Amazon RDS instances running the Microsoft SQL Server DB engine.

Topics

- Using Password Policy for SQL Server logins on RDS for SQL Server
- Integrating an Amazon RDS for SQL Server DB instance with Amazon S3
- Using Database Mail on Amazon RDS for SQL Server
- Instance store support for the tempdb database on Amazon RDS for SQL Server
- Using extended events with Amazon RDS for Microsoft SQL Server
- Access to transaction log backups with RDS for SQL Server

Using Password Policy for SQL Server logins on RDS for SQL Server

Amazon RDS allows you to set the password policy for your Amazon RDS DB instance running Microsoft SQL Server. Use this to set complexity, length, and lockout requirements for logins that use SQL Server Authentication to authenticate to your DB instance.

Key terms

Login

In SQL Server, a server-level principal that can authenticate to a database instance is referred to as a **login**. Other database engines might refer to this principal as a *user*. In RDS for SQL Server, a login can authenticate using SQL Server Authentication or Windows Authentication.

SQL Server login

A login that uses a username and password to authenticate using SQL Server Authentication is a SQL Server login. The password policy you configure through DB parameters only applies to SQL Server logins.

Windows login

A login that is based on a Windows principal and authenticates using Windows Authentication is a Windows login. You can configure the password policy for your Windows logins in Active Directory. For more information, see Working with Active Directory with RDS for SQL Server.

Enabling and disabling policy for each login

Each SQL Server login has flags for `CHECK_POLICY` and `CHECK_EXPIRATION`. By default, new logins are created with `CHECK_POLICY` set to `ON` and `CHECK_EXPIRATION` set to `OFF`.

If `CHECK_POLICY` is enabled for a login, RDS for SQL Server validates the password against the complexity and minimum length requirements. Lockout policies also apply. An example T-SQL statement to enable `CHECK_POLICY` and `CHECK_EXPIRATION`:

```
ALTER LOGIN [master_user] WITH CHECK_POLICY = ON, CHECK_EXPIRATION = ON;
```

If `CHECK_EXPIRATION` is enabled, passwords are subject to password age policies. The T-SQL statement to check if `CHECK_POLICY` and `CHECK_EXPIRATION` are set:

```
SELECT name, is_policy_checked, is_expiration_checked FROM sys.sql_logins;
```

Password policy parameters

All password policy parameters are dynamic and do not require DB reboot to take effect. The following table lists the DB parameters you can set to modify the password policy for SQL Server logins:

DB parameter	Description	Allowed Values	Default Value	

rds.password_complexity_enabled	Password complexity requirements must be satisfied when creating or changing passwords for SQL Server logins. The following constraints must be met:
	• The password must include characters from three of the following categories:
	  • Latin lowercase letter (a through z)
	  • Latin uppercase letter (A through Z)
	  • Non-alpha numeric
		0,1	0	

DB parameter	Description	Allowed Values	Default Value	
	characters such as: exclamation point (!), dollar sign ($), number sign (#), or percent (%). • The password doesn't contain the account name of the user.			
rds.password_min_length	The minimum number of characters required in a password for a SQL Server login.	0-14	0	
rds.password_min_age	The minimum number of days a SQL Server login password must be used before the user can change it. Passwords can be changed immediately when set to 0.	0-998	0	

DB parameter	Description	Allowed Values	Default Value	
rds.password_max_age	The maximum number of days a SQL Server login password can be used after which the user is required to change it. Passwords never expire when set to 0.	0-999	42	
rds.password_lockout_threshold	The number of consecutive failed login attempts that cause a SQL Server login to become locked out.	0-999	0	
rds.password_lockout_duration	The number of minutes a locked out SQL Server login must wait before being unlocked.	1-60	10	

DB parameter	Description	Allowed Values	Default Value	
rds.password_lockout_reset_counter_after	The number of minutes that must elapse after a failed login attempt before the failed login attempt counter is reset to 0.	1-60	10	

> **Note**
>
> For more information about SQL Server password policy, see Password Policy.
> The password complexity and minimum length policies also apply to DB users in contained databases. For more information, see Contained Databases.

The following constraints apply to the password policy parameters:

- The `rds.password_min_age` parameter must be less than `rds.password_max_age` parameter, unless `rds.password_max_age` is set to 0
- The `rds.password_lockout_reset_counter_after` parameter must be less than or equal to the `rds.password_lockout_duration` parameter.
- If `rds.password_lockout_threshold` is set to 0, `rds.password_lockout_duration` and `rds.password_lockout_reset_counter_after` do not apply.

Considerations for existing logins

After modifying the password policy on an instance, existing passwords for logins are **not** retroactively evaluated against the new password complexity and length requirements. Only new passwords are validated against the new policy.

SQL Server **does** evaluate existing passwords for age requirements.

It is possible for passwords to expire immediately once a password policy is modified. For example, if a login has `CHECK_EXPIRATION` enabled and its password was last changed 100 days ago and you set the `rds.password_max_age` parameter to 5 days, the password immediately expires and the login needs to change their password at their next attempt to log in.

> **Note**
>
> RDS for SQL Server doesn't support password history policies. History policies prevent logins from reusing previously used passwords.

Considerations for Multi-AZ deployments

The failed login attempt counter and lockout state for Multi-AZ instances does not replicate between nodes. In the event of a login being locked out when a Multi-AZ instance fails over, it is possible for the login to be already unlocked on the new node.

Password considerations for the master login

When you create an RDS for SQL Server DB instance, the master user password is not evaluated against the password policy. A new master password is also not evaluated against the password when performing operations to the master user, specifically when setting `MasterUserPassword` in the `ModifyDBInstance` command. In both cases, you can set a password for the master user that does not satisfy your password policy, and the operation still succeeds. If the policy is not satisfied, RDS attempts to raise an RDS event, with the recommendation to set a strong password. Take care to only use strong passwords for the master user.

RDS attempts to generate the following event messages when the master user password does not meet the password policy requirements:

- The master user was created, but the password doesn't meet the minimum length requirement of your password policy. Consider using a stronger password.
- The master user was created, but the password doesn't meet the complexity requirement of your password policy. Consider using a stronger password.
- The master user password was reset, but the password doesn't meet the minimum length requirement of your password policy. Consider using a stronger password.
- The master user password was reset, but the password doesn't meet the complexity requirement of your password policy. Consider using a stronger password.

By default, the master user is created with `CHECK_POLICY` and `CHECK_EXPIRATION` set to `OFF`. To apply the password policy to the master user, you must manually enable these flags for the master user after DB instance creation. After you enable these flags, modify the master user password directly in SQL Server (eg. via T-SQL statements or SSMS) to validate the new password against the password policy.

> **Note**
>
> If the master user gets locked out, you can unlock the user by resetting the master user password using the `ModifyDBInstance` command.

Modifying the master user password

You can modify the master user password by using the ModifyDBInstance command.

> **Note**
>
> When you reset the master user password, RDS resets various permissions for the master user and the master user might lose certain permissions. Resetting the master user password also unlocks the master user, if it was locked out.

RDS validates the new master user password and attempts to emit an RDS event if the password does not satisfy the policy. RDS sets the password even if it does not satisfy the password policy.

Integrating an Amazon RDS for SQL Server DB instance with Amazon S3

You can transfer files between a DB instance running Amazon RDS for SQL Server and an Amazon S3 bucket. By doing this, you can use Amazon S3 with SQL Server features such as BULK INSERT. For example, you can download .csv, .xml, .txt, and other files from Amazon S3 to the DB instance host and import the data from `D:\S3\` into the database. All files are stored in `D:\S3\` on the DB instance.

The following limitations apply:

> **Note**
>
> Traffic between the RDS host and S3 routes through VPC endpoints in RDS internal VPCs for all SQL Server features that use S3. This traffic doesn't use the RDS instance endpoint ENI. S3 bucket policies can't restrict RDS traffic by networking conditions.

- Files in the `D:\S3` folder are deleted on the standby replica after a failover on Multi-AZ instances. For more information, see Multi-AZ limitations for S3 integration.
- The DB instance and the S3 bucket must be in the same AWS Region.
- If you run more than one S3 integration task at a time, the tasks run sequentially, not in parallel.

  > **Note**
  >
  > S3 integration tasks share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. Therefore, two running native backup and restore tasks will block any S3 integration tasks.

- You must re-enable the S3 integration feature on restored instances. S3 integration isn't propagated from the source instance to the restored instance. Files in `D:\S3` are deleted on a restored instance.
- Downloading to the DB instance is limited to 100 files. In other words, there can't be more than 100 files in `D:\S3\`.
- Only files without file extensions or with the following file extensions are supported for download: .abf, .asdatabase, .bcp, .configsettings, .csv, .dat, .deploymentoptions, .deploymenttargets, .fr and .xmla.

- The S3 bucket must have the same owner as the related AWS Identity and Access Management (IAM) role. Therefore, cross-account S3 integration isn't supported.
- The S3 bucket can't be open to the public.
- The file size for uploads from RDS to S3 is limited to 50 GB per file.
- The file size for downloads from S3 to RDS is limited to the maximum supported by S3.

Topics

- Prerequisites for integrating RDS for SQL Server with S3
- Enabling RDS for SQL Server integration with S3
- Transferring files between RDS for SQL Server and Amazon S3
- Listing files on the RDS DB instance
- Deleting files on the RDS DB instance
- Monitoring the status of a file transfer task
- Canceling a task
- Multi-AZ limitations for S3 integration
- Disabling RDS for SQL Server integration with S3

For more information on working with files in Amazon S3, see Getting started with Amazon Simple Storage Service.

Prerequisites for integrating RDS for SQL Server with S3

Before you begin, find or create the S3 bucket that you want to use. Also, add permissions so that the RDS DB instance can access the S3 bucket. To configure this access, you create both an IAM policy and an IAM role.

Console

To create an IAM policy for access to Amazon S3

1. In the IAM Management Console, choose **Policies** in the navigation pane.
2. Create a new policy, and use the **Visual editor** tab for the following steps.
3. For **Service**, enter **S3** and then choose the **S3** service.

4. For **Actions**, choose the following to grant the access that your DB instance requires:

   - `ListAllMyBuckets` – required
   - `ListBucket` – required
   - `GetBucketAcl` – required
   - `GetBucketLocation` – required
   - `GetObject` – required for downloading files from S3 to `D:\S3\`
   - `PutObject` – required for uploading files from `D:\S3\` to S3
   - `ListMultipartUploadParts` – required for uploading files from `D:\S3\` to S3
   - `AbortMultipartUpload` – required for uploading files from `D:\S3\` to S3

5. For **Resources**, the options that display depend on which actions you choose in the previous step. You might see options for **bucket**, **object**, or both. For each of these, add the appropriate Amazon Resource Name (ARN).

   For **bucket**, add the ARN for the bucket that you want to use. For example, if your bucket is named *`amzn-s3-demo-bucket`*, set the ARN to `arn:aws:s3:::`*`amzn-s3-demo-bucket`*.

   For **object**, enter the ARN for the bucket and then choose one of the following:

   - To grant access to all files in the specified bucket, choose **Any** for both **Bucket name** and **Object name**.
   - To grant access to specific files or folders in the bucket, provide ARNs for the specific buckets and objects that you want SQL Server to access.

6. Follow the instructions in the console until you finish creating the policy.

   The preceding is an abbreviated guide to setting up a policy. For more detailed instructions on creating IAM policies, see Creating IAM policies in the *IAM User Guide.*

To create an IAM role that uses the IAM policy from the previous procedure

1. In the IAM Management Console, choose **Roles** in the navigation pane.
2. Create a new IAM role, and choose the following options as they appear in the console:

   - **AWS service**
   - **RDS**
   - **RDS – Add Role to Database**

Then choose **Next:Permissions** at the bottom.

3. For **Attach permissions policies**, enter the name of the IAM policy that you previously created. Then choose the policy from the list.
4. Follow the instructions in the console until you finish creating the role.

   The preceding is an abbreviated guide to setting up a role. If you want more detailed instructions on creating roles, see IAM roles in the *IAM User Guide.*

AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket, use the following process:

1. Create an IAM policy that grants Amazon RDS access to an S3 bucket.
2. Create an IAM role that Amazon RDS can assume on your behalf to access your S3 buckets.

   For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.
3. Attach the IAM policy that you created to the IAM role that you created.

To create the IAM policy

Include the appropriate actions to grant the access your DB instance requires:

- `ListAllMyBuckets` – required
- `ListBucket` – required
- `GetBucketAcl` – required
- `GetBucketLocation` – required
- `GetObject` – required for downloading files from S3 to `D:\S3\`
- `PutObject` – required for uploading files from `D:\S3\` to S3
- `ListMultipartUploadParts` – required for uploading files from `D:\S3\` to S3
- `AbortMultipartUpload` – required for uploading files from `D:\S3\` to S3

1. The following AWS CLI command creates an IAM policy named `rds-s3-integration-policy` with these options. It grants access to a bucket named *`amzn-s3-demo-bucket`*.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
  --policy-name rds-s3-integration-policy \
  --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Action": "s3:ListAllMyBuckets",
                "Resource": "*"
            },
            {
                "Effect": "Allow",
                "Action": [
                    "s3:ListBucket",
                    "s3:GetBucketAcl",
                    "s3:GetBucketLocation"
                ],
                "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
            },
            {
                "Effect": "Allow",
                "Action": [
                    "s3:GetObject",
                    "s3:PutObject",
                    "s3:ListMultipartUploadParts",
                    "s3:AbortMultipartUpload"
                ],
                "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
            }
        ]
    }'
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the `policy.json` file with the following permission policy:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketACL",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
        }
    ]
}
```

Then use the following command to create the policy:

```
aws iam create-policy ^
     --policy-name rds-s3-integration-policy ^
     --policy-document file://file_path/assume_role_policy.json
```

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a later step.

To create the IAM role

- The following AWS CLI command creates the `rds-s3-integration-role` IAM role for this purpose.

  Example

  For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name rds-s3-integration-role \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
             "Service": "rds.amazonaws.com"
           },
          "Action": "sts:AssumeRole"
        }
      ]
    }'
```

  For Windows:

  Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

  First, create the `assume_role_policy.json` file with the following policy:

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Then use the following command to create the IAM role:

```
aws iam create-role ^
     --role-name rds-s3-integration-role ^
     --assume-role-policy-document file://file_path/assume_role_policy.json
```

Example of using the global condition context key to create the IAM role

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For S3 integration, make sure to include the DB instance ARNs, as shown in the following example.

For Linux, macOS, or Unix:

```
aws iam create-role \
    --role-name rds-s3-integration-role \
    --assume-role-policy-document '{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
             "Service": "rds.amazonaws.com"
           },
          "Action": "sts:AssumeRole",
                "Condition": {
                    "StringEquals": {

 "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    }
                }
        }
      ]
    }'
```

For Windows:

Add the global condition context key to `assume_role_policy.json`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
```

```
            "aws:SourceArn":"arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    }
                }
            }
        ]
}
```

To attach the IAM policy to the IAM role

- The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`. Replace *your-policy-arn* with the policy ARN that you noted in a previous step.

  Example

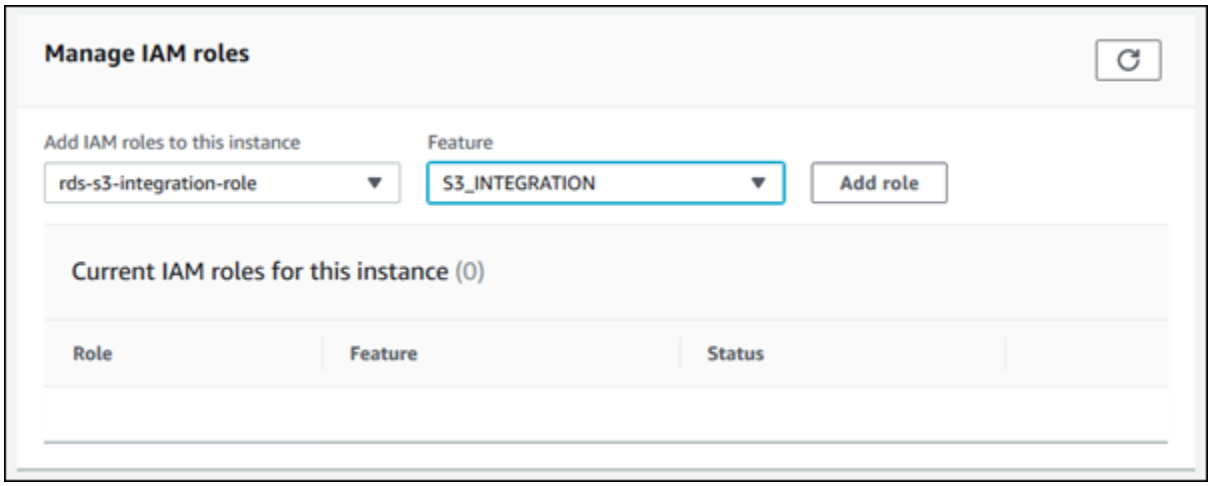
  For Linux, macOS, or Unix:

  ```
  aws iam attach-role-policy \
      --policy-arn your-policy-arn \
      --role-name rds-s3-integration-role
  ```

  For Windows:

  ```
  aws iam attach-role-policy ^
      --policy-arn your-policy-arn ^
      --role-name rds-s3-integration-role
  ```

Enabling RDS for SQL Server integration with S3



In the following section, you can find how to enable Amazon S3 integration with Amazon RDS for SQL Server. To work with S3 integration, your DB instance must be associated with the IAM role that you previously created before you use the `S3_INTEGRATION` feature-name parameter.

> **Note**
>
> To add an IAM role to a DB instance, the status of the DB instance must be **available**.

Console

To associate your IAM role with your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to add for **Add IAM roles to this instance**.
4. For **Feature**, choose **S3_INTEGRATION**.

5. Choose **Add role**.

AWS CLI

To add the IAM role to the RDS for SQL Server DB instance

- The following AWS CLI command adds your IAM role to an RDS for SQL Server DB instance named *mydbinstance*.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --db-instance-identifier mydbinstance \
    --feature-name S3_INTEGRATION \
    --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
    --db-instance-identifier mydbinstance ^
    --feature-name S3_INTEGRATION ^
    --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. `S3_INTEGRATION` must be specified for the `--feature-name` option.

Transferring files between RDS for SQL Server and Amazon S3

You can use Amazon RDS stored procedures to download and upload files between Amazon S3 and your RDS DB instance. You can also use Amazon RDS stored procedures to list and delete files on the RDS instance.

The files that you download from and upload to S3 are stored in the `D:\S3` folder. This is the only folder that you can use to access your files. You can organize your files into subfolders, which are created for you when you include the destination folder during download.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your S3 bucket and file. The format for your ARN is `arn:aws:s3:::`*amzn-s3-demo-bucket*`/file_name`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

S3 integration tasks run sequentially and share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. It can take up to five minutes for the task to begin processing.

Downloading files from an Amazon S3 bucket to a SQL Server DB instance

To download files from an S3 bucket to an RDS for SQL Server DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_download_from_s3` with the following parameters.

Parameter name	Data type	Default	Required	Description
`@s3_arn_of_file`	NVARCHAR	–	Required	The S3 ARN of the file to download, for example: `arn:aws:s3:::` *amzn-*

Parameter name	Data type	Default	Required	Description
				s3-demo-bucket / mydata.csv
@rds_file_path	NVARCHAR	–	Optional	The file path for the RDS instance. If not specified, the file path is D:\S3*<filename in s3>*. RDS supports absolute paths and relative paths. If you want to create a subfolder, include it in the file path.
@overwrite_file	INT	0	Optional	Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite

You can download files without a file extension and files with the following file extensions: .bcp, .csv, .dat, .fmt, .info, .lst, .tbl, .txt, and .xml.

Note

Files with the .ispac file extension are supported for download when SQL Server Integration Services is enabled. For more information on enabling SSIS, see SQL Server Integration Services.
Files with the following file extensions are supported for download when SQL Server Analysis Services is
enabled: .abf, .asdatabase, .configsettings, .deploymentoptions, .deploymenttargets, and .xmla. For more information on enabling SSAS, see SQL Server Analysis Services.

The following example shows the stored procedure to download files from S3.

```
exec msdb.dbo.rds_download_from_s3
     @s3_arn_of_file='arn:aws:s3:::amzn-s3-demo-bucket/bulk_data.csv',
     @rds_file_path='D:\S3\seed_data\data.csv',
     @overwrite_file=1;
```

The example `rds_download_from_s3` operation creates a folder named `seed_data` in `D:\S3\`, if the folder doesn't exist yet. Then the example downloads the source file `bulk_data.csv` from S3 to a new file named `data.csv` on the DB instance. If the file previously existed, it's overwritten because the `@overwrite_file` parameter is set to 1.

Uploading files from a SQL Server DB instance to an Amazon S3 bucket

To upload files from an RDS for SQL Server DB instance to an S3 bucket, use the Amazon RDS stored procedure `msdb.dbo.rds_upload_to_s3` with the following parameters.

Parameter name	Data type	Default	Required	Description
`@s3_arn_of_file`	NVARCHAR	–	Required	The S3 ARN of the file to be created in S3, for example: `arn:aws:s3:::` *`amzn-s3-demo-bucket`* `/mydata.csv`
`@rds_file_path`	NVARCHAR	–	Required	The file path of the file to upload to S3. Absolute and relative paths are supported.
`@overwrite_file`	INT	–	Optional	Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite

The following example uploads the file named `data.csv` from the specified location in `D:\S3\seed_data\` to a file `new_data.csv` in the S3 bucket specified by the ARN.

```
exec msdb.dbo.rds_upload_to_s3
  @rds_file_path='D:\S3\seed_data\data.csv',
  @s3_arn_of_file='arn:aws:s3:::amzn-s3-demo-bucket/new_data.csv',
  @overwrite_file=1;
```

If the file previously existed in S3, it's overwritten because the @overwrite_file parameter is set to 1.

Listing files on the RDS DB instance

To list the files available on the DB instance, use both a stored procedure and a function. First, run the following stored procedure to gather file details from the files in `D:\S3\`.

```
exec msdb.dbo.rds_gather_file_details;
```

The stored procedure returns the ID of the task. Like other tasks, this stored procedure runs asynchronously. As soon as the status of the task is SUCCESS, you can use the task ID in the `rds_fn_list_file_details` function to list the existing files and directories in D:\S3\, as shown following.

```
SELECT * FROM msdb.dbo.rds_fn_list_file_details(TASK_ID);
```

The `rds_fn_list_file_details` function returns a table with the following columns.

Output parameter	Description
`filepath`	Absolute path of the file (for example, `D:\S3\mydata.csv`)
`size_in_bytes`	File size (in bytes)
`last_modified_utc`	Last modification date and time in UTC format
`is_directory`	Option that indicates whether the item is a directory (`true`/`false`)

Deleting files on the RDS DB instance

To delete the files available on the DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_delete_from_filesystem` with the following parameters.

Parameter name	Data type	Default	Required	Description
`@rds_file_path`	NVARCHAR	–	Required	The file path of the file to delete. Absolute and relative paths are supported.
`@force_delete`	INT	0	Optional	To delete a directory, this flag must be included and set to 1. 1 = delete a directory This parameter is ignored if you are deleting a file.

To delete a directory, the `@rds_file_path` must end with a backslash (\) and `@force_delete` must be set to 1.

The following example deletes the file `D:\S3\delete_me.txt`.

```
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\delete_me.txt';
```

The following example deletes the directory `D:\S3\example_folder\`.

```
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\example_folder\',
    @force_delete=1;
```

Monitoring the status of a file transfer task

To track the status of your S3 integration task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to S3 integration. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
`task_id`	The ID of the task.
`task_type`	For S3 integration, tasks can have the following task types: • `DOWNLOAD_FROM_S3` • `UPLOAD_TO_S3` • `LIST_FILES_ON_DISK` • `DELETE_FILES_ON_DISK`
`database_name`	Not applicable to S3 integration tasks.
`% complete`	The progress of the task as a percentage.
`duration(mins)`	The amount of time spent on the task, in minutes.
`lifecycle`	The status of the task. Possible statuses are the following:

Output parameter	Description
	• CREATED – After you call one of the S3 integration stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS . It can take up to five minutes for the status to change from CREATED to IN_PROGRESS . • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call rds_cancel_task , the status of the task is set to CANCEL_REQUESTED . • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED .
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	The ARN of the S3 object downloaded from or uploaded to.
overwrite_S3_backup_file	Not applicable to S3 integration tasks.
KMS_master_key_arn	Not applicable to S3 integration tasks.

Output parameter	Description
`filepath`	The file path on the RDS DB instance.
`overwrite_file`	An option that indicates if an existing file is overwritten.
`task_metadata`	Not applicable to S3 integration tasks.

Canceling a task

To cancel S3 integration tasks, use the `msdb.dbo.rds_cancel_task` stored procedure with the `task_id` parameter. Delete and list tasks that are in progress can't be cancelled. The following example shows a request to cancel a task.

```
exec msdb.dbo.rds_cancel_task @task_id = 1234;
```

To get an overview of all tasks and their task IDs, use the `rds_fn_task_status` function as described in Monitoring the status of a file transfer task.

Multi-AZ limitations for S3 integration

On Multi-AZ instances, files in the `D:\S3` folder are deleted on the standby replica after a failover. A failover can be planned, for example, during DB instance modifications such as changing the instance class or upgrading the engine version. Or a failover can be unplanned, during an outage of the primary.

> **Note**
>
> We don't recommend using the `D:\S3` folder for file storage. The best practice is to upload created files to Amazon S3 to make them durable, and download files when you need to import data.

To determine the last failover time, you can use the `msdb.dbo.rds_failover_time` stored procedure. For more information, see Determining the last failover time for Amazon RDS for SQL Server.

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

Therefore, all files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host. Files downloaded before that time might also be available.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

All files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

Disabling RDS for SQL Server integration with S3

Following, you can find how to disable Amazon S3 integration with Amazon RDS for SQL Server. Files in `D:\S3\` aren't deleted when disabling S3 integration.

> **Note**
>
> To remove an IAM role from a DB instance, the status of the DB instance must be `available`.

Console

To disassociate your IAM role from your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to remove.
4. Choose **Delete**.

AWS CLI

To remove the IAM role from the RDS for SQL Server DB instance

- The following AWS CLI command removes the IAM role from a RDS for SQL Server DB instance named *mydbinstance*.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-role-from-db-instance \
    --db-instance-identifier mydbinstance \
    --feature-name S3_INTEGRATION \
    --role-arn your-role-arn
```

  For Windows:

```
aws rds remove-role-from-db-instance ^
    --db-instance-identifier mydbinstance ^
    --feature-name S3_INTEGRATION ^
    --role-arn your-role-arn
```

  Replace *your-role-arn* with the appropriate IAM role ARN for the `--feature-name` option.

Using Database Mail on Amazon RDS for SQL Server

You can use Database Mail to send email messages to users from your Amazon RDS on SQL Server database instance. The messages can contain files and query results. Database Mail includes the following components:

- **Configuration and security objects** – These objects create profiles and accounts, and are stored in the `msdb` database.
- **Messaging objects** – These objects include the sp_send_dbmail stored procedure used to send messages, and data structures that hold information about messages. They're stored in the `msdb` database.
- **Logging and auditing objects** – Database Mail writes logging information to the `msdb` database and the Microsoft Windows application event log.
- **Database Mail executable** – `DatabaseMail.exe` reads from a queue in the `msdb` database and sends email messages.

RDS supports Database Mail for all SQL Server versions on the Web, Standard, and Enterprise Editions.

Limitations

The following limitations apply to using Database Mail on your SQL Server DB instance:

- Database Mail isn't supported for SQL Server Express Edition.
- Modifying Database Mail configuration parameters isn't supported. To see the preset (default) values, use the sysmail_help_configure_sp stored procedure.
- File attachments aren't fully supported. For more information, see Working with file attachments.
- The maximum file attachment size is 1 MB.
- Database Mail requires additional configuration on Multi-AZ DB instances. For more information, see Considerations for Multi-AZ deployments.
- Configuring SQL Server Agent to send email messages to predefined operators isn't supported.

Enabling Database Mail

Use the following process to enable Database Mail for your DB instance:

1. Create a new parameter group.
2. Modify the parameter group to set the `database mail xps` parameter to 1.
3. Associate the parameter group with the DB instance.

Creating the parameter group for Database Mail

Create a parameter group for the `database mail xps` parameter that corresponds to the SQL Server edition and version of your DB instance.

> **Note**
>
> You can also modify an existing parameter group. Follow the procedure in Modifying the parameter that enables Database Mail.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`dbmail-sqlserver-se-13`**.
   c. For **Description**, enter **`Database Mail XPs`**.
5. Choose **Create**.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name dbmail-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "Database Mail XPs"
```

  For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name dbmail-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "Database Mail XPs"
```

Modifying the parameter that enables Database Mail

Modify the `database mail xps` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

To enable Database Mail, set the `database mail xps` parameter to 1.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **dbmail-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **`mail`**.
5. Choose **database mail xps**.

6. Choose **Edit parameters**.
7. Enter **1**.
8. Choose **Save changes**.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name dbmail-sqlserver-se-13 \
    --parameters "ParameterName='database mail
 xps',ParameterValue=1,ApplyMethod=immediate"
```

  For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name dbmail-sqlserver-se-13 ^
    --parameters "ParameterName='database mail
 xps',ParameterValue=1,ApplyMethod=immediate"
```

Associating the parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the Database Mail parameter group with the DB instance.

Console

You can associate the Database Mail parameter group with a new or existing DB instance.

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the Database Mail parameter group with a new or existing DB instance.

To create a DB instance with the Database Mail parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li
    --db-parameter-group-name dbmail-sqlserver-se-13
```

  For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --db-parameter-group-name dbmail-sqlserver-se-13
```

To modify a DB instance and associate the Database Mail parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name dbmail-sqlserver-se-13 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name dbmail-sqlserver-se-13 ^
    --apply-immediately
```

Configuring Database Mail

You perform the following tasks to configure Database Mail:

1. Create the Database Mail profile.
2. Create the Database Mail account.
3. Add the Database Mail account to the Database Mail profile.
4. Add users to the Database Mail profile.

> **Note**
>
> To configure Database Mail, make sure that you have `execute` permission on the stored procedures in the `msdb` database.

Creating the Database Mail profile

To create the Database Mail profile, you use the sysmail_add_profile_sp stored procedure. The following example creates a profile named `Notifications`.

To create the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_profile_sp
    @profile_name         = 'Notifications',
    @description          = 'Profile used for sending outgoing notifications using
 Amazon SES.';
GO
```

Creating the Database Mail account

To create the Database Mail account, you use the sysmail_add_account_sp stored procedure. The following example creates an account named SES on an RDS for SQL Server DB instance in a private VPC, using Amazon Simple Email Service.

Using Amazon SES requires the following parameters:

- `@email_address` – An Amazon SES verified identity. For more information, see Verified identities in Amazon SES.
- `@mailserver_name` – An Amazon SES SMTP endpoint. For more information, see Connecting to an Amazon SES SMTP endpoint.
- `@username` – An Amazon SES SMTP user name. For more information, see Obtaining Amazon SES SMTP credentials.

  Don't use an AWS Identity and Access Management user name.
- `@password` – An Amazon SES SMTP password. For more information, see Obtaining Amazon SES SMTP credentials.

To create the account

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_account_sp
    @account_name        = 'SES',
    @description         = 'Mail account for sending outgoing notifications.',
    @email_address       = 'nobody@example.com',
    @display_name        = 'Automated Mailer',
    @mailserver_name     = 'vpce-0a1b2c3d4e5f-01234567.email-smtp.us-
west-2.vpce.amazonaws.com',
    @port                = 587,
    @enable_ssl          = 1,
    @username            = 'Smtp_Username',
    @password            = 'Smtp_Password';
GO
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

Adding the Database Mail account to the Database Mail profile

To add the Database Mail account to the Database Mail profile, you use the sysmail_add_profileaccount_sp stored procedure. The following example adds the SES account to the `Notifications` profile.

To add the account to the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_profileaccount_sp
    @profile_name        = 'Notifications',
    @account_name        = 'SES',
```

```
    @sequence_number     = 1;
GO
```

Adding users to the Database Mail profile

To grant permission for an `msdb` database principal to use a Database Mail profile, you use the sysmail_add_principalprofile_sp stored procedure. A *principal* is an entity that can request SQL Server resources. The database principal must map to a SQL Server authentication user, a Windows Authentication user, or a Windows Authentication group.

The following example grants public access to the `Notifications` profile.

To add a user to the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_principalprofile_sp
    @profile_name       = 'Notifications',
    @principal_name     = 'public',
    @is_default         = 1;
GO
```

Amazon RDS stored procedures and functions for Database Mail

Microsoft provides stored procedures for using Database Mail, such as creating, listing, updating, and deleting accounts and profiles. In addition, RDS provides the stored procedures and functions for Database Mail shown in the following table.

Procedure/Function	Description
rds_fn_sysmail_allitems	Shows sent messages, including those submitted by other users.
rds_fn_sysmail_event_log	Shows events, including those for messages submitted by other users.

Procedure/Function	Description
rds_fn_sysmail_mailattachments	Shows attachments, including those to messages submitted by other users.
rds_sysmail_control	Starts and stops the mail queue (DatabaseMail.exe process).
rds_sysmail_delete_mailitems_sp	Deletes email messages sent by all users from the Database Mail internal tables.

Sending email messages using Database Mail

You use the sp_send_dbmail stored procedure to send email messages using Database Mail.

Usage

```
EXEC msdb.dbo.sp_send_dbmail
@profile_name = 'profile_name',
@recipients = 'recipient1@example.com[; recipient2; ... recipientn]',
@subject = 'subject',
@body = 'message_body',
[@body_format = 'HTML'],
[@file_attachments = 'file_path1; file_path2; ... file_pathn'],
[@query = 'SQL_query'],
[@attach_query_result_as_file = 0|1]';
```

The following parameters are required:

- `@profile_name` – The name of the Database Mail profile from which to send the message.
- `@recipients` – The semicolon-delimited list of email addresses to which to send the message.
- `@subject` – The subject of the message.
- @body – The body of the message. You can also use a declared variable as the body.

The following parameters are optional:

- `@body_format` – This parameter is used with a declared variable to send email in HTML format.
- `@file_attachments` – The semicolon-delimited list of message attachments. File paths must be absolute paths.

- `@query` – A SQL query to run. The query results can be attached as a file or included in the body of the message.
- `@attach_query_result_as_file` – Whether to attach the query result as a file. Set to 0 for no, 1 for yes. The default is 0.

Examples

The following examples demonstrate how to send email messages.

Example of sending a message to a single recipient

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
     @subject            = 'Automated DBMail message - 1',
     @body               = 'Database Mail configuration was successful.';
GO
```

Example of sending a message to multiple recipients

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'recipient1@example.com;recipient2@example.com',
     @subject            = 'Automated DBMail message - 2',
     @body               = 'This is a message.';
GO
```

Example of sending a SQL query result as a file attachment

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
```

```
     @subject            = 'Test SQL query',
     @body               = 'This is a SQL query test.',
     @query              = 'SELECT * FROM abc.dbo.test',
     @attach_query_result_as_file = 1;
GO
```

Example of sending a message in HTML format

```
USE msdb
GO

DECLARE @HTML_Body as NVARCHAR(500) = 'Hi, <h4> Heading </h4> </br> See the report. <b>
 Regards </b>';

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
     @subject            = 'Test HTML message',
     @body               = @HTML_Body,
     @body_format        = 'HTML';
GO
```

Example of sending a message using a trigger when a specific event occurs in the database

```
USE AdventureWorks2017
GO
IF OBJECT_ID ('Production.iProductNotification', 'TR') IS NOT NULL
DROP TRIGGER Purchasing.iProductNotification
GO

CREATE TRIGGER iProductNotification ON Production.Product
   FOR INSERT
   AS
   DECLARE @ProductInformation nvarchar(255);
   SELECT
   @ProductInformation = 'A new product, ' + Name + ', is now available for $' +
 CAST(StandardCost AS nvarchar(20)) + '!'
   FROM INSERTED i;

EXEC msdb.dbo.sp_send_dbmail
     @profile_name       = 'Notifications',
     @recipients         = 'nobody@example.com',
     @subject            = 'New product information',
```

```
    @body                = @ProductInformation;
GO
```

Viewing messages, logs, and attachments

You use RDS stored procedures to view messages, event logs, and attachments.

To view all email messages

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_allitems(); --WHERE sent_status='sent' or
 'failed' or 'unsent'
```

To view all email event logs

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_event_log();
```

To view all email attachments

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_mailattachments();
```

Deleting messages

You use the `rds_sysmail_delete_mailitems_sp` stored procedure to delete messages.

> **Note**
>
> RDS automatically deletes mail table items when DBMail history data reaches 1 GB in size, with a retention period of at least 24 hours.
> If you want to keep mail items for a longer period, you can archive them. For more information, see Create a SQL Server Agent job to archive Database Mail messages and event logs in the Microsoft documentation.

To delete all email messages

- Use the following SQL statement.

```
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_before = @GETDATE;
GO
```

To delete all email messages with a particular status

- Use the following SQL statement to delete all failed messages.

```
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_status = 'failed';
GO
```

Starting and stopping mail queue

Use the following instructions to start and stop the DB mail queue:

Topics

- Starting the mail queue
- Stopping the mail queue

Starting the mail queue

You use the `rds_sysmail_control` stored procedure to start the Database Mail process.

> **Note**
>
> Enabling Database Mail automatically starts the mail queue.

To start the mail queue

- Use the following SQL statement.

```
EXECUTE msdb.dbo.rds_sysmail_control start;
GO
```

Stopping the mail queue

You use the `rds_sysmail_control` stored procedure to stop the Database Mail process.

To stop the mail queue

- Use the following SQL statement.

```
EXECUTE msdb.dbo.rds_sysmail_control stop;
GO
```

Working with file attachments

The following file attachment extensions aren't supported in Database Mail messages from RDS on SQL
Server: .ade, .adp, .apk, .appx, .appxbundle, .bat, .bak, .cab, .chm, .cmd, .com, .cpl, .dll, .dmg, .exe, .hta, .inf1 and .wsh.

Database Mail uses the Microsoft Windows security context of the current user to control access to files. Users who log in with SQL Server Authentication can't attach files using the `@file_attachments` parameter with the `sp_send_dbmail` stored procedure. Windows doesn't allow SQL Server to provide credentials from a remote computer to another remote computer. Therefore, Database Mail can't attach files from a network share when the command is run from a computer other than the computer running SQL Server.

However, you can use SQL Server Agent jobs to attach files. For more information on SQL Server Agent, see Using SQL Server Agent for Amazon RDS and SQL Server Agent in the Microsoft documentation.

Considerations for Multi-AZ deployments

When you configure Database Mail on a Multi-AZ DB instance, the configuration isn't automatically propagated to the secondary. We recommend converting the Multi-AZ instance to a Single-AZ instance, configuring Database Mail, and then converting the DB instance back to Multi-AZ. Then both the primary and secondary nodes have the Database Mail configuration.

If you create a read replica from your Multi-AZ instance that has Database Mail configured, the replica inherits the configuration, but without the password to the SMTP server. Update the Database Mail account with the password.

Removing the SMTP (port 25) restriction

By default, AWS blocks outbound traffic on SMTP (port 25) for RDS for SQL Server DB instances. This is done to prevent spam based on the elastic network interface owner's policies. You can remove this restriction if needed. For more information, see How do I remove the restriction on port 25 from my Amazon EC2 instance or Lambda function?.

Instance store support for the tempdb database on Amazon RDS for SQL Server

An *instance store* provides temporary block-level storage for your DB instance. This storage is located on disks that are physically attached to the host computer. These disks have Non-Volatile Memory Express (NVMe) instance storage that is based on solid-state drives (SSDs). This storage is optimized for low latency, very high random I/O performance, and high sequential read throughput.

By placing `tempdb` data files and `tempdb` log files on the instance store, you can achieve lower read and write latencies compared to standard storage based on Amazon EBS.

> **Note**
>
> SQL Server database files and database log files aren't placed on the instance store.

Enabling the instance store

When RDS provisions DB instances with one of the following instance classes, the `tempdb` database is automatically placed onto the instance store:

- db.m5d
- db.r5d
- db.x2iedn

To enable the instance store, do one of the following:

- Create a SQL Server DB instance using one of these instance types. For more information, see Creating an Amazon RDS DB instance.
- Modify an existing SQL Server DB instance to use one of them. For more information, see Modifying an Amazon RDS DB instance.

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the `db.m5d` and `db.r5d` instance classes, see DB instance classes. For more information on the instance classes supported by Amazon RDS for SQL Server, see DB instance class support for Microsoft SQL Server.

File location and size considerations

On instances without an instance store, RDS stores the `tempdb` data and log files in the `D:\rdsdbdata\DATA` directory. Both files start at 8 MB by default.

On instances with an instance store, RDS stores the `tempdb` data and log files in the `T:\rdsdbdata\DATA` directory.

When `tempdb` has only one data file (`tempdb.mdf`) and one log file (`templog.ldf`), `templog.ldf` starts at 8 MB by default and `tempdb.mdf` starts at 80% or more of the instance's storage capacity. Twenty percent of the storage capacity or 200 GB, whichever is less, is kept free to start. Multiple `tempdb` data files split the 80% disk space evenly, while log files always have an 8-MB initial size.

For example, if you modify your DB instance class from `db.m5.2xlarge` to `db.m5d.2xlarge`, the size of `tempdb` data files increases from 8 MB each to 234 GB in total.

> **Note**
>
> Besides the `tempdb` data and log files on the instance store (`T:\rdsdbdata\DATA`), you can still create extra `tempdb` data and log files on the data volume (`D:\rdsdbdata\DATA`). Those files always have an 8 MB initial size.

Backup considerations

You might need to retain backups for long periods, incurring costs over time. The `tempdb` data and log blocks can change very often depending on the workload. This can greatly increase the DB snapshot size.

When `tempdb` is on the instance store, snapshots don't include temporary files. This means that snapshot sizes are smaller and consume less of the free backup allocation compared to EBS-only storage.

Disk full errors

If you use all of the available space in the instance store, you might receive errors such as the following:

- The transaction log for database 'tempdb' is full due to 'ACTIVE_TRANSACTION'.

- Could not allocate space for object 'dbo.SORT temporary run storage: 140738941419520' in database 'tempdb' because the 'PRIMARY' filegroup is full. Create disk space by deleting unneeded files, dropping objects in the filegroup, adding additional files to the filegroup, or setting autogrowth on for existing files in the filegroup.

You can do one or more of the following when the instance store is full:

- Adjust your workload or the way you use `tempdb`.
- Scale up to use a DB instance class with more NVMe storage.
- Stop using the instance store, and use an instance class with only EBS storage.
- Use a mixed mode by adding secondary data or log files for `tempdb` on the EBS volume.

Removing the instance store

To remove the instance store, modify your SQL Server DB instance to use an instance type that doesn't support instance store, such as db.m5, db.r5, or db.x1e.

> **Note**
>
> When you remove the instance store, the temporary files are moved to the `D:\rdsdbdata\DATA` directory and reduced in size to 8 MB.

Using extended events with Amazon RDS for Microsoft SQL Server

You can use extended events in Microsoft SQL Server to capture debugging and troubleshooting information for Amazon RDS for SQL Server. Extended events replace SQL Trace and Server Profiler, which have been deprecated by Microsoft. Extended events are similar to profiler traces but with more granular control on the events being traced. Extended events are supported for SQL Server versions 2016 and later on Amazon RDS. For more information, see Extended events overview in the Microsoft documentation.

Extended events are turned on automatically for users with master user privileges in Amazon RDS for SQL Server.

Topics

- Limitations and recommendations
- Configuring extended events on RDS for SQL Server
- Considerations for Multi-AZ deployments
- Querying extended event files

Limitations and recommendations

When using extended events on RDS for SQL Server, the following limitations apply:

- Extended events are supported only for the Enterprise and Standard Editions.
- You can't alter default extended event sessions.
- Make sure to set the session memory partition mode to `NONE`.
- Session event retention mode can be either `ALLOW_SINGLE_EVENT_LOSS` or `ALLOW_MULTIPLE_EVENT_LOSS`.
- Event Tracing for Windows (ETW) targets aren't supported.
- Make sure that file targets are in the `D:\rdsdbdata\log` directory.
- For pair matching targets, set the `respond_to_memory_pressure` property to 1.
- Ring buffer target memory can't be greater than 4 MB.
- The following actions aren't supported:
  - `debug_break`
  - `create_dump_all_threads`

- `create_dump_single_threads`

- The `rpc_completed` event is supported on the following versions and later: 15.0.4083.2, 14.0.3370.1, 13.0.5865.1, 12.0.6433.1, 11.0.7507.2.

Configuring extended events on RDS for SQL Server

On RDS for SQL Server, you can configure the values of certain parameters of extended event sessions. The following table describes the configurable parameters.

Parameter name	Description
`xe_session_max_memory`	Specifies the maximum amount of memory to allocate t corresponds to the `max_memory` setting of the event s
`xe_session_max_event_size`	Specifies the maximum memory size allowed for large e `_size` setting of the event session.
`xe_session_max_dispatch_latency`	Specifies the amount of time that events are buffered in session targets. This value corresponds to the `max_disp`
`xe_file_target_size`	Specifies the maximum size of the file target. This value file target.
`xe_file_retention`	Specifies the retention time in days for files generated b

> **Note**
>
> Setting `xe_file_retention` to zero causes .xel files to be removed automatically after the lock on these files is released by SQL Server. The lock is released whenever an .xel file reaches the size limit set in `xe_file_target_size`.

You can use the `rdsadmin.dbo.rds_show_configuration` stored procedure to show the current values of these parameters. For example, use the following SQL statement to view the current setting of `xe_session_max_memory`.

```
exec rdsadmin.dbo.rds_show_configuration 'xe_session_max_memory'
```

You can use the `rdsadmin.dbo.rds_set_configuration` stored procedure to modify them. For example, use the following SQL statement to set `xe_session_max_memory` to 4 MB.

```
exec rdsadmin.dbo.rds_set_configuration 'xe_session_max_memory', 4
```

Considerations for Multi-AZ deployments

When you create an extended event session on a primary DB instance, it doesn't propagate to the standby replica. You can fail over and create the extended event session on the new primary DB instance. Or you can remove and then re-add the Multi-AZ configuration to propagate the extended event session to the standby replica. RDS stops all nondefault extended event sessions on the standby replica, so that these sessions don't consume resources on the standby. Because of this, after a standby replica becomes the primary DB instance, make sure to manually start the extended event sessions on the new primary.

> **Note**
>
> This approach applies to both Always On Availability Groups and Database Mirroring.

You can also use a SQL Server Agent job to track the standby replica and start the sessions if the standby becomes the primary. For example, use the following query in your SQL Server Agent job step to restart event sessions on a primary DB instance.

```
BEGIN
    IF (DATABASEPROPERTYEX('rdsadmin','Updateability')='READ_WRITE'
    AND DATABASEPROPERTYEX('rdsadmin','status')='ONLINE'
    AND (DATABASEPROPERTYEX('rdsadmin','Collation') IS NOT NULL OR
 DATABASEPROPERTYEX('rdsadmin','IsAutoClose')=1)
    )
    BEGIN
        IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe1')
            ALTER EVENT SESSION xe1 ON SERVER STATE=START
        IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe2')
            ALTER EVENT SESSION xe2 ON SERVER STATE=START
    END
END
```

This query restarts the event sessions `xe1` and `xe2` on a primary DB instance if these sessions are in a stopped state. You can also add a schedule with a convenient interval to this query.

Querying extended event files

You can either use SQL Server Management Studio or the `sys.fn_xe_file_target_read_file` function to view data from extended events that use file targets. For more information on this function, see sys.fn_xe_file_target_read_file (Transact-SQL) in the Microsoft documentation.

Extended event file targets can only write files to the `D:\rdsdbdata\log` directory on RDS for SQL Server.

As an example, use the following SQL query to list the contents of all files of extended event sessions whose names start with `xe`.

```
SELECT * FROM sys.fn_xe_file_target_read_file('d:\rdsdbdata\log\xe*', null,null,null);
```

Access to transaction log backups with RDS for SQL Server

With access to transaction log backups for RDS for SQL Server, you can list the transaction log backup files for a database and copy them to a target Amazon S3 bucket. By copying transaction log backups in an Amazon S3 bucket, you can use them in combination with full and differential database backups to perform point in time database restores. You use RDS stored procedures to set up access to transaction log backups, list available transaction log backups, and copy them to your Amazon S3 bucket.

Access to transaction log backups provides the following capabilities and benefits:

- List and view the metadata of available transaction log backups for a database on an RDS for SQL Server DB instance.
- Copy available transaction log backups from RDS for SQL Server to a target Amazon S3 bucket.
- Perform point-in-time restores of databases without the need to restore an entire DB instance. For more information on restoring a DB instance to a point in time, see Restoring a DB instance to a specified time for Amazon RDS.

Availability and support

Access to transaction log backups is supported in all AWS Regions. Access to transaction log backups is available for all editions and versions of Microsoft SQL Server supported on Amazon RDS.

Requirements

The following requirements must be met before enabling access to transaction log backups:

- Automated backups must be enabled on the DB instance and the backup retention must be set to a value of one or more days. For more information on enabling automated backups and configuring a retention policy, see Enabling automated backups.
- An Amazon S3 bucket must exist in the same account and Region as the source DB instance. Before enabling access to transaction log backups, choose an existing Amazon S3 bucket or create a new bucket to use for your transaction log backup files.
- An Amazon S3 bucket permissions policy must be configured as follows to allow Amazon RDS to copy transaction log files into it:

  1. Set the object account ownership property on the bucket to **Bucket Owner Preferred**.

2. Add the following policy. There will be no policy by default, so use the bucket Access Control Lists (ACL) to edit the bucket policy and add it.

The following example uses an ARN to specify a resource. We recommend using the `SourceArn` and `SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. For more information on working with ARNs, see Amazon resource names (ARNs) and Amazon Resource Names (ARNs) in Amazon RDS.

Example of an Amazon S3 permissions policy for access to transaction log backups

JSON

```
   {
   "Version":"2012-10-17",
   "Statement": [
       {
           "Sid": "Only allow writes to my bucket with bucket owner full
 control",
           "Effect": "Allow",
           "Principal": {
               "Service": "backups.rds.amazonaws.com"
           },
           "Action": "s3:PutObject",
           "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/{customer_path}/*",
           "Condition": {
               "StringEquals": {
                   "s3:x-amz-acl": "bucket-owner-full-control",
                   "aws:sourceAccount": "{customer_account}",
                   "aws:sourceArn": "{db_instance_arn}"
               }
           }
       }
   ]
}
```

- An AWS Identity and Access Management (IAM) role to access the Amazon S3 bucket. If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the `SQLSERVER_BACKUP_RESTORE` option by using the AWS Management Console. Alternatively, you can create a new one manually. For more information on creating and

configuring an IAM role with SQLSERVER_BACKUP_RESTORE, see Manually creating an IAM role for native backup and restore.

- The SQLSERVER_BACKUP_RESTORE option must be added to an option group on your DB instance. For more information on adding the SQLSERVER_BACKUP_RESTORE option, see Support for native backup and restore in SQL Server.

> **Note**
>
> If your DB instance has storage encryption enabled, the AWS KMS (KMS) actions and key must be provided in the IAM role provided in the native backup and restore option group.

Optionally, if you intend to use the `rds_restore_log` stored procedure to perform point in time database restores, we recommend using the same Amazon S3 path for the native backup and restore option group and access to transaction log backups. This method ensures that when Amazon RDS assumes the role from the option group to perform the restore log functions, it has access to retrieve transaction log backups from the same Amazon S3 path.

- If the DB instance is encrypted, regardless of encryption type (AWS managed key or customer managed key), you must provide a customer managed KMS key in the IAM role and in the `rds_tlog_backup_copy_to_S3` stored procedure.

Limitations and recommendations

Access to transaction log backups has the following limitations and recommendations:

- You can list and copy up to the last seven days of transaction log backups for any DB instance that has backup retention configured between one to 35 days.
- The Amazon S3 bucket used for access to transaction log backups must exist in the same account and Region as the source DB instance. Cross-account and cross-region copy is not supported.
- Only one Amazon S3 bucket can be configured as a target to copy transaction log backups into. You can choose a new target Amazon S3 bucket with the `rds_tlog_copy_setup` stored procedure. For more information on choosing a new target Amazon S3 bucket, see Setting up access to transaction log backups.
- You cannot specify the KMS key when using the `rds_tlog_backup_copy_to_S3` stored procedure if your RDS instance is not enabled for storage encryption.

- Multi-account copying is not supported. The IAM role used for copying will only permit write access to Amazon S3 buckets within the owner account of the DB instance.
- Only two concurrent tasks of any type may be run on an RDS for SQL Server DB instance.
- Only one copy task can run for a single database at a given time. If you want to copy transaction log backups for multiple databases on the DB instance, use a separate copy task for each database.
- If you copy a transaction log backup that already exists with the same name in the Amazon S3 bucket, the existing transaction log backup will be overwritten.
- You can only run the stored procedures that are provided with access to transaction log backups on the primary DB instance. You can't run these stored procedures on an RDS for SQL Server read replica or on a secondary instance of a Multi-AZ DB cluster.
- If the RDS for SQL Server DB instance is rebooted while the `rds_tlog_backup_copy_to_S3` stored procedure is running, the task will automatically restart from the beginning when the DB instance is back online. Any transaction log backups that had been copied to the Amazon S3 bucket while the task was running before the reboot will be overwritten.
- The Microsoft SQL Server system databases and the `RDSAdmin` database cannot be configured for access to transaction log backups.
- Copying to buckets encrypted by SSE-KMS isn't supported.

Setting up access to transaction log backups

To set up access to transaction log backups, complete the list of requirements in the Requirements section, and then run the `rds_tlog_copy_setup` stored procedure. The procedure will enable the access to transaction log backups feature at the DB instance level. You don't need to run it for each individual database on the DB instance.

> **Important**
>
> The database user must be granted the `db_owner` role within SQL Server on each database to configure and use the access to transaction log backups feature.

Example usage:

```
exec msdb.dbo.rds_tlog_copy_setup
```

```
@target_s3_arn='arn:aws:s3:::amzn-s3-demo-bucket/myfolder';
```

The following parameter is required:

- `@target_s3_arn` – The ARN of the target Amazon S3 bucket to copy transaction log backups files to.

Example of setting an Amazon S3 target bucket:

```
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::amzn-s3-demo-logging-bucket/mytestdb1';
```

To validate the configuration, call the `rds_show_configuration` stored procedure.

Example of validating the configuration:

```
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

To modify access to transaction log backups to point to a different Amazon S3 bucket, you can view the current Amazon S3 bucket value and re-run the `rds_tlog_copy_setup` stored procedure using a new value for the `@target_s3_arn`.

Example of viewing the existing Amazon S3 bucket configured for access to transaction log backups

```
exec rdsadmin.dbo.rds_show_configuration @name='target_s3_arn_for_tlog_copy';
```

Example of updating to a new target Amazon S3 bucket

```
exec msdb.dbo.rds_tlog_copy_setup @target_s3_arn='arn:aws:s3:::amzn-s3-demo-logging-bucket1/mynewfolder';
```

Listing available transaction log backups

With RDS for SQL Server, databases configured to use the full recovery model and a DB instance backup retention set to one or more days have transaction log backups automatically enabled. By enabling access to transaction log backups, up to seven days of those transaction log backups are made available for you to copy into your Amazon S3 bucket.

After you have enabled access to transaction log backups, you can start using it to list and copy available transaction log backup files.

Listing transaction log backups

To list all transaction log backups available for an individual database, call the `rds_fn_list_tlog_backup_metadata` function. You can use an `ORDER BY` or a `WHERE` clause when calling the function.

Example of listing and filtering available transaction log backup files

```
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename');
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE
 rds_backup_seq_id = 3507;
SELECT * from msdb.dbo.rds_fn_list_tlog_backup_metadata('mydatabasename') WHERE
 backup_file_time_utc > '2022-09-15 20:44:01' ORDER BY backup_file_time_utc DESC;
```

The `rds_fn_list_tlog_backup_metadata` function returns the following output:

Column name	Data type	Description
db_name	sysname	The database name provided to list the transacti on log backups for.
db_id	int	The internal database identifier for the input parameter db_name.
family_guid	uniqueidentifier	The unique ID of the original database at creation. This value remains the same when the database is restored, even to a different database name.
rds_backu p_seq_id	int	The ID that RDS uses internally to maintain a sequence number for each transaction log backup file.
backup_fi le_epoch	bigint	The epoch time that a transaction backup file was generated.
backup_fi le_time_utc	datetime	The UTC time-converted value for the backup_fi le_epoch value.
starting_lsn	numeric(25,0)	The log sequence number of the first or oldest log record of a transaction log backup file.
ending_lsn	numeric(25,0)	The log sequence number of the last or next log record of a transaction log backup file.
is_log_ch ain_broken	bit	A boolean value indicating if the log chain is broken between the current transaction log backup file and the previous transaction log backup file.
file_size _bytes	bigint	The size of the transactional backup set in bytes.
Error	varchar(4000)	Error message if the rds_fn_list_tlog_b ackup_metadata function throws an exception. NULL if no exceptions.

Copying transaction log backups

To copy a set of available transaction log backups for an individual database to your Amazon S3 bucket, call the `rds_tlog_backup_copy_to_S3` stored procedure. The `rds_tlog_backup_copy_to_S3` stored procedure will initiate a new task to copy transaction log backups.

> **Note**
>
> The `rds_tlog_backup_copy_to_S3` stored procedure will copy the transaction log backups without validating against `is_log_chain_broken` attribute. For this reason, you should manually confirm an unbroken log chain before running the `rds_tlog_backup_copy_to_S3` stored procedure. For further explanation, see Validating the transaction log backup log chain.

Example usage of the `rds_tlog_backup_copy_to_S3` stored procedure

```
exec msdb.dbo.rds_tlog_backup_copy_to_S3
 @db_name='mydatabasename',
 [@kms_key_arn='arn:aws:kms:region:account-id:key/key-id'],
 [@backup_file_start_time='2022-09-01 01:00:15'],
 [@backup_file_end_time='2022-09-01 21:30:45'],
 [@starting_lsn=149000000112100001],
 [@ending_lsn=149000000120400001],
 [@rds_backup_starting_seq_id=5],
 [@rds_backup_ending_seq_id=10];
```

The following input parameters are available:

Parameter	Description
@db_name	The name of the database to copy transaction log backups for
@kms_key_arn	A customer managed KMS key. If you encrypt your DB instance with an AWS managed KMS key, you must create a customer managed key. If you encrypt your DB instance with a customer managed key, you can use the same KMS key ARN.

Parameter	Description
@backup_file_start_time	The UTC timestamp as provided from the [backup_file_time_utc] column of the rds_fn_list_tlog_backup_metadata function.
@backup_file_end_time	The UTC timestamp as provided from the [backup_file_time_utc] column of the rds_fn_list_tlog_backup_metadata function.
@starting_lsn	The log sequence number (LSN) as provided from the [starting_lsn] column of the rds_fn_list_tlog_backup_metadata function
@ending_lsn	The log sequence number (LSN) as provided from the [ending_lsn] column of the rds_fn_list_tlog_backup_metadata function.
@rds_backup_starting_seq_id	The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.
@rds_backup_ending_seq_id	The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.

You can specify a set of either the time, LSN, or sequence ID parameters. Only one set of parameters are required.

You can also specify just a single parameter in any of the sets. For example, by providing a value for only the backup_file_end_time parameter, all available transaction log backup files prior to that time within the seven-day limit will be copied to your Amazon S3 bucket.

Following are the valid input parameter combinations for the rds_tlog_backup_copy_to_S3 stored procedure.

Parameters provided	Expected result
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_file_start_time='2022-08-23 00:00:00', @backup_file_end_time='2022-08-30 00:00:00';`	Copies transaction log backups from the last seven days and exist between the provided range of `backup_file_start_time` and `backup_file_end_time` . In this example, the stored procedure will copy transaction log backups that were generated between '2022-08-23 00:00:00' and '2022-08-30 00:00:00'.
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_file_start_time='2022-08-23 00:00:00';`	Copies transaction log backups from the last seven days and starting from the provided `backup_file_start_time` . In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to the

Parameters provided	Expected result	
	latest transaction log backup.	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name = 'testdb1', @backup_file_end_time='2022-08-30 00:00:00';`	Copies transaction log backups from the last seven days up to the provided `backup_file_end_time` . In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00 up to '2022-08-30 00:00:00'.	

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn =14900000 00040007, @ending_lsn = 149000000 0050009;`	Copies transaction log backups that are available from the last seven days and are between the provided range of the `starting_lsn` and `ending_lsn` . In this example, the stored procedure will copy transacti on log backups from the last seven days with an LSN range between 149000000 0040007 and 149000000 0050009.	

Parameters provided	Expected result
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @starting_lsn =14900000 00040007;`	Copies transacti on log backups that are available from the last seven days, beginning from the provided `starting_lsn` . In this example, the stored procedure will copy transaction log backups from LSN 149000000 0040007 up to the latest transaction log backup.
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @ending_lsn =14900000 00050009;`	Copies transaction log backups that are available from the last seven days, up to the provided `ending_lsn` . In this example, the stored procedure will copy transacti on log backups beginning from the last seven days up to lsn 149000000 0050009.

Parameters provided	Expected result
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id= 2000, @rds_backup_ending_seq_id= 5000;`	Copies transaction log backups that are available from the last seven days, and exist between the provided range of `rds_backup_starting_seq_id` and `rds_backup_ending_seq_id` . In this example, the stored procedure will copy transaction log backups beginning from the last seven days and within the provided rds backup sequence id range, starting from seq_id 2000 up to seq_id 5000.

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id= 2000;`	Copies transaction log backups that are available from the last seven days, beginning from the provided `rds_backup_starting_seq_id` . In this example, the stored procedure will copy transaction log backups beginning from seq_id 2000, up to the latest transaction log backup.	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_ending_seq_id= 5000;`	Copies transaction log backups that are available from the last seven days, up to the provided `rds_backup_ending_seq_id` . In this example, the stored procedure will copy transaction log backups beginning from the last seven days, up to seq_id 5000.	

Parameters provided	Expected result	
`exec msdb.dbo.rds_tlog_backup_copy_to_S3 @db_name='testdb1', @rds_backup_starting_seq_id= 2000; @rds_backup_ending_seq_id= 2000;`	Copies a single transaction log backup with the provided `rds_backup_starting_seq_id` , if available within the last seven days. In this example, the stored procedure will copy a single transaction log backup that has a seq_id of 2000, if it exists within the last seven days.	

Validating the transaction log backup log chain

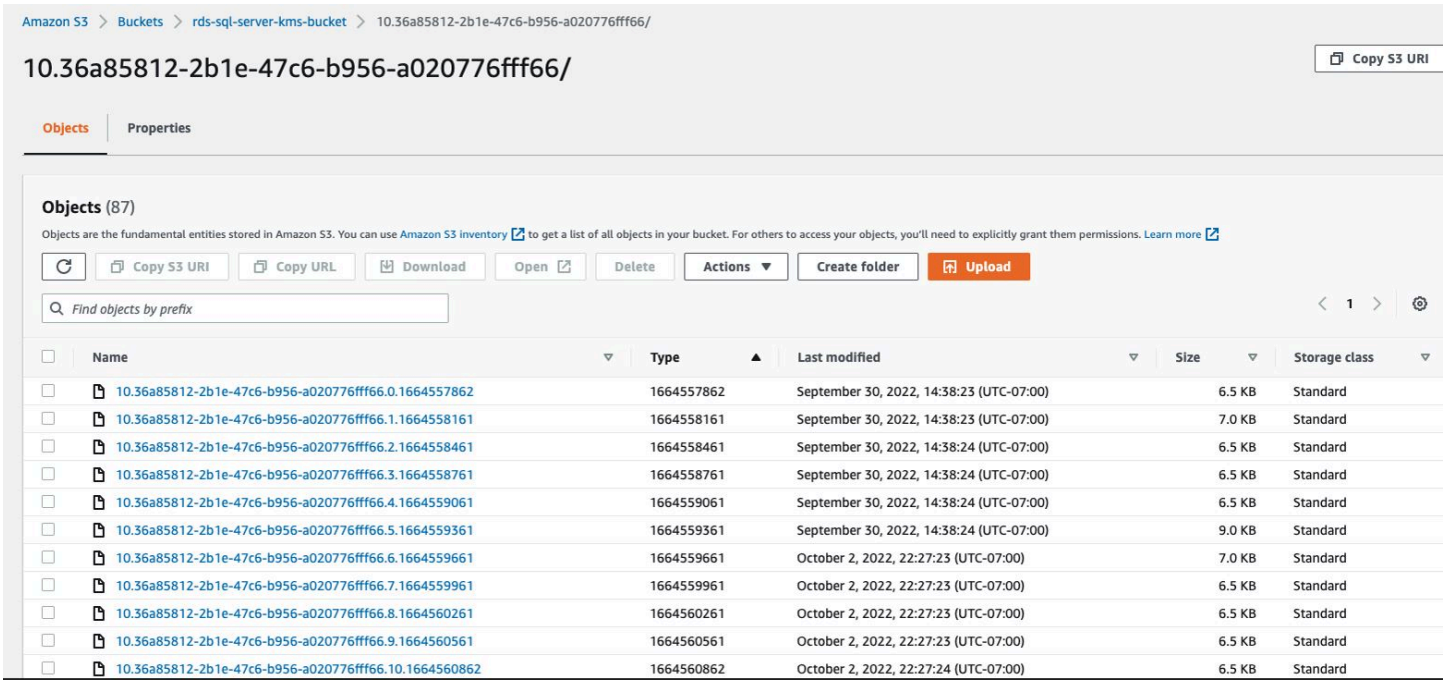
Databases configured for access to transaction log backups must have automated backup retention enabled. Automated backup retention sets the databases on the DB instance to the FULL recovery model. To support point in time restore for a database, avoid changing the database recovery model, which can result in a broken log chain. We recommend keeping the database set to the FULL recovery model.

To manually validate the log chain before copying transaction log backups, call the `rds_fn_list_tlog_backup_metadata` function and review the values in the `is_log_chain_broken` column. A value of "1" indicates the log chain was broken between the current log backup and the previous log backup.

The following example shows a broken log chain in the output from the `rds_fn_list_tlog_backup_metadata` stored procedure.

rds_sequence_id	first_lsn	last_lsn	is_log_chain_broken
43	90023	90457	0
44	90457	90985	0
45	90987	92034	1

In a normal log chain, the log sequence number (LSN) value for first_lsn for given rds_sequence_id should match the value of last_lsn in the preceding rds_sequence_id. In the image, the rds_sequence_id of 45 has a first_lsn value 90987, which does not match the last_lsn value of 90985 for preceeding rds_sequence_id 44.



For more information about SQL Server transaction log architecture and log sequence numbers, see Transaction Log Logical Architecture in the Microsoft SQL Server documentation.

Amazon S3 bucket folder and file structure

Transaction log backups have the following standard structure and naming convention within an Amazon S3 bucket:

- A new folder is created under the `target_s3_arn` path for each database with the naming structure as `{db_id}.{family_guid}`.
- Within the folder, transaction log backups have a filename structure as `{db_id}.{family_guid}.{rds_backup_seq_id}.{backup_file_epoch}`.
- You can view the details of `family_guid,db_id,rds_backup_seq_id` and `backup_file_epoch` with the `rds_fn_list_tlog_backup_metadata`function.

The following example shows the folder and file structure of a set of transaction log backups within an Amazon S3 bucket.

Tracking the status of tasks

To track the status of your copy tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks.

Example usage:

```
exec msdb.dbo.rds_task_status
  @db_name='database_name',
  @task_id=ID_number;
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
- `@task_id` – The ID of the task to show the task status for.

Example of listing the status for a specific task ID:

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task:

```
exec msdb.dbo.rds_task_status@db_name='my_database',@task_id=5;
```

Example of listing all tasks and their status for a specific database:

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their status on the current DB instance:

```
exec msdb.dbo.rds_task_status;
```

Canceling a task

To cancel a running task, call the `rds_cancel_task` stored procedure.

Example usage:

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can view the task ID by calling the `rds_task_status` stored procedure.

For more information on viewing and canceling running tasks, see Importing and exporting SQL Server databases using native backup and restore.

Troubleshooting access to transaction log backups

The following are issues you might encounter when you use the stored procedures for access to transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	Backups are disabled on this DB instance. Enable DB instance backups with a retention of at least "1" and try again.	Automated backups are not enabled for the DB instance.	DB instance backup retention must be enabled with a retention of at least one day. For more information on enabling automated backups and configuring backup retention, see Backup retention period.
rds_tlog_copy_setup	Error running the rds_tlog_copy_setup stored procedure. Reconnect to the RDS endpoint and try again.	An internal error occurred.	Reconnect to the RDS endpoint and run the `rds_tlog_copy_setup` stored procedure again.
rds_tlog_copy_setup	Running the rds_tlog_backup_copy_setup stored procedure inside a transacti	The stored procedure was attempted within a transaction using `BEGIN` and `END`.	Avoid using `BEGIN` and `END` when running the `rds_tlog_copy_setup` stored procedure.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
	on is not supported . Verify that the session has no open transacti ons and try again.		
rds_tlog_ copy_setup	The S3 bucket name for the input parameter `@target_s 3_arn` should contain at least one character other than a space.	An incorrect value was provided for the input parameter `@target_s3_arn` .	Ensure the input parameter `@target_s3_arn` specifies the complete Amazon S3 bucket ARN.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	The SQLSERVER_BACKUP_RESTORE option isn't enabled or is in the process of being enabled. Enable the option or try again later.	The SQLSERVER_BACKUP_RESTORE option is not enabled on the DB instance or was just enabled and pending internal activation.	Enable the SQLSERVER_BACKUP_RESTORE option as specified in the Requirements section. Wait a few minutes and run the rds_tlog_copy_setup stored procedure again.
rds_tlog_copy_setup	The target S3 arn for the input parameter @target_s3_arn can't be empty or null.	An NULL value was provided for the input parameter @target_s3_arn , or the value wasn't provided.	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.
rds_tlog_copy_setup	The target S3 arn for the input parameter @target_s3_arn must begin with arn:aws.	The input parameter @target_s3_arn was provide without arn:aws on the front.	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	The target S3 ARN is already set to the provided value.	The `rds_tlog_copy_setup` stored procedure previously ran and was configured with an Amazon S3 bucket ARN.	To modify the Amazon S3 bucket value for access to transaction log backups, provide a different `target S3 ARN`.
rds_tlog_copy_setup	Unable to generate credentials for enabling Access to Transaction Log Backups. Confirm the S3 path ARN provided with `rds_tlog_copy_setup`, and try again later.	There was an unspecified error while generating credentials to enable access to transaction log backups.	Review your setup configuration and try again.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	You cannot run the rds_tlog_copy_setup stored procedure while there are pending tasks. Wait for the pending tasks to complete and try again.	Only two tasks may run at any time. There are pending tasks awaiting completion.	View pending tasks and wait for them to complete. For more information on monitoring task status, see Tracking the status of tasks.
rds_tlog_backup_copy_to_S3	A T-log backup file copy task has already been issued for database: %s with task Id: %d, please try again later.	Only one copy task may run at any time for a given database. There is a pending copy task awaiting completion.	View pending tasks and wait for them to complete. For more information on monitoring task status, see Tracking the status of tasks.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	At least one of these three parameter sets must be provided. SET-1:(@backup_file_start_time, @backup_file_end_time) | SET-2:(@starting_lsn, @ending_lsn) | SET-3:(@rds_backup_starting_seq_id, @rds_backup_ending_seq_id)	None of the three parameter sets were provided, or a provided parameter set is missing a required parameter.	You can specify either the time, lsn, or sequence ID parameters. One set from these three sets of parameters are required. For more information on required parameters, see Copying transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Backups are disabled on your instance. Please enable backups and try again in some time.	Automated backups are not enabled for the DB instance.	For more information on enabling automated backups and configuring backup retention, see Backup retention period.
rds_tlog_backup_copy_to_S3	Cannot find the given database %s.	The value provided for input parameter `@db_name` does not match a database name on the DB instance.	Use the correct database name. To list all databases by name, run `SELECT * from sys.databases`
rds_tlog_backup_copy_to_S3	Cannot run the rds_tlog_backup_copy_to_S3 stored procedure for SQL Server system databases or the rdsadmin database.	The value provided for input parameter `@db_name` matches a SQL Server system database name or the RDSAdmin database.	The following databases are not allowed to be used with access to transaction log backups: `master, model, msdb, tempdb, RDSAdmin.`

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Database name for the input parameter @db_name can't be empty or null.	The value provided for input parameter `@db_name` was empty or `NULL`.	Use the correct database name. To list all databases by name, run `SELECT * from sys.databases`
rds_tlog_backup_copy_to_S3	DB instance backup retention period must be set to at least 1 to run the rds_tlog_backup_copy_setup stored procedure.	Automated backups are not enabled for the DB instance.	For more information on enabling automated backups and configuring backup retention, see Backup retention period.
rds_tlog_backup_copy_to_S3	Error running the stored procedure rds_tlog_backup_copy_to_S3. Reconnect to the RDS endpoint and try again.	An internal error occurred.	Reconnect to the RDS endpoint and run the `rds_tlog_backup_copy_to_S3` stored procedure again.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Only one of these three parameter sets can be provided. SET-1:(@backup_file_start_time, @backup_file_end_time) | SET-2:(@starting_lsn, @ending_lsn) | SET-3:(@rds_backup_starting_seq_id, @rds_backup_ending_seq_id)	Multiple parameter sets were provided.	You can specify either the time, lsn, or sequence ID parameters. One set from these three sets of parameters are required. For more information on required parameters, see Copying transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Running the rds_tlog_backup_copy_to_S3 stored procedure inside a transaction is not supported. Verify that the session has no open transactions and try again.	The stored procedure was attempted within a transaction using `BEGIN` and `END`.	Avoid using `BEGIN` and `END` when running the `rds_tlog_backup_copy_to_S3` stored procedure.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The provided parameters fall outside of the transaction backup log retention period. To list of available transaction log backup files, run the rds_fn_list_tlog_backup_metadata function.	There are no available transactional log backups for the provided input parameters that fit in the copy retention window.	Try again with a valid set of parameters. For more information on required parameters, see Copying transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	There was a permissions error in processing the request. Ensure the bucket is in the same Account and Region as the DB Instance, and confirm the S3 bucket policy permissions against the template in the public documentation.	There was an issue detected with the provided S3 bucket or its policy permissions.	Confirm your setup for access to transaction log backups is correct. For more information on setup requirements for your S3 bucket, see Requirements.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Running the `rds_tlog_backup_copy_to_S3` stored procedure on an RDS read replica instance isn't permitted.	The stored procedure was attempted on a RDS read replica instance.	Connect to the RDS primary DB instance to run the `rds_tlog_backup_copy_to_S3` stored procedure.
rds_tlog_backup_copy_to_S3	The LSN for the input parameter `@starting_lsn` must be less than `@ending_lsn .`	The value provided for input parameter `@starting_lsn` was greater than the value provided for input parameter `@ending_lsn .`	Ensure the value provided for input parameter `@starting_lsn` is less than the value provided for input parameter `@ending_lsn .`

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The `rds_tlog_backup_copy_to_S3` stored procedure can only be performed by the members of `db_owner` role in the source database.	The `db_owner` role has not been granted for the account attempting to run the `rds_tlog_backup_copy_to_S3` stored procedure on the provided `db_name`.	Ensure the account running the stored procedure is permissioned with the `db_owner` role for the provided `db_name`.
rds_tlog_backup_copy_to_S3	The sequence ID for the input parameter `@rds_backup_starting_seq_id` must be less than or equal to `@rds_backup_ending_seq_id` .	The value provided for input parameter `@rds_backup_starting_seq_id` was greater than the value provided for input parameter `@rds_backup_ending_seq_id` .	Ensure the value provided for input parameter `@rds_backup_starting_seq_id` is less than the value provided for input parameter `@rds_backup_ending_seq_id` .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The SQLSERVER_BACKUP_RESTORE option isn't enabled or is in the process of being enabled. Enable the option or try again later.	The SQLSERVER_BACKUP_RESTORE option is not enabled on the DB instance or was just enabled and pending internal activation.	Enable the SQLSERVER_BACKUP_RESTORE option as specified in the Requirements section. Wait a few minutes and run the rds_tlog_backup_copy_to_S3 stored procedure again.
rds_tlog_backup_copy_to_S3	The start time for the input parameter @backup_file_start_time must be less than @backup_file_end_time .	The value provided for input parameter @backup_file_start_time was greater than the value provided for input parameter @backup_file_end_time .	Ensure the value provided for input parameter @backup_file_start_time is less than the value provided for input parameter @backup_file_end_time .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	We were unable to process the request due to a lack of access. Please check your setup and permissions for the feature.	There may be an issue with the Amazon S3 bucket permissions, or the Amazon S3 bucket provided is in another account or Region.	Ensure the Amazon S3 bucket policy permissions are permissioned to allow RDS access. Ensure the Amazon S3 bucket is in the same account and Region as the DB instance.
rds_tlog_backup_copy_to_S3	You cannot provide a KMS Key ARN as input parameter to the stored procedure for instances that are not storage-encrypted.	When storage encryption is not enabled on the DB instance, the input parameter `@kms_key_arn` should not be provided.	Do not provide an input parameter for `@kms_key_arn` .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	You must provide a KMS Key ARN as input parameter to the stored procedure for storage encrypted instances.	When storage encryption is enabled on the DB instance, the input parameter `@kms_key_arn` must be provided.	Provide an input parameter for `@kms_key_arn` with a value that matches the ARN of the Amazon S3 bucket to use for transaction log backups.
rds_tlog_backup_copy_to_S3	You must run the `rds_tlog_copy_setup` stored procedure and set the `@target_s3_arn` , before running the `rds_tlog_backup_copy_to_S3` stored procedure.	The access to transaction log backups setup procedure was not completed before attempting to run the `rds_tlog_backup_copy_to_S3` stored procedure.	Run the `rds_tlog_copy_setup` stored procedure before running the `rds_tlog_backup_copy_to_S3` stored procedure . For more information on running the setup procedure for access to transaction log backups, see Setting up access to transaction log backups.

Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups.

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see Additional features for Microsoft SQL Server on Amazon RDS.

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

Option	Option ID	Engine editions
Linked Servers with Oracle OLEDB	`OLEDB_ORACLE`	SQL Server Enterprise Edition SQL Server Standard Edition
Native backup and restore	`SQLSERVER_BACKUP_RESTORE`	SQL Server Enterprise Edition SQL Server Standard Edition SQL Server Web Edition SQL Server Express Edition
Transparent Data Encryption	`TRANSPARENT_DATA_ENCRYPTION` (RDS console)	SQL Server 2016–2022 Enterprise Edition SQL Server 2022 Standard Edition

Option	Option ID	Engine editions
	TDE (AWS CLI and RDS API)	
SQL Server Audit	SQLSERVER_AUDIT	In RDS, starting with SQL Server 2016, all editions of SQL Server support server-level audits, and Enterprise Edition also supports database-level audits. Starting with SQL Server SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.
SQL Server Analysis Services	SSAS	SQL Server Enterprise Edition SQL Server Standard Edition

Option	Option ID	Engine editions
SQL Server Integration Services	SSIS	SQL Server Enterprise Edition SQL Server Standard Edition
SQL Server Reporting Services	SSRS	SQL Server Enterprise Edition SQL Server Standard Edition
Microsoft Distributed Transaction Coordinator	MSDTC	In RDS, starting with SQL Server 2016, all editions of SQL Server support distributed transactions.
SQL Server resource governor	RESOURCE_GOVERNOR	SQL Server Enterprise Edition SQL Server 2022 Developer Edition

Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version
 15.00
```

The output resembles the following:

```
{
    "OptionGroupOptions": [
        {
            "Name": "MSDTC",
            "Description": "Microsoft Distributed Transaction Coordinator",
            "EngineName": "sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "MinimumRequiredMinorEngineVersion": "4043.16.v1",
            "PortRequired": true,
            "DefaultPort": 5000,
            "OptionsDependedOn": [],
            "OptionsConflictsWith": [],
            "Persistent": false,
            "Permanent": false,
            "RequiresAutoMinorEngineVersionUpgrade": false,
            "VpcOnly": false,
            "OptionGroupOptionSettings": [
                {
                    "SettingName": "ENABLE_SNA_LU",
                    "SettingDescription": "Enable support for SNA LU protocol",
                    "DefaultValue": "true",
                    "ApplyType": "DYNAMIC",
                    "AllowedValues": "true,false",
                    "IsModifiable": true,
                    "IsRequired": false,
                    "MinimumEngineVersionPerAllowedValue": []
                },
        ...

        {
            "Name": "TDE",
            "Description": "SQL Server - Transparent Data Encryption",
            "EngineName": "sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "MinimumRequiredMinorEngineVersion": "4043.16.v1",
            "PortRequired": false,
            "OptionsDependedOn": [],
            "OptionsConflictsWith": [],
            "Persistent": true,
            "Permanent": false,
            "RequiresAutoMinorEngineVersionUpgrade": false,
            "VpcOnly": false,
            "OptionGroupOptionSettings": []
```

```
        }
    ]
}
```

Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server

Linked servers with the Oracle Provider for OLEDB on RDS for SQL Server lets you access external data sources on an Oracle database. You can read data from remote Oracle data sources and run commands against remote Oracle database servers outside of your RDS for SQL Server DB instance. Using linked servers with Oracle OLEDB, you can:

- Directly access data sources other than SQL Server
- Query against diverse Oracle data sources with the same query without moving the data
- Issue distributed queries, updates, commands, and transactions on data sources across an enterprise ecosystem
- Integrate connections to an Oracle database from within the Microsoft Business Intelligence suite (SSIS, SSRS, SSAS)
- Migrate from an Oracle database to RDS for SQL Server

You can activate one or more linked servers for Oracle on either an existing or new RDS for SQL Server DB instance. Then you can integrate external Oracle data sources with your DB instance.

Contents

- Supported versions and Regions
- Limitations and recommendations
- Activating linked servers with Oracle
  - Creating the option group for OLEDB_ORACLE
  - Adding the OLEDB_ORACLE option to the option group
  - Modifying the OLEDB_ORACLE version option to another version
  - Associating the option group with your DB instance
- Modifying OLEDB provider properties
- Modifying OLEDB driver properties
- Deactivating linked servers with Oracle

Supported versions and Regions

RDS for SQL Server supports linked servers with Oracle OLEDB in all Regions for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, all versions
- SQL Server 2017, all versions

Linked servers with Oracle OLEDB is supported for the following Oracle Database versions:

- Oracle Database 21c, all versions
- Oracle Database 19c, all versions
- Oracle Database 18c, all versions

Linked servers with Oracle OLEDB is supported for the following OLEDB Oracle driver versions:

- 21.7
- 21.16

Limitations and recommendations

Keep in mind the following limitations and recommendations that apply to linked servers with Oracle OLEDB:

- Allow network traffic by adding the applicable TCP port in the security group for each RDS for SQL Server DB instance. For example, if you're configuring a linked server between an EC2 Oracle DB instance and an RDS for SQL Server DB instance, then you must allow traffic from the IP address of the EC2 Oracle DB instance. You also must allow traffic on the port that SQL Server is using to listen for database communication. For more information on security groups, see Controlling access with security groups.
- Perform a reboot of the RDS for SQL Server DB instance after turning on, turning off, or modifying the `OLEDB_ORACLE` option in your option group. The option group status displays `pending_reboot` for these events and is required. For RDS for SQL Server Multi-AZ instances with AlwaysOn or Mirroring option enabled, a failover is expected when instance is rebooted after the new instance creation or restore.

- Only simple authentication is supported with a user name and password for the Oracle data source.
- Open Database Connectivity (ODBC) drivers are not supported. Only the OLEDB driver versions listed above are supported.
- Distributed transactions (XA) are supported. To activate distributed transactions, turn on the `MSDTC` option in the Option Group for your DB instance and make sure XA transactions are turned on. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server.
- Creating data source names (DSNs) to use as a shortcut for a connection string is not supported.
- OLEDB driver tracing is not supported. You can use SQL Server Extended Events to trace OLEDB events. For more information, see Set up Extended Events in RDS for SQL Server.
- Access to the catalogs folder for an Oracle linked server is not supported using SQL Server Management Studio (SSMS).

Activating linked servers with Oracle

Activate linked servers with Oracle by adding the `OLEDB_ORACLE` option to your RDS for SQL Server DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the `OLEDB_ORACLE` option to the option group.
3. Choose a version of the OLEDB driver to use.
4. Associate the option group with the DB instance.
5. Reboot the DB instance.

Creating the option group for OLEDB_ORACLE

To work with linked servers with Oracle, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2019.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`oracle-oledb-se-2019`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`OLEDB_ORACLE option group for SQL Server SE 2019`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **15.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2019.

To create the option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --engine-name sqlserver-se \
    --major-engine-version 15.00 \
    --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

  For Windows:

```
aws rds create-option-group ^
```

```
    --option-group-name oracle-oledb-se-2019 ^
    --engine-name sqlserver-se ^
    --major-engine-version 15.00 ^
    --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

Adding the OLEDB_ORACLE option to the option group

Next, use the AWS Management Console or the AWS CLI to add the OLEDB_ORACLE option to your option group.

Console

To add the OLEDB_ORACLE option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, which is **oracle-oledb-se-2019** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **OLEDB_ORACLE** for **Option name**.
6. Under **Version**, choose the version of the OLEDB Oracle driver you want to install.
7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

CLI

To add the OLEDB_ORACLE option

- Add the OLEDB_ORACLE option to the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --options OptionName=OLEDB_ORACLE, OptionVersion=21.16 \
```

```
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name oracle-oledb-se-2019 ^
    --options OptionName=OLEDB_ORACLE, OptionVersion=21.16 ^
    --apply-immediately
```

Modifying the OLEDB_ORACLE version option to another version

To modify the OLEDB_ORACLE option version to another version, use the AWS Management Console or the AWS CLI.

Console

To Modify the OLEDB_ORACLE option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the OLEDB_ORACLE option (**oracle-oledb-se-2019** in the previous example).
4. Choose **Modify option**.
5. Under **Option details**, choose **OLEDB_ORACLE** for **Option name**.
6. Under **Version**, choose the version of the OLEDB Oracle driver you want to use.
7. Under **Scheduling**, choose whether to modify the option immediately or at the next maintenance window.
8. Choose **Modify option**.

CLI

To modify the OLEDB_ORACLE option version, use the `rds add-option-to-option-group` AWS CLI command with the option group and option version that you want to use.

To modify the OLEDB_ORACLE option

- **Example**

  For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --options OptionName=OLEDB_ORACLE, OptionVersion=21.7 \
    --apply-immediately
```

  For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name oracle-oledb-se-2019 ^
    --options OptionName=OLEDB_ORACLE, OptionVersion=21.7 ^
    --apply-immediately
```

Associating the option group with your DB instance

To associate the `OLEDB_ORACLE` option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

Console

To finish activating linked servers for Oracle, associate your `OLEDB_ORACLE` option group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the `OLEDB_ORACLE` option group and parameter group with a new or existing DB instance.

To create an instance with the `OLEDB_ORACLE` option group and parameter group

- Specify the same DB engine type and major version that you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mytestsqlserveroracleoledbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 15.0.4236.7.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name oracle-oledb-se-2019 \
    --db-parameter-group-name my-parameter-group-name
```

  For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mytestsqlserveroracleoledbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 15.0.4236.7.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name oracle-oledb-se-2019 ^
    --db-parameter-group-name my-parameter-group-name
```

To modify an instance and associate the `OLEDB_ORACLE` option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mytestsqlserveroracleoledbinstance \
    --option-group-name oracle-oledb-se-2019 \
    --db-parameter-group-name my-parameter-group-name \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mytestsqlserveroracleoledbinstance ^
    --option-group-name oracle-oledb-se-2019 ^
    --db-parameter-group-name my-parameter-group-name ^
    --apply-immediately
```

Modifying OLEDB provider properties

You can view and change the properties of the OLEDB provider. Only the `master` user can perform this task. All linked servers for Oracle that are created on the DB instance use the same properties of that OLEDB provider. Call the `sp_MSset_oledb_prop` stored procedure to change the properties of the OLEDB provider.

To change the OLEDB provider properties

```
USE [master]
GO
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'AllowInProcess', 1
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'DynamicParameters', 0
GO
```

The following properties can be modified:

Property name	Recommended Value (1 = On, 0 = Off)	Description
`Dynamic parameter`	1	Allows SQL placeholders (represented by '?') in parameterized queries.
`Nested queries`	1	Allows nested `SELECT` statements in the `FROM` clause, such as sub-queries.
`Level zero only`	0	Only base-level OLEDB interfaces are called against the provider.
`Allow inprocess`	1	If turned on, Microsoft SQL Server allows the provider to be instantiated as an in-process server. Set this property to 1 to use Oracle linked servers.
`Non transacted updates`	0	If non-zero, SQL Server allows updates.
`Index as access path`	False	If non-zero, SQL Server attempts to use indexes of the provider to fetch data.
`Disallow adhoc access`	False	If set, SQL Server does not allow running pass-through queries against the OLEDB provider. While this option can be checked, it is sometimes appropriate to run pass-through queries.
`Supports LIKE operator`	1	Indicates that the provider supports queries using the LIKE keyword.

Modifying OLEDB driver properties

You can view and change the properties of the OLEDB driver when creating a linked server for Oracle. Only the `master` user can perform this task. Driver properties define how the OLEDB driver handles data when working with a remote Oracle data source. Driver properties are specific to each

Oracle linked server created on the DB instance. Call the `master.dbo.sp_addlinkedserver` stored procedure to change the properties of the OLEDB driver.

Example: To create a linked server and change the OLEDB driver `FetchSize` property

```
EXEC master.dbo.sp_addlinkedserver
@server = N'Oracle_link2',
@srvproduct=N'Oracle',
@provider=N'OraOLEDB.Oracle',
@datasrc=N'my-oracle-test.cnetsipka.us-west-2.rds.amazonaws.com:1521/ORCL',
@provstr='FetchSize=200'
GO
```

```
EXEC master.dbo.sp_addlinkedsrvlogin
@rmtsrvname=N'Oracle_link2',
@useself=N'False',
@locallogin=NULL,
@rmtuser=N'master',
@rmtpassword='Test#1234'
GO
```

Note

Specify a password other than the prompt shown here as a security best practice.

Deactivating linked servers with Oracle

To deactivate linked servers with Oracle, remove the `OLEDB_ORACLE` option from its option group.

Important

Removing the option doesn't delete the existing linked server configurations on the DB instance. You must manually drop them to remove them from the DB instance.
You can reactivate the `OLEDB_ORACLE` option after removal to reuse the linked server configurations that were previously configured on the DB instance.

Console

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the OLEDB_ORACLE option (`oracle-oledb-se-2019` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **OLEDB_ORACLE** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it during the next maintenance window.
7. Choose **Delete**.

CLI

The following procedure removes the OLEDB_ORACLE option.

To remove the OLEDB_ORACLE option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name oracle-oledb-se-2019 \
    --options OLEDB_ORACLE \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name oracle-oledb-se-2019 ^
    --options OLEDB_ORACLE ^
```

```
    --apply-immediately
```

Linked Servers with Teradata ODBC in RDS for SQL Server

Support for linked servers with the Teradata ODBC driver on RDS for SQL Server lets you access external data sources on a Teradata database. You can read data and run commands from remote Teradata database servers outside of your RDS for SQL Server instance. Use linked-servers with Teradata ODBC to enable the following capabilities:

- Directly access data sources other than SQL Server.
- Query against diverse Teradata data sources with the same query without moving the data.
- Issue distributed queries, updates, commands, and transactions on data sources across an enterprise ecosystem.
- Integrate connections to a Teradata database from within the Microsoft Business Intelligence Suite (SSIS, SSRS, SSAS).
- Migrate from a Teradata database to RDS for SQL Server.

You can choose to activate one or more linked servers for Teradata on either an existing or new RDS for SQL Server DB instance. You can then integrate external Teradata data sources with your DB instance.

Topics

- Supported versions and Regions
- Limitations and recommendations
- Considerations for Multi-AZ deployment
- Activating linked servers with Teradata
- Creating linked servers with Teradata
- Deactivating servers linked to Teradata

Supported versions and Regions

RDS for SQL Server supports linked servers with Teradata ODBC in all AWS Regions for SQL Server Standard and Enterprise Edition for the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, all versions
- SQL Server 2017, all versions

The following Teradata database versions support linking with RDS for SQL Server

- Teradata 17.20, all versions

Limitations and recommendations

The following limitations apply to linked servers with Teradata ODBC:

- RDS for SQL Server support only simple authentication with a username and password for the Teradata source.
- RDS for SQL Server supports only Teradata ODBC driver version 17.20.0.33.
- RDS for SQL Server does not support creating data source names (DSNs) to use as shortcuts for a connection string.
- RDS for SQL Server does not support ODBC driver tracing. Use SQL Server Extended Events to trace ODBC events. For more information, see Set up Extended Events in RDS for SQL Server.
- RDS for SQL Server does not support access to the catalogs folder for a Teradata linked server when using SQL Server Management Studio (SSMS).

Consider the following recommendations when using linked servers with Teradata ODBC:

- Allow network traffic by adding the applicable TCP port in the security group for each RDS for SQL Server DB instance. If you're configuring a linked server between an EC2 Teradata DB instance and an RDS for SQL Server DB instance, then you must allow traffic from the IP address of the EC2 Teradata DB instance. You also must allow traffic on the port that the RDS for SQL Server DB instance is using to listen for database communication. For more information on security groups, see Controlling access with security groups.
- Distributed transactions (XA) are supported. To activate distributed transactions, turn on the `MSDTC` option in the option group for your DB instance and make sure XA transactions are turned on. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server.
- Linked Teradata ODBC support SSL/TLS as long as configured on the Teradata Server. For more information, see Enable TLS Connectivity on Teradata Vantage.

Considerations for Multi-AZ deployment

RDS for SQL Server currently doesn't replicate linked servers to the mirrored database server (or Always-On availability group secondary server) in a Multi-AZ deployment. If the linked servers are added before the configuration is changed to add mirroring or Always-On, then the linked servers are copied for the existing linked servers.

Alternatively, you can create the linked servers on the primary instance, fail over to the high availability server instance and then create the linked servers again so that they are on both RDS for SQL Server instances.

Activating linked servers with Teradata

Activate linked servers with Teradata by adding the `ODBC_TERADATA` option to your RDS for SQL Server DB instance. Use the following process:

Topics

- Creating the option group for ODBC_TERADATA
- Adding the ODBC_TERADATA option to the option group
- Associating the ODBC_TERADATA option with your DB instance

Creating the option group for `ODBC_TERADATA`

To work with linked servers with Teradata, create an option group or modify an option group that corresponds to the SQL Server eddition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

Console

Use the following procedure to create an option group for SQL Server Standard Edition 2019.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:

a. For **Name**, enter a name for the option group that is unique within your AWS account, such as `teradata-odbc-se-2019`. The name can contain only letters, digits, and hyphens.

b. For **Description**, enter a brief description of the option group.

c. For **Engine**, choose **sqlserver-se**.

d. For **Major engine version**, choose **15.00**.

5. Choose **Create**.

AWS CLI

The following procedure creates an option group for SQL Server Standard Edition 2019.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name teradata-odbc-se-2019 \
    --engine-name sqlserver-se \
    --major-engine-version 15.00 \
    --option-group-description "ODBC_TERADATA option group for SQL Server SE 2019"
```

Example

For Windows:

```
aws rds create-option-group ^
    --option-group-name teradata-odbc-se-2019 ^
    --engine-name sqlserver-se ^
    --major-engine-version 15.00 ^
    --option-group-description "ODBC_TERADATA option group for SQL Server SE 2019"
```

Adding the `ODBC_TERADATA` option to the option group

Next, use the AWS Management Console or the AWS CLI to add the `ODBC_Teradata` option to your option group.

Console

Use the following procedure creates an option group for SQL Server Standard Edition 2019.

To add the ODBC_TERADATA option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose your new option group.
4. Choose **Add option**.
5. Under **Option details**:
   a. Choose **ODBC_TERADATA** for **Option name**.
   b. For `17.20.33.00` for **Option version**.
6. Under scheduling, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

AWS CLI

The following procedure adds the ODBC_TERADATA option to your option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name teradata-odbc-se-2019 \
    --options "OptionName=ODBC_TERADATA,OptionVersion=17.20.33.00" \
    --apply-immediately
```

Example

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name teradata-odbc-se-2019 ^
    --options "OptionName=ODBC_TERADATA,OptionVersion=17.20.33.00" ^
    --apply-immediately
```

Associating the ODBC_TERADATA option with your DB instance

To associate the ODBC_TERADATA option group with your DB instance, use the AWS Management Console or AWS CLI.

Console

To finish activating linked servers for Teradata, associate your option group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

Specify the same DB engine type and major version that you used when creating the option group.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mytestsqlserverteradataodbcinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 15.00 \
    --license-model license-included \
    --allocated-storage 100 \
    --master-username admin \
    --master-user-password password \
    --storage-type gp2 \
    --option-group-name teradata-odbc-se-2019
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mytestsqlserverteradataodbcinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 15.00 ^
```

```
    --license-model license-included ^
    --allocated-storage 100 ^
    --master-username admin ^
    --master-user-password password ^
    --storage-type gp2 ^
    --option-group-name teradata-odbc-se-2019
```

To modify an instance and associate the new option group:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mytestsqlserverteradataodbcinstance \
    --option-group-name teradata-odbc-se-2019 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mytestsqlserverteradataodbcinstance ^
    --option-group-name teradata-odbc-se-2019 ^
    --apply-immediately
```

Creating linked servers with Teradata

To create a linked server with Teradata, run the following commands:

```
EXECUTE master.dbo.sp_addlinkedserver
    @server = N'LinkedServer_NAME',
    @srvproduct=N'',
    @provider=N'MSDASQL',
    @provstr=N'"PROVIDER=MSDASQL;DRIVER={Teradata Database ODBC Driver 17.20};
                DBCName=Server;UID=user_name;PWD=user_password;
                UseDataEncryption=YES/NO;SSLMODE=PREFER/ALLOW/DISABLE>;"',
    @catalog='database'
```

```
EXECUTE master.dbo.sp_addlinkedsrvlogin
    @rmtsrvname = N'LinkedServer_NAME',
    @locallogin = NULL ,
    @useself = N'False',
    @rmtuser = N'user_name',
```

```
    @rmtpassword = N'user_password'
```

An example of the the commands above are shown here:

```
EXECUTE master.dbo.sp_addlinkedserver
    @server = N'LinkedServerToTeradata',
    @srvproduct=N'',
    @provider=N'MSDASQL',
    @provstr=N'"PROVIDER=MSDASQL;DRIVER={Teradata Database ODBC Driver 17.20};
                DBCName=my-teradata-test.cnetsipka.us-west-2.rds.amazonaws.com;
                UID=master;
                PWD=Test#1234;
                UseDataEncryption=YES;
                SSLMODE=PREFER;"',
    @catalog='MyTestTeradataDB'

EXECUTE master.dbo.sp_addlinkedsrvlogin
    @rmtsrvname = N'LinkedServerToTeradata',
    @locallogin = NULL ,
    @useself = N'False',
    @rmtuser = N'master',
    @rmtpassword = N'Test#1234'
```

Note

Specify a password other than the prompt shown here as a security best practice.

Deactivating servers linked to Teradata

To deactivate linked servers to Teradata, remove the `ODBC_TERADATA` option from its option group.

Important

Deleting the option doesn't delete the linked server configurations on the DB instance. You must manually drop them to remove them from the DB instance.
You can reactivate the `ODBC_TERADATA` after removal to reuse the linked server configurations that were previously configured on the DB instance.

Console

To remove the ODBC_TERADATA option from the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the ODBC_TERADATA option.
4. Choose **Delete**.
5. Under **Deletion options**, choose ODBC_TERADATA under **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it during the next maintenance window.
7. Choose **Delete**.

AWS CLI

The following commands removes the ODBC_TERADATA option.

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name teradata-odbc-se-2019 \
    --options ODBC_TERADATA \
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name teradata-odbc-se-2019 ^
    --options ODBC_TERADATA ^
    --apply-immediately
```

Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see Importing and exporting SQL Server databases using native backup and restore.

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

   That is, the option must have as its option setting a valid Amazon Resource Name (ARN) in the format `arn:aws:iam::`*`account-id`*`:role/`*`role-name`*. For more information, see Amazon Resource Names (ARNs) in the *AWS General Reference.*

   The IAM role must also have a trust relationship and a permissions policy attached. The trust relationship allows RDS to assume the role, and the permissions policy defines the actions that the role can perform. For more information, see Manually creating an IAM role for native backup and restore.
4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.

Console

To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see Creating an option group.

   To use an existing option group, skip to the next step.
4. Add the **SQLSERVER_BACKUP_RESTORE** option to the option group. For more information about adding options, see Adding an option to an option group.
5. Do one of the following:

   - To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for **IAM Role**. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.
   - To create a new role and configure Amazon S3 settings, do the following:

     1. For **IAM role**, choose **Create a new role**.
     2. For **S3 bucket**, choose an S3 bucket from the list.
     3. For **S3 prefix (optional)**, specify a prefix to use for the files stored in your Amazon S3 bucket.

        This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

        If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.
     4. Choose the **Enable encryption** check box to encrypt the backup file. Leave the check box cleared (the default) to have the backup file unencrypted.

If you chose **Enable encryption**, choose an encryption key for **AWS KMS key**. For more information about encryption keys, see Getting started in the *AWS Key Management Service Developer Guide.*

6. Choose **Add option**.
7. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

CLI

This procedure makes the following assumptions:

- You're adding the SQLSERVER_BACKUP_RESTORE option to an option group that already exists. For more information about adding options, see Adding an option to an option group.
- You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.
- You're applying the option group to a DB instance that already exists. For more information, see Modifying an Amazon RDS DB instance.

To add the native backup and restore option

1. Add the SQLSERVER_BACKUP_RESTORE option to the option group.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
 --apply-immediately \
 --option-group-name mybackupgroup \
 --options "OptionName=SQLSERVER_BACKUP_RESTORE, \
   OptionSettings=[{Name=IAM_ROLE_ARN,Value=arn:aws:iam::account-id:role/role-
name}]"
```

For Windows:

```
aws rds add-option-to-option-group ^
 --option-group-name mybackupgroup ^
 --options "[{\"OptionName\": \"SQLSERVER_BACKUP_RESTORE\", ^
 \"OptionSettings\": [{\"Name\": \"IAM_ROLE_ARN\", ^
 \"Value\": \"arn:aws:iam::account-id:role/role-name"}]}]" ^
 --apply-immediately
```

> **Note**
>
> When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

2. Apply the option group to the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
 --db-instance-identifier mydbinstance \
 --option-group-name mybackupgroup \
 --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
 --db-instance-identifier mydbinstance ^
 --option-group-name mybackupgroup ^
 --apply-immediately
```

Modifying native backup and restore option settings

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see Modifying an option setting.

Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don't need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2022 Standard and Enterprise Editions
- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition

> **Note**
>
> RDS for SQL Server does not support TDE for read-only databases.

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the `model` or `master` databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but make sure that you understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see Transparent Data Encryption (TDE) in the Microsoft documentation.

Topics

- Turning on TDE for RDS for SQL Server
- Encrypting data on RDS for SQL Server

- Backing up and restoring TDE certificates on RDS for SQL Server
- Backing up and restoring TDE certificates for on-premises databases
- Turning off TDE for RDS for SQL Server

Turning on TDE for RDS for SQL Server

To turn on Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that's associated with that DB instance:

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.
2. If the DB instance isn't associated with an option group that has TDE turned on, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

   > **Note**
   >
   > In the RDS console, the option is named `TRANSPARENT_DATA_ENCRYPTION`. In the AWS CLI and RDS API, it's named `TDE`.

   For information about creating or modifying an option group, see Working with option groups. For information about adding an option to an option group, see Adding an option to an option group.
3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance.

Option group considerations

The TDE option is a persistent option. You can't remove it from an option group unless all DB instances and backups are no longer associated with the option group. After you add the TDE option to an option group, the option group can be associated only with DB instances that use TDE. For more information about persistent options in an option group, see Option groups overview.

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict in the following situations:

- The current option group has the TDE option, and you replace it with an option group that doesn't have the TDE option.
- You restore from a DB snapshot to a new DB instance that doesn't have an option group that contains the TDE option. For more information about this scenario, see Considerations for option groups.

SQL Server performance considerations

Using Transparent Data Encryption can affect the performance of a SQL Server DB instance.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

Encrypting data on RDS for SQL Server

When the TDE option is added to an option group, Amazon RDS generates a certificate that's used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance.

The following example uses the RDS-created certificate called `RDSTDECertificateName` to encrypt a database called `myDatabase`.

```
---------- Turning on TDE -------------

-- Find an RDS TDE certificate to use
USE [master]
GO
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'
GO

USE [myDatabase]
GO
-- Create a database encryption key (DEK) using one of the certificates from the
 previous step
CREATE DATABASE ENCRYPTION KEY WITH ALGORITHM = AES_256
ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]
GO

-- Turn on encryption for the database
ALTER DATABASE [myDatabase] SET ENCRYPTION ON
```

```
GO

-- Verify that the database is encrypted
USE [master]
GO
SELECT name FROM sys.databases WHERE is_encrypted = 1
GO
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO
```

The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether the instance uses Provisioned IOPS storage, the amount of data, and other factors.

Backing up and restoring TDE certificates on RDS for SQL Server

RDS for SQL Server provides stored procedures for backing up, restoring, and dropping TDE certificates. RDS for SQL Server also provides a function for viewing restored user TDE certificates.

User TDE certificates are used to restore databases to RDS for SQL Server that are on-premises and have TDE turned on. These certificates have the prefix `UserTDECertificate_`. After restoring databases, and before making them available to use, RDS modifies the databases that have TDE turned on to use RDS-generated TDE certificates. These certificates have the prefix `RDSTDECertificate`.

User TDE certificates remain on the RDS for SQL Server DB instance, unless you drop them using the `rds_drop_tde_certificate` stored procedure. For more information, see Dropping restored TDE certificates.

You can use a user TDE certificate to restore other databases from the source DB instance. The databases to restore must use the same TDE certificate and have TDE turned on. You don't have to import (restore) the same certificate again.

Topics

- Prerequisites
- Limitations
- Backing up a TDE certificate
- Restoring a TDE certificate
- Viewing restored TDE certificates

- Dropping restored TDE certificates

Prerequisites

Before you can back up or restore TDE certificates on RDS for SQL Server, make sure to perform the following tasks. The first three are described in Setting up for native backup and restore.

1. Create Amazon S3 general purpose buckets or directory buckets for storing files to back up and restore.

   We recommend that you use separate buckets for database backups and for TDE certificate backups.
2. Create an IAM role for backing up and restoring files.

   The IAM role must be both a user and an administrator for the AWS KMS key.

   When using directory buckets, no additional permissions are required other than the permissions required for Manually creating an IAM role for native backup and restore with directory buckets.

   When using S3 resources, the IAM role also requires the following permissions in addition to the permissions required for Manually creating an IAM role for native backup and restore:

   - `s3:GetBucketAcl`, `s3:GetBucketLocation`, and `s3:ListBucket` on the S3 bucket resource
3. Add the `SQLSERVER_BACKUP_RESTORE` option to an option group on your DB instance.

   This is in addition to the `TRANSPARENT_DATA_ENCRYPTION` (`TDE`) option.
4. Make sure that you have a symmetric encryption KMS key. You have the following options:
   - If you have an existing KMS key in your account, you can use it. No further action is necessary.
   - If you don't have an existing symmetric encryption KMS key in your account, create a KMS key by following the instructions in Creating keys in the *AWS Key Management Service Developer Guide*.
5. Enable Amazon S3 integration to transfer files between the DB instance and Amazon S3.

   For more information on enabling Amazon S3 integration, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

   Note that directory buckets are not supported for S3 integration. This step is only required for Backing up and restoring TDE certificates for on-premises databases.

Limitations

Using stored procedures to back up and restore TDE certificates has the following limitations:

- Both the SQLSERVER_BACKUP_RESTORE and TRANSPARENT_DATA_ENCRYPTION (TDE) options must be added to the option group that you associated with your DB instance.
- TDE certificate backup and restore aren't supported on Multi-AZ DB instances.
- Canceling TDE certificate backup and restore tasks isn't supported.
- You can't use a user TDE certificate for TDE encryption of any other database on your RDS for SQL Server DB instance. You can use it to restore only other databases from the source DB instance that have TDE turned on and that use the same TDE certificate.
- You can drop only user TDE certificates.
- The maximum number of user TDE certificates supported on RDS is 10. If the number exceeds 10, drop unused TDE certificates and try again.
- The certificate name can't be empty or null.
- When restoring a certificate, the certificate name can't include the keyword RDSTDECERTIFICATE, and must start with the UserTDECertificate_ prefix.
- The @certificate_name parameter can include only the following characters: a-z, 0-9, @, $, #, and underscore (_).
- The file extension for @certificate_file_s3_arn must be .cer (case-insensitive).
- The file extension for @private_key_file_s3_arn must be .pvk (case-insensitive).
- The S3 metadata for the private key file must include the x-amz-meta-rds-tde-pwd tag. For more information, see Backing up and restoring TDE certificates for on-premises databases.
- RDS for SQL Server does not support using cross-account keys for TDE.

Backing up a TDE certificate

To back up TDE certificates, use the rds_backup_tde_certificate stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name |
 RDSTDECertificatetimestamp',
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id',
```

```
    [@overwrite_s3_files=0|1];
```

The following parameters are required:

- `@certificate_name` – The name of the TDE certificate to back up.
- `@certificate_file_s3_arn` – The destination Amazon Resource Name (ARN) for the certificate backup file in Amazon S3.
- `@private_key_file_s3_arn` – The destination S3 ARN of the private key file that secures the TDE certificate.
- `@kms_password_key_arn` – The ARN of the symmetric KMS key used to encrypt the private key password.

The following parameter is optional:

- `@overwrite_s3_files` – Indicates whether to overwrite the existing certificate and private key files in S3:
  - `0` – Doesn't overwrite the existing files. This value is the default.

    Setting `@overwrite_s3_files` to 0 returns an error if a file already exists.
  - 1 – Overwrites an existing file that has the specified name, even if it isn't a backup file.

Example of backing up a TDE certificate

```
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='RDSTDECertificate20211115T185333',
    @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
    @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
    @kms_password_key_arn='arn:aws:kms:us-
west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE',
    @overwrite_s3_files=1;
```

Restoring a TDE certificate

You use the `rds_restore_tde_certificate` stored procedure to restore (import) user TDE certificates. It has the following syntax.

```
EXECUTE msdb.dbo.rds_restore_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name',
```

```
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id';
```

The following parameters are required:

- `@certificate_name` – The name of the TDE certificate to restore. The name must start with the `UserTDECertificate_` prefix.
- `@certificate_file_s3_arn` – The S3 ARN of the backup file used to restore the TDE certificate.
- `@private_key_file_s3_arn` – The S3 ARN of the private key backup file of the TDE certificate to be restored.
- `@kms_password_key_arn` – The ARN of the symmetric KMS key used to encrypt the private key password.

Example of restoring a TDE certificate

```
EXECUTE msdb.dbo.rds_restore_tde_certificate
    @certificate_name='UserTDECertificate_myTDEcertificate',
    @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
    @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
    @kms_password_key_arn='arn:aws:kms:us-
west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Viewing restored TDE certificates

You use the `rds_fn_list_user_tde_certificates` function to view restored (imported) user TDE certificates. It has the following syntax.

```
SELECT * FROM msdb.dbo.rds_fn_list_user_tde_certificates();
```

The output resembles the following. Not all columns are shown here.

```
name   certif princi pvt_ke issuer cert_s thumbp subjec start_ expiry pvt_key_l
       te_id  _id    ncrypt me     al_num t      t       e      te     ast_backu
                     _type_                                            p_date
                     c
```

UserTDrtific_tde_c	343	1	ENCRYP_BY_MAR_KEY	AnyCony Shippi	793e57a369fd1d9e472c32671d9cca af	0x6BB2341103 80B FE1BA2C69509 5B5	AnyCony Shippi	2022-05 19:49:000000	2023-05 19:49:000000	NULL

Dropping restored TDE certificates

To drop restored (imported) user TDE certificates that you aren't using, use the `rds_drop_tde_certificate` stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
 @certificate_name='UserTDECertificate_certificate_name';
```

The following parameter is required:

- `@certificate_name` – The name of the TDE certificate to drop.

You can drop only restored (imported) TDE certificates. You can't drop RDS-created certificates.

Example of dropping a TDE certificate

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
 @certificate_name='UserTDECertificate_myTDEcertificate';
```

Backing up and restoring TDE certificates for on-premises databases

You can back up TDE certificates for on-premises databases, then later restore them to RDS for SQL Server. You can also restore an RDS for SQL Server TDE certificate to an on-premises DB instance.

> **Note**
>
> RDS for SQL Server does not support using cross-account keys for TDE.

The following procedure backs up a TDE certificate and private key. The private key is encrypted using a data key generated from your symmetric encryption KMS key.

To back up an on-premises TDE certificate

1. Generate the data key using the AWS CLI generate-data-key command.

```
aws kms generate-data-key \
    --key-id my_KMS_key_ID \
    --key-spec AES_256
```

   The output resembles the following.

```
{
"CiphertextBlob": "AQIDAHimL2NEoAlOY6Bn7LJfnxi/OZe9kTQo/
XQXduug1rmerwGiL7g5ux4av9GfZLxYTDATAAAAfjB8BgkqhkiG9w0B
BwagbzBtAgEAMGgGCSqGSIb3DQEHATAeBglghkgBZQMEAS4wEQQMyCxLMi7GRZgKqD65AgEQgDtjvZLJo2cQ31Vetng
2RezQy3sAS6ZHrCjfnfn0c65bFdhsXxjSMnudIY7AKw==",
"Plaintext": "U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/aOn939ZnKi/0=",
"KeyId": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-00ee-99ff-88dd-
aa11bb22cc33"
}
```

   You use the plain text output in the next step as the private key password.

2. Back up your TDE certificate as shown in the following example.

```
BACKUP CERTIFICATE myOnPremTDEcertificate TO FILE = 'D:\tde-cert-backup.cer'
WITH PRIVATE KEY (
```

```
FILE = 'C:\Program Files\Microsoft SQL Server\MSSQL14.MSSQLSERVER\MSSQL\DATA\cert-backup-key.pvk',
ENCRYPTION BY PASSWORD = 'U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/aOn939ZnKi/0=');
```

3. Save the certificate backup file to your Amazon S3 certificate bucket.
4. Save the private key backup file to your S3 certificate bucket, with the following tag in the file's metadata:

   - Key – `x-amz-meta-rds-tde-pwd`
   - Value – The `CiphertextBlob` value from generating the data key, as in the following example.

   ```
   AQIDAHimL2NEoAlOY6Bn7LJfnxi/OZe9kTQo/
   XQXduug1rmerwGiL7g5ux4av9GfZLxYTDATAAAAfjB8BgkqhkiG9w0B
   BwagbzBtAgEAMGgGCSqGSIb3DQEHATAeBglghkgBZQMEAS4wEQQMyCxLMi7GRZgKqD65AgEQgDtjvZLJo2cQ31Vet
   2RezQy3sAS6ZHrCjfnfn0c65bFdhsXxjSMnudIY7AKw==
   ```

The following procedure restores an RDS for SQL Server TDE certificate to an on-premises DB instance. You copy and restore the TDE certificate on your destination DB instance using the certificate backup, corresponding private key file, and data key. The restored certificate is encrypted by the database master key of the new server.

To restore a TDE certificate

1. Copy the TDE certificate backup file and private key file from Amazon S3 to the destination instance. For more information on copying files from Amazon S3, see Transferring files between RDS for SQL Server and Amazon S3.
2. Use your KMS key to decrypt the output cipher text to retrieve the plain text of the data key. The cipher text is located in the S3 metadata of the private key backup file.

   ```
   aws kms decrypt \
       --key-id my_KMS_key_ID \
       --ciphertext-blob fileb://exampleCiphertextFile | base64 -d \
       --output text \
       --query Plaintext
   ```

   You use the plain text output in the next step as the private key password.
3. Use the following SQL command to restore your TDE certificate.

```
CREATE CERTIFICATE myOnPremTDEcertificate FROM FILE='D:\tde-cert-backup.cer'
WITH PRIVATE KEY (FILE = N'D:\tde-cert-key.pvk',
DECRYPTION BY PASSWORD = 'plain_text_output');
```

For more information on KMS decryption, see decrypt in the KMS section of the *AWS CLI Command Reference*.

After the TDE certificate is restored on the destination DB instance, you can restore encrypted databases with that certificate.

> **Note**
>
> You can use the same TDE certificate to encrypt multiple SQL Server databases on the source DB instance. To migrate multiple databases to a destination instance, copy the TDE certificate associated with them to the destination instance only once.

Turning off TDE for RDS for SQL Server

To turn off TDE for an RDS for SQL Server DB instance, first make sure that there are no encrypted objects left on the DB instance. To do so, either decrypt the objects or drop them. If any encrypted objects exist on the DB instance, you can't turn off TDE for the DB instance. If a user TDE certificate for encryption was restored (imported), then it should be dropped. When you use the console to remove the TDE option from an option group, the console indicates that it's processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called `customerDatabase`.

```
------------ Removing TDE ---------------

USE [customerDatabase]
GO

-- Turn off encryption of the database
ALTER DATABASE [customerDatabase]
SET ENCRYPTION OFF
GO
```

```
-- Wait until the encryption state of the database becomes 1. The state is 5
 (Decryption in progress) for a while
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

-- Drop the DEK used for encryption
DROP DATABASE ENCRYPTION KEY
GO

-- Drop a user TDE certificate if it was restored (imported)
EXECUTE msdb.dbo.rds_drop_tde_certificate
 @certificate_name='UserTDECertificate_certificate_name';

-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated
USE [master]
GO
ALTER DATABASE [customerDatabase] SET RECOVERY SIMPLE
GO
```

When all objects are decrypted, you have two options:

1. You can modify the DB instance to be associated with an option group without the TDE option.
2. You can remove the TDE option from the option group.

SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see SQL Server Audit (database engine) in the Microsoft SQL Server documentation.

SQL Server Audit with Database Activity Streams

You can use Database Activity Streams for RDS to integrate SQL Server Audit events with database activity monitoring tools from Imperva, McAfee, and IBM. For more information about auditing with Database Activity Streams for RDS SQL Server, see Auditing in Microsoft SQL Server

Topics

- Support for SQL Server Audit
- Adding SQL Server Audit to the DB instance options
- Using SQL Server Audit
- Viewing audit logs
- Using SQL Server Audit with Multi-AZ instances
- Configuring an S3 bucket
- Manually creating an IAM role for SQL Server Audit

Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2016, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

Option setting	Valid values	Description
IAM_ROLE_ARN	A valid Amazon Resource Name (ARN) in the format arn:aws:iam:: *account-id* :role/*role-name* .	The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more informati on, see Amazon Resource Names (ARNs) in the *AWS General Reference.*
S3_BUCKET_ARN	A valid ARN in the format arn:aws:s3::: *amzn-s3-demo-bucket* or arn:aws:s3::: *amzn-s3-demo-bucket* /key-pref ix	The ARN for the S3 bucket where you want to store your audit logs.
ENABLE_COMPRESSION	true or false	Controls audit log compressi on. By default, compression is enabled (set to true).
RETENTION_TIME	0 to 840	The retention time (in hours) that SQL Server audit records are kept on your RDS instance. By default, retention is disabled.

Adding SQL Server Audit to the DB instance options

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

To add and configure SQL Server Audit on a DB instance's option group

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group and use that option group. For more information, see Creating an option group.
2. Add the **SQLSERVER_AUDIT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group.
   - For **IAM role**, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose **Create a New Role**. For information about the required policies, see Manually creating an IAM role for SQL Server Audit.
   - For **Select S3 destination**, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose **Create a New S3 Bucket**.
   - For **Enable Compression**, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear **Enable Compression**.
   - For **Audit log retention**, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.
3. Apply the option group to a new or existing DB instance. Choose one of the following:
   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Modifying the SQL Server Audit option

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see Modifying an option setting.

Removing SQL Server Audit from the DB instance options

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

To remove auditing

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see Security catalog views in the Microsoft SQL Server documentation.
2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
   - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see Removing an option from an option group.
   - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.
3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see CREATE SERVER AUDIT in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use `RDS_` as a prefix in the server audit name.
- For `FILEPATH`, specify `D:\rdsdbdata\SQLAudit`.
- For `MAXSIZE`, specify a size between 2 MB and 50 MB.
- Don't configure `MAX_ROLLOVER_FILES` or `MAX_FILES`.

- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see CREATE SERVER AUDIT SPECIFICATION and CREATE DATABASE AUDIT SPECIFICATION in the Microsoft SQL Server documentation.

To avoid errors, don't use RDS_ as a prefix in the name of the database audit specification or server audit specification.

Viewing audit logs

Your audit logs are stored in `D:\rdsdbdata\SQLAudit`.

After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: `D:\rdsdbdata\SQLAudit\transmitted`.

For information about configuring retention, see Adding SQL Server Audit to the DB instance options.

Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```
SELECT   *
 FROM     msdb.dbo.rds_fn_get_audit_file
             ('D:\rdsdbdata\SQLAudit\*.sqlaudit'
             , default
             , default )
```

You can use the same command to view audit records in your retention folder by changing the filter to `D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit`.

```
SELECT   *
 FROM     msdb.dbo.rds_fn_get_audit_file
             ('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit'
             , default
             , default )
```

Using SQL Server Audit with Multi-AZ instances

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

Configuring an S3 bucket

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region and AWS account as the DB instance.
- It must not be open to the public.
- The bucket owner must also be the IAM role owner.
- Your IAM role must have permissions for the customer-managed KMS key associated with the S3 bucket server-side encryption.

The target key that is used to store the data follows this naming schema: *`amzn-s3-demo-bucket`*`/key-prefix/instance-name/audit-name/node_file-name.ext`

> **Note**
>
> You set both the bucket name and the key prefix values with the (`S3_BUCKET_ARN`) option setting.

The schema is composed of the following elements:

- ***amzn-s3-demo-bucket*** – The name of your S3 bucket.
- **key-prefix** – The custom key prefix you want to use for audit logs.
- **instance-name** – The name of your Amazon RDS instance.
- **audit-name** – The name of the audit.
- **node** – The identifier of the node that is the source of the audit logs (node1 or node2). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
  - **node1** – The first replication node (Single-AZ has one node only).
  - **node2** – The second replication node (Multi-AZ has two nodes).
- **file-name** – The target file name. The file name is taken as-is from SQL Server.
- **ext** – The extension of the file (`zip` or `sqlaudit`):
  - **zip** – If compression is enabled (default).
  - **sqlaudit** – If compression is disabled.

Manually creating an IAM role for SQL Server Audit

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see Creating a role to delegate permissions to an AWS service in the *AWS Identity and Access Management User Guide*.

You can use the examples in this section to create the trust relationships and permissions policies you need.

The following example shows a trust relationship for SQL Server Audit. It uses the *service principal* `rds.amazonaws.com` to allow RDS to write to the S3 bucket. A *service principal* is an identifier that is used to grant permissions to a service. Anytime you allow access to `rds.amazonaws.com` in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see AWS JSON policy elements: Principal.

Example trust relationship for SQL Server Audit

JSON

```
{
     "Version":"2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Principal": {
                 "Service": "rds.amazonaws.com"
             },
             "Action": "sts:AssumeRole"
         }
     ]
 }
```

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For SQL Server Audit, make sure to include both the DB option group and the DB instances, as shown in the following example.

Example trust relationship with global condition context key for SQL Server Audit

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [

 "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier",
                        "arn:aws:rds:Region:my_account_ID:og:option_group_name"
                    ]
                }
            }
        }
    ]
}
```

In the following example of a permissions policy for SQL Server Audit, we specify an ARN for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see Amazon resource names (ARNs).

Example permissions policy for SQL Server Audit

JSON

```
{
     "Version":"2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
```

```
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketACL",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
        }
    ]
}
```

Note

The `s3:ListAllMyBuckets` action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.

S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.

Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment.

You can turn on SSAS for existing or new DB instances. It's installed on the same DB instance as your database engine. For more information on SSAS, see the Microsoft Analysis services documentation.

Amazon RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

- Tabular mode:
  - SQL Server 2019, version 15.00.4043.16.v1 and higher
  - SQL Server 2017, version 14.00.3223.3.v1 and higher
  - SQL Server 2016, version 13.00.5426.0.v1 and higher
- Multidimensional mode:
  - SQL Server 2019, version 15.00.4153.1.v1 and higher
  - SQL Server 2017, version 14.00.3381.3.v1 and higher
  - SQL Server 2016, version 13.00.5882.1.v1 and higher

Contents

- Limitations
- Turning on SSAS
  - Creating an option group for SSAS
  - Adding the SSAS option to the option group
  - Associating the option group with your DB instance
  - Allowing inbound access to your VPC security group
  - Enabling Amazon S3 integration
- Deploying SSAS projects on Amazon RDS

- Monitoring the status of a deployment task
- Using SSAS on Amazon RDS
  - Setting up a Windows-authenticated user for SSAS
  - Adding a domain user as a database administrator
  - Creating an SSAS proxy
  - Scheduling SSAS database processing using SQL Server Agent
  - Revoking SSAS access from the proxy
- Backing up an SSAS database
- Restoring an SSAS database
  - Restoring a DB instance to a specified time
- Changing the SSAS mode
- Turning off SSAS
- Troubleshooting SSAS issues

Limitations

The following limitations apply to using SSAS on RDS for SQL Server:

- RDS for SQL Server supports running SSAS in Tabular or Multidimensional mode. For more information, see Comparing tabular and multidimensional solutions in the Microsoft documentation.
- You can only use one SSAS mode at a time. Before changing modes, make sure to delete all of the SSAS databases.

  For more information, see Changing the SSAS mode.
- Multi-AZ instances aren't supported.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSAS authentication. For more information, see Working with Active Directory with RDS for SQL Server.
- Users aren't given SSAS server administrator access, but they can be granted database-level administrator access.
- The only supported port for accessing SSAS is 2383.
- You can't deploy projects directly. We provide an RDS stored procedure to do this. For more information, see Deploying SSAS projects on Amazon RDS.

- Processing during deployment isn't supported.
- Using .xmla files for deployment isn't supported.
- SSAS project input files and database backup output files can only be in the `D:\S3` folder on the DB instance.

Turning on SSAS

Use the following process to turn on SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSAS listener port.
5. Turn on Amazon S3 integration.

Creating an option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

> **Note**
>
> You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following console procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:

a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`ssas-se-2017`**. The name can contain only letters, digits, and hyphens.

b. For **Description**, enter a brief description of the option group, such as **`SSAS option group for SQL Server SE 2017`**. The description is used for display purposes.

c. For **Engine**, choose **sqlserver-se**.

d. For **Major engine version**, choose **14.00**.

5. Choose **Create**.

CLI

The following CLI example creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssas-se-2017 \
    --engine-name sqlserver-se \
    --major-engine-version 14.00 \
    --option-group-description "SSAS option group for SQL Server SE 2017"
```

  For Windows:

```
aws rds create-option-group ^
    --option-group-name ssas-se-2017 ^
    --engine-name sqlserver-se ^
    --major-engine-version 14.00 ^
    --option-group-description "SSAS option group for SQL Server SE 2017"
```

Adding the SSAS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

Console

To add the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSAS** for **Option name**.
6. Under **Option settings**, do the following:

   a. For **Max memory**, enter a value in the range 10–80.

      Max memory specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.

   b. For **Mode**, choose the SSAS server mode, **Tabular** or **Multidimensional**.

      If you don't see the **Mode** option setting, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations.

      Tabular is the default.

   c. For **Security groups**, choose the VPC security group to associate with the option.

   > **Note**
   >
   > The port for accessing SSAS, 2383, is prepopulated.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

CLI

To add the SSAS option

1. Create a JSON file, for example `ssas-option.json`, with the following parameters:

   - `OptionGroupName` – The name of option group that you created or chose previously (`ssas-se-2017` in the following example).
   - `Port` – The port that you use to access SSAS. The only supported port is 2383.
   - `VpcSecurityGroupMemberships` – Memberships for VPC security groups for your RDS DB instance.
   - `MAX_MEMORY` – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   - `MODE` – The SSAS server mode, either `Tabular` or `Multidimensional`. `Tabular` is the default.

     If you receive an error that the `MODE` option setting isn't valid, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations.

   The following is an example of a JSON file with SSAS option settings.

   ```
   {
   "OptionGroupName": "ssas-se-2017",
   "OptionsToInclude": [
    {
    "OptionName": "SSAS",
    "Port": 2383,
    "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
    "OptionSettings": [{"Name":"MAX_MEMORY","Value":"60"},
   {"Name":"MODE","Value":"Multidimensional"}]
    }],
   "ApplyImmediately": true
   }
   ```

2. Add the SSAS option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://ssas-option.json \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --cli-input-json file://ssas-option.json ^
    --apply-immediately
```

Associating the option group with your DB instance

You can use the console or the CLI to associate the option group with your DB instance.

Console

Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

CLI

You can associate your option group with a new or existing DB instance.

> **Note**
>
> If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

To create a DB instance that uses the option group

- Specify the same DB engine type and major version that you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myssasinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 14.00.3223.3.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name ssas-se-2017
```

  For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myssasinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 14.00.3223.3.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
```

```
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name ssas-se-2017
```

To modify a DB instance to associate the option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssasinstance \
    --option-group-name ssas-se-2017 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssasinstance ^
    --option-group-name ssas-se-2017 ^
    --apply-immediately
```

Allowing inbound access to your VPC security group

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.

Enabling Amazon S3 integration

To download model configuration files to your host for deployment, use Amazon S3 integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

> **Note**
>
> Using .xmla files for deployment isn't supported.

Before you deploy projects, make sure of the following:

- Amazon S3 integration is turned on. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.
- The `Processing Option` configuration setting is set to `Do Not Process`. This setting means that no processing happens after deployment.
- You have both the *`myssasproject`*`.asdatabase` and *`myssasproject`*`.deploymentoptions` files. They're automatically generated when you build the SSAS project.

To deploy an SSAS project on RDS

1. Download the `.asdatabase` (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see Downloading files from an Amazon S3 bucket to a SQL Server DB instance.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.asdatabase',
[@rds_file_path='D:\S3\myssasproject.asdatabase'],
[@overwrite_file=1];
```

2. Download the `.deploymentoptions` file from your S3 bucket to your DB instance.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
[@rds_file_path='D:\S3\myssasproject.deploymentoptions'],
[@overwrite_file=1];
```

3. Deploy the project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_DEPLOY_PROJECT',
@file_path='D:\S3\myssasproject.asdatabase';
```

Monitoring the status of a deployment task

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
`task_id`	The ID of the task.
`task_type`	For SSAS, tasks can have the following task types: • `SSAS_DEPLOY_PROJECT` • `SSAS_ADD_DB_ADMIN_MEMBER` • `SSAS_BACKUP_DB` • `SSAS_RESTORE_DB`
`database_name`	Not applicable to SSAS tasks.
`% complete`	The progress of the task as a percentage.

Output parameter	Description
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	The status of the task. Possible statuses are the following: • CREATED – After you call one of the SSAS stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS. • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED. • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.

Output parameter	Description
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error. For more information, see Troubleshooting SSAS issues.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSAS tasks.
overwrite_S3_backup_file	Not applicable to SSAS tasks.
KMS_master_key_arn	Not applicable to SSAS tasks.
filepath	Not applicable to SSAS tasks.
overwrite_file	Not applicable to SSAS tasks.
task_metadata	Metadata associated with the SSAS task.

Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand **Databases**. The newly deployed SSAS database appears.
3. Locate the connection string, and update the user name and password to give access to the source SQL database. Doing this is required for processing SSAS objects.

a. For Tabular mode, do the following:

   1. Expand the **Connections** tab.
   2. Open the context (right-click) menu for the connection object, and then choose **Properties**.
   3. Update the user name and password in the connection string.

b. For Multidimensional mode, do the following:

   1. Expand the **Data Sources** tab.
   2. Open the context (right-click) menu for the data source object, and then choose **Properties**.
   3. Update the user name and password in the connection string.

4. Open the context (right-click) menu for the SSAS database that you created and choose **Process Database**.

   Depending on the size of the input data, the processing operation might take several minutes to complete.

Topics

- Setting up a Windows-authenticated user for SSAS
- Adding a domain user as a database administrator
- Creating an SSAS proxy
- Scheduling SSAS database processing using SQL Server Agent
- Revoking SSAS access from the proxy

Setting up a Windows-authenticated user for SSAS

The main administrator user (sometimes called the master user) can use the following code example to set up a Windows-authenticated login and grant the required procedure permissions. Doing this grants permissions to the domain user to run SSAS customer tasks, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

You can grant some or all of the following permissions as needed to Windows-authenticated users.

Example

```
-- Create a server-level domain user login, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create domain user, if it doesn't already exist
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GO

-- Grant necessary privileges to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO

USE [msdb]
GO
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant
 option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] with grant option
```

```
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO
```

Adding a domain user as a database administrator

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with `admin` privileges, then add users to that role.
- You can use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_ADD_DB_ADMIN_MEMBER',
@database_name='myssasdb',
@ssas_role_name='exampleRole',
@ssas_role_member='domain_name\domain_user_name';
```

  The following parameters are required:

  - `@task_type` – The type of the MSBI task, in this case `SSAS_ADD_DB_ADMIN_MEMBER`.
  - `@database_name` – The name of the SSAS database to which you're granting administrator privileges.
  - `@ssas_role_name` – The SSAS database administrator role name. If the role doesn't already exist, it's created.
  - `@ssas_role_member` – The SSAS database user that you're adding to the administrator role.

Creating an SSAS proxy

To be able to schedule SSAS database processing using SQL Server Agent, create an SSAS credential and an SSAS proxy. Run these procedures as a Windows-authenticated user.

To create the SSAS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```
USE [master]
GO
CREATE CREDENTIAL [SSAS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
 N'mysecret'
```

```
GO
```

> **Note**
>
> IDENTITY must be a domain-authenticated login. Replace *mysecret* with the password for the domain-authenticated login.

To create the SSAS proxy

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
 @proxy_name=N'SSAS_Proxy',@credential_name=N'SSAS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
 @proxy_name=N'SSAS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSAS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
```

```
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling SSAS database processing using SQL Server Agent

After you create the credential and proxy and grant SSAS access to the proxy, you can create a SQL Server Agent job to schedule SSAS database processing.

To schedule SSAS database processing

- Use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL. You can further configure its job schedule through SSMS or T-SQL.
  - The `@command` parameter outlines the XML for Analysis (XMLA) command to be run by the SQL Server Agent job. This example configures SSAS Multidimensional database processing.
  - The `@server` parameter outlines the target SSAS server name of the SQL Server Agent job.

    To call the SSAS service within the same RDS DB instance where the SQL Server Agent job resides, use `localhost:2383`.

    To call the SSAS service from outside the RDS DB instance, use the RDS endpoint. You can also use the Kerberos Active Directory (AD) endpoint (*`your-DB-instance-name`*`.`*`your-AD-domain-name`*) if the RDS DB instances are joined by the same domain. For external DB instances, make sure to properly configure the VPC security group associated with the RDS DB instance for a secure connection.

  You can further edit the query to support various XMLA operations. Make edits either by directly modifying the T-SQL query or by using the SSMS UI following SQL Server Agent job creation.

```
USE [msdb]
GO
```

```
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'SSAS_Job',
    @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=0,
    @notify_level_netsend=0,
    @notify_level_page=0,
    @delete_level=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver
    @job_name=N'SSAS_Job',
    @server_name = N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'SSAS_Job',
 @step_name=N'Process_SSAS_Object',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_success_step_id=0,
    @on_fail_action=2,
    @on_fail_step_id=0,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0, @subsystem=N'ANALYSISCOMMAND',
    @command=N'<Batch xmlns="http://schemas.microsoft.com/analysisservices/2003/
engine">
        <Parallel>
            <Process xmlns:xsd="http://www.w3.org/2001/XMLSchema"

                <Type>ProcessFull</Type>
                <WriteBackTableCreation>UseExisting</WriteBackTableCreation>
            </Process>
        </Parallel>
    </Batch>',
    @server=N'localhost:2383',
    @database_name=N'master',
    @flags=0,
    @proxy_name=N'SSAS_Proxy'
GO
```

Revoking SSAS access from the proxy

You can revoke access to the SSAS subsystem and delete the SSAS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
 @proxy_name=N'SSAS_Proxy',@name=N'mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSAS_Proxy'
GO
```

Backing up an SSAS database

You can create SSAS database backup files only in the `D:\S3` folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the `admin` role for a particular database can use SSMS to back up the database to the `D:\S3` folder.

  For more information, see Adding a domain user as a database administrator.
- You can use the following stored procedure. This stored procedure doesn't support encryption.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_BACKUP_DB',
@database_name='myssasdb',
@file_path='D:\S3\ssas_db_backup.abf',
[@ssas_apply_compression=1],
[@ssas_overwrite_file=1];
```

  The following parameters are required:

  - `@task_type` – The type of the MSBI task, in this case SSAS_BACKUP_DB.
  - `@database_name` – The name of the SSAS database that you're backing up.
  - `@file_path` – The path for the SSAS backup file. The `.abf` extension is required.

  The following parameters are optional:

  - `@ssas_apply_compression` – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
  - `@ssas_overwrite_file` – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

Restoring an SSAS database

Use the following stored procedure to restore an SSAS database from a backup.

You can't restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn't support encrypted backup files.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case `SSAS_RESTORE_DB`.
- `@database_name` – The name of the new SSAS database that you're restoring to.
- `@file_path` – The path to the SSAS backup file.

Restoring a DB instance to a specified time

Point-in-time recovery (PITR) doesn't apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.

To have up-to-date SSAS databases on a restored DB instance

1. Back up your SSAS databases to the `D:\S3` folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the `D:\S3` folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

   You can also reprocess the SSAS project to restore the databases.

Changing the SSAS mode

You can change the mode in which SSAS runs, either Tabular or Multidimensional. To change the mode, use the AWS Management Console or the AWS CLI to modify the options settings in the SSAS option.

> **Important**
>
> You can only use one SSAS mode at a time. Make sure to delete all of the SSAS databases before changing the mode, or you receive an error.

Console

The following Amazon RDS console procedure changes the SSAS mode to Tabular and sets the `MAX_MEMORY` parameter to 70 percent.

To modify the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to modify (`ssas-se-2017` in the previous examples).
4. Choose **Modify option**.
5. Change the option settings:
   a. For **Max memory**, enter **70**.
   b. For **Mode**, choose **Tabular**.
6. Choose **Modify option**.

AWS CLI

The following AWS CLI example changes the SSAS mode to Tabular and sets the `MAX_MEMORY` parameter to 70 percent.

For the CLI command to work, make sure to include all of the required parameters, even if you're not modifying them.

To modify the SSAS option

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name ssas-se-2017 \
    --options
 "OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,
{Name=MODE,Value=Tabular}]" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name ssas-se-2017 ^
    --options
 OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,V
{Name=MODE,Value=Tabular}] ^
    --apply-immediately
```

Turning off SSAS

To turn off SSAS, remove the SSAS option from its option group.

> **Important**
>
> Before you remove the SSAS option, delete your SSAS databases.
> We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

Console

To remove the SSAS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.

3. Choose the option group with the SSAS option that you want to remove (`ssas-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSAS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

AWS CLI

To remove the SSAS option from its option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssas-se-2017 \
    --options SSAS \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssas-se-2017 ^
    --options SSAS ^
    --apply-immediately
```

Troubleshooting SSAS issues

You might encounter the following issues when using SSAS.

Issue	Type	Troubleshooting suggestions
Unable to configure the SSAS option. The requested SSAS mode	RDS event	You can't change the SSAS mode if you still have SSAS databases that use the current

Issue	Type	Troubleshooting suggestions
is *new_mode*, but the current DB instance has *number current_mode* databases. Delete the existing databases before switching to *new_mode* mode. To regain access to *current_mode* mode for database deletion, either update the current DB option group, or attach a new option group with %s as the MODE option setting value for the SSAS option.		mode. Delete the SSAS databases, then try again.
Unable to remove the SSAS option because there are *number* existing *mode* databases. The SSAS option can't be removed until all SSAS databases are deleted. Add the SSAS option again, delete all SSAS databases, and try again.	RDS event	You can't turn off SSAS if you still have SSAS databases. Delete the SSAS databases , then try again.
The SSAS option isn't enabled or is in the process of being enabled. Try again later.	RDS stored procedure	You can't run SSAS stored procedures when the option is turned off, or when it's being turned on.

Issue	Type	Troubleshooting suggestions
The SSAS option is configured incorrectly. Make sure that the option group membership status is "in-sync" , and review the RDS event logs for relevant SSAS configuration error messages. Following these investiga tions, try again. If errors continue to occur, contact AWS Support.	RDS stored procedure	You can't run SSAS stored procedures when your option group membership isn't in the `in-sync` status. This puts the SSAS option in an incorrect configuration state. If your option group membership status changes to `failed` due to SSAS option modification, there are two possible reasons: 1. The SSAS option was removed without the SSAS databases being deleted. 2. The SSAS mode was updated from Tabular to Multidimensional, or from Multidimenisonal to Tabular, without the existing SSAS databases being deleted. Reconfigure the SSAS option, because RDS allows only one SSAS mode at a time, and doesn't support SSAS option removal with SSAS databases present. Check the RDS event logs for configuration errors for your SSAS instance, and resolve the issues accordingly.
Deployment failed. The change can only be deployed on a server running in *`deployment_file_mode`* mode. The current server mode is *`current_mode`* .	RDS stored procedure	You can't deploy a Tabular database to a Multidimensional server, or a Multidime nsional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the `MODE` option setting is set to the appropriate value.

Issue	Type	Troubleshooting suggestions
The restore failed. The backup file can only be restored on a server running in *restore_file_mode* mode. The current server mode is *current_mode* .	RDS stored procedure	You can't restore a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the MODE option setting is set to the appropriate value.
The restore failed. The backup file and the RDS DB instance versions are incompatible.	RDS stored procedure	You can't restore an SSAS database with a version incompatible to the SQL Server instance version. For more information, see Compatibility levels for tabular models and Compatibility level of a multidimensional database in the Microsoft documentation.
The restore failed. The backup file specified in the restore operation is damaged or is not an SSAS backup file. Make sure that @rds_file_path is correctly formatted.	RDS stored procedure	You can't restore an SSAS database with a damaged file. Make sure that the file isn't damaged or corrupted. This error can also be raised when `@rds_file_path` isn't correctly formatted (for example, it has double backslashes as in `D:\S3\\incorrect_format.abf`).

Issue	Type	Troubleshooting suggestions
The restore failed. The restored database name can't contain any reserved words or invalid character s: . , ; ' ` : / \\ * | ? \" & % $! + = ( ) [ ] { } < >, or be longer than 100 characters.	RDS stored procedure	The restored database name can't contain any reserved words or characters that aren't valid, or be longer than 100 charac ters. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.
An invalid role name was provided. The role name can't contain any reserved strings.	RDS stored procedure	The role name can't contain any reserved strings. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.
An invalid role name was provided. The role name can't contain any of the following reserved characters: . , ; ' ` : / \\ * | ? \" & % $! + = ( ) [ ] { } < >	RDS stored procedure	The role name can't contain any reserved characters. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.

Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5426.0.v1 and higher

Contents

- Limitations and recommendations
- Enabling SSIS
  - Creating the option group for SSIS
  - Adding the SSIS option to the option group
  - Creating the parameter group for SSIS
  - Modifying the parameter for SSIS
  - Associating the option group and parameter group with your DB instance
  - Enabling S3 integration
- Administrative permissions on SSISDB

- Setting up a Windows-authenticated user for SSIS
- Deploying an SSIS project
- Monitoring the status of a deployment task
- Using SSIS
  - Setting database connection managers for SSIS projects
  - Creating an SSIS proxy
  - Scheduling an SSIS package using SQL Server Agent
  - Revoking SSIS access from the proxy
- Disable and drop SSIS database
  - Disabling SSIS
  - Dropping the SSISDB database

Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:

- The DB instance must have an associated parameter group with the `clr enabled` parameter set to 1. For more information, see Modifying the parameter for SSIS.

  > **Note**
  >
  > If you enable the `clr enabled` parameter on SQL Server 2017 or 2019, you can't use the common language runtime (CLR) on your DB instance. For more information, see Features not supported and features with limited support.

- The following control flow tasks are supported:
  - Analysis Services Execute DDL Task
  - Analysis Services Processing Task
  - Bulk Insert Task
  - Check Database Integrity Task
  - Data Flow Task
  - Data Mining Query Task
  - Data Profiling Task

  - Execute Package Task
  - Execute SQL Server Agent Job Task
  - Execute SQL Task
  - Execute T-SQL Statement Task
  - Notify Operator Task
  - Rebuild Index Task
  - Reorganize Index Task
  - Shrink Database Task
  - Transfer Database Task
  - Transfer Jobs Task
  - Transfer Logins Task
  - Transfer SQL Server Objects Task
  - Update Statistics Task
- Only project deployment is supported.
- Running SSIS packages by using SQL Server Agent is supported.
- SSIS log records can be inserted only into user-created databases.
- Use only the `D:\S3` folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
  - Place SSIS project input and output files in the `D:\S3` folder.
  - For the Data Flow Task, change the location for `BLOBTempStoragePath` and `BufferTempStoragePath` to a file inside the `D:\S3` folder. The file path must start with `D:\S3\`.
  - Ensure that all parameters, variables, and expressions used for file connections point to the `D:\S3` folder.
  - On Multi-AZ instances, files created by SSIS in the `D:\S3` folder are deleted after a failover. For more information, see Multi-AZ limitations for S3 integration.
  - Upload the files created by SSIS in the `D:\S3` folder to your Amazon S3 bucket to make them durable.
- Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
- You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.

- The SSIS Scale Out feature isn't supported.
- You can't deploy projects directly. We provide RDS stored procedures to do this. For more information, see Deploying an SSIS project.
- Build SSIS project (.ispac) files with the `DoNotSavePasswords` protection mode for deploying on RDS.
- SSIS isn't supported on Always On instances with read replicas.
- You can't back up the SSISDB database that is associated with the `SSIS` option.
- Importing and restoring the SSISDB database from other instances of SSIS isn't supported.
- You can connect to other SQL Server DB instances or to an Oracle data source. Connecting to other database engines, such as MySQL or PostgreSQL, isn't supported for SSIS on RDS for SQL Server. For more information on connecting to an Oracle data source, see Linked Servers with Oracle OLEDB.
- SSIS does not support a domain joined instance with an outgoing trust to an on-premises domain. When using an outgoing trust, run the SSIS job from an account in the local AWS domain.
- Executing file system based packages is not supported.

Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the `SSIS` option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `clr enabled` parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

> **Note**
>
> If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.

Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`ssis-se-2016`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`SSIS option group for SQL Server SE 2016`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
```

```
    --option-group-name ssis-se-2016 \
    --engine-name sqlserver-se \
    --major-engine-version 13.00 \
    --option-group-description "SSIS option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name ssis-se-2016 ^
    --engine-name sqlserver-se ^
    --major-engine-version 13.00 ^
    --option-group-description "SSIS option group for SQL Server SE 2016"
```

Adding the SSIS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSIS option to your option group.

Console

To add the SSIS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, **ssis-se-2016** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **SSIS** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

CLI

To add the SSIS option

- Add the SSIS option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name ssis-se-2016 \
    --options OptionName=SSIS \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name ssis-se-2016 ^
    --options OptionName=SSIS ^
    --apply-immediately
```

Creating the parameter group for SSIS

Create or modify a parameter group for the `clr enabled` parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`ssis-sqlserver-se-13`**.
   c. For **Description**, enter **`clr enabled parameter group`**.
5. Choose **Create**.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "clr enabled parameter group"
```

  For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name ssis-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "clr enabled parameter group"
```

Modifying the parameter for SSIS

Modify the `clr enabled` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the `clr enabled` parameter to 1.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **ssis-sqlserver-se-13**.

4. Under **Parameters**, filter the parameter list for **`clr`**.
5. Choose **clr enabled**.
6. Choose **Edit parameters**.
7. From **Values**, choose **1**.
8. Choose **Save changes**.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --parameters "ParameterName='clr
 enabled',ParameterValue=1,ApplyMethod=immediate"
```

  For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name ssis-sqlserver-se-13 ^
    --parameters "ParameterName='clr
 enabled',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with your DB instance

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

> **Note**
>
> If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

Console

To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the SSIS option group and parameter group with a new or existing DB instance.

To create an instance with the SSIS option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myssisinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
```

```
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name ssis-se-2016 \
    --db-parameter-group-name ssis-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myssisinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name ssis-se-2016 ^
    --db-parameter-group-name ssis-sqlserver-se-13
```

To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssisinstance \
    --option-group-name ssis-se-2016 \
    --db-parameter-group-name ssis-sqlserver-se-13 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssisinstance ^
```

```
    --option-group-name ssis-se-2016 ^
    --db-parameter-group-name ssis-sqlserver-se-13 ^
    --apply-immediately
```

Enabling S3 integration

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.

Administrative permissions on SSISDB

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the ssis_admin and ssis_logreader roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on ssis_admin role
- alter on ssis_logreader role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the ssis_admin and ssis_logreader roles. Doing this is useful for giving access to your domain users for using SSIS.

Setting up a Windows-authenticated user for SSIS

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

> **Note**
>
> You can grant some or all of the following permissions as needed to Windows-authenticated users.

Example

```
-- Create a server-level SQL login for the domain user, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create a database-level account for the domain user, if it doesn't already exist

USE [SSISDB]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Add SSIS role membership to the domain user
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\user_name]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\user_name]
GO

-- Add MSDB role membership to the domain user
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Grant MSDB stored procedure privileges to the domain user
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option

GO
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

-- Grant the ALTER ANY CREDENTIAL privilege to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
```

Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see Setting up a Windows-authenticated user for SSIS.

To deploy the SSIS project

1. Download the project (.ispac) file.

   ```
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
   @rds_file_path='D:\S3\ssisproject.ispac',
   @overwrite_file=1;
   ```

2. Submit the deployment task, making sure of the following:

   - The folder is present in the SSIS catalog.
   - The project name matches the project name that you used while developing the SSIS project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSIS_DEPLOY_PROJECT',
@folder_name='DEMO',
@project_name='ssisproject',
@file_path='D:\S3\ssisproject.ispac';
```

Monitoring the status of a deployment task

To track the status of your deployment task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
`task_id`	The ID of the task.
`task_type`	`SSIS_DEPLOY_PROJECT`
`database_name`	Not applicable to SSIS tasks.
`% complete`	The progress of the task as a percentage.
`duration (mins)`	The amount of time spent on the task, in minutes.

Output parameter	Description
lifecycle	The status of the task. Possible statuses are the following: • CREATED – After you call the msdb.dbo.rds_msbi_task stored procedure, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS. • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED. • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.

Output parameter	Description
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSIS tasks.
overwrite_S3_backup_file	Not applicable to SSIS tasks.
KMS_master_key_arn	Not applicable to SSIS tasks.
filepath	Not applicable to SSIS tasks.
overwrite_file	Not applicable to SSIS tasks.
task_metadata	Metadata associated with the SSIS task.

Using SSIS

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see Setting up a Windows-authenticated user for SSIS.

Topics

- Setting database connection managers for SSIS projects
- Creating an SSIS proxy
- Scheduling an SSIS package using SQL Server Agent
- Revoking SSIS access from the proxy

Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections using AWS Managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use

DB_instance_name.*fully_qualified_domain_name* as the server name of the connection string.

An example is `myssisinstance.corp-ad.example.com`, where `myssisinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.

- For remote connections, always use SQL authentication.
- For local database connections using self-managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use `.` or *`LocalHost`* as the server name of the connection string.

Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```
USE [master]
GO
CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
 N'mysecret'
GO
```

> **Note**
>
> `IDENTITY` must be a domain-authenticated login. Replace *`mysecret`* with the password for the domain-authenticated login.
> Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
 @proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
 @proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

To schedule the SSIS package

- You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
@enabled=1,
@notify_level_eventlog=0,
@notify_level_email=2,
@notify_level_page=2,
@delete_level=0,
@category_name=N'[Uncategorized (Local)]',
@job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver @job_name=N'MYSSISJob',@server_name=N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep
 @job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
@step_id=1,
@cmdexec_success_code=0,
@on_success_action=1,
@on_fail_action=2,
@retry_attempts=0,
@retry_interval=0,
@os_run_priority=0,
@subsystem=N'SSIS',
@command=N'/ISSERVER "\"\SSISDB\MySSISFolder\MySSISProject\MySSISPackage.dtsx\"" /
SERVER "\"my-rds-ssis-instance.corp-ad.company.com/\""
/Par "\"$ServerOption::LOGGING_LEVEL(Int16)\"";1 /Par
 "\"$ServerOption::SYNCHRONIZED(Boolean)\"";True /CALLERINFO SQLAGENT /REPORTING
 E',
@database_name=N'master',
@flags=0,
@proxy_name=N'SSIS_Proxy'
GO
```

Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
 @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
 @proxy_name=N'SSIS_Proxy',@name=N'mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
GO
```

Disable and drop SSIS database

Use the following steps to disable or drop SSIS databases:

Topics

- Disabling SSIS
- Dropping the SSISDB database

Disabling SSIS

To disable SSIS, remove the `SSIS` option from its option group.

> **Important**
>
> Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects.
> You can re-enable the `SSIS` option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

Console

The following procedure removes the `SSIS` option.

To remove the SSIS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the `SSIS` option (`ssis-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

The following procedure removes the `SSIS` option.

To remove the SSIS option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssis-se-2016 \
    --options SSIS \
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssis-se-2016 ^
    --options SSIS ^
    --apply-immediately
```

Dropping the SSISDB database

After removing the SSIS option, the SSISDB database isn't deleted. To drop the SSISDB database, use the `rds_drop_ssis_database` stored procedure after removing the SSIS option.

To drop the SSIS database

- Use the following stored procedure.

```
USE [msdb]
GO
EXEC dbo.rds_drop_ssis_database
GO
```

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.

Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can use SSRS with existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5820.21.v1 and higher

Contents

- Limitations and recommendations
- Turning on SSRS
  - Creating an option group for SSRS
  - Adding the SSRS option to your option group
  - Associating your option group with your DB instance
  - Allowing inbound access to your VPC security group
- Report server databases
- SSRS log files
- Accessing the SSRS web portal
  - Using SSL on RDS
  - Granting access to domain users
  - Accessing the web portal
- Deploying reports and configuring report data sources

- Deploying reports to SSRS
- Configuring the report data source
- Using SSRS Email to send reports
- Revoking system-level permissions
- Monitoring the status of a task
- Disabling and deleting SSRS databases
  - Turning off SSRS
  - Deleting the SSRS databases

Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- You can't use SSRS on DB instances that have read replicas.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSRS web portal and web server authentication. For more information, see Working with Active Directory with RDS for SQL Server.
- You can't back up the reporting server databases that are created with the SSRS option.
- Importing and restoring report server databases from other instances of SSRS isn't supported. For more information, see Report server databases.
- You can't configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
- Subscriptions through a Microsoft Windows file share aren't supported.
- Using Reporting Services Configuration Manager isn't supported.
- Creating and modifying roles isn't supported.
- Modifying report server properties isn't supported.
- System administrator and system user roles aren't granted.
- You can't edit system-level role assignments through the web portal.

Turning on SSRS

Use the following process to turn on SSRS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSRS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

> **Note**
>
> You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`ssrs-se-2017`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`SSRS option group for SQL Server SE 2017`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **14.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssrs-se-2017 \
    --engine-name sqlserver-se \
    --major-engine-version 14.00 \
    --option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name ssrs-se-2017 ^
    --engine-name sqlserver-se ^
    --major-engine-version 14.00 ^
    --option-group-description "SSRS option group for SQL Server SE 2017"
```

Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.

Console

To add the SSRS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, then choose **Add option**.
4. Under **Option details**, choose **SSRS** for **Option name**.

5. Under **Option settings**, do the following:

   a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see Limitations and recommendations.

   b. Enter a value for **Max memory**.

      Max memory specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

   c. For **Security groups**, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.

6. To use SSRS Email to send reports, choose the **Configure email delivery options** check box under **Email delivery in reporting services**, and then do the following:

   a. For **Sender email address**, enter the email address to use in the **From** field of messages sent by SSRS Email.

      Specify a user account that has permission to send mail from the SMTP server.

   b. For **SMTP server**, specify the SMTP server or gateway to use.

      It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.

   c. For **SMTP port**, enter the port to use to connect to the mail server. The default is 25.

   d. To use authentication:

      i. Select the **Use authentication** check box.

      ii. For **Secret Amazon Resource Name (ARN)** enter the AWS Secrets Manager ARN for the user credentials.

      Use the following format:

      ```
      arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomChara
      ```

      For example:

      ```
      arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-
      a1b2c3
      ```

      For more information on creating the secret, see Using SSRS Email to send reports.

e. Select the **Use Secure Sockets Layer (SSL)** check box to encrypt email messages using SSL.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

CLI

To add the SSRS option

1. Create a JSON file, for example `ssrs-option.json`.

   a. Set the following required parameters:

   - `OptionGroupName` – The name of option group that you created or chose previously (`ssrs-se-2017` in the following example).
   - `Port` – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see Limitations and recommendations.
   - `VpcSecurityGroupMemberships` – VPC security group memberships for your RDS DB instance.
   - `MAX_MEMORY` – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

   b. (Optional) Set the following parameters to use SSRS Email:

   - `SMTP_ENABLE_EMAIL` – Set to `true` to use SSRS Email. The default is `false`.
   - `SMTP_SENDER_EMAIL_ADDRESS` – The email address to use in the **From** field of messages sent by SSRS Email. Specify a user account that has permission to send mail from the SMTP server.
   - `SMTP_SERVER` – The SMTP server or gateway to use. It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.
   - `SMTP_PORT` – The port to use to connect to the mail server. The default is 25.
   - `SMTP_USE_SSL` – Set to `true` to encrypt email messages using SSL. The default is `true`.

- SMTP_EMAIL_CREDENTIALS_SECRET_ARN – The Secrets Manager ARN that holds the user credentials. Use the following format:

  arn:aws:secretsmanager:*Region*:*AccountId*:secret:*SecretName*-*6RandomCharact*

  For more information on creating the secret, see Using SSRS Email to send reports.
- SMTP_USE_ANONYMOUS_AUTHENTICATION – Set to `true` and don't include SMTP_EMAIL_CREDENTIALS_SECRET_ARN if you don't want to use authentication.

  The default is `false` when SMTP_ENABLE_EMAIL is `true`.

The following example includes the SSRS Email parameters, using the secret ARN.

```
{
"OptionGroupName": "ssrs-se-2017",
"OptionsToInclude": [
 {
 "OptionName": "SSRS",
 "Port": 8443,
 "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
 "OptionSettings": [
            {"Name": "MAX_MEMORY","Value": "60"},
            {"Name": "SMTP_ENABLE_EMAIL","Value": "true"}
            {"Name": "SMTP_SENDER_EMAIL_ADDRESS","Value": "nobody@example.com"},
            {"Name": "SMTP_SERVER","Value": "email-smtp.us-west-2.amazonaws.com"},
            {"Name": "SMTP_PORT","Value": "25"},
            {"Name": "SMTP_USE_SSL","Value": "true"},
            {"Name": "SMTP_EMAIL_CREDENTIALS_SECRET_ARN","Value":
 "arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3"}
            ]
 }],
"ApplyImmediately": true
}
```

2. Add the SSRS option to the option group.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
```

```
    --cli-input-json file://ssrs-option.json \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --cli-input-json file://ssrs-option.json ^
    --apply-immediately
```

Associating your option group with your DB instance

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Working with Active Directory with RDS for SQL Server.

Console

You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, modify the instance and associate the new option group. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate your option group with a new or existing DB instance.

To create a DB instance that uses your option group

- Specify the same DB engine type and major version as you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myssrsinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 14.00.3223.3.v1 \
    --allocated-storage 100 \
    --manage-master-user-password  \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name ssrs-se-2017
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier myssrsinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 14.00.3223.3.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name ssrs-se-2017
```

To modify a DB instance to use your option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssrsinstance \
```

```
    --option-group-name ssrs-se-2017 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssrsinstance ^
    --option-group-name ssrs-se-2017 ^
    --apply-immediately
```

Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.

Report server databases

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance:

- `rdsadmin_ReportServer`
- `rdsadmin_ReportServerTempDB`

These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database. For more information, see Report Server Database in the Microsoft documentation.

RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted. Access isn't permitted on the `rdsadmin_ReportServerTempDB` database. However, you can perform read operations on the `rdsadmin_ReportServer`database.

SSRS log files

You can list, view, and download SSRS log files. SSRS log files follow a naming convention of ReportServerService_*timestamp*.log. These report server logs are located in the `D:\rdsdbdata\Log\SSRS` directory. (The `D:\rdsdbdata\Log` directory is also the parent directory for error logs and SQL Server Agent logs.). For more information, see Viewing and listing database log files.

For existing SSRS instances, restarting the SSRS service might be necessary to access report server logs. You can restart the service by updating the SSRS option.

For more information, see Working with Amazon RDS for Microsoft SQL Server logs.

Accessing the SSRS web portal

Use the following process to access the SSRS web portal:

1. Turn on Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

Using SSL on RDS

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For more information about using SSL with SQL Server, see Using SSL with a Microsoft SQL Server DB instance.

Granting access to domain users

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

To grant access to a domain user on the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_GRANT_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

The domain user or user group is granted the RDS_SSRS_ROLE system role. This role has the following system-level tasks granted to it:

- Run reports

- Manage jobs
- Manage shared schedules
- View shared schedules

The item-level role of `Content Manager` on the root folder is also granted.

Accessing the web portal

After the `SSRS_GRANT_PORTAL_PERMISSION` task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- *`rds_endpoint`* – The endpoint for the RDS DB instance that you're using with SSRS.

  You can find the endpoint on the **Connectivity & security** tab for your DB instance. For more information, see Connecting to your Microsoft SQL Server DB instance.
- *`port`* – The listener port for SSRS that you set in the SSRS option.

To access the web portal

1. Enter the web portal URL in your browser.

   ```
   https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports
   ```
2. Log in with the credentials for a domain user that you granted access with the `SSRS_GRANT_PORTAL_PERMISSION` task.

Deploying reports and configuring report data sources

Use the following procedures to deploy reports to SSRS and configure the reporting data sources:

Topics

- Deploying reports to SSRS
- Configuring the report data source

Deploying reports to SSRS

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from SQL Server data tools (SSDT). When deploying from SSDT, ensure the following:

- The user who launched SSDT has access to the SSRS web portal.
- The `TargetServerURL` value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with `ReportServer`, for example:

```
https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/ReportServer
```

Configuring the report data source

After you deploy a report to SSRS, you should configure the report data source. When configuring the report data source, ensure the following:

- For RDS for SQL Server DB instances joined to AWS Directory Service for Microsoft Active Directory, use the fully qualified domain name (FQDN) as the data source name of the connection string. An example is *`myssrsinstance.corp-ad.example.com`*, where *`myssrsinstance`* is the DB instance name and *`corp-ad.example.com`* is the fully qualified domain name.
- For RDS for SQL Server DB instances joined to self-managed Active Directory, use `.`, or *`LocalHost`* as the data source name of the connection string.

Using SSRS Email to send reports

SSRS includes the SSRS Email extension, which you can use to send reports to users.

To configure SSRS Email, use the SSRS option settings. For more information, see Adding the SSRS option to your option group.

After configuring SSRS Email, you can subscribe to reports on the report server. For more information, see Email delivery in Reporting Services in the Microsoft documentation.

Integration with AWS Secrets Manager is required for SSRS Email to function on RDS. To integrate with Secrets Manager, you create a secret.

> **Note**
>
> If you change the secret later, you also have to update the SSRS option in the option group.

To create a secret for SSRS Email

1. Follow the steps in Create a secret in the *AWS Secrets Manager User Guide*.

   a. For **Select secret type**, choose **Other type of secrets**.

   b. For **Key/value pairs**, enter the following:

   - **SMTP_USERNAME** – Enter a user with permission to send mail from the SMTP server.
   - **SMTP_PASSWORD** – Enter a password for the SMTP user.

   c. For **Encryption key**, don't use the default AWS KMS key. Use your own existing key, or create a new one.

   The KMS key policy must allow the `kms:Decrypt` action, for example:

```
{
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "rds.amazonaws.com"
        ]
    },
    "Action": [
        "kms:Decrypt"
    ],
    "Resource": "*"
}
```

2. Follow the steps in Attach a permissions policy to a secret in the *AWS Secrets Manager User Guide*. The permissions policy gives the `secretsmanager:GetSecretValue` action to the `rds.amazonaws.com` service principal.

   We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the *confused deputy* problem. Use your AWS account for

`aws:sourceAccount` and the option group ARN for `aws:sourceArn`. For more information, see Preventing cross-service confused deputy problems.

The following example shows a permissions policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement" : [ {
    "Effect" : "Allow",
    "Principal" : {
      "Service" : "rds.amazonaws.com"
    },
    "Action" : "secretsmanager:GetSecretValue",
    "Resource" : "*",
    "Condition" : {
      "StringEquals" : {
        "aws:sourceAccount" : "123456789012"
      },
      "ArnLike" : {
        "aws:sourceArn" : "arn:aws:rds:us-west-2:123456789012:og:ssrs-
se-2017"
      }
    }
  } ]
}
```

For more examples, see Permissions policy examples for AWS Secrets Manager in the *AWS Secrets Manager User Guide*.

Revoking system-level permissions

The `RDS_SSRS_ROLE` system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from `RDS_SSRS_ROLE`, use the same stored procedure that you used to grant the role but use the `SSRS_REVOKE_PORTAL_PERMISSION` task type.

To revoke access from a domain user for the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_REVOKE_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the `Content Manager` item-level role if the user has it.

Monitoring the status of a task

To track the status of your granting or revoking task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
`task_id`	The ID of the task.
`task_type`	For SSRS, tasks can have the following task types: • `SSRS_GRANT_PORTAL_PERMISSION` • `SSRS_REVOKE_PORTAL_PERMISSION`

Output parameter	Description
database_name	Not applicable to SSRS tasks.
% complete	The progress of the task as a percentage.
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	The status of the task. Possible statuses are the following: • CREATED – After you call one of the SSRS stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS . It can take up to five minutes for the status to change from CREATED to IN_PROGRESS . • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call the rds_cancel_task stored procedure, the status of the task is set to CANCEL_REQUESTED . • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED .

Output parameter	Description
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSRS tasks.
overwrite_S3_backup_file	Not applicable to SSRS tasks.
KMS_master_key_arn	Not applicable to SSRS tasks.
filepath	Not applicable to SSRS tasks.
overwrite_file	Not applicable to SSRS tasks.
task_metadata	Metadata associated with the SSRS task.

Disabling and deleting SSRS databases

Use the following procedures to disable SSRS and delete SSRS databases:

Topics

- Turning off SSRS
- Deleting the SSRS databases

Turning off SSRS

To turn off SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see Deleting the SSRS databases.

You can turn SSRS on again by adding back the SSRS option. If you have also deleted the SSRS databases, readding the option on the same DB instance creates new report server databases.

Console

To remove the SSRS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSRS option (`ssrs-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSRS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the SSRS option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssrs-se-2017 \
    --options SSRS \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssrs-se-2017 ^
    --options SSRS ^
    --apply-immediately
```

Deleting the SSRS databases

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

To delete the SSRS databases

- Use the following stored procedure.

```
exec msdb.dbo.rds_drop_ssrs_databases
```

Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A *distributed transaction* is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see Distributed Transaction Coordinator in the Microsoft documentation.

Contents

- Limitations
- Enabling MSDTC
  - Creating the option group for MSDTC
  - Adding the MSDTC option to the option group
  - Creating the parameter group for MSDTC
  - Modifying the parameter for MSDTC
  - Associating the option group and parameter group with the DB instance
  - Modifying the MSDTC option
- Using transactions
  - Using distributed transactions
  - Using XA transactions
  - Using transaction tracing
- Disabling MSDTC
- Troubleshooting MSDTC for RDS for SQL Server

Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see Transactions - availability groups and database mirroring.
- The `in-doubt xact resolution` parameter must be set to 1 or 2. For more information, see Modifying the parameter for MSDTC.
- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.
- Using custom XA dynamic link libraries isn't supported.

Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the `MSDTC` option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `in-doubt xact resolution` parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.

> **Note**
>
> You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`msdtc-se-2016`**. The name can contain only letters, digits, and hyphens.
   b. For **Description**, enter a brief description of the option group, such as **`MSDTC option group for SQL Server SE 2016`**. The description is used for display purposes.
   c. For **Engine**, choose **sqlserver-se**.
   d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

CLI

The following example creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name msdtc-se-2016 \
    --engine-name sqlserver-se \
    --major-engine-version 13.00 \
    --option-group-description "MSDTC option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name msdtc-se-2016 ^
    --engine-name sqlserver-se ^
    --major-engine-version 13.00 ^
    --option-group-description "MSDTC option group for SQL Server SE 2016"
```

Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

  Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see Can't connect to Amazon RDS DB instance.
- **Security groups** – The VPC security group memberships for your RDS DB instance.
- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  - Mutual – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  - None – No authentication is performed between hosts. We don't recommend using this mode in production environments.

- **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

- **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.
- **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.
- **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see XA specification.
- **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see Managing IBM CICS LU 6.2 transactions in the Microsoft documentation.

Console

To add the MSDTC option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
    a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
    b. For **Security groups**, choose the VPC security group to associate with the option.
    c. For **Authentication type**, choose **Mutual** or **None**.
    d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
    a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.

b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.

8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

   To add this option, no reboot is required.

CLI

To add the MSDTC option

1. Create a JSON file, for example `msdtc-option.json`, with the following required parameters.

```
{
"OptionGroupName":"msdtc-se-2016",
"OptionsToInclude": [
 {
 "OptionName":"MSDTC",
 "Port":5000,
 "VpcSecurityGroupMemberships":["sg-0abcdef123"],
 "OptionSettings":[{"Name":"AUTHENTICATION","Value":"MUTUAL"},
{"Name":"TRANSACTION_LOG_SIZE","Value":"4"}]
 }],
"ApplyImmediately": true
}
```

2. Add the MSDTC option to the option group.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://msdtc-option.json \
    --apply-immediately
```

   For Windows:

```
aws rds add-option-to-option-group ^
```

```
    --cli-input-json file://msdtc-option.json ^
    --apply-immediately
```

No reboot is required.

Creating the parameter group for MSDTC

Create or modify a parameter group for the `in-doubt xact resolution` parameter that corresponds to the SQL Server edition and version of your DB instance.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   a. For **Parameter group family**, choose **sqlserver-se-13.0**.
   b. For **Group name**, enter an identifier for the parameter group, such as **`msdtc-sqlserver-se-13`**.
   c. For **Description**, enter **`in-doubt xact resolution`**.
5. Choose **Create**.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "in-doubt xact resolution"
```

For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "in-doubt xact resolution"
```

Modifying the parameter for MSDTC

Modify the `in-doubt xact resolution` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the `in-doubt xact resolution` parameter to one of the following:

- 1 – `Presume commit`. Any MSDTC in-doubt transactions are presumed to have committed.
- 2 – `Presume abort`. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see in-doubt xact resolution server configuration option in the Microsoft documentation.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **msdtc-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **`xact`**.

5. Choose **in-doubt xact resolution**.
6. Choose **Edit parameters**.
7. Enter **1** or **2**.
8. Choose **Save changes**.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
    --parameters "ParameterName='in-doubt xact
 resolution',ParameterValue=1,ApplyMethod=immediate"
```

  For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --parameters "ParameterName='in-doubt xact
 resolution',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

Console

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server.

CLI

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

> **Note**
>
> If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server.

To create a DB instance with the MSDTC option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
```

```
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --manage-master-user-password \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name msdtc-se-2016 \
    --db-parameter-group-name msdtc-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --manage-master-user-password ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name msdtc-se-2016 ^
    --db-parameter-group-name msdtc-sqlserver-se-13
```

To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --option-group-name msdtc-se-2016 \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
```

```
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --option-group-name msdtc-se-2016 ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --apply-immediately
```

Modifying the MSDTC option

After you enable the MSDTC option, you can modify its settings. For information about how to modify option settings, see Modifying an option setting.

> **Note**
>
> Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

Using transactions

Using distributed transactions

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

  In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see Implementing an implicit transaction using transaction scope in the Microsoft documentation.

  Promotable transactions are supported with these .NET implementations:

- Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see System.Transactions integration with SQL Server in the Microsoft documentation.
- ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the `TransactionsScope` scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see Microsoft Distributed Transaction Coordinator integration in the Microsoft documentation.
- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see BEGIN DISTRIBUTED TRANSACTION (Transact-SQL) in the Microsoft documentation.

Using XA transactions

Starting from RDS for SQL Server 2017 version14.00.3223.3, you can control distributed transactions using JDBC. When you set the `Enable XA` option setting to `true` in the `MSDTC` option, RDS automatically enables JDBC transactions and grants the `SqlJDBCXAUser` role to the `guest` user. This allows executing distributed transactions through JDBC. For more information, including a code example, see Understanding XA transactions in the Microsoft documentation.

Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
[@traceall='0|1'],
[@traceaborted='0|1'],
[@tracelong='0|1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be `START`, `STOP`, or `STATUS`.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.

- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

Example of START tracing action

To start a new transaction tracing session, run the following example statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
@traceall='0',
@traceaborted='1',
@tracelong='1';
```

> **Note**
>
> Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

Example of STOP tracing action

To stop a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

```
OK: Trace session has been successfully stopped.
Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\msdtctr.mof for message formats,  8 found.
Searching for TMF files on path: (null)
Logfile D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
 OS version    10.0.14393  (Currently running on 6.2.9200)
 Start Time    <timestamp>
 End Time      <timestamp>
```

```
 Timezone is   @tzres.dll,-932 (Bias is 0mins)
 BufferSize            16384 B
 Maximum File Size     10 MB
 Buffers  Written      Not set (Logger may not have been stopped).
 Logger Mode Settings (11000002) ( circular paged
 ProcessorCount         1
Processing completed   Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0,
 Unknowns: 3
Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log
```

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see Monitoring Amazon RDS log files.

The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

Example of STATUS tracing action

To trace the status of a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
OK
SessionStatus: <Started|Stopped>
TraceAll: <True|False>
TraceAborted: <True|False>
TraceLongLived: <True|False>
```

The first line indicates the overall result of the operation: `OK` or `ERROR` with details, if applicable. The subsequent lines indicate details about the tracing session status:

- `SessionStatus` can be one of the following:
  - `Started` if a tracing session is running.
  - `Stopped` if no tracing session is running.
- The tracing session flags can be `True` or `False` depending on how they were set in the `START` command.

Disabling MSDTC

To disable MSDTC, remove the `MSDTC` option from its option group.

Console

To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the `MSDTC` option (`msdtc-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **MSDTC** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the MSDTC option from its option group

- Use one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name msdtc-se-2016 \
    --options MSDTC \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name msdtc-se-2016 ^
    --options MSDTC ^
```

```
    --apply-immediately
```

Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see Can't connect to Amazon RDS DB instance.
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open **Component Services**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Component Services**.
2. Expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **Distributed Transaction Coordinator**.
3. Open the context (right-click) menu for **Local DTC** and choose **Properties**.
4. Choose the **Security** tab.
5. Choose all of the following:

   - **Network DTC Access**
   - **Allow Inbound**
   - **Allow Outbound**
6. Make sure that the correct authentication mode is chosen:

   - **Mutual Authentication Required** – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
   - **No Authentication Required** – All other cases.
7. Choose **OK** to save your changes.
8. If prompted to restart the service, choose **Yes**.

To enable MSDTC firewall rules

1. Open Windows Firewall, then choose **Advanced settings**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Windows Firewall with Advanced Security**.

   > **Note**
   >
   > Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose **Inbound Rules** in the left pane.
3. Enable the following firewall rules, if they are not already enabled:

   - **Distributed Transaction Coordinator (RPC)**
   - **Distributed Transaction Coordinator (RPC)-EPMAP**
   - **Distributed Transaction Coordinator (TCP-In)**
4. Close Windows Firewall.

Microsoft SQL Server resource governor with RDS for SQL Server

Resource governor is a SQL Server Enterprise Edition feature that gives you precise control over your instance resources. It enables you to set specific limits on how workloads use CPU, memory, and physical I/O resources. With resource governor, you can:

- Prevent resource monopolization in multi-tenant environments by managing how different workloads share instance resources
- Deliver predictable performance by setting specific resource limits and priorities for different users and applications

You can enable resource governor on either an existing or new RDS for SQL Server DB instance.

Resource governor uses three fundamental concepts:

- **Resource pool** - A container that manages your instance physical resources (CPU, memory, and I/O). You get two built-in pools (internal and default) and you can create additional custom pools.
- **Workload group** - A container for database sessions with similar characteristics. Every workload group belongs to a resource pool. You get two built-in workload groups (internal and default) and you can create additional custom workload groups.
- **Classification** - The process that determines which workload group handles incoming sessions based on user name, application name, database name or host name.

For additional details about resource governor functionality in SQL Server, see Resource Governor in the Microsoft documentation.

Supported versions and Regions

Amazon RDS supports resource governor for the following SQL Server versions and editions in all AWS Regions where RDS for SQL Server is available:

- SQL Server 2022 Developer and Enterprise Editions
- SQL Server 2019 Enterprise Edition
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition

Limitations and recommendations

The following limitations and recommendations apply to resource governor:

- Edition and service restrictions:
  - Available only in SQL Server Enterprise Edition.
  - Resource management is limited to the SQL Server Database Engine. Resource governor for Analysis Services, Integration Services, and Reporting Services are not supported.
- Configuration restrictions:
  - Must use Amazon RDS stored procedures for all configurations.
  - Native DDL statements and SQL Server Management Studio GUI configurations aren't supported.
- Resource pool parameters:
  - Pool names starting with `rds_` aren't supported.
  - Internal and default resource pool modifications aren't permitted.
  - For the user-defined resource pools the following resource pool parameters aren't supported:
    - `MIN_MEMORY_PERCENT`
    - `MIN_CPU_PERCENT`
    - `MIN_IOPS_PER_VOLUME`
    - `AFFINITY`
- Workload group parameters:
  - Workload group names starting with `rds_` aren't supported.
  - Internal workload group modification isn't permitted.
  - For the default workload group:
    - Only the `REQUEST_MAX_MEMORY_GRANT_PERCENT` parameter can be modified.
    - For the default workload group, `REQUEST_MAX_MEMORY_GRANT_PERCENT` must be between 1 and 70.
    - All other parameters are locked and can't be changed.
  - User-defined workload groups allow modification of all parameters.
- Classifier function limitations:
  - Classifier function routes connections to custom workload groups based on specified criteria (user name, database, host, or application name).

- Supports up to two user-defined workload groups with their respective routing conditions.
- Combines criterion with AND conditions within each group.
- Requires at least one routing criterion per workload group.
- Only the classification methods listed above are supported.
- Function name must start with `rg_classifier_`.
- Default group assignment if no conditions match.

Enabling Microsoft SQL Server resource governor for your RDS for SQL Server instance

Enable resource governor by adding the RESOURCE_GOVERNOR option to your RDS for SQL Server DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the RESOURCE_GOVERNOR option to the option group.
3. Associate the option group with the DB instance.

> **Note**
>
> Enabling resource governor through an option group doesn't require a reboot.

Creating the option group for RESOURCE_GOVERNOR

To enable resource governor, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

Console

Use the following procedure to create an option group for SQL Server Enterprise Edition 2022.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:

   a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **`resource-governor-ee-2022`**. The name can contain only letters, digits, and hyphens.

   b. For **Description**, enter a brief description of the option group, such as **`RESOURCE_GOVERNOR option group for SQL Server EE 2022`**. The description is used for display purposes.

   c. For **Engine**, choose **sqlserver-ee**.

   d. For **Major engine version**, choose **16.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Enterprise Edition 2022.

To create the option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name resource-governor-ee-2022 \
    --engine-name sqlserver-ee \
    --major-engine-version 16.00 \
    --option-group-description "RESOURCE_GOVERNOR option group for SQL Server EE
 2022"
```

  For Windows:

```
aws rds create-option-group ^
    --option-group-name resource-governor-ee-2022 ^
    --engine-name sqlserver-ee ^
    --major-engine-version 16.00 ^
```

```
    --option-group-description "RESOURCE_GOVERNOR option group for SQL Server EE
 2022"
```

Adding the RESOURCE_GOVERNOR option to the option group

Next, use the AWS Management Console or the AWS CLI to add the RESOURCE_GOVERNOR option to your option group.

Console

To add the RESOURCE_GOVERNOR option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, **resource-governor-ee-2022** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **RESOURCE_GOVERNOR** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

CLI

To add the RESOURCE_GOVERNOR option

- Add the RESOURCE_GOVERNOR option to the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name resource-governor-ee-2022 \
    --options "OptionName=RESOURCE_GOVERNOR" \
    --apply-immediately
```

  For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name resource-governor-ee-2022 ^
    --options "OptionName=RESOURCE_GOVERNOR" ^
    --apply-immediately
```

Associating the option group with your DB instance

To associate the RESOURCE_GOVERNOR option group with your DB instance, use the AWS Management Console or the AWS CLI.

Console

To finish activating resource governor, associate your RESOURCE_GOVERNOR option group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance.

CLI

You can associate the RESOURCE_GOVERNOR option group with a new or existing DB instance.

To create an instance with the RESOURCE_GOVERNOR option group

- Specify the same DB engine type and major version that you used when creating the option group.

  Example

  For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mytestsqlserverresourcegovernorinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-ee \
    --engine-version 16.00 \
    --license-model license-included \
```

```
    --allocated-storage 100 \
    --master-username admin \
    --master-user-password password \
    --storage-type gp2 \
    --option-group-name resource-governor-ee-2022
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mytestsqlserverresourcegovernorinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-ee ^
    --engine-version 16.00 ^
    --license-model license-included ^
    --allocated-storage 100 ^
    --master-username admin ^
    --master-user-password password ^
    --storage-type gp2 ^
    --option-group-name resource-governor-ee-2022
```

To modify an instance and associate the `RESOURCE_GOVERNOR` option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mytestinstance \
    --option-group-name resource-governor-ee-2022 \
    --apply-immediately
```

  For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mytestinstance ^
    --option-group-name resource-governor-ee-2022 ^
    --apply-immediately
```

Using Microsoft SQL Server resource governor for your RDS for SQL Server instance

After adding the resource governor option to your option group, resource governor is not yet active at the database engine level. To fully enable resource governor, you must use RDS for SQL Server stored procedures to enable it and create the necessary resource governor objects. For more information, see Connecting to your Microsoft SQL Server DB instance.

First, connect to your SQL Server database, then call the appropriate RDS for SQL Server stored procedures to complete the configuration. For instructions on connecting to your database, see Connecting to your Microsoft SQL Server DB instance.

For instructions on how to call each stored procedure, see the following topics:

Topics

- Manage resource pool
- Manage workload groups
- Create and register classifier function
- Drop classifier function
- De-register classifier function
- Reset statistics
- Resource governor configuration changes
- Bind TempDB to a resource pool
- Unbind TempDB from a resource pool
- Cleanup resource governor

Manage resource pool

Create resource Pool

Once resource governor is enabled on the option group, you can create custom resource pools using `rds_create_resource_pool`. These pools let you allocate specific percentages of CPU, memory, and IOPS to different workloads.

Usage

```
USE [msdb]
```

```
EXEC dbo.rds_create_resource_pool
    @pool_name=value,
    @MAX_CPU_PERCENT=value,
    @CAP_CPU_PERCENT=value,
    @MAX_MEMORY_PERCENT=value,
    @MAX_IOPS_PER_VOLUME=value
```

The following parameters are required:

- `@group_name` - Is the name of an existing user-defined workload group.
- `@pool_name` - Is the user-defined name for the resource pool. *`pool_name`* is alphanumeric, can be up to 128 characters, must be unique within a Database Engine instance, and must comply with the rules for database identifiers.

The following parameters are optional:

- `@MAX_CPU_PERCENT` - Specifies the maximum average CPU bandwidth that all requests in resource pool receive when there's CPU contention. *`value`* is an integer with a default setting of 100. The allowed range for *`value`* is from 1 through 100.
- `@CAP_CPU_PERCENT` - Specifies a hard cap on the CPU bandwidth that all requests in the resource pool receive. Limits the maximum CPU bandwidth level to be the same as the specified value. *`value`* is an integer with a default setting of 100. The allowed range for *`value`* is from 1 through 100.
- `@MAX_MEMORY_PERCENT` - Specifies the maximum amount of query workspace memory that requests in this resource pool can use. *`value`* is an integer with a default setting of 100. The allowed range for *`value`* is from 1 through 100.
- `@MAX_IOPS_PER_VOLUME` - Specifies the maximum I/O operations per second (IOPS) per disk volume to allow for the resource pool. The allowed range for *`value`* is from 0 through 2^31-1 (2,147,483,647). Specify 0 to remove an IOPS limit for the pool. The default is 0.

Examples

Example of creating resource pool with all default values:

```
--This creates resource pool 'SalesPool' with all default values
USE [msdb]
EXEC rds_create_resource_pool @pool_name = 'SalesPool';
```

```
--Apply changes
USE [msdb]
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
select * from sys.resource_governor_resource_pools
```

Example of creating resource pool with different parameters specified:

```
--creates resource pool
USE [msdb]
EXEC dbo.rds_create_resource_pool
@pool_name='analytics',
@MAX_CPU_PERCENT = 30,
@CAP_CPU_PERCENT = 40,
@MAX_MEMORY_PERCENT = 20;

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
select * from sys.resource_governor_resource_pools
```

Alter resource pool

Usage

```
USE [msdb]
EXEC dbo.rds_alter_resource_pool
    @pool_name=value,
    @MAX_CPU_PERCENT=value,
    @CAP_CPU_PERCENT=value,
    @MAX_MEMORY_PERCENT=value,
    @MAX_IOPS_PER_VOLUME=value;
```

The following parameters are required:

- `@pool_name` - Is the name of an existing user-defined resource pool. Altering default resource pool isn't allowed in Amazon RDS SQL Server.

At least one of the optional parameter must be specified:

- @MAX_CPU_PERCENT - Specifies the maximum average CPU bandwidth that all requests in resource pool receive when there's CPU contention. *value* is an integer with a default setting of 100. The allowed range for *value* is from 1 through 100.
- @CAP_CPU_PERCENT - Specifies a hard cap on the CPU bandwidth that all requests in the resource pool receive. Limits the maximum CPU bandwidth level to be the same as the specified value. *value* is an integer with a default setting of 100. The allowed range for *value* is from 1 through 100.
- @MAX_MEMORY_PERCENT - Specifies the maximum amount of query workspace memory that requests in this resource pool can use. *value* is an integer with a default setting of 100. The allowed range for *value* is from 1 through 100.
- @MAX_IOPS_PER_VOLUME - Specifies the maximum I/O operations per second (IOPS) per disk volume to allow for the resource pool. The allowed range for *value* is from 0 through 2^31-1 (2,147,483,647). Specify 0 to remove an IOPS limit for the pool. The default is 0.

Examples

```
--This alters resource pool
USE [msdb]
EXEC dbo.rds_alter_resource_pool
    @pool_name='analytics',
    @MAX_CPU_PERCENT = 10,
    @CAP_CPU_PERCENT = 20,
    @MAX_MEMORY_PERCENT = 50;

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration.
select * from sys.resource_governor_resource_pools
```

Drop resource pool

Usage

```
USE [msdb]
EXEC dbo.rds_drop_resource_pool
@pool_name=value;
```

The following parameter is required:

- `@pool_name` - Is the name of an existing user-defined resource pool.

> **Note**
>
> Dropping Internal or default resource pool isn't allowed in SQL Server.

Examples

```
--This drops resource pool
USE [msdb]
EXEC dbo.rds_drop_resource_pool
@pool_name='analytics'

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
select * from sys.resource_governor_resource_pools
```

Manage workload groups

Workload groups, created and managed with `rds_create_workload_group` and `rds_alter_workload_group`, allow you to set importance levels, memory grants, and other parameters for groups of queries.

Create workload group

Usage

```
USE [msdb]
EXEC dbo.rds_create_workload_group
@group_name = value,
@IMPORTANCE ={ LOW | MEDIUM | HIGH },
@REQUEST_MAX_MEMORY_GRANT_PERCENT =value,
@REQUEST_MAX_CPU_TIME_SEC = value ,
@REQUEST_MEMORY_GRANT_TIMEOUT_SEC = value,
@MAX_DOP = value,
@GROUP_MAX_REQUESTS = value,
@pool_name = value
```

The following parameters are required:

- `@pool_name` - Is the name of an existing user-defined resource pool.
- `@group_name` - Is the name of an existing user-defined workload group.

The following parameters are optional:

- `@IMPORTANCE` - Specifies the relative importance of a request in the workload group. The default value is `MEDIUM`.
- `@REQUEST_MAX_MEMORY_GRANT_PERCENT` - Specifies the maximum amount of query workspace memory that a single request can take from the pool. *`value`* is a percentage of the resource pool size defined by `MAX_MEMORY_PERCENT`. Default value is 25.
- `@REQUEST_MAX_CPU_TIME_SEC` - Specifies the maximum amount of CPU time, in seconds, that a batch request can use. *`value`* must be 0 or a positive integer. The default setting for *`value`* is 0, which means unlimited.
- `@REQUEST_MEMORY_GRANT_TIMEOUT_SEC` - Specifies the maximum time, in seconds, that a query can wait for a memory grant from the query workspace memory to become available. *`value`* must be 0 or a positive integer. The default setting for *`value`*, 0, uses an internal calculation based on query cost to determine the maximum time.
- `@MAX_DOP` - Specifies the maximum degree of parallelism (`MAXDOP`) for parallel query execution. The allowed range for *`value`* is from 0 through 64. The default setting for *`value`*, 0, uses the global setting.
- `@GROUP_MAX_REQUESTS` = Specifies the maximum number of simultaneous requests that are allowed to execute in the workload group. *`value`* must be 0 or a positive integer. The default setting for *`value`* is 0, and allows unlimited requests.
- `@pool_name` = Associates the workload group with the user-defined resource pool identified by *`pool_name`*, or with the `default` resource pool. If *`pool_name`* isn't provided, the workload group is associated with the built-in `default` pool.

Examples

```
--This creates workload group named 'analytics'
USE msdb;
EXEC dbo.rds_create_workload_group
    @group_name = 'analytics',
    @IMPORTANCE = 'HIGH',
```

```
    @REQUEST_MAX_MEMORY_GRANT_PERCENT = 25,
    @REQUEST_MAX_CPU_TIME_SEC = 0,
    @REQUEST_MEMORY_GRANT_TIMEOUT_SEC = 0,
    @MAX_DOP = 0,
    @GROUP_MAX_REQUESTS = 0,
    @pool_name = 'analytics';

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
select * from sys.resource_governor_workload_groups
```

Alter workload group

Usage

```
EXEC msdb.dbo.rds_alter_workload_group
    @group_name = value,
    @IMPORTANCE = 'LOW|MEDIUM|HIGH',
    @REQUEST_MAX_MEMORY_GRANT_PERCENT = value,
    @REQUEST_MAX_CPU_TIME_SEC = value,
    @REQUEST_MEMORY_GRANT_TIMEOUT_SEC = value,
    @MAX_DOP = value,
    @GROUP_MAX_REQUESTS = value,
    @pool_name = value
```

The following parameters are required:

- `@group_name` - Is the name of default or an existing user-defined workload group.

> **Note**
>
> Changing only `REQUEST_MAX_MEMORY_GRANT_PERCENT` parameter on the default workload group is supported. For default workload group the `REQUEST_MAX_MEMORY_GRANT_PERCENT` must be between 1 and 70. No other parameters can be modified in default workload group. All parameters can be modified in the user-defined workload group.

The following parameters are optional:

- @IMPORTANCE - Specifies the relative importance of a request in the workload group. The default value is MEDIUM.
- @REQUEST_MAX_MEMORY_GRANT_PERCENT - Specifies the maximum amount of query workspace memory that a single request can take from the pool. *value* is a percentage of the resource pool size defined by MAX_MEMORY_PERCENT. Default value is 25. On Amazon RDS, REQUEST_MAX_MEMORY_GRANT_PERCENT must be between 1 and 70.
- @REQUEST_MAX_CPU_TIME_SEC - Specifies the maximum amount of CPU time, in seconds, that a batch request can use. *value* must be 0 or a positive integer. The default setting for *value* is 0, which means unlimited.
- @REQUEST_MEMORY_GRANT_TIMEOUT_SEC - Specifies the maximum time, in seconds, that a query can wait for a memory grant from the query workspace memory to become available. *value* must be 0 or a positive integer. The default setting for *value*, 0, uses an internal calculation based on query cost to determine the maximum time.
- @MAX_DOP - Specifies the maximum degree of parallelism (MAXDOP) for parallel query execution. The allowed range for *value* is from 0 through 64. The default setting for *value*, 0, uses the global setting.
- @GROUP_MAX_REQUESTS - Specifies the maximum number of simultaneous requests that are allowed to execute in the workload group. *value* must be 0 or a positive integer. The default setting for *value* is 0, and allows unlimited requests.
- @pool_name - Associates the workload group with the user-defined resource pool identified by *pool_name*.

Examples

Example to Modify default workload group change REQUEST_MAX_MEMORY_GRANT_PERCENT:

```
--Modify default workload group (set memory grant cap to 10%)
USE msdb
EXEC dbo.rds_alter_workload_group
    @group_name = 'default',
    @REQUEST_MAX_MEMORY_GRANT_PERCENT=10;

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
SELECT * FROM sys.resource_governor_workload_groups WHERE name='default';
```

Example to modify non-default workload group:

```
EXEC msdb.dbo.rds_alter_workload_group
    @group_name = 'analytics',
    @IMPORTANCE = 'HIGH',
    @REQUEST_MAX_MEMORY_GRANT_PERCENT = 30,
    @REQUEST_MAX_CPU_TIME_SEC = 3600,
    @REQUEST_MEMORY_GRANT_TIMEOUT_SEC = 60,
    @MAX_DOP = 4,
    @GROUP_MAX_REQUESTS = 100;

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;
```

Example to move a Non-Default Workload Group to another resource pool:

```
EXEC msdb.dbo.rds_alter_workload_group
@group_name = 'analytics',
@pool_name='abc'

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
select * from sys.resource_governor_workload_groups
```

Drop workload group

Usage

```
EXEC msdb.dbo.rds_drop_workload_group
@group_name = value
```

The following parameters are required:

- `@group_name` - Is the name of an existing user-defined workload group.

Examples

```
--Drops a Workload Group:
EXEC msdb.dbo.rds_drop_workload_group
```

```
@group_name = 'analytics';

--Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;

--Validate configuration
select * from sys.resource_governor_workload_groups
```

Create and register classifier function

This procedure creates a resource governor classifier function in master database that routes connections to custom workload groups based on specified criteria (user name, database, host, or application name). If resource governor is enabled and a classifier function is specified in the resource governor configuration, then the function output determines the workload group used for new sessions. In the absence of a classifier function, all sessions are classified into the `default` group.

Features:

- Supports up to two workload groups with their respective routing conditions.
- Combines criterion with `AND` conditions within each group.
- Requires at least one routing criterion per workload group.
- Function name must start with `rg_classifier_`.
- Default group assignment if no conditions match.

The classifier function has the following characteristics and behaviors:

- The function is defined in the server scope (in the master database).
- The function is defined with schema binding.
- The function is evaluated for every new session, even when connection pooling is enabled.
- The function returns the workload group context for the session. The session is assigned to the workload group returned by the classifier for the lifetime of the session.
- If the function returns NULL, default, or the name of a nonexistent workload group, the session is given the default workload group context. The session is also given the default context if the function fails for any reason.
- You can create multiple classifier functions. However, SQL Server allows only one classifier function to be registered at a time.

- The classifier function can't be dropped unless its classifier status is removed using the de-register procedure (`EXEC dbo.msdb.rds_alter_resource_governor_configuration @deregister_function = 1;`) that sets the function name to NULL or another classifier function is registered using (`EXEC dbo.msdb.rds_alter_resource_governor_configuration @classifier_function = <function_name>;`)
- In the absence of a classifier function, all sessions are classified into the default group.
- You can't modify a classifier function while it is referenced in the resource governor configuration. However, you can modify the configuration to use a different classifier function. If you want to make changes to the classifier, consider creating a pair of classifier functions. For example, you might create `rg_classifier_a` and `rg_classifier_b`.

Usage

```
EXEC msdb.dbo.rds_create_classifier_function
@function_name = value,
@workload_group1 = value,
@user_name1 = value,
@db_name1 = value,
@host_name1 = value,
@app_name1 = value,
@workload_group2 = value,
@user_name2 = value,
@db_name2 = value,
@host_name2 = value,
@app_name2 = value
```

The following parameters are required:

- `@function_name` - Name of the classifier function. Must start with `rg_classifier_`
- `@workload_group1` - Name of the first workload group

The following parameters are optional:

(At least one of these criteria must be specified for group 1)

- `@user_name1` - Login name for group 1
- `@db_name1` - Database name for group 1

- @host_name1 - Host name for group 1
- @app_name1 - Application name for group 1

(If group 2 is specified, at least one criterion must be provided)

- @workload_group2 - Name of the second workload group
- @user_name2 - Login name for group 2
- @db_name2 - Database name for group 2
- @host_name2 - Host name for group 2
- @app_name2 - Application name for group 2

> **Note**
>
> System accounts, databases, applications and host are restricted.

Examples

Basic Example with One Workload Group:

```
/*Create a classifier to route all requests from 'PowerBI' app to workload group
'reporting_group'*/

EXEC msdb.dbo.rds_create_classifier_function
@function_name = 'rg_classifier_a',
@workload_group1 = 'reporting_group',
@app_name1 = 'PowerBI';

--Register the classifier
EXEC msdb.dbo.rds_alter_resource_governor_configuration
@classifier_function = 'rg_classifier_a';

-- Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration

/*Query sys.resource_governor_configuration to validate that resource governor is
 enabled and is using the classifier function we created and registered*/

use master
```

```
go
SELECT OBJECT_SCHEMA_NAME(classifier_function_id) AS classifier_schema_name,
       OBJECT_NAME(classifier_function_id) AS classifier_object_name,
       is_enabled
FROM sys.resource_governor_configuration;
```

Drop classifier function

Usage

```
USE [msdb]
EXEC dbo.rds_drop_classifier_function
@function_name = value;
```

The following parameter is required:

- `@function_name` - Is the name of an existing user-defined classifier function

Example

```
EXEC msdb.dbo.rds_drop_classifier_function
@function_name = 'rg_classifier_b';
```

De-register classifier function

Use this procedure to de-register classifier function. After the function is de-registered, new sessions are automatically assigned to the default workload group.

Usage

```
USE [msdb]
EXEC dbo.rds_alter_resource_governor_configuration
@deregister_function = 1;
```

For de-registration the following parameter is required:

- `@deregister_function` must be 1

Example

```
EXEC msdb.dbo.rds_alter_resource_governor_configuration
    @deregister_function = 1;
GO

-- Apply changes
EXEC msdb.dbo.rds_alter_resource_governor_configuration;
```

Reset statistics

Resource governor statistics are cumulative since the last server restart. If you need to collect statistics starting from a certain time, you can reset statistics using the following Amazon RDS stored procedure.

Usage

```
USE [msdb]
EXEC dbo.rds_alter_resource_governor_configuration
@reset_statistics = 1;
```

For reset stats the following parameter is required:

- `@reset_statistics` must be 1

Resource governor configuration changes

When resource governor isn't enabled, `rds_alter_resource_governor_configuration` enables resource governor. Enabling resource governor has the following results:

- The classifier function, if any, is executed for new sessions, assigning them to workload groups.
- The resource limits that are specified in resource governor configuration are honored and enforced.
- The resource limits that are specified in resource governor configuration are honored and enforced.
- Requests that existed before enabling resource governor might be affected by any configuration changes made when resource governor is enabled.
- Existing requests, before enabling resource governor, might be affected by any configuration changes made when resource governor is enabled.

- On RDS for SQL Server, `EXEC msdb.dbo.rds_alter_resource_governor_configuration` must be executed for any resource governor configuration changes to take effect.

Usage

```
USE [msdb]
EXEC dbo.rds_alter_resource_governor_configuration
```

Bind TempDB to a resource pool

You can bind tempdb memory optimized metadata to a specific resource pool using `rds_bind_tempdb_metadata_to_resource_pool` in Amazon RDS SQL Server version 2019 and above.

> **Note**
>
> Memory-optimized tempdb metadata feature must be enabled before binding tempdb metadata to resource pool. To enable this feature on Amazon RDS its a static parameter `tempdb metadata memory-optimized`.

Enable the static parameter on Amazon RDS and perform a reboot without failover for the parameter to take effect:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name test-sqlserver-ee-2022 \
    --parameters "ParameterName='tempdb metadata memory-
optimized',ParameterValue=True,ApplyMethod=pending-reboot"
```

Usage

```
USE [msdb]
EXEC dbo.rds_bind_tempdb_metadata_to_resource_pool
@pool_name=value;
```

The following parameter is required:

- `@pool_name` - Is the name of an existing user-defined resource pool.

> **Note**
>
> This change also requires sql service reboot without failover to take effect, even if Memory-optimized TempDB metadata feature is already enabled.

Unbind TempDB from a resource pool

Unbind tempdb memory optimized metadata from a resource pool.

> **Note**
>
> This change also requires sql service reboot without failover to take effect

Usage

```
USE [msdb]
EXEC dbo.rds_unbind_tempdb_metadata_from_resource_pool
```

Cleanup resource governor

This procedure is to clean up all associated objects after you have removed the resource governor option from the option group. This disables resource governor, reverts default workload group to default settings, remove custom workload groups, resource pools, and classifier functions.

Key features

- Reverts default workload group to default settings
- Disables resource governor
- Removes custom workload groups
- Removes custom resource pools
- Drops classifier functions
- Removes tempdb resource pool binding if enabled

Important

This cleanup can error out if there are active sessions on the workload group. Either wait for the active sessions to finish or terminate the active sessions as per your business requirement. It's recommended to run this during the maintenance window.
This cleanup can error out if a resource pool was bound to tempdb and reboot without failover hasn't been taken place yet. If you bound a resource pool to tempdb or unbound a resource pool from tempdb earlier, perform a reboot without failover to make the change effective. It's recommended to run this during the maintenance window.

Usage

```
USE [msdb]
EXEC dbo.rds_cleanup_resource_governor
```

Considerations for Multi-AZ deployment

RDS for SQL Server replicates resource governor to secondary instance in a Multi-AZ deployment. You can verify when modified and new resource governor last synchronized with the secondary instance.

Use the following query to check the `last_sync_time` of the replication:

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

In the query results, if the sync time is past the resource governor updated or creation time, then the resource governor syncs with the secondary.

To perform a manual DB failover to confirm that the resource governor replicate, wait for the `last_sync_time` to update first. Then, proceed with the Multi-AZ failover.

Considerations for read replicas

- For SQL Server replicas in the same Region as the source DB instance, use the same option group as the source. Changes to the option group propagate to replicas immediately, regardless of their maintenance windows.
- When you create a SQL Server cross-Region replica, RDS creates a dedicated option group for it.

- You can't remove an SQL Server cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for a SQL Server cross-Region replica.
- Resource governor option is non-replicated options. You can add or remove non-replicated options from a dedicated option group.
- When you promote a SQL Server cross-Region read replica, the promoted replica behaves the same as other SQL Server DB instances, including the management of its options.

> **Note**
>
> When using Resource governor on a read replica, you must manually ensure that resource governor has been configured on your read replica using Amazon RDS stored procedures after the option is added to the option group. Resource governor configurations do not automatically replicate to the read replica. Also, the workload on read replica is typically different than the primary instance. Hence, it's recommended to apply the resource configuration on the replica based on your workload and instance type. You can run these Amazon RDS stored procedures on read replica independently to configure resource governor on read replica.

Monitor Microsoft SQL Server resource governor using system views for your RDS for SQL Server instance

Resource Governor statistics are cumulative since the last server restart. If you need to collect statistics starting from a certain time, you can reset statistics using the following Amazon RDS stored procedure:

```
EXEC msdb.dbo.rds_alter_resource_governor_configuration
@reset_statistics = 1;
```

Resource pool runtime statistics

For each resource pool, resource governor tracks CPU and memory utilization, out-of-memory events, memory grants, I/O, and other statistics. For more information, see sys.dm_resource_governor_resource_pools.

The following query returns a subset of available statistics for all resource pools:

```
SELECT rp.pool_id,
```

```
        rp.name AS resource_pool_name,
        wg.workload_group_count,
        rp.statistics_start_time,
        rp.total_cpu_usage_ms,
        rp.target_memory_kb,
        rp.used_memory_kb,
        rp.out_of_memory_count,
        rp.active_memgrant_count,
        rp.total_memgrant_count,
        rp.total_memgrant_timeout_count,
        rp.read_io_completed_total,
        rp.write_io_completed_total,
        rp.read_bytes_total,
        rp.write_bytes_total,
        rp.read_io_stall_total_ms,
        rp.write_io_stall_total_ms
FROM sys.dm_resource_governor_resource_pools AS rp
OUTER APPLY (
            SELECT COUNT(1) AS workload_group_count
            FROM sys.dm_resource_governor_workload_groups AS wg
            WHERE wg.pool_id = rp.pool_id
            ) AS wg;
```

Disabling Microsoft SQL Server resource governor for your RDS for SQL Server instance

When you disable resource governor on RDS for SQL Server, the service stops managing workload resources. Before you disable resource governor, review how this affects your database connections and configurations.

Disabling resource governor has the following results:

- The classifier function isn't executed when a new connection is opened.
- New connections are automatically classified into the default workload group.
- All existing workload group and resource pool settings are reset to their default values.
- No events are fired when limits are reached.
- Resource governor configuration changes can be made, but the changes don't take effect until resource governor is enabled.

To disable resource governor, remove the `RESOURCE_GOVERNOR` option from its option group.

Console

The following procedure removes the RESOURCE_GOVERNOR option.

To remove the RESOURCE_GOVERNOR option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the RESOURCE_GOVERNOR option (`resource-governor-ee-2022` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **RESOURCE_GOVERNOR** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it during the next maintenance window.
7. Choose **Delete**.

CLI

The following procedure removes the RESOURCE_GOVERNOR option.

To remove the RESOURCE_GOVERNOR option from its option group

- Run one of the following commands.

  Example

  For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name resource-governor-ee-2022 \
    --options RESOURCE_GOVERNOR \
    --apply-immediately
```

  For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name resource-governor-ee-2022 ^
    --options RESOURCE_GOVERNOR ^
```

```
    --apply-immediately
```

Best practices for configuring resource governor on RDS for SQL Server

To control resource consumption, RDS for SQL Server supports Microsoft SQL Server resource governor. The following best practices help you avoid common configuration issues and optimize database performance.

1. Resource governor configuration is stored in the `master` database. We recommend that you always save a copy of resource governor configuration scripts separately.
2. The classifier function extends login processing time hence it's recommended to avoid complex logic in the classifier. An overly complex function can cause login delays or connection timeouts including Amazon RDS automation sessions. This can impact the ability of Amazon RDS automation to monitor the instance health. Hence, it's always recommended to test the classifier function in a pre-production environment before implementing in production environments.
3. Avoid setting high values (above 70) for `REQUEST_MAX_MEMORY_GRANT_PERCENT` in workload groups, as this can prevent the database instance from allocating sufficient memory for other concurrent queries, potentially resulting in memory grant timeout errors (Error 8645). Conversely, setting this value too low (less than 1) or to 0 might prevent queries that need memory workspace (like those involving sort or hash operations) from executing properly in user-defined workload groups. RDS enforces these limits by restricting values to between 1 and 70 on default workload groups.
4. For binding tempdb to resource pool, after binding memory optimized tempdb metadata to a pool, the pool might reach its maximum setting, and any queries that use `tempdb` might fail with out-of-memory errors. Under certain circumstances, the SQL Server could potentially stop if an out-of-memory error occurs. To reduce the chance of this happening, set the memory pool's `MAX_MEMORY_PERCENT` to a high value.

Common DBA tasks for Amazon RDS for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

> **Note**
>
> When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

Topics

- Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS
- Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor
- Changing the db_owner to the rdsa account for your Amazon RDS for SQL Server database
- Managing collations and character sets for Amazon RDS for Microsoft SQL Server
- Creating a database user for Amazon RDS for SQL Server
- Determining a recovery model for your Amazon RDS for SQL Server database
- Determining the last failover time for Amazon RDS for SQL Server
- Troubleshooting point-in-time-recovery failures due to a log sequence number gap
- Deny or allow viewing database names for Amazon RDS for SQL Server
- Disabling fast inserts during bulk loading for Amazon RDS for SQL Server
- Dropping a database in an Amazon RDS for Microsoft SQL Server DB instance
- Renaming a Amazon RDS for Microsoft SQL Server database in a Multi-AZ deployment
- Resetting the db_owner role membership for master user for Amazon RDS for SQL Server
- Restoring license-terminated DB instances for Amazon RDS for SQL Server
- Transitioning a Amazon RDS for SQL Server database from OFFLINE to ONLINE
- Using change data capture for Amazon RDS for SQL Server
- Using SQL Server Agent for Amazon RDS

- Working with trace and dump files for Amazon RDS for SQL Server

Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see Connecting to your Microsoft SQL Server DB instance.

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

> **Note**
>
> You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see tempdb database in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see Optimizing tempdb performance in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the rds_shrink_tempdbfile procedure, or you can set the SIZE property,

Using the rds_shrink_tempdbfile procedure

You can use the Amazon RDS procedure msdb.dbo.rds_shrink_tempdbfile to shrink the tempdb database. You can only call rds_shrink_tempdbfile if you have CONTROL access to tempdb. When you call rds_shrink_tempdbfile, there is no downtime for your DB instance.

The rds_shrink_tempdbfile procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
@temp_filename	SYSNAME	—	required	The logical name of the file to shrink.
@target_size	int	null	optional	The new size for the file, in megabytes.

The following example gets the names of the files for the tempdb database.

```
use tempdb;
GO

select name, * from sys.sysfiles;
GO
```

The following example shrinks a tempdb database file named test_file, and requests a new size of 10 megabytes:

```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

Setting the SIZE property

You can also shrink the tempdb database by setting the SIZE property and then restarting your DB instance. For more information about restarting your DB instance, see Rebooting a DB instance.

The following example demonstrates setting the SIZE property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

TempDB configuration for Multi-AZ deployments

If your RDS for SQL Server DB instance is in a Multi-AZ Deployment using Database Mirroring (DBM) or Always On Availability Groups (AGs), keep in mind the following considerations for using the tempdb database.

You can't replicate tempdb data from your primary DB instance to your secondary DB instance. When you fail over to a secondary DB instance, tempdb on that secondary DB instance will be empty.

You can synchronize the configuration of the tempdb database options, including its file sizing and autogrowth settings, from your primary DB instance to your secondary DB instance. Synchronizing the tempDB configuration is supported on all RDS for SQL Server versions. You can turn on automatic synchronization of the tempdb configuration by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'TempDbFile';
```

> **Important**
>
> Before using the rds_set_system_database_sync_objects stored procedure, ensure you've set your preferred tempdb configuration on your primary DB instance, rather than on your secondary DB instance. If you made the configuration change on your secondary DB instance, your preferred tempdb configuration could be deleted when you turn on automatic synchronization.

You can use the following function to confirm whether automatic synchronization of the tempdb configuration is turned on:

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

When automatic synchronization of the tempdb configuration is turned on, there will be a return value for the object_class field. When it's turned off, no value is returned.

You can use the following function to find the last time objects were synchronized, in UTC time:

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, if you modified the tempdb configuration at 01:00 and then run the rds_fn_server_object_last_sync_time function, the value returned for last_sync_time should be after 01:00, indicating that an automatic synchronization occurred.

If you are also using SQL Server Agent job replication, you can enable replication for both SQL Agent jobs and the tempdb configuration by providing them in the @object_type parameter:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types =
 'SQLAgentJob,TempDbFile';
```

For more information on SQL Server Agent job replication, see Turning on SQL Server Agent job replication.

As an alternative to using the rds_set_system_database_sync_objects stored procedure to ensure that tempdb configuration changes are automatically synchronized, you can use one of the following manual methods:

> **Note**
>
> We recommend turning on automatic synchronization of the tempdb configuration by using the rds_set_system_database_sync_objects stored procedure. Using automatic synchronization prevents the need to perform these manual tasks each time you change your tempdb configuration.

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.

  For more information, see Modifying an Amazon RDS DB instance.

- First modify `tempdb` in the original primary instance, then fail over manually, and finally modify `tempdb` in the new primary instance. This method involves downtime.

  For more information, see Rebooting a DB instance.

Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see Database Engine Tuning Advisor in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is

important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

Running a client-side trace on a SQL Server DB instance

To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose **New Trace**. In the **Connect to Server** dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, TSQL_Replay, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.

   For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see Database Engine Tuning Advisor in the Microsoft documentation.
4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.
5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on you DB instance.

Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT

EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
   EXEC sp_trace_setevent @traceid, 10, 1, @on
   EXEC sp_trace_setevent @traceid, 10, 2, @on
   EXEC sp_trace_setevent @traceid, 10, 3, @on
 . . .
   EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
   EXEC sp_trace_setstatus @traceid, 1
   END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1

IF @traceid IS NOT NULL BEGIN
   EXEC sp_trace_setstatus @traceid, 0
   EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```

To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

Running Tuning Advisor with a trace

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of **`dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`**. The example includes the master user name **`admin`** and the master user password **`test`**, the example database to tune is named machine named **`C:\RDSTrace.trc`**. The example command line code also specifies a trace session named **`RDSTrace1`** and specifies output files to the local machine named **`RDSTrace.sql`** for the SQL output script, **`RDSTrace.txt`** for a result file, and **`RDSTrace.xml`** for an XML file of the analysis. There is also an error table specified on the RDSDTA database named **`RDSTraceErrors`**.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -
if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\
 RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named **`RDSTrace`** which is on the **`RDSDTA`** database.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -it
 RDSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\
 RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

For a full list of dta utility command-line parameters, see dta Utility in the Microsoft documentation.

Changing the db_owner to the rdsa account for your Amazon RDS for SQL Server database

When you create or restore a database in an RDS for SQL Server DB instance, Amazon RDS sets the owner of the database to `rdsa`. If you have a Multi-AZ deployment using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs), Amazon RDS sets the owner of the database on the secondary DB instance to `NT AUTHORITY\SYSTEM`. The owner of the secondary database can't be changed until the secondary DB instance is promoted to the primary role. In most cases, setting the owner of the database to `NT AUTHORITY\SYSTEM` isn't problematic when executing queries, however, can throw errors when executing system stored procedures such as `sys.sp_updatestats` that require elevated permissions to execute.

You can use the following query to identify the owner of the databases owned by `NT AUTHORITY\SYSTEM`:

```
SELECT name FROM sys.databases WHERE SUSER_SNAME(owner_sid) = 'NT AUTHORITY\SYSTEM';
```

You can use the Amazon RDS stored procedure `rds_changedbowner_to_rdsa` to change the owner of the database to `rdsa`. The following databases are not allowed to be used with `rds_changedbowner_to_rdsa`: `master, model, msdb, rdsadmin, rdsadmin_ReportServer, rdsadmin_ReportServerTempDB, SSISDB`.

To change the owner of the database to `rdsa`, call the `rds_changedbowner_to_rdsa` stored procedure and provide the name of the database.

Example usage:

```
exec msdb.dbo.rds_changedbowner_to_rdsa 'TestDB1';
```

The following parameter is required:

- @db_name – The name of the database to change the owner of the database to `rdsa`.

Important

You can't use `rds_changedbowner_to_rdsa` to change ownership of a database to a login other than `rdsa`. For example, you can't change the ownership to the login with which you created the database. To restore lost membership in the `db_owner` role for your master user when no other database user can be used to grant the membership, reset the master user password to obtain membership in the `db_owner` role. For more information, see Resetting the db_owner role membership for master user for Amazon RDS for SQL Server.

Managing collations and character sets for Amazon RDS for Microsoft SQL Server

This topic provide guidance on how to manage collations and character sets for Microsoft SQL Server in Amazon RDS. It explains how to configure collations during database creation and modify them later, ensuring proper handling of text data based on language and locale requirements. Additionally, it covers best practices for maintaining compatibility and performance in SQL Server environments in Amazon RDS.

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

Topics

- Server-level collation for Microsoft SQL Server
- Database-level collation for Microsoft SQL Server

Server-level collation for Microsoft SQL Server

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to SQL_Latin1_General_CP1_CI_AS. The server collation is applied by default to all databases and database objects.

Note

You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

Collation	Description
Arabic_CI_AS	Arabic, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Chinese_PRC_BIN2	Chinese-PRC, binary code point sort order
Chinese_PRC_CI_AS	Chinese-PRC, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Chinese_Taiwan_Stroke_CI_AS	Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Danish_Norwegian_CI_AS	Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Danish_Norwegian_CI_AS_KS	Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive
Danish_Norwegian_CI_AS_KS_WS	Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-sensitive, width-sensitive
Danish_Norwegian_CI_AS_WS	Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-insensitive, width-sensitive
Danish_Norwegian_CS_AI	Danish-Norwegian, case-sensitive, accent-insensitive, kanatype-insensitive, width-insensitive
Danish_Norwegian_CS_AI_KS	Danish-Norwegian, case-sensitive, accent-insensitive, kanatype-sensitive, width-insensitive
Finnish_Swedish_100_BIN	Finnish-Swedish-100, binary sort
Finnish_Swedish_100_BIN2	Finnish-Swedish-100, binary code point comparison sort

Collation	Description
Finnish_Swedish_100_CI_AI	Finnish-Swedish-100, case-insensitive, accent-insensitive, kanatype-insensitive, width-ins ensitive
Finnish_Swedish_100_CI_AS	Finnish-Swedish-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-ins ensitive
Finnish_Swedish_CI_AS	Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
French_CI_AS	French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Greek_CI_AS	Greek, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Greek_CS_AS	Greek, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Hebrew_BIN	Hebrew, binary sort
Hebrew_CI_AS	Hebrew, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_BIN	Japanese, binary sort
Japanese_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_CS_AS	Japanese, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive

Collation	Description
Japanese_XJIS_140_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector insensitive
Japanese_XJIS_140_CI_AS_KS_VSS	Japanese, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, variation selector sensitive
Japanese_XJIS_140_CI_AS_VSS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector sensitive
Japanese_XJIS_140_CS_AS_KS_WS	Japanese, case-sensitive, accent-sensitive, kanatype-sensitive, width-sensitive, supplementary characters, variation selector insensitive
Korean_Wansung_CI_AS	Korean-Wansung, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Latin1_General_100_BIN	Latin1-General-100, binary sort
Latin1_General_100_BIN2	Latin1-General-100, binary code point sort order
Latin1_General_100_BIN2_UTF8	Latin1-General-100, binary code point sort order, UTF-8 encoded
Latin1_General_100_CI_AS	Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-ins ensitive

Collation	Description
Latin1_General_100_CI_AS_SC_UTF8	Latin1-General-100, case-insensitive, accent-sensitive, supplementary characters, UTF-8 encoded
Latin1_General_BIN	Latin1-General, binary sort
Latin1_General_BIN2	Latin1-General, binary code point sort order
Latin1_General_CI_AI	Latin1-General, case-insensitive, accent-in sensitive, kanatype-insensitive, width-ins ensitive
Latin1_General_CI_AS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Latin1_General_CI_AS_KS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-sensitive, width-insensitive
Latin1_General_CS_AS	Latin1-General, case-sensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Modern_Spanish_CI_AS	Modern-Spanish, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive
Polish_CI_AS	Polish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
SQL_1xCompat_CP850_CI_AS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 49 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP1_CI_AI	Latin1-General, case-insensitive, accent-in sensitive, kanatype-insensitive, width-ins ensitive for Unicode Data, SQL Server Sort Order 54 on Code Page 1252 for non-Unicode Data

Collation	Description
SQL_Latin1_General_CP1_CI_AS (default)	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 52 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP1_CS_AS	Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 51 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP437_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 34 on Code Page 437 for non-Unicode Data
SQL_Latin1_General_CP850_BIN	Latin1-General, binary sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_BIN2	Latin1-General, binary code point sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 44 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 42 on Code Page 850 for non-Unicode Data

Collation	Description
SQL_Latin1_General_Pref_CP850_CI_AS	Latin1-General-Pref, case-insensitive, accent-sensitive, kanatype-insensitive, width-ins ensitive for Unicode Data, SQL Server Sort Order 183 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP1256_CI_AS	Latin1-General, case-insensitive, accent-se nsitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 146 on Code Page 1256 for non-Unicode Data
SQL_Latin1_General_CP1255_CS_AS	Latin1-General, case-sensitive, accent-se nsitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 137 on Code Page 1255 for non-Unicode Data
Thai_CI_AS	Thai, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Turkish_CI_AS	Turkish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive

You can also retrieve the list of supported collations programmatically using the AWS CLI:

```
aws rds describe-db-engine-versions --engine sqlserver-ee --list-supported-character-
sets --query 'DBEngineVersions[].SupportedCharacterSets[].CharacterSetName' | sort -u
```

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then enter the collation in the **Collation** field. For more information, see Creating an Amazon RDS DB instance.
- If you're using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see create-db-instance.

- If you're using the Amazon RDS API, use the `CharacterSetName` parameter with the `CreateDBInstance` operation. For more information, see CreateDBInstance.

Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is SQL_Latin1_General_CP1_CI_AS, you can change it to Mohawk_100_CI_AS for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the AccountName column to Mohawk_100_CI_AS

```
CREATE TABLE [dbo].[Account]
 (
     [AccountID] [nvarchar](10) NOT NULL,
     [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
 ) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in NCHAR, NVARCHAR, and NTEXT data types. For example, if you need CJK support, use these Unicode data types for character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- Working with collations
- Collation and international terminology
- Using SQL Server collations
- International considerations for databases and database engine applications

Creating a database user for Amazon RDS for SQL Server

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see Adding a user to the SQLAgentUser role.

Note

If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see Resetting the db_owner role membership for master user for Amazon RDS for SQL Server.
It is not a best practice to clone master user permissions in your applications. For more information, see How to clone master user permissions in Amazon RDS for SQL Server.

Determining a recovery model for your Amazon RDS for SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked.

It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to `0` days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to `0` days, RDS resets the recovery model to SIMPLE.

Important

Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL.

This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see Recovery models (SQL Server) in the Microsoft documentation.

Determining the last failover time for Amazon RDS for SQL Server

To determine the last failover time, use the following stored procedure:

```
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

Output parameter	Description
errorlog_available_from	Shows the time from when error logs are available in the log directory.
recent_failover_time	Shows the last failover time if it's available from the error logs. Otherwise it shows `null`.

> **Note**
>
> The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

Troubleshooting point-in-time-recovery failures due to a log sequence number gap

When attempting point-in-time-recovery (PITR) in RDS for SQL Server, you might encounter failures due to gaps in log sequence numbers (LSNs). These gaps prevent RDS from restoring your database to the requested time and RDS places your restoring instance in `incompatible-restore` state.

Common causes for this issue are:

- Manual changes to the database recovery model.
- Automatic recovery model changes by RDS due to insufficient resources for completing transaction log backups.

To identify LSN gaps in your database, run this query:

```
SELECT * FROM msdb.dbo.rds_fn_list_tlog_backup_metadata(database_name)
ORDER BY backup_file_time_utc desc;
```

If you discover an LSN gap, you can:

- Choose a restore point before the LSN gap.
- Wait and restore to a point after the next instance backup completes.

To prevent this issue, we recommend you don't manually change the recovery model of your RDS for SQL Server databases, as it interrupts instance durability. We also recommend you choose an instance type with sufficient resources for your workload to ensure regular transaction log backups.

For more information about transaction log management, see SQL Server transaction log architecture and management guide in the Microsoft SQL Server documentation.

Deny or allow viewing database names for Amazon RDS for SQL Server

The master user cannot set `DENY VIEW ANY DATABASE TO LOGIN`
to hide databases from a user.
To change this permission, use the following stored procedure instead:

- Denying database view access to *LOGIN*:

```
EXEC msdb.dbo.rds_manage_view_db_permission @permission='DENY',
 @server_principal='LOGIN'

go
```

- Allowing database view access to *LOGIN*:

```
EXEC msdb.dbo.rds_manage_view_db_permission @permission='GRANT',
 @server_principal='LOGIN'
```

```
go
```

Consider the following when using this stored procedure:

- Database names are hidden from the SSMS and internal DMV (dynamic management views). However, database names are still visible from audit, logs and metadata tables. These are secured `VIEW ANY DATABASE` server permissions. For more information, see DENY Server Permissions.
- Once the permission is reverted to `GRANT` (allowed), the *`LOGIN`* can view all databases.
- If you delete and recreate *`LOGIN`*, the view permission related to the LOGIN is reset to `ALLOW`.
- For Multi-AZ instances, set the `DENY` or `GRANT` permission only for the *`LOGIN`* on the primary host. The changes are propagated to the secondary host automatically.
- This permission only changes whether a login can view the database names. However, access to databases and objects within are managed separately.

Disabling fast inserts during bulk loading for Amazon RDS for SQL Server

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see Parameter groups for Amazon RDS.

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see DBCC TRACEON - trace flags in the Microsoft documentation.

Dropping a database in an Amazon RDS for Microsoft SQL Server DB instance

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```
--replace your-database-name with the name of the database you want to drop
EXECUTE msdb.dbo.rds_drop_database  N'your-database-name'
```

> **Note**
>
> Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

To grant backup and restore allowance to other users, follow this procedure:

```
USE master
GO
CREATE LOGIN user1 WITH PASSWORD=N'changeThis', DEFAULT_DATABASE=master,
 CHECK_EXPIRATION=OFF, CHECK_POLICY=OFF
GO
USE msdb
GO
CREATE USER user1 FOR LOGIN user1
GO
use msdb
GO
GRANT EXECUTE ON msdb.dbo.rds_backup_database TO user1
GO
GRANT EXECUTE ON msdb.dbo.rds_restore_database TO user1
GO
```

Renaming a Amazon RDS for Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running `rdsadmin.dbo.rds_modify_db_name`.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance.

> **Note**
>
> If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running `rdsadmin.dbo.rds_modify_db_name`.
> You can't rename a database on a read replica source instance.

Example: In the following example, the `rdsadmin.dbo.rds_modify_db_name` stored procedure renames a database from **MOO** to **ZAR**. This is similar to running the statement `DDL ALTER DATABASE [MOO] MODIFY NAME = [ZAR]`.

```
EXEC rdsadmin.dbo.rds_modify_db_name N'MOO', N'ZAR'
GO
```

Resetting the db_owner role membership for master user for Amazon RDS for SQL Server

If you lock your master user out of the `db_owner` role membership on your RDS for SQL Server database and no other database user can grant the membership, you can restore lost membership by modifying the DB instance master user password.

By changing the DB instance master user password, RDS grants the `db_owner` membership to the databases in the DB instance that might have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Restoring license-terminated DB instances for Amazon RDS for SQL Server

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

You can restore from a snapshot of Standard Edition to either Standard Edition or Enterprise Edition.

You can restore from a snapshot of Enterprise Edition to either Standard Edition or Enterprise Edition.

To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format *instance_name*`-final-snapshot`. For example, if your DB instance name is **`mytest.cdxgahslksma.us-east-1.rds.com`**, the final snapshot is called **`mytest-final-snapshot`** and is located in the same AWS Region as the original DB instance.
4. For **Actions**, choose **Restore Snapshot**.

   The **Restore DB Instance** window appears.
5. For **License Model**, choose **license-included**.
6. Choose the SQL Server DB engine that you want to use.
7. For **DB Instance Identifier**, enter the name for the restored DB instance.
8. Choose **Restore DB Instance**.

For more information about restoring from a snapshot, see Restoring to a DB instance.

Transitioning a Amazon RDS for SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from `OFFLINE` to `ONLINE`.

SQL Server method	Amazon RDS method
ALTER DATABASE *db_name* SET ONLINE;	EXEC rdsadmin.dbo.rds_set_database_online *db_name*

Using change data capture for Amazon RDS for SQL Server

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see Change data capture in the Microsoft documentation. Before you use CDC with your Amazon RDS DB instances, enable it in the database by running `msdb.dbo.rds_cdc_enable_db`. After CDC is enabled, any user who is db_owner of that database can enable or disable CDC on tables in that database.

> **Important**
>
> During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores and point-in-time restores. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

To grant CDC permissions to a user, use the following procedure:

```
go
  GRANT EXECUTE ON msdb.dbo.rds_cdc_enable_db TO User1
  GRANT EXECUTE ON msdb.dbo.rds_cdc_disable_db TO User1
```

Topics

- Tracking tables with change data capture
- Change data capture jobs
- Change data capture for Multi-AZ instances

Tracking tables with change data capture

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running sys.sp_cdc_enable_table.

```
--Begin tracking a table
exec sys.sp_cdc_enable_table
   @source_schema           = N'source_schema'
,  @source_name             = N'source_name'
,  @role_name               = N'role_name'

--The following parameters are optional:

--, @capture_instance       = 'capture_instance'
--, @supports_net_changes   = supports_net_changes
--, @index_name             = 'index_name'
--, @captured_column_list   = 'captured_column_list'
--, @filegroup_name         = 'filegroup_name'
--, @allow_partition_switch = 'allow_partition_switch'
;
```

To view the CDC configuration for your tables, run sys.sp_cdc_help_change_data_capture.

```
--View CDC configuration
exec sys.sp_cdc_help_change_data_capture

--The following parameters are optional and must be used together.
--  'schema_name', 'table_name'
```

```
;
```

For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- Change data capture stored procedures (Transact-SQL)
- Change data capture functions (Transact-SQL)
- Change data capture tables (Transact-SQL)

Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (`db_owner`) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as sp_cdc_enable_table and sp_cdc_start_job. To change CDC job parameters, like `maxtrans` and `maxscans`, you can use sp_cdc_change_job..

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- sys.dm_cdc_errors
- sys.dm_cdc_log_scan_sessions
- sysjobs
- sysjobhistory

Change data capture for Multi-AZ instances

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the `database_id`. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```
-- Show configuration for each parameter on either primary and secondary replicas.
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to *`1000`*:

```
--To set values on secondary. These are used after failover.
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```

To set the CDC job parameters on the principal, use sys.sp_cdc_change_job instead.

Using SQL Server Agent for Amazon RDS

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see SQL Server Agent in the Microsoft documentation.

Note

Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.
In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see Turning on SQL Server Agent job replication.
Multi-AZ deployments have a limit of 10,000 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting Support. Open the AWS Support Center page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose **View History**.

Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
- Email notifications through SQL Server Agent aren't available from a DB instance.
- SQL Server Agent alerts and operators aren't supported.
- Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.
- Currently, RDS for SQL Server does not support the use SQL Server Agent tokens.

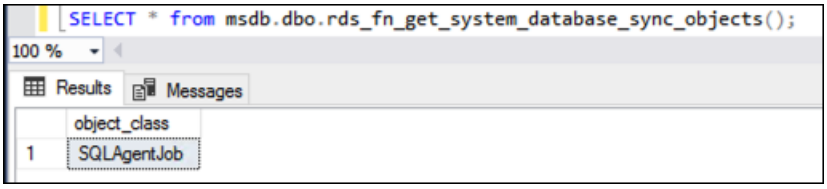
Turning on SQL Server Agent job replication

You can turn on SQL Server Agent job replication by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob';
```

You can run the stored procedure on all SQL Server versions supported by Amazon RDS for SQL Server. Jobs in the following categories are replicated:

- [Uncategorized (Local)]
- [Uncategorized (Multi-Server)]
- [Uncategorized]
- Data Collector
- Database Engine Tuning Advisor
- Database Maintenance
- Full-Text



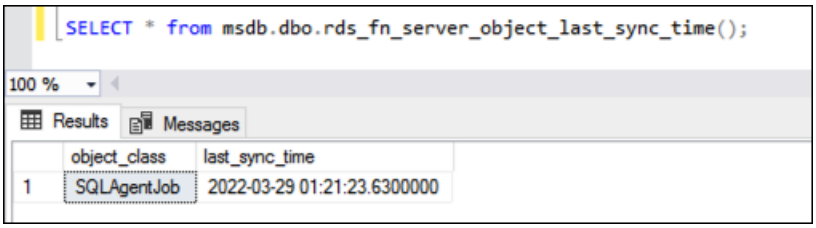
Only jobs that use T-SQL job steps are replicated. Jobs with step types such as SQL Server Integration Services (SSIS), SQL Server Reporting Services (SSRS), Replication, and PowerShell aren't replicated. Jobs that use Database Mail and server-level objects aren't replicated.

> **Important**
>
> The primary host is the source of truth for replication. Before turning on job replication, make sure that your SQL Server Agent jobs are on the primary. If you don't do this, it could lead to the deletion of your SQL Server Agent jobs if you turn on the feature when newer jobs are on the secondary host.

You can use the following function to confirm whether replication is turned on.

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

The T-SQL query returns the following if SQL Server Agent jobs are replicating. If they're not replicating, it returns nothing for `object_class`.



You can use the following function to find the last time objects were synchronized in UTC time.

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, suppose that you modify a SQL Server Agent job at 01:00. You expect the most recent synchronization time to be after 01:00, indicating that synchronization has taken place.

After synchronization, the values returned for `date_created` and `date_modified` on the secondary node are expected to match.

If you are also using `tempdb` replication, you can enable replication for both SQL Agent jobs and the `tempdb` configuration by providing them in the `@object_type` parameter:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types =
 'SQLAgentJob,TempDbFile';
```

For more information on `tempdb` replication, see TempDB configuration for Multi-AZ deployments.

SQL Server Agent roles

RDS for SQL Server supports the following SQL Server Agent roles with different levels of permissions for managing jobs:

- **SQLAgentUserRole**

  Permissions

  - Create and manage their own jobs, schedules, and operators
  - View the properties of their own jobs and schedules
  - Cannot view or manage jobs created by other users

  This role is suitable for users who need to create and manage their own jobs but do not require access to jobs created by other users.

- **SQLAgentReaderRole**

  Permissions

  - All permissions of SQLAgentUserRole
  - View a list of all jobs and schedules, including those created by others

- View the properties of all jobs
- Review job history

This role is suitable for users who need to monitor the status of all jobs but do not need to manage them.

- **SQLAgentOperatorRole**

  Permissions

  - All permissions of SQLAgentUserRole and SQLAgentReaderRole
  - Execute, stop, or start jobs
  - Manage job history
  - Enable/disable jobs and schedules
  - View operators and proxies

  This role provides the most comprehensive permissions and is suitable for users who need to have full control over all jobs.

Use the following command to assign the roles to your SQL Server login:

```
USE msdb;
EXEC sp_addrolemember 'SQLAgentOperatorRole', 'username';
```

Managing SQLAgentOperatorRole in RDS for SQL Server

To view the current jobs, you must add the SQLAgentOperatorRole to your SQL Server login and remove it before disconnecting from your database.

To visualize the SQL Server Agent tree in the SQL Server Management Studio, follow these instructions:

View SQL Server Agent on SQL Server Management Studio (SSMS)

1. Using the RDS master credentials, login into the RDS SQL Server instance and grant the desired user the SQLAgentUserRole.

   ```
   USE msdb
   GO
   IF NOT EXISTS(SELECT name FROM sys.database_principals WHERE name = 'UserName')
   ```

```
BEGIN
CREATE USER UserName FROM LOGIN UserName
END
GO
ALTER ROLE SQLAgentUserRole ADD MEMBER UserName
GO
GRANT ALTER ON ROLE::[SQLAgentOperatorRole] to UserName
GO
```

These commands create the user on the `msdb` database, in case it doesn't exists. It also adds the user on the SQLAgentUserRole, so the SQL Server Agent tree on SSMS can be seen. Finally, it grants alter permissions on the SQLAgentOperatorRole to the user. This allows the user to add/remove itself from that role.

2. To add yourself to the above-mentioned role, connect to the RDS SQL Server instance, with the user that needs to see the jobs, and run the following script.

```
use msdb
go
ALTER ROLE SQLAgentOperatorRole ADD MEMBER UserName
GO
```

After this, right click on the **Jobs** folder, and choose **Refresh**.

3. When you perform this action, the **Jobs** tab displays a **+** (plus) button. Click to expand the the list of SQL Server Agent Jobs.

4. **Important**

   Before you disconnect from the RDS SQL Server instance, you need to remove yourself from the SQLAgentOperatorRole.

   To remove your login from the SQLAgentOperatorRole, run the following query before disconnecting or closing the Management Studio:

```
USE msdb
GO
ALTER ROLE SQLAgentOperatorRole DROP MEMBER UserName
GO
```

For more information, see Leveraging SQLAgentOperatorRole in RDS SQL Server.

Adding a user to the SQLAgentUser role

To allow an additional login or user to use SQL Server Agent, log in as the master user and do the following:

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the `SQLAgentUserRole` using the `sp_addrolemember` system stored procedure.

For example, suppose that your master user name is **`admin`** and you want to give access to SQL Server Agent to a user named **`theirname`** with a password **`theirpassword`**. In that case, you can use the following procedure.

To add a user to the SQLAgentUser role

1. Log in as the master user.
2. Run the following commands:

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login
 theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
--Added database user theirname in msdb to SQLAgentUserRole in msdb
EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
```

Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database
 'mssqlsystemresource', schema 'sys'.
```

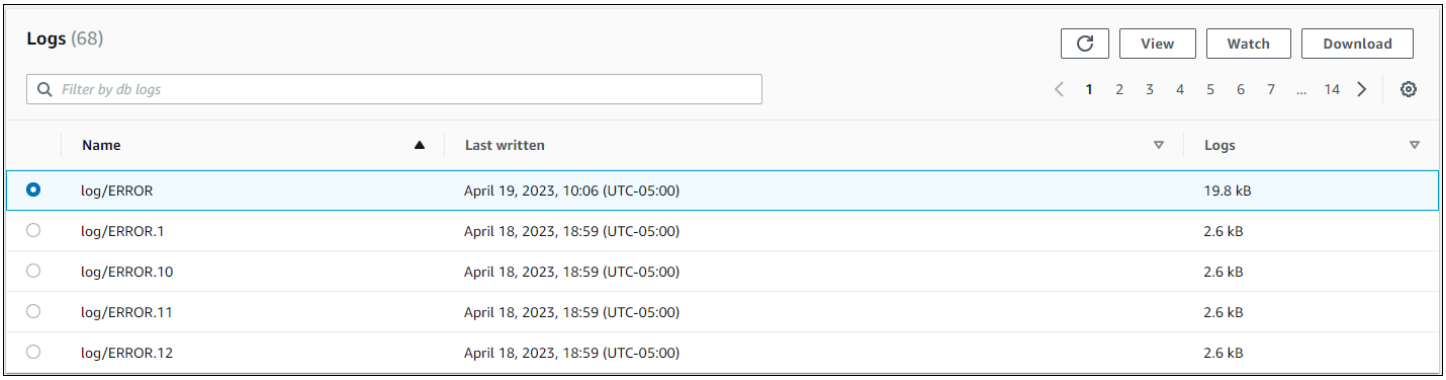
As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (`xp_regread`) for which RDS isn't authorized.

> **Note**
>
> On RDS for SQL Server, only members of the sysadmin role are allowed to update or delete jobs owned by a different login. For more information, see Leveraging SQLAgentOperatorRole in RDS SQL Server.

To delete a SQL Server Agent job

- Run the following T-SQL statement:

```
EXEC msdb..sp_delete_job @job_name = 'job_name';
```



Working with Amazon RDS for Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs, Microsoft SQL Server error logs, and SQL Server Reporting Services (SSRS) logs.

Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.

Only the latest log is active for watching. For example, suppose you have the following logs shown:

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see Amazon S3 basics in the *Amazon Simple Storage Service Getting Started Guide* and click **Get Started**.

Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure `rds_read_error_log` with the following parameters:

- **`@index`** – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- **`@type`** – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

Example

The following example requests the current error log.

```
EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
```

For more information on SQL Server errors, see Database engine errors in the Microsoft documentation.

Working with trace and dump files for Amazon RDS for SQL Server

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

Generating a trace SQL query

```
declare @rc int
declare @TraceID int
declare @maxfilesize bigint

set @maxfilesize = 5

exec @rc = sp_trace_create @TraceID output,  0, N'D:\rdsdbdata\log\rdstest',
 @maxfilesize, NULL
```

Viewing an open trace

```
select * from ::fn_trace_getinfo(default)
```

Viewing trace contents

```
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```
exec rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.

Amazon RDS for MySQL

Amazon RDS supports several versions of MySQL for DB instances. For complete information about the supported versions, see MySQL on Amazon RDS versions.

To create an Amazon RDS for MySQL DB instance, use the Amazon RDS management tools or interfaces. You can then do the following:

- Resize your DB instance
- Authorize connections to your DB instance
- Create and restore from backups or snapshots
- Create Multi-AZ secondaries
- Create read replicas
- Monitor the performance of your DB instance

To store and access the data in your DB instance, you use standard MySQL utilities and applications.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications. You can use RDS for MySQL databases to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. In addition, Amazon RDS for MySQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

For information about the features in each version of MySQL, see The main features of MySQL in the MySQL documentation.

Before creating a DB instance, complete the steps in Setting up your Amazon RDS environment. When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots

- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MySQL inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MySQL DB instance by turning on various options. Amazon RDS supports Multi-AZ deployments for MySQL as a high-availability, failover solution.

> **Important**
>
> To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

MySQL feature support on Amazon RDS

RDS for MySQL supports most of the features and capabilities of MySQL. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **`MySQL 2022`**.

> **Note**
>
> The following lists are not exhaustive.

Topics

- MySQL feature support on Amazon RDS for MySQL major versions
- Supported storage engines for RDS for MySQL
- Using memcached and other options with MySQL on Amazon RDS
- InnoDB cache warming for MySQL on Amazon RDS
- Inclusive language changes for RDS for MySQL 8.4
- MySQL features not supported by Amazon RDS

MySQL feature support on Amazon RDS for MySQL major versions

In the following sections, find information about MySQL feature support on Amazon RDS for MySQL major versions:

Topics

- MySQL 8.4 support on Amazon RDS

For information about supported minor versions of Amazon RDS for MySQL, see Supported MySQL minor versions on Amazon RDS.

MySQL 8.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MySQL version 8.4 or higher.

- **Cryptographic library** – RDS for MySQL replaced OpenSSL with AWS Libcrypto (AWS-LC), which is FIPS 140-3 certified. For more information, see the AWS-LC GitHub repository at https://github.com/aws/aws-lc.
- **TLS changes** – RDS for MySQL only supports TLS 1.2 and TLS 1.3. For more information, see the section called "SSL/TLS support with MySQL".
- **memcached support** – The memcached interface is no longer available on MySQL 8.4. For more information, see MySQL memcached support.
- **Default authentication plugin** – The default authentication plugin is `caching_sha2_password`. For more information, see the section called "MySQL default authentication plugin".
- **`mysqlpump` client utility** – The `mysqlpump` client utility is no longer available in MySQL 8.4. For more information, see Role-based privilege model for RDS for MySQL and mysqldump and mysqlpump in the *AWS Prescriptive Guidance*.
- **Managed replication stored procedures** – When using stored procedures to manage replication with a replication user configured with `caching_sha2_password`, you must configure TLS by specifying `SOURCE_SSL=1`. `caching_sha2_password` is the default authentication plugin for RDS for MySQL 8.4.
- **Parameter behavior changes** – The following parameters changed for MySQL 8.4.
  - `innodb_dedicated_server` – This parameter is now enabled by default. For more information, see Configuring buffer pool size and redo log capacity in MySQL 8.4.
  - `innodb_buffer_pool` – The database engine now calculates this parameter, but you can override this setting. For more information, see Configuring buffer pool size and redo log capacity in MySQL 8.4.
  - `innodb_redo_log_capacity` – This parameter now controls the size of the redo log files. The database engine now calculates this parameter, but you can override this setting. For more information, see Configuring buffer pool size and redo log capacity in MySQL 8.4.
- **Deprecated or removed parameters** – RDS for MySQL removed the following parameters from parameter groups for MySQL 8.4 DB instances. The `innodb_redo_log_capacity` parameter now controls the size of the redo log files.
  - `innodb_log_file_size`
  - `innodb_log_files_in_group`
- **New default values for parameters** – The following parameters have new default values for MySQL 8.4 DB instances:

- Various MySQL community parameters related to performance changed. For more information, see What is New in MySQL 8.4 since MySQL 8.0.

  We recommend that you test your application's performance on RDS for MySQL 8.4 before migrating a production instance.

- `innodb_purge_threads` – The default value is set to the formula `LEAST({DBInstanceVCPU/2},4)` to prevent the InnoDB history list length from growing too large.
- `group_replication_exit_state_action` – The default value is `OFFLINE_MODE`, which aligns with the default in MySQL Community. For more information, see Considerations and best practices for RDS for MySQL active-active clusters.
- `binlog_format` – The default value is `ROW`, which aligns with the default in MySQL Community. You can modify the parameter for Single-AZ DB instances or Multi-AZ DB instances, but not for Multi-AZ DB clusters. Multi-AZ DB clusters use semisynchronous replication, and when `binlog_format` is set to `MIXED` or `STATEMENT`, replication fails.

- **Inclusive language changes** – RDS for MySQL 8.4 includes changes from RDS for MySQL 8.0 related to keywords and system schemas for inclusive language. For more information, see Inclusive language changes for RDS for MySQL 8.4.

For a list of all MySQL 8.4 features and changes, see What Is New in MySQL 8.4 since MySQL 8.0 in the MySQL documentation.

For a list of unsupported features, see the section called “Features not supported”.

Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. For more information, see MySQL memcached support.

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time

restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

> **Note**
>
> System tables in the `mysql` schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command (for example, `alter table TABLE_NAME engine=innodb;`). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1, 5.5, and 5.6 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1, 5.5, and 5.6 snapshots. When you restore a MySQL 5.1, 5.5, or 5.6 snapshot, the DB instance is automatically upgraded to MySQL 5.7.

Using memcached and other options with MySQL on Amazon RDS

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. RDS for MySQL DB instances support the `memcached` option, a simple, key-based cache. For more information about `memcached` and other options, see Options for MySQL DB instances. For more information about working with option groups, see Working with option groups.

InnoDB cache warming for MySQL on Amazon RDS

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see Saving and restoring the buffer pool state in the MySQL documentation.

RDS for MySQL DB instances support InnoDB cache warming. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see Parameter groups for Amazon RDS.

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

Important

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see Event syntax in the MySQL documentation.

Dumping and loading the buffer pool on demand

You can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the mysql.rds_innodb_buffer_pool_dump_now stored procedure.

- To load the saved state of the buffer pool from disk, call the mysql.rds_innodb_buffer_pool_load_now stored procedure.
- To cancel a load operation in progress, call the mysql.rds_innodb_buffer_pool_load_abort stored procedure.

Inclusive language changes for RDS for MySQL 8.4

RDS for MySQL 8.4 includes changes from the MySQL 8.4 community edition related to keywords and system schemas for inclusive language. For example, the `SHOW REPLICA STATUS` command replaces `SHOW SLAVE STATUS`.

Topics

- Configuration parameter name changes
- Stored procedure name changes

Configuration parameter name changes

The following configuration parameters have new names in RDS for MySQL 8.4.

For compatibility, you can check the parameter names in the `mysql` client by using either name. You can only use the new names when modifying values in a custom MySQL 8.4 parameter group. For more information, see Default and custom parameter groups.

Name to be removed	New or preferred name
`init_slave`	`init_replica`
`log_slave_updates`	`log_replica_updates`
`log_slow_slave_statements`	`log_slow_replica_statements`
`rpl_stop_slave_timeout`	`rpl_stop_replica_timeout`
`skip_slave_start`	`skip_replica_start`

Name to be removed	New or preferred name
slave_checkpoint_group	replica_checkpoint_group
slave_checkpoint_period	replica_checkpoint_period
slave_compressed_protocol	replica_compressed_protocol
slave_exec_mode	replica_exec_mode
slave_load_tmpdir	replica_load_tmpdir
slave_max_allowed_packet	replica_max_allowed_packet
slave_net_timeout	replica_net_timeout
slave_parallel_type	replica_parallel_type
slave_parallel_workers	replica_parallel_workers
slave_pending_jobs_size_max	replica_pending_jobs_size_max
slave_preserve_commit_order	replica_preserve_commit_order
slave_skip_errors	replica_skip_errors
slave_sql_verify_checksum	replica_sql_verify_checksum
slave_transaction_retries	replica_transaction_retries

Name to be removed	New or preferred name	
slave_type_conversions	replica_type_conversions	
sql_slave_skip_counter	sql_replica_skip_counter	

> **Note**
>
> The parameter replica_allow_batching isn't available because Amazon RDS doesn't support NDB clusters.

Stored procedure name changes

The following stored procedures have new names in RDS for MySQL 8.4.

For compatibility, you can use either name in the initial RDS for MySQL 8.4 release. The old procedure names are to be removed in a future release. For more information, see Configuring, starting, and stopping binary log (binlog) replication.

Name to be removed	New or preferred name	
mysql.rds_next_master_log	mysql.rds_next_source_log	
mysql.rds_reset_external_master	mysql.rds_reset_external_source	
mysql.rds_set_external_master	mysql.rds_set_external_source	
mysql.rds_set_external_master_with_auto_position	mysql.rds_set_external_source_with_auto_position	

Name to be removed	New or preferred name	
`mysql.rds_set_external_master_with_delay`	`mysql.rds_set_external_source_with_delay`	
`mysql.rds_set_master_auto_position`	`mysql.rds_set_source_auto_position`	

MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
- Error Logging to the System Log
- InnoDB Tablespace Encryption
- NDB clusters
- Password Strength Plugin
- Persisted system variables
- Rewriter Query Rewrite Plugin
- Semisynchronous replication, except for Multi-AZ DB clusters
- Transportable tablespace
- X Plugin

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned as *db_owner* for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.

MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 8.0.32 to 8.0.34.

Supported MySQL minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MySQL.

> **Note**
>
> Amazon RDS Extended Support isn't available for minor versions.

The following table shows the minor versions of MySQL 8.4 that Amazon RDS currently supports.

MySQL engine version	Community release date	RDS release date	RDS end of standard support date
8.4.8	20 January 2026	3 February 2026	3 February 2027
8.4.7	21 October 2025	13 November 2025	30 November 2026

MySQL engine version	Community release date	RDS release date	RDS end of standard support date
8.4.6	22 July 2025	1 August 2025	30 September 2026
8.4.5	15 April 2025	29 April 2025	30 September 2026
8.4.4	21 January 2025	19 February 2025	31 May 2026
8.4.3	15 October 2024	21 November 2024	31 May 2026

The following table shows the minor versions of MySQL 8.0 that Amazon RDS currently supports.

Note

Minor versions can reach end of standard support before major versions do. For example, minor version 8.0.28 reached its end of standard support date on March 28, 2024 while major version 8.0 reaches this date on July 31, 2026. RDS will support additional 8.0.* minor versions that the MySQL community releases between these dates. We recommend that you upgrade to the latest available minor version as often as possible for all major versions.

MySQL engine version	Community release date	RDS release date	RDS end of standard support date
8.0.45	20 January 2026	3 February 2026	31 July 2026
8.0.44	21 October 2025	13 November 2025	31 July 2026
8.0.43	22 July 2025	1 August 2025	31 July 2026
8.0.42	15 April 2025	29 April 2025	31 July 2026
8.0.41	21 January 2025	19 February 2025	31 May 2026
8.0.40	15 October 2024	13 November 2024	31 May 2026

The following table shows the minor versions of MySQL 5.7 that are available under Amazon RDS Extended Support.

> **Note**
>
> Minor versions can reach end of Extended Support before major versions do. For example, minor version 5.7.44-RDS.20240529 reaches its end of Extended Support date in September 2025 while major version 5.7 reaches this date on February 28, 2027. RDS will generate and release additional 5.7.44-RDS.xxyyzz minor versions between these dates. We recommend that you upgrade to the latest available minor version as often as possible for all major versions.

MySQL engine version	Community release date	RDS release date	RDS end of Extended Support date
5.7.44-RDS.20260212*	Not applicable	26 February 2026	28 February 2027
5.7.44-RDS.20251212*	Not applicable	12 December 2025	30 December 2026
5.7.44-RDS.20250818*	Not applicable	15 September 2025	30 September 2026
5.7.44-RDS.20250508*	Not applicable	20 May 2025	30 September 2026
5.7.44-RDS.20250213*	Not applicable	12 March 2025	30 September 2026
5.7.44-RDS.20250103*	Not applicable	13 February 2025	31 May 2026

* MySQL Community retired major version 5.7 and won't be releasing new minor versions. This is a minor version that Amazon RDS released with critical security patches and bug fixes for MySQL 5.7 databases that are covered under RDS Extended Support. For more information about these minor

versions, see the section called "RDS Extended Support versions". For more information about RDS Extended Support, see Amazon RDS Extended Support with Amazon RDS.

You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, run the `describe-db-engine-versions` AWS CLI command.

For example, to list the supported engine versions for RDS for MySQL, run the following CLI command:

```
aws rds describe-db-engine-versions --engine mysql --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region by running the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mysql
 --engine-version major_engine_version --region region --query "*[].
{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *`major_engine_version`* with the major engine version, and replace *`region`* with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version 5.7
 --region us-west-2 --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output
 text
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version.

Amazon RDS currently supports the following upgrades for major versions of the MySQL database engine:

- MySQL 5.7 to MySQL 8.0
- MySQL 8.0 to MySQL 8.4

Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see Upgrades of the RDS for MySQL DB engine.

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.

MySQL minor versions on Amazon RDS

For the changes that the MySQL community made to the minor versions, see Critical Patch Updates, Security Alerts and Bulletins on the Oracle website. Under **Critical Patch Update**, choose the month when Oracle released the minor version. And then choose the MySQL minor version under **Affected Products and Versions**.

Minor versions

- MySQL version 8.4.8
- MySQL version 8.4.7
- MySQL version 8.4.6
- MySQL version 8.4.5

- MySQL version 8.4.4
- MySQL version 8.0.45
- MySQL version 8.0.44
- MySQL version 8.0.43
- MySQL version 8.0.42
- MySQL version 8.0.41
- MySQL version 8.0.40
- MySQL version 8.0.39
- MySQL version 8.0.37

MySQL version 8.4.8

MySQL version 8.4.8 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025c`.

- Fixed an issue which can cause some SQL statements to not get logged in the audit log.

MySQL version 8.4.7

MySQL version 8.4.7 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

MySQL version 8.4.6

MySQL version 8.4.6 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

MySQL version 8.4.5

MySQL version 8.4.5 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025b`.

MySQL version 8.4.4

MySQL version 8.4.4 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025a`.
- Fixed a bug that caused a collation error while executing the Amazon RDS stored procedures `mysql.rds_set_configuration` and `mysql.rds_kill`.

MySQL version 8.0.45

MySQL version 8.0.45 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025c`.

- Fixed an issue which can cause some SQL statements to not get logged in the audit log.

MySQL version 8.0.44

MySQL version 8.0.44 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

MySQL version 8.0.43

MySQL version 8.0.43 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

MySQL version 8.0.42

MySQL version 8.0.42 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025b`.

MySQL version 8.0.41

MySQL version 8.0.41 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Updated the time zone information to base it on `tzdata2025a`.
- Fixed a bug that caused a collation error while executing the Amazon RDS stored procedures `mysql.rds_set_configuration` and `mysql.rds_kill`.

MySQL version 8.0.40

MySQL version 8.0.40 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Fixed a bug that caused character set mismatch failures during database upgrades.

MySQL version 8.0.39

MySQL version 8.0.39 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Fixed a bug that prevented `sql_log_off` from working properly with the `SESSION_VARIABLES_ADMIN` privilege.
- Fixed a bug that prevented the master user from being able to grant the `SESSION_VARIABLE_ADMIN` privilege other database users.
- Fixed a bug that caused an illegal mix of collation while executing RDS-provided stored procedures.

MySQL version 8.0.37

MySQL version 8.0.37 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

New features and enhancements

- Fixed a bug with executing an instant DDL statement followed by an UPDATE that lead to an assertion failure.

Supported MySQL major versions on Amazon RDS

RDS for MySQL major versions are available under standard support at least until community end of life for the corresponding community version. You can continue running a major version past its RDS end of standard support date for a fee. For more information, see Amazon RDS Extended Support with Amazon RDS and Amazon RDS for MySQL pricing.

You can use the following dates to plan your testing and upgrade cycles.

> **Note**
>
> You can also view information about support dates for major engine versions by using the AWS CLI or the RDS API. For more information, see Viewing support dates for engine versions in Amazon RDS Extended Support.

MySQL major version	Communit release date	RDS release date	Communit end of life date	RDS end of standard support date	RDS start of Extended Support year 1 pricing date	RDS start of Extended Support year 3 pricing date	RDS end of Extended Support date
MySQL 8.4	30 April 2024	21 November 2024	30 April 2029	31 July 2029	1 August, 2029	1 August 2031	31 July 2032

MySQL major version	Communit release date	RDS release date	Communit end of life date	RDS end of standard support date	RDS start of Extended Support year 1 pricing date	RDS start of Extended Support year 3 pricing date	RDS end of Extended Support date
MySQL 8.0	19 April 2018	23 October 2018	30 April 2026	31 July 2026	1 August 2026	1 August 2028	31 July 2029
MySQL 5.7*	21 October 2015	22 February 2016	31 October 2023	29 February 2024	1 March 2024	1 March 2026	28 February 2027

* MySQL 5.7 is now only available under RDS Extended Support. For more information, see Amazon RDS Extended Support with Amazon RDS.

Amazon RDS Extended Support versions for RDS for MySQL

The following content lists all releases of RDS Extended Support for RDS for MySQL versions.

Releases

- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20260212
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20251212
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250818
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250508
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250213
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250103
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529
- RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20260212

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20260212 is available.

Bugs fixed:

- Refresh test certificate used to test fix for bug 22295186.
- Fixes a memory leak with prefix index on blob columns.

CVEs fixed:

- CVE-2026-21936
- CVE-2026-21968
- CVE-2026-21941
- CVE-2026-21948

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20251212

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20251212 is available.

Bugs fixed:

- Fixed an issue with server startup when the buffer pool size exceeded the upper limit.
- Fixed read from `INFORMATION_SCHEMA.INNODB_LOCKS` that caused the server to exit abnormally.
- Fixed an issue with JUnit reporting support in MySQL Test Run (MTR).
- Fixed compilation issues when building with `-DWITH_INNODB_MEMCACHED=ON` option.
- Fixed an issue with MySQL Test Run (MTR) execution for bug 25182306.

CVEs fixed:

- CVE-2025-53054
- CVE-2025-53044
- CVE-2025-53045
- CVE-2025-53062

- CVE-2025-53040
- CVE-2025-53042
- CVE-2025-53067

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250818

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250818 is available.

Bugs fixed:

- Fixed an issue where the query rewrite plugin failed when the server operated with `autocommit=OFF`.
- Fixed a permission issue that prevented Debian and Ubuntu builds from running in rootless mode.
- Fixed missing update for bug 30875669.

CVEs fixed:

- CVE-2025-50082
- CVE-2025-50083
- CVE-2025-50079
- CVE-2025-50084
- CVE-2025-50087
- CVE-2025-50091
- CVE-2025-50101
- CVE-2025-50102
- CVE-2025-50098
- CVE-2025-53023
- CVE-2025-50081
- CVE-2025-50085
- CVE-2025-50077
- CVE-2025-50088
- CVE-2025-50092

- CVE-2025-50099
- CVE-2025-50096

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250508

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250508 is available.

Bugs fixed:

- Fixed virtual index unstable after rollback when `index_id` is greater than max `uint32`.
- Fixed Tests fails with memory issue.
- Fixed `<COMMAND_CLASS>` is empty for `<NAME>Execute</NAME>`.
- Fixed Compile MySQL with GCC 14 [noclose 5.7].

CVEs fixed:

- CVE-2025-30682
- CVE-2025-30687
- CVE-2025-30688
- CVE-2025-21581
- CVE-2025-21585
- CVE-2025-30689
- CVE-2025-30722
- CVE-2025-21577
- CVE-2025-30693
- CVE-2025-30695
- CVE-2025-30703

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250213

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250213 is available.

Bugs fixed:

- Fixed InnoDB failing assertion `result != FTS_INVALID`.

- Fixed crashing and widespread corruption of spatial indexes after `ALTER TABLE` operation rebuilds InnoDB table using the `INPLACE` algorithm.
- Fixed `ON DELETE CASCADE` with generated column crashes in `innobase_get_computed_value`.
- Fixed assertion failure in `row_MySQL_pad_col`.
- Fixed an issue where online DDL causes the following error: `ERROR 1712 (HY000): Index PRIMARY is corrupted`.
- Fixed crashes at `Item_rollup_sum_switcher::current_arg`.
- Fixed an issue where the database cache is not flushed on `DROP USER`.
- Fixed buffer overrun in `my_print_help`.
- Fixed an InnoDB issue where `FULLTEXT` index limits `FTS_DOC_ID` to max unsigned 32-bit value.

CVEs fixed:

- CVE-2025-21497
- CVE-2025-21555
- CVE-2025-21559
- CVE-2025-21490
- CVE-2025-21491
- CVE-2025-21500
- CVE-2025-21501
- CVE-2025-21540
- CVE-2025-21543
- CVE-2025-21520

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250103

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20250103 is available.

Bugs fixed:

- Fixed FTS clean-up issue when dropping and adding a `FULLTEXT` index in the same transaction.
- Optimized the memory allocation timing in the MySQL client to prevent any potential leaks.

- Fixed the truncation of results at 34 bytes when using the `UNION` operator.
- Fixed potential out-of-bounds access due to `ulong bitmask` in the authorization code.

CVEs fixed:

- CVE-2024-21230
- CVE-2024-21201
- CVE-2024-21241
- CVE-2024-21203

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808 is available.

Bugs fixed:

- Fixed assertion failure related to dictionary column index.
- Fixed issue with the `is_binlog_cache_empty()` function.
- Fixed `heap-use-after-free` errors in `sql/item.cc` files.
- Fixed several spatial index issues by disabling them for `index-only` reads.
- Fixed instrumentation issue with the `LOCK_ORDER: CONNECTION_CONTROL` plugin.
- Fixed threads getting stuck with the `CONNECTION_CONTROL` plugin.
- Fixed `PSI_THREAD_INFO` not updating for `PREPARED STATEMENTS`.
- Fixed double processing of FTS index words with `innodb_optimize_fulltext_only`.

CVEs fixed:

- CVE-2024-21177

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529 is available.

Bugs fixed:

- Fixed `field.cc` assertion failure by implementing `fix_after_pullout`.

- Fixed a null pointer failure when returning metadata to the client for certain SQL queries. These queries contained dynamic parameters and subqueries in `SELECT` clauses.
- Fixed incorrect results when using `GROUP BY` for loose index scans, or scans of noncontiguous ranges of an index.
- Fixed loss of GTID information on MySQL crash during persistence.
- Fixed a race condition that could cause an InnoDB transaction to hang indefinitely.
- Fixed a race condition in Group Replication's certification information cleanup.
- Fixed backward index scan issue with concurrent page operations.
- Fixed an inconsistent full-text search (FTS) state issue in concurrent scenarios.
- Fixed assertion issue with change buffer on deleting tables.
- Unified behavior for calling `deinit` function across all plugin types.

CVEs fixed:

- CVE-2024-20963
- CVE-2024-20993
- CVE-2024-20998
- CVE-2024-21009
- CVE-2024-21054
- CVE-2024-21055
- CVE-2024-21057
- CVE-2024-21062
- CVE-2024-21008
- CVE-2024-21013
- CVE-2024-21047
- CVE-2024-21087
- CVE-2024-21096

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408 is available.

This release contains patches for the following CVEs:

- CVE-2024-20963

Working with the Database Preview environment

In July 2023, Oracle announced a new release model for MySQL. This model includes two types of releases: Innovation Releases and LTS releases. Amazon RDS makes MySQL Innovation Releases available in the RDS Preview environment. To learn more about the MySQL Innovation releases, see Introducing MySQL Innovation and Long-Term Support (LTS) versions.

RDS for MySQL DB instances in the Database Preview environment are functionally similar to other RDS for MySQL DB instances. However, you can't use the Database Preview environment for production workloads.

Preview environments have the following limitations:

- Amazon RDS deletes all DB instances 60 days after you create them, along with any backups and snapshots.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the preview.

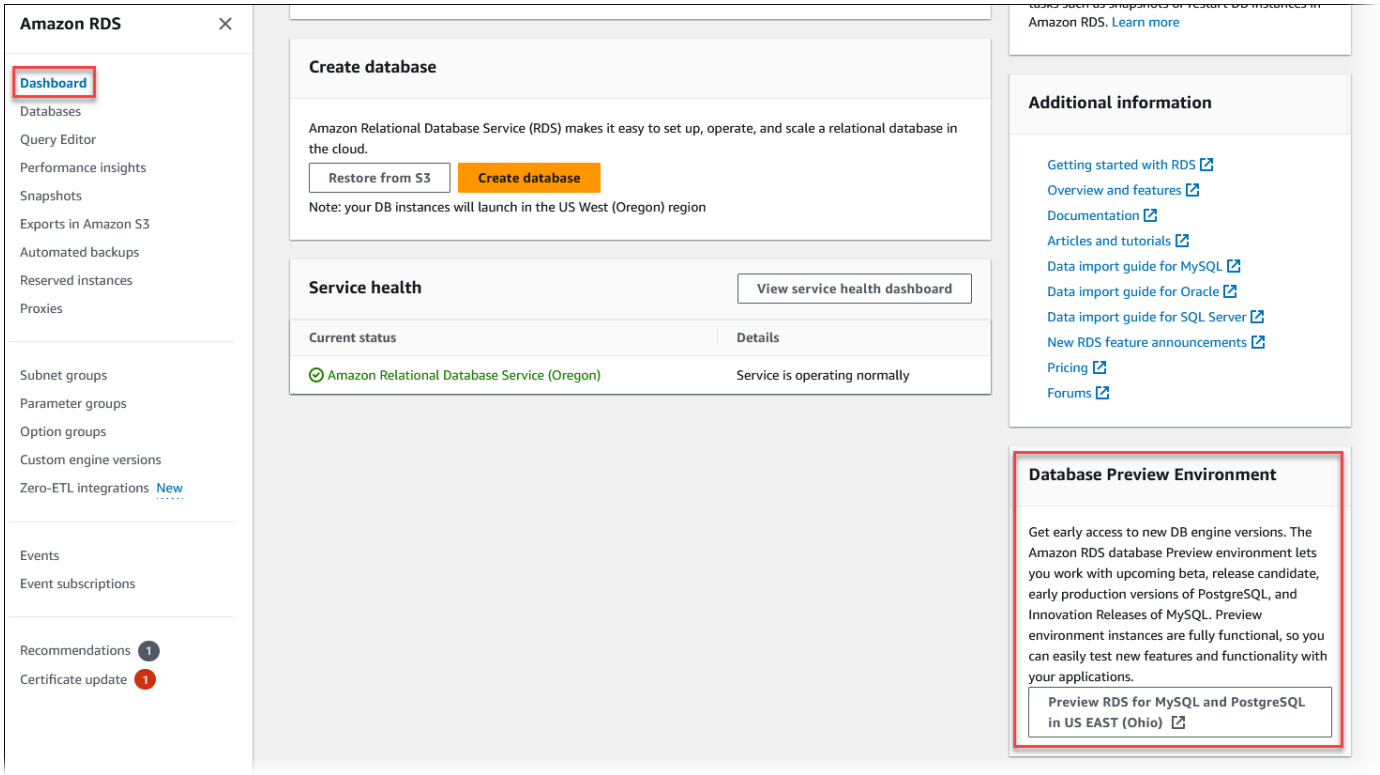
- You can create DB instances using db.m6i, db.r6i, db.m6g, db.m5, db.t3, db.r6g, and db.r5 DB instance classes. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard MySQL dump and load functions to export databases from or import databases to the Database Preview environment.

Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

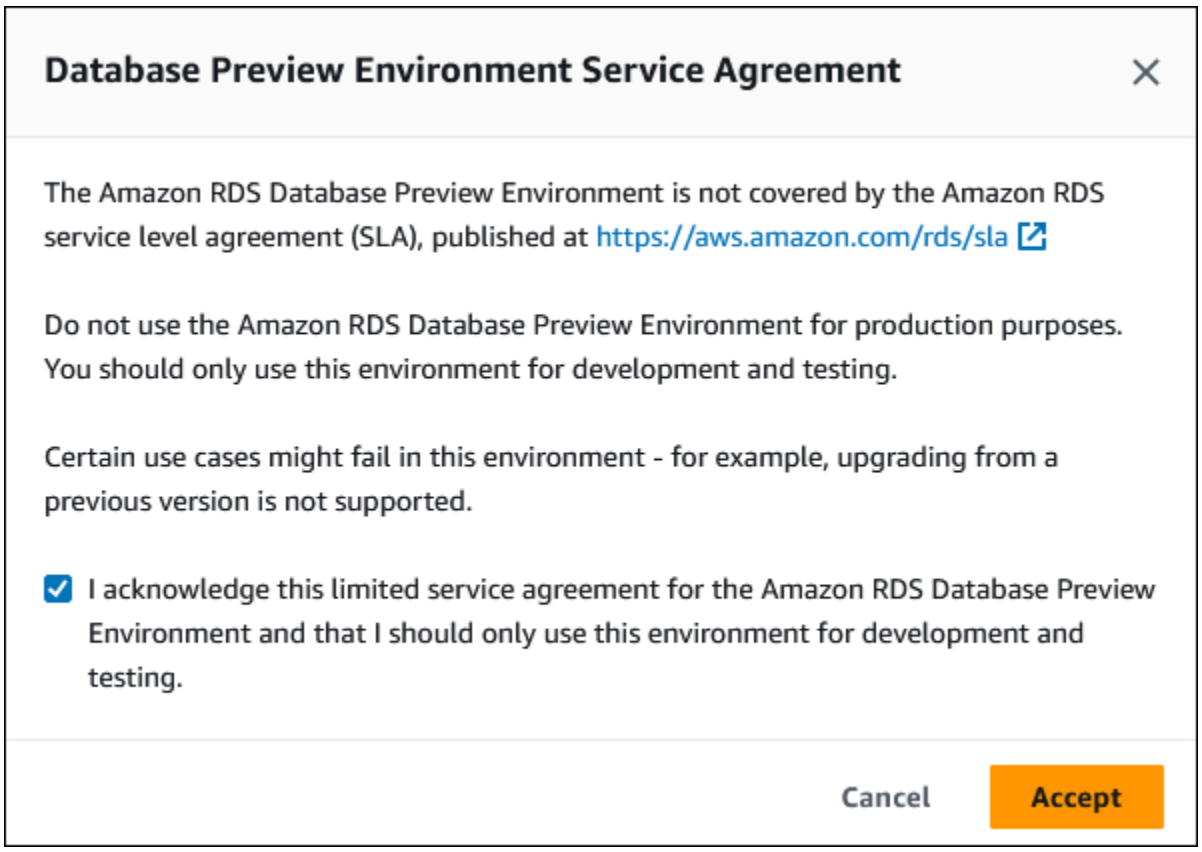
- Cross-Region snapshot copy
- Cross-Region read replicas

- RDS Proxy



Creating a new DB instance in the Database Preview environment

You can create a DB instance in the Database Preview environment using the AWS Management Console, AWS CLI, or RDS API.



Console

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Dashboard** from the navigation pane.
3. In the **Dashboard** page, locate the **Database Preview Environment** section, as shown in the following image.

You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.

4. To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

AWS CLI

To create a DB instance in the Database Preview environment using the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the AWS CLI procedure in Creating a DB instance.

RDS API

To create a DB instance in the Database Preview environment using the RDS API, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the RDS API procedure in Creating a DB instance.

MySQL version 9.5 in the Database Preview environment

MySQL version 9.5 is now available in the Amazon RDS Database Preview environment. MySQL version 9.5 contains several improvements that are described in Changes in MySQL 9.5.0.

For information on the Database Preview environment, see the section called "Database Preview environment". To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

MySQL version 9.4 in the Database Preview environment

MySQL version 9.4 is now available in the Amazon RDS Database Preview environment. MySQL version 9.4 contains several improvements that are described in Changes in MySQL 9.4.0.

For information on the Database Preview environment, see the section called "Database Preview environment". To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

MySQL version 9.3 in the Database Preview environment

MySQL version 9.3 is now available in the Amazon RDS Database Preview environment. MySQL version 9.3 contains several improvements that are described in Changes in MySQL 9.3.0.

For information on the Database Preview environment, see the section called "Database Preview environment". To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

Deprecated versions for Amazon RDS for MySQL

Amazon RDS for MySQL version 5.1, 5.5, and 5.6 are deprecated.

Amazon RDS for MySQL version 9.1 and 9.2 are deprecated in the Database Preview environment.

For information about the Amazon RDS deprecation policy for MySQL, see Amazon RDS FAQs.

Connecting to your MySQL DB instance

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see Creating an Amazon RDS DB instance. After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see Authentication method in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql - the MySQL command-line client in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance.

You can use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption on connections to a MySQL DB instance. For information, see SSL/TLS support for MySQL DB instances on Amazon RDS. If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL/TLS connection. For information, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.

You can also connect to a DB instance from a web server. For more information, see Tutorial: Create a web server and an Amazon RDS DB instance.

> **Note**
>
> For information on connecting to a MariaDB DB instance, see Connecting to your MariaDB DB instance.

To find and connect to a RDS for MySQL DB instance, see the following topics.

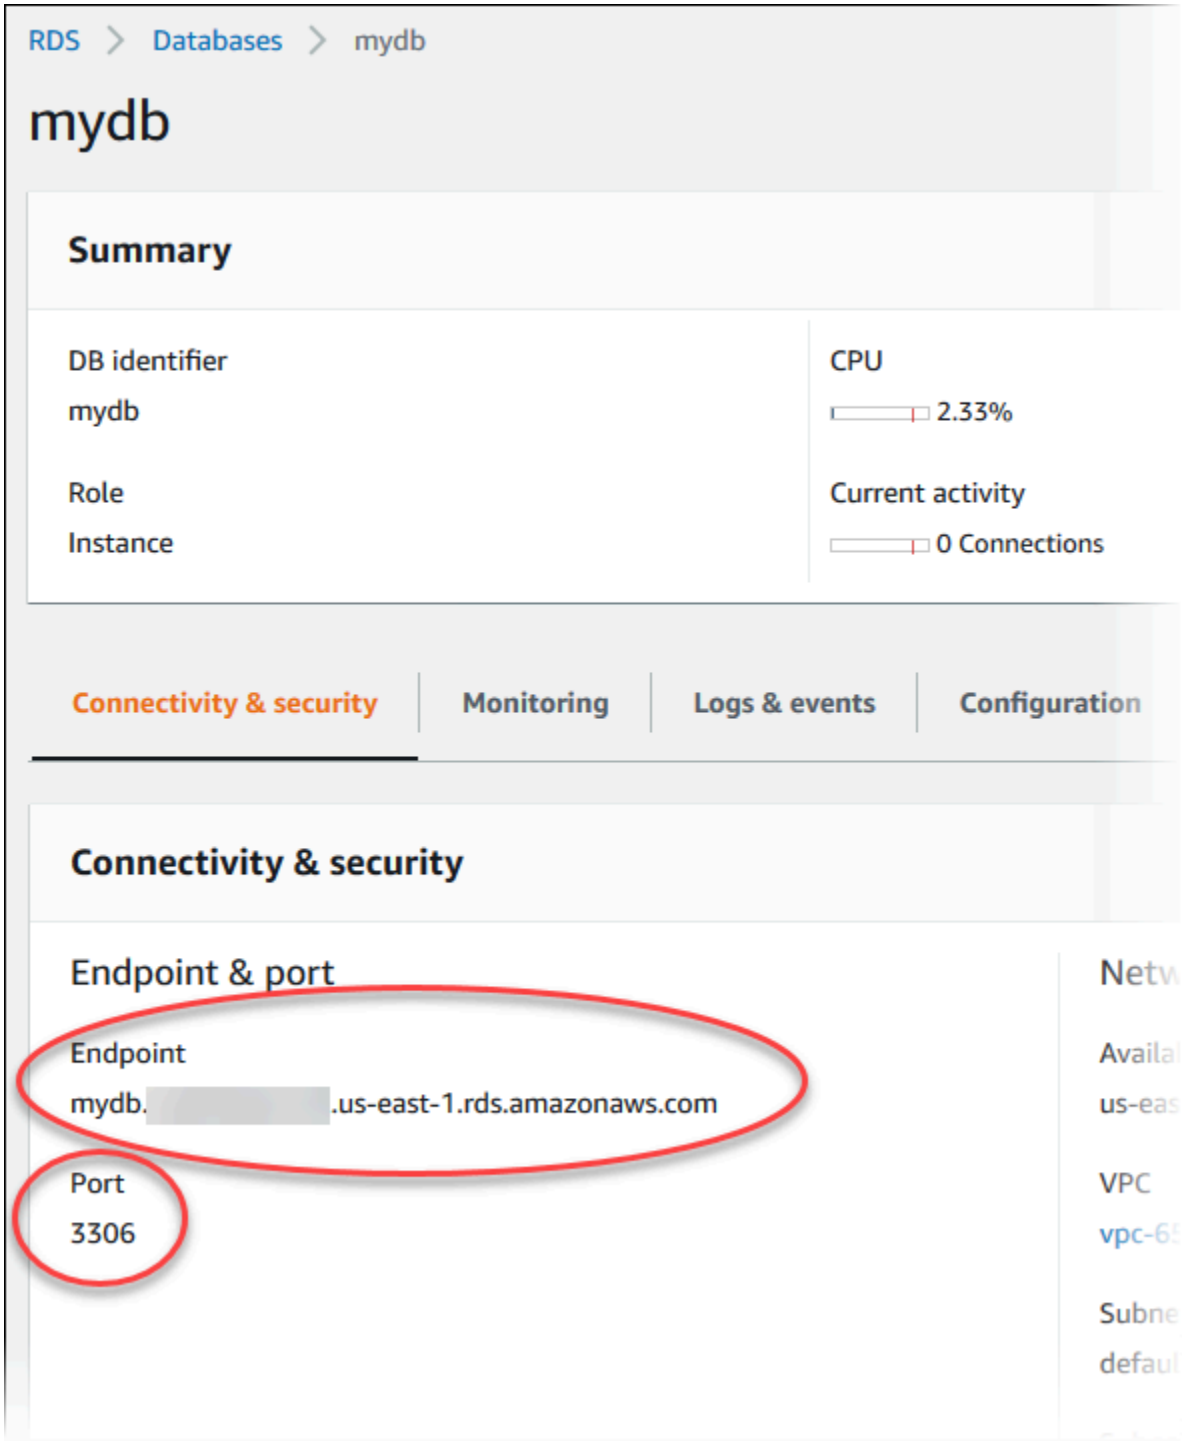
Topics

- Finding the connection information for an RDS for MySQL DB instance
- Installing the MySQL command-line client
- Connecting from the MySQL command-line client (unencrypted)
- Connecting from MySQL Workbench
- Connecting to RDS for MySQL with the AWS JDBC Driver, AWS Python Driver, and AWS ODBC Driver for MySQL
- Troubleshooting connections to your MySQL DB instance

Finding the connection information for an RDS for MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.



To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MySQL DB instance by using the AWS CLI, run the describe-db-instances command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
    [
        "mydb1",
        "mydb1.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ],
    [
        "mydb2",
        "mydb2.123456789012.us-east-1.rds.amazonaws.com",
        3306,
        "admin"
    ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Installing the MySQL command-line client

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command:

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command:

```
man mysql
```

Connecting from the MySQL command-line client (unencrypted)

> **Important**
>
> Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting to your MySQL DB instance on Amazon RDS with SSL/TLS from the MySQL command-line client (encrypted).

To connect to a DB instance using the MySQL command-line client, enter the following command at the command prompt. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the -P parameter, substitute the port for your DB instance. For the -u parameter,

substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -
u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

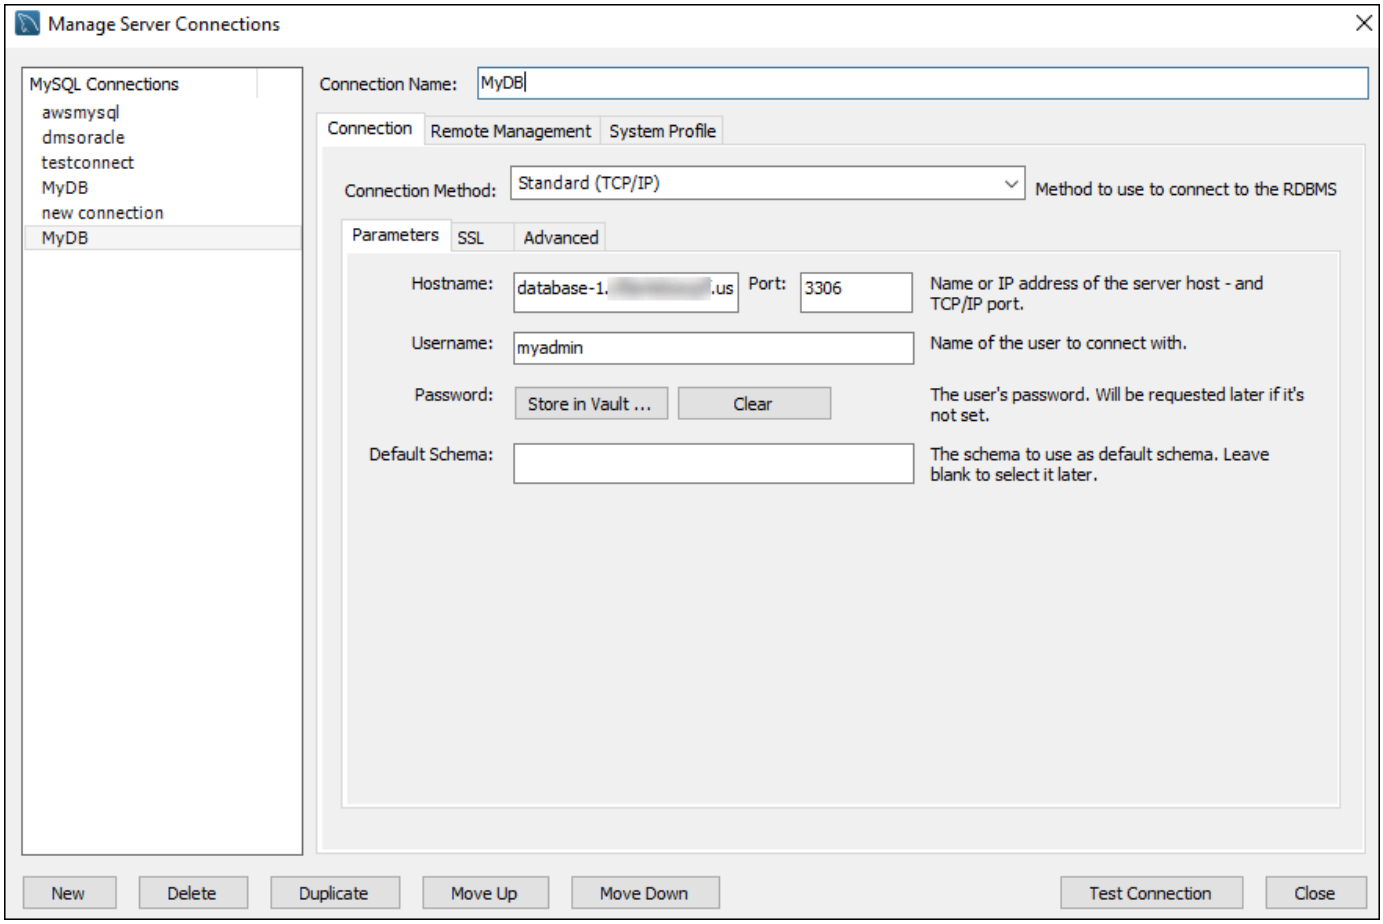
```
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 9738
Server version: 8.0.28 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

Connecting from MySQL Workbench

To connect from MySQL Workbench



1. Download and install MySQL Workbench at Download MySQL Workbench.
2. Open MySQL Workbench.

3. From **Database**, choose **Manage Connections**.
4. In the **Manage Server Connections** window, choose **New**.
5. In the **Connect to Database** window, enter the following information:

- **Stored Connection** – Enter a name for the connection, such as **MyDB**.
- **Hostname** – Enter the DB instance endpoint.
- **Port** – Enter the port used by the DB instance.
- **Username** – Enter the user name of a valid database user, such as the master user.
- **Password** – Optionally, choose **Store in Vault** and then enter and save the password for the user.

The window looks similar to the following:

You can use the features of MySQL Workbench to customize connections. For example, you can use the **SSL** tab to configure SSL/TLS connections. For information about using MySQL Workbench, see the MySQL Workbench documentation. Encrypting client connections to MySQL DB instances with SSL/TLS, see Encrypting client connections with SSL/TLS to MySQL DB instances on Amazon RDS.

6. Optionally, choose **Test Connection** to confirm that the connection to the DB instance is successful.
7. Choose **Close**.
8. From **Database**, choose **Connect to Database**.
9. From **Stored Connection**, choose your connection.
10. Choose **OK**.

Connecting to RDS for MySQL with the AWS JDBC Driver, AWS Python Driver, and AWS ODBC Driver for MySQL

Connect to RDS for MySQL DB instances with the AWS JDBC Driver, the AWS Python Driver, and the AWS ODBC Driver for MySQL. For more information, see the following topics.

Topics

- Connecting to RDS for MySQL with the Amazon Web Services (AWS) JDBC Driver
- Connecting to RDS for MySQL with the Amazon Web Services (AWS) Python Driver
- Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL

Connecting to RDS for MySQL with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community MySQL Connector/J driver and the community MariaDB Connector/J driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:mysql://` to `jdbc:aws-wrapper:mysql://`
- `jdbc:mariadb://` to `jdbc:aws-wrapper:mariadb://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to RDS for MySQL with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL

The AWS ODBC Driver for MySQL is a client driver designed for the high availability of RDS for MySQL. The driver can exist alongside the MySQL Connector/ODBC driver and is compatible with the same workflows.

For more information about the AWS ODBC Driver for MySQL and complete instructions for installing and using it, see the Amazon Web Services (AWS) ODBC Driver for MySQL GitHub repository.

Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see Amazon VPC and Amazon RDS.

  You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.
- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Securing MySQL DB instance connections

You can implement robust security measures to protect MySQL DB instances from unauthorized access and potential threats. Security groups, SSL/TLS encryption, and IAM database authentication work together to create multiple layers of connection security for your MySQL DB instances. These security controls help you meet compliance requirements, prevent data breaches, and maintain secure communication channels between applications and databases. You can secure your MySQL DB instances by encrypting data in transit, restricting access to specific IP ranges, and managing user authentication through IAM roles rather than database passwords.

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon RDS.
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them:
  - You can take the same approach as with a stand-alone instance of MySQL. Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in on-premises databases, as does directly modifying database schema tables. However, directly modifying the database schema tables isn't a best practice, and starting from RDS for MySQL version 8.0.36, it isn't supported. For information, see Access control and account management in the MySQL documentation.
  - You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token. An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.

- Another option is Kerberos authentication for RDS for MySQL. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with Directory Service. For more information, see Using Kerberos authentication for Amazon RDS for MySQL.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

Engine version	System privilege	Database role
RDS for MySQL version 8.4.3 and higher	`GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES ,INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE , REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE ROLE, DROP ROLE, APPLICATION_PASSWORD_ADMIN , FLUSH_OPTIMIZER_COSTS , FLUSH_PRIVILEGES , FLUSH_STATUS , FLUSH_TABLES , FLUSH_USER_RESOURCES , ROLE_ADMIN , SENSITIVE_VARIABLES_OBSERVER , SESSION_VARIABLES_ADMIN , SET_ANY_DEFINER , SHOW_ROUTINE , XA_RECOVER_ADMIN`	`rds_superuser_role` For more information about `rds_superuser_role` , see Role-based privilege model for RDS for MySQL.
RDS for MySQL version 8.0.36 and higher	`SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE ROLE, DROP ROLE, APPLICATION_PASSWORD_ADMIN ,`	`rds_superuser_role` For more information about `rds_superuser_role` , see Role-based privilege model for RDS for MySQL.

Engine version	System privilege	Database role
	ROLE_ADMIN , SET_USER_ID , XA_RECOVER_ADMIN	
RDS for MySQL versions lower than 8.0.36	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	None

Note

Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the ModifyDBInstance RDS API operation or run the modify-db-instance AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the `rdsadmin` account will result in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `rds_kill` and `rds_kill_query` are provided to allow you to end user sessions or queries on DB instances.

Password validation for RDS for MySQL

MySQL provides the `validate_password` plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.7, 8.0, and 8.4. For more

information about the `validate_password` plugin, see The Password Validation Plugin in the MySQL documentation.

To enable the `validate_password` plugin for a MySQL DB instance

1. Connect to your MySQL DB instance and run the following command.

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

   For more information about the parameters, see Password Validation Plugin Options and Variables in the MySQL documentation.

   For more information about modifying DB instance parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

3. Restart the DB instance.

After enabling the `validate_password` plugin, reset existing passwords to comply with your new validation policies.

Your MySQL DB instance handles password validation for Amazon RDS. To change a password, you first submit a password update request through the AWS Management Console, `modify-db-instance` CLI command, or `ModifyDBInstance` API operation. RDS initially accepts your request, even if the password doesn't meet your policies. RDS then processes the request asynchronously. It updates the password in your MySQL DB instance only if the password meets your defined policies. If the password doesn't meet these policies, RDS keeps the existing password and logs an error event.

```
   Unable to reset your password. Error information: Password failed to meet
validation rules.
```

For more information about Amazon RDS events, see Working with Amazon RDS event notification.

Encrypting client connections with SSL/TLS to MySQL DB instances on Amazon RDS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MySQL DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MySQL DB instance. SSL/TLS support is available in all AWS Regions for MySQL.

With Amazon RDS, you can secure data in transit by encrypting client connections to MySQL DB instances with SSL/TLS, requiring SSL/TLS for all connections to a MySQL DB instance, and connecting from the MySQL command-line client with SSL/TLS (encrypted). The following sections provide guidance on configuring and utilizing SSL/TLS encryption for MySQL DB instances on Amazon RDS.

Topics

- SSL/TLS support for MySQL DB instances on Amazon RDS
- Requiring SSL/TLS for specific user accounts to a MySQL DB instance on Amazon RDS
- Requiring SSL/TLS for all connections to a MySQL DB instance on Amazon RDS
- Connecting to your MySQL DB instance on Amazon RDS with SSL/TLS from the MySQL command-line client (encrypted)

SSL/TLS support for MySQL DB instances on Amazon RDS

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases, but might fail if your application doesn't accept certificate chains. If your application doesn't accept certificate chains, try using an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions with SSL/TLS.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For more information about using SSL/TLS with MySQL, see Updating applications to connect to MySQL DB instances using new SSL/TLS certificates.

For MySQL version 8.0 and lower, Amazon RDS for MySQL uses OpenSSL for secure connections. For MySQL version 8.4 and higher, Amazon RDS for MySQL uses AWS-LC. TLS support depends on the MySQL version. The following table shows the TLS support for MySQL versions.

MySQL version	TLS 1.0	TLS 1.1	TLS 1.2	TLS 1.3
MySQL 8.4	Not supported	Not supported	Supported	Supported
MySQL 8.0	Not supported	Not supported	Supported	Supported
MySQL 5.7	Supported	Supported	Supported	Not supported

Requiring SSL/TLS for specific user accounts to a MySQL DB instance on Amazon RDS

You can require SSL/TLS encryption for specified user account connections to your MySQL DB instances on Amazon RDS. Protecting sensitive information from unauthorized access or interception is crucial to enforce security policies where data confidentiality is a concern.

To require SSL/TLS connections for specific users' accounts, use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account `encrypted_user`.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MySQL, see the Using encrypted connections in the MySQL documentation.

Requiring SSL/TLS for all connections to a MySQL DB instance on Amazon RDS

Use the `require_secure_transport` parameter to require that all user connections to your MySQL DB instance use SSL/TLS. By default, the `require_secure_transport` parameter is set

to OFF. You can set the `require_secure_transport` parameter to ON to require SSL/TLS for connections to your DB instance.

You can set the `require_secure_transport` parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the `require_secure_transport` parameter is set to ON for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --
require_secure_transport=ON.
```

For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

For more information about the `require_secure_transport` parameter, see the MySQL documentation.

Connecting to your MySQL DB instance on Amazon RDS with SSL/TLS from the MySQL command-line client (encrypted)

The `mysql` client program parameters are slightly different depending on which version of MySQL or MariaDB you are using.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql  Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca` parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
   ```

   To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u myadmin -p
   ```

   The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
   ```

3. Enter the master user password when prompted.

You will see output similar to the following.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 9738
Server version: 8.0.28 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

> **Note**
>
> Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.
> You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and connects without encryption.
> We recommend avoiding `preferred` mode. In `preferred` mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For information about using SSL/TLS with MySQL DB instances, see SSL/TLS support for MySQL DB instances on Amazon RDS.

Topics

- Determining whether any applications are connecting to your MySQL DB instance using SSL
- Determining whether a client requires certificate verification to connect
- Updating your application trust store

- Example Java code for establishing SSL connections

Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7, 8.0, or 8.4 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see Performance Schema quick start in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
       FROM performance_schema.threads pst
       INNER JOIN information_schema.processlist isp
       ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (`admin`) and an application logged in as `webapp1` are using SSL.

```
+----+-----------------+------------------+-----------------+
| id | user            | host             | connection_type |
+----+-----------------+------------------+-----------------+
|  8 | admin           | 10.0.4.249:42590 | SSL/TLS         |
|  4 | event_scheduler | localhost        | NULL            |
| 10 | webapp1         | 159.28.1.1:42189 | SSL/TLS         |
+----+-----------------+------------------+-----------------+
3 rows in set (0.00 sec)
```

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For

more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the DB server certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL Client version 5.7 and higher, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
 --ssl-mode=VERIFY_CA
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see Installing SSL certificates in the MySQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_trust_store/MyTruststore.jks -
Djavax.net.ssl.trustStorePassword=my_trust_store_password com.companyName.MyApplication
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```
public class MySQLSSLTest {

        private static final String DB_USER = "username";
        private static final String DB_PASSWORD = "password";
        // This trust store has only the prod root ca.
        private static final String TRUST_STORE_FILE_PATH = "file-path-to-trust-store";
        private static final String TRUST_STORE_PASS = "trust-store-password";

        public static void test(String[] args) throws Exception {
            Class.forName("com.mysql.jdbc.Driver");

            System.setProperty("javax.net.ssl.trustStore", TRUST_STORE_FILE_PATH);
            System.setProperty("javax.net.ssl.trustStorePassword", TRUST_STORE_PASS);

            Properties properties = new Properties();
            properties.setProperty("sslMode", "VERIFY_IDENTITY");
            properties.put("user", DB_USER);
            properties.put("password", DB_PASSWORD);

            Connection connection = null;
            Statement stmt = null;
            ResultSet rs = null;
            try {
                connection =
 DriverManager.getConnection("jdbc:mysql://mydatabase.123456789012.us-
east-1.rds.amazonaws.com:3306",properties);
                stmt = connection.createStatement();
                rs=stmt.executeQuery("SELECT 1 from dual");
            } finally {
                if (rs != null) {
                    try {
                        rs.close();
                    } catch (SQLException e) {
                    }
                }
                if (stmt != null) {
```

```
                try {
                     stmt.close();
                 } catch (SQLException e) {
                }
            }
            if (connection != null) {
                try {
                    connection.close();
                } catch (SQLException e) {
                    e.printStackTrace();
                }
            }
        }
        return;
    }
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.
Specify a password other than the prompt shown here as a security best practice.

Using Kerberos authentication for Amazon RDS for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

Overview of Setting up Kerberos authentication for MySQL DB instances

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the Directory Service to create the directory. For details about doing so, see Create your AWS Managed Microsoft AD directory in the *AWS Directory Service Administration Guide*.
2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The role allows Amazon RDS to make calls to your directory.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.
3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the *AWS Directory Service Administration Guide*.
4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the `Domain` parameter. Use the `d-*` identifier that was generated when you created your directory and the name of the role that you created.

   If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.
5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the `CREATE USER` clause `IDENTIFIED WITH 'auth_pam'`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

Step 1: Create a directory using AWS Managed Microsoft AD

Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  > **Note**
  >
  > Be sure to save this password. Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers

- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the Directory Service console at https://console.aws.amazon.com/directoryservicev2/.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   Directory DNS name

   The fully qualified name for the directory, such as **`corp.example.com`**.

   Directory NetBIOS name

   The short name for the directory, such as **`CORP`**.

   Directory description

   (Optional) A description for the directory.

   Admin password

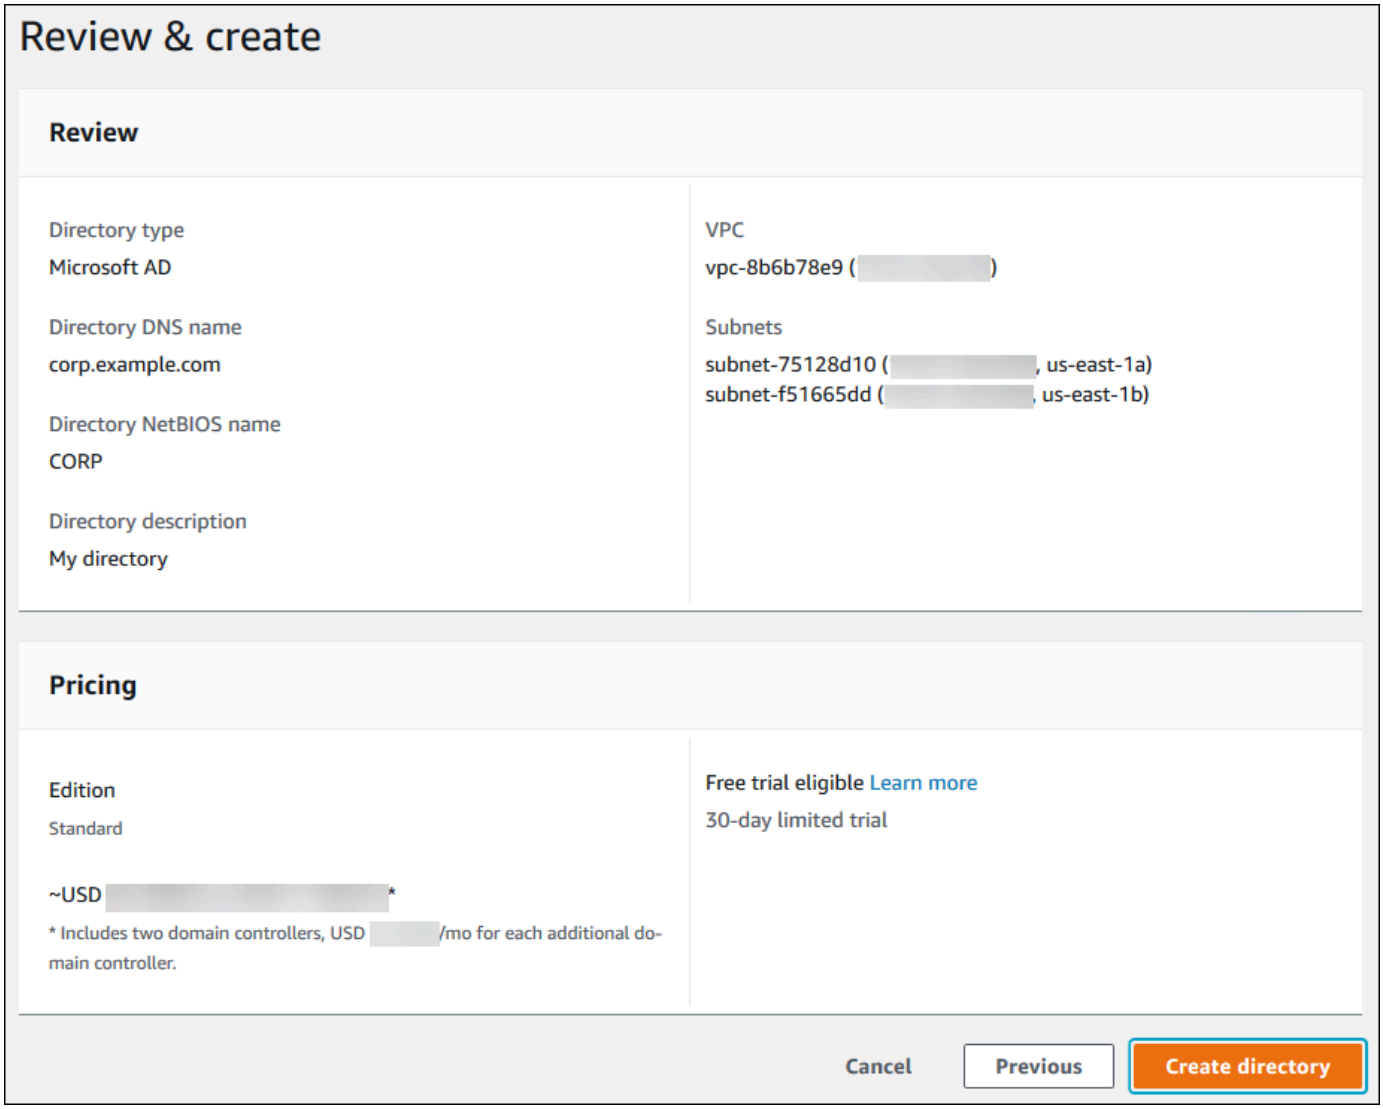
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

The administrator password retyped.



5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

   VPC

   The VPC for the directory. Create the MySQL DB instance in this same VPC.

   Subnets

   Subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your MySQL DB instance.

Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon RDS to make calls to the Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the

IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the Directory Service directory and be logged in as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the *AWS Directory Service Administration Guide*.

Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance.

- Modify an existing MySQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.

- Restore a MySQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.

- Restore a MySQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the AWS CLI or RDS API, associate a DB instance with a directory. The following parameters are required for the DB instance to use the domain directory you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you're logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL by running the following command. Replace *testuser* with the user name.

```
CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';
```

Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

Important

We strongly recommended that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command and replace *testuser* with the user name:

```
ALTER USER 'testuser'@'%' REQUIRE SSL;
```

For more information, see SSL/TLS support for MySQL DB instances on Amazon RDS.

Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To disable Kerberos authentication on a DB instance, use the `ModifyDBInstance` API operation and specify none as the domain parameter.

- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the `DescribeDBInstances` API operation.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – The enabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – The disabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an `IDENTIFIED WITH` clause on the `CREATE USER` statement. For instructions, see Step 5: Create Kerberos authentication MySQL logins.

To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at https://downloads.mariadb.org/.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in Connecting to your MySQL DB instance. When you're prompted for the password, enter the Kerberos password associated with that user name.

Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in Step 4: Create or modify a MySQL DB instance to add the DB instance to a domain.

Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see Automatic minor version upgrades for RDS for MySQL.
- To delete a DB instance with this feature enabled, first disable the feature. To do so, run the `modify-db-instance` CLI command for the DB instance and specify `none` for the `--domain` parameter.

If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.

- RDS for MySQL doesn't support Kerberos authentication across a forest trust between your on-premise or self-hosted AD and the AWS Managed Microsoft AD.

Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for MySQL with Amazon RDS Optimized Reads. An RDS for MySQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance or cluster that doesn't use it.

Topics

- Overview of RDS Optimized Reads
- Use cases for RDS Optimized Reads
- Best practices for RDS Optimized Reads
- Using RDS Optimized Reads
- Monitoring DB instances that use RDS Optimized Reads
- Limitations for RDS Optimized Reads

Overview of RDS Optimized Reads

When you use an RDS for MySQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves faster query performance through the use of an instance store. An *instance store* provides temporary block-level storage for your DB instance or Multi-AZ DB cluster. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance or Multi-AZ DB cluster uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see Amazon EC2 instance store in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

The workloads that generate temporary objects in MySQL for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance,

regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes, and background engine operations, such as flushing and insert buffer merges.

> **Note**
>
> Both manual and automated RDS snapshots only contain engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with `GROUP BY` and `ORDER BY` clauses
- Workloads that use internal temporary tables for query processing

  You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.
- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
- When your DB instance or Multi-AZ DB cluster has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

  The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.
- For MySQL 8.0 versions and lower, use the default value of `MIXED` for the `binlog_format` parameter. Depending on the size of the transactions, setting `binlog_format` to `ROW` can result in large binlog cache files on the instance store. For MySQL 8.4 and higher, use the default value of `ROW` for the `binlog_format` parameter.
- Set the internal_tmp_mem_storage_engine parameter to `TempTable`, and set the temptable_max_mmap parameter to match the size of the available storage on the instance store.
- Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.
- Use the default value of `ABORT_SERVER` for the `binlog_error_action` parameter. Doing so avoids issues with the binary logging on DB instances with backups enabled.

Using RDS Optimized Reads

When you provision an RDS for MySQL DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for MySQL DB instance or Multi-AZ DB cluster using one of these DB instance classes. For more information, see Creating an Amazon RDS DB instance.

- Modify an existing RDS for MySQL DB instance or Multi-AZ DB cluster to use one of these DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions RDS where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see the section called "DB instance classes".

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".

If you don't want to use RDS Optimized Reads, modify your DB instance or Multi-AZ DB cluster so that it doesn't use a DB instance class that supports the feature.

Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- `FreeLocalStorage`
- `ReadIOPSLocalStorage`
- `ReadLatencyLocalStorage`
- `ReadThroughputLocalStorage`
- `WriteIOPSLocalStorage`
- `WriteLatencyLocalStorage`
- `WriteThroughputLocalStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Limitations for RDS Optimized Reads

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for the following versions:
  - RDS for MySQL version 8.0.28 and higher major and minor versions

For information about RDS for MySQL versions, see MySQL on Amazon RDS versions.

- You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.
- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MySQL, any session that requires more storage than the value of `binlog_cache_size` writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.

Improving write performance with RDS Optimized Writes for MySQL

You can improve the performance of write transactions with RDS Optimized Writes for MySQL. When your RDS for MySQL database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

Topics

- Overview of RDS Optimized Writes
- Using RDS Optimized Writes
- Enabling RDS Optimized Writes on an existing database
- Limitations for RDS Optimized Writes

Overview of RDS Optimized Writes

When you turn on RDS Optimized Writes, your RDS for MySQL databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MySQL, provide the *ACID properties* of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MySQL uses a data storage area called the *doublewrite buffer* that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MySQL database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MySQL doublewrite buffer, see Doublewrite Buffer in the MySQL documentation.

With RDS Optimized Writes turned on, RDS for MySQL databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MySQL databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter `rds.optimized_writes` to control the RDS Optimized Writes feature for RDS for MySQL databases. Access this parameter in the DB parameter groups of RDS for MySQL version 8.0 and RDS for MySQL version 8.4. Set the parameter using the following values:

- `AUTO` – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- `OFF` – Turn off RDS Optimized Writes even if the database supports it.

If you have an existing database with an engine version, DB instance class, and/or file system format that doesn't support RDS Optimized Writes, you can enable the feature by creating a blue/green deployment. For more information, see the section called “Enabling on an existing database”.

If you migrate an RDS for MySQL database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MySQL doublewrite buffer.

To determine whether an RDS for MySQL database is using RDS Optimized Writes, view the current value of the `innodb_doublewrite` parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to `FALSE` (`0`).

Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MySQL database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
  - RDS Optimized Writes is supported for RDS for MySQL version 8.0.30 and higher. For information about RDS for MySQL versions, see MySQL on Amazon RDS versions.
  - RDS Optimized Writes is supported for RDS for MySQL databases that use the following DB instance classes:

- db.m7i
- db.m7g
- db.m6g
- db.m6gd
- db.m6i
- db.m5
- db.m5d
- db.r7i
- db.r7g
- db.r6g
- db.r6gd
- db.r6i
- db.r5
- db.r5b
- db.r5d
- db.x2idn
- db.x2iedn

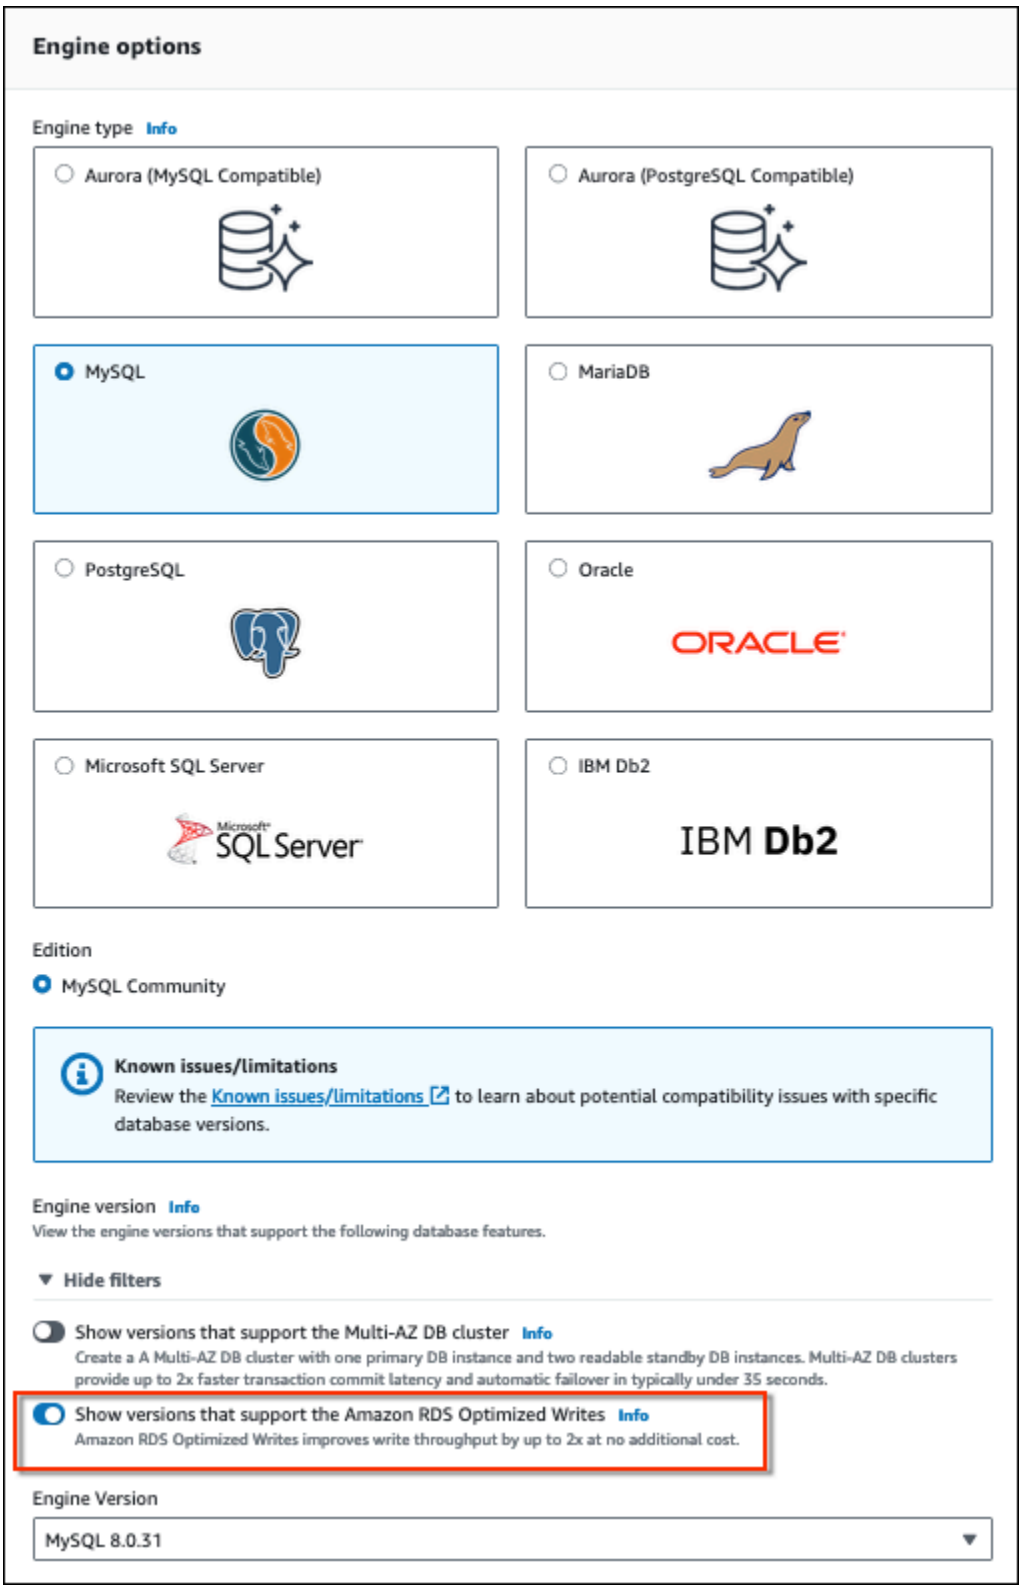
  For information about DB instance classes, see the section called "DB instance classes".

  DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see the section called "Determining DB instance class support in AWS Regions".

  To upgrade your database to a DB instance class that supports RDS Optimized Writes, you can create a blue/green deployment. For more information, see the section called "Enabling on an existing database".

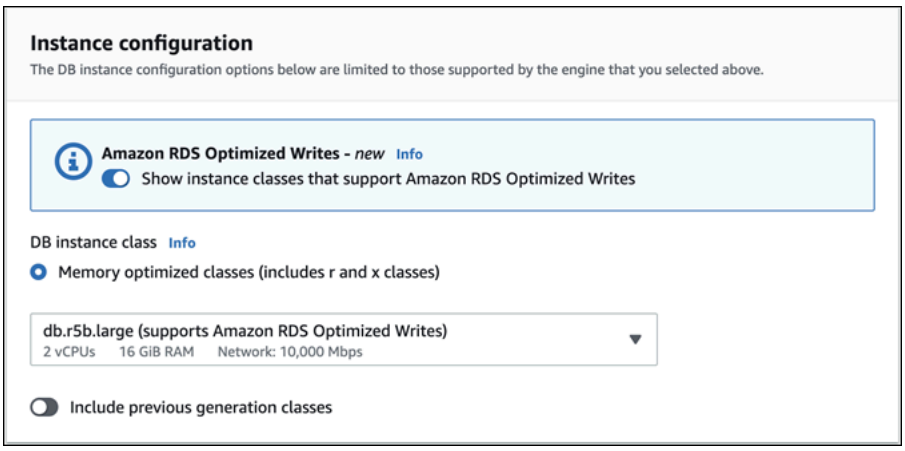
- In the parameter group associated with the database, the `rds.optimized_writes` parameter is set to AUTO. In default parameter groups, this parameter is always set to AUTO.

If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the `rds.optimized_writes` parameter to OFF. If



you want the database to use RDS Optimized Writes later, you can set the parameter to AUTO to turn it on. For information about creating custom parameter groups and setting parameters, see Parameter groups for Amazon RDS.

For information about creating a DB instance, see Creating an Amazon RDS DB instance.



Console

When you use the RDS console to create an RDS for MySQL database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MySQL DB engine versions that support it in **Engine version**, and then choose a version.

In the **Instance configuration** section, filter for the DB instance classes that support RDS Optimized Writes, and then choose a DB instance class.

After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MySQL database with the console.

AWS CLI

To create a DB instance by using the AWS CLI, run the create-db-instance command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO. This example associates the default parameter group with the DB instance.

Example Creating a DB instance that uses RDS Optimized Writes

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mysql \
    --engine-version 8.0.30 \
    --db-instance-class db.r5b.large \
    --manage-master-user-password \
    --master-username admin \
    --allocated-storage 200
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine mysql ^
```

```
    --engine-version 8.0.30 ^
    --db-instance-class db.r5b.large ^
    --manage-master-user-password ^
    --master-username admin ^
    --allocated-storage 200
```

RDS API

You can create a DB instance using the CreateDBInstance operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to AUTO.

Enabling RDS Optimized Writes on an existing database

In order to modify an existing RDS for MySQL database to turn on RDS Optimized Writes, the database must have been created with a supported DB engine version and DB instance class. In addition, the database must have been created *after* RDS Optimized Writes was released on November 27, 2022, as the required underlying file system configuration is incompatible with that of databases created before it was released. If these conditions are met, you can turn on RDS Optimized Writes by setting the `rds.optimized_writes` parameter to AUTO.

If your database was *not* created with a supported engine version, instance class, or file system configuration, you can use RDS Blue/Green Deployments to migrate to a supported configuration. While creating the blue/green deployment, do the following:

- Select **Enable Optimized Writes on green database**, then specify an engine version and DB instance class that supports RDS Optimized Writes. For a list of supported engine versions and instance classes, see Using RDS Optimized Writes.
- Under **Storage**, choose **Upgrade storage file system configuration**. This option upgrades the database to a compatible underlying file system configuration.

When you create the blue/green deployment, if the `rds.optimized_writes` parameter is set to AUTO, RDS Optimized Writes will be automatically enabled on the green environment. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment.

For more information, see the section called “Creating a blue/green deployment”.

Limitations for RDS Optimized Writes

When you're restoring an RDS for MySQL database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:

- The snapshot was created from a database that supports RDS Optimized Writes.
- The snapshot was created from a database that was created *after* RDS Optimized Writes was released.
- The snapshot is restored to a database that supports RDS Optimized Writes.
- The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to `AUTO`.

Upgrades of the RDS for MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL databases: major version upgrades and minor version upgrades.

Major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. Before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for RDS for MySQL.

For major version upgrades of Multi-AZ DB instance deployments, Amazon RDS simultaneously upgrades the primary and standby replicas. Your DB instance won't be available until the upgrade completes. For major version upgrades of Multi-AZ DB cluster deployments, Amazon RDS upgrades the cluster member instances one at a time.

> **Tip**
>
> You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Minor version upgrades

Minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or, you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that Amazon RDS automatically upgrades your DB instance after testing and approving the new version. For information about performing an upgrade, see Upgrading a DB instance engine version.

When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

> **Note**
>
> The downtime for a minor version upgrade of a Multi-AZ DB *instance* deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see *Amazon RDS Proxy*. Alternately, you can use an open source database proxy such as ProxySQL,PgBouncer, or the AWS Advanced JDBC Wrapper Driver.

Amazon RDS also supports upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

If your MySQL DB instance uses read replicas, then you must upgrade all of the read replicas before upgrading the source instance.

Topics

- Considerations for MySQL upgrades
- Finding valid upgrade targets
- MySQL version numbers
- RDS version numbers in RDS for MySQL
- Major version upgrades for RDS for MySQL
- Testing an RDS for MySQL upgrade
- Upgrading a MySQL DB instance
- Automatic minor version upgrades for RDS for MySQL
- Using a read replica to reduce downtime when upgrading an RDS for MySQL database
- Monitoring RDS for MySQL engine upgrades with events

Considerations for MySQL upgrades

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance *before* making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes.

Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

> **Note**
>
> Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance.

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance uses read replication, then you must upgrade all of the read replicas before upgrading the source instance.

Finding valid upgrade targets

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also run the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version version_number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
```

```
  --engine mysql ^
  --engine-version version_number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MySQL version 8.0.28 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version 8.0.28 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

MySQL version numbers

The version numbering sequence for the RDS for MySQL database engine is either in the form of *major.minor.patch.YYYYMMDD* or *major.minor.patch*, for example, 8.0.33.R2.20231201 or 5.7.44. The format used depends on the MySQL engine version. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

major

The major version number is both the integer and the first fractional part of the version number, for example, 8.0. A major version upgrade increases the major part of the version number. For example, an upgrade from *5.7*.44 to 8.0.33 is a major version upgrade, where *5.7* and *8.0* are the major version numbers.

minor

The minor version number is the third part of the version number, for example, the 33 in 8.0.33.

patch

The patch is the fourth part of the version number, for example, the R2 in 8.0.33.R2. An RDS patch version includes important bug fixes added to a minor version after its release.

YYYYMMDD

The date is the fifth part of the version number, for example, the 20231201 in 8.0.33.R2.20231201. An RDS date version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.

The following table explains the naming scheme for RDS for MySQL version 8.4.

8.4 minor version	Naming scheme
≥ 3	New DB instances use *major.minor.patch.YYMMDD*, for example, 8.4.3.R2.20241201. Existing DB instances might use *major.minor.patch*, for example, 8.4.3.R2, until your next major or minor version upgrade.

The following table explains the naming scheme for RDS for MySQL version 8.0.

8.0 minor version	Naming scheme
≥ 33	New DB instances use *major.minor.patch.YYMMDD*, for example, 8.0.33.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 8.0.33.R2, until your next major or minor version upgrade.
< 33	Existing DB instances use *major.minor.patch*, for example, 8.0.32.R2.

The following table explains the naming scheme for RDS for MySQL version 5.7.

5.7 minor version	Naming scheme
≥ 42	New DB instances use *major.minor.patch.YYMMDD*, for example, 5.7.42.R2.20231201. Existing DB instances might use *major.minor.patch*, for example, 5.7.42.R2, until your next major or minor version upgrade.

RDS version numbers in RDS for MySQL

RDS version numbers use either the *major*.*minor*.*patch* or the *major*.*minor*.*patch*.*YYYYMMDD* naming scheme. Amazon RDS Extended Support versions use the *minor-RDS*.*YYYYMMDD* minor version naming scheme.

An RDS patch version includes important bug fixes added to a minor version after its release. An RDS date version (*YYYYMMDD*) is a security patch. A security patch doesn't include any fixes that might change the engine's behavior. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

You can find out the RDS version number of your RDS for MySQL database with the following SQL query:

```
mysql> select mysql.rds_version();
```

For example, querying an RDS for MySQL 8.0.34 database returns the following output:

```
+---------------------+
| mysql.rds_version() |
+---------------------+
| 8.0.34.R2.20231201  |
+---------------------+
1 row in set (0.01 sec)
```

Major version upgrades for RDS for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.7 to MySQL 8.0
- MySQL 8.0 to MySQL 8.4

> **Note**
>
> You can only create MySQL version 5.7, 8.0, and 8.4 DB instances with latest-generation and current-generation DB instance classes.
> In some cases, you want to upgrade a DB instance running on a previous-generation DB instance class to a DB instance with a higher MySQL engine version. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the higher MySQL database engine version. For information on Amazon RDS DB instance classes, see DB instance classes.

Topics

- Overview of MySQL major version upgrades
- Prechecks for upgrades
- Rollback after failure to upgrade

Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade, first perform any available OS updates. After OS updates are complete, upgrade to each major version, for example, 5.7 to 8.0 and then 8.0 to 8.4. For information about upgrading an RDS for MySQL Multi-AZ DB cluster, see Upgrading the engine version of a Multi-AZ DB cluster for Amazon RDS. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see Applying updates to a DB instance .

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary `mysql_upgrade` to upgrade tables, if necessary. Also, Amazon RDS empties the `slow_log` and `general_log`

tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in Best practices for Amazon RDS. If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the describe-db-instances command and check the `Status` value.

Prechecks for upgrades

Amazon RDS runs prechecks before upgrading to check for incompatibilities. These incompatibilities vary based on the MySQL version being upgraded to.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see Upgrade checker utility.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see Working with Amazon RDS event notification.

Amazon RDS records detailed information about each incompatibility in the log file `PrePatchCompatibility.log`. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files.

Because of the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

Topics

- Prechecks for upgrades from MySQL 8.0 to 8.4
- Prechecks for upgrades from MySQL 5.7 to 8.0

Prechecks for upgrades from MySQL 8.0 to 8.4

MySQL 8.4 includes a number of incompatibilities with MySQL 8.0. These incompatibilities can cause problems during an upgrade from MySQL 8.0 to MySQL 8.4. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.4 that were not reserved previously.

  For more information, see Keywords and reserved words in the MySQL documentation.
- There must be no tables in the MySQL 8.0 `mysql` system database that have the same name as a table used by the MySQL 8.4 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.
- There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters or 1020 bytes in length.
- Your MySQL 8.0 installation must not use features that are not supported in MySQL 8.4.

  For more information, see Features removed in MySQL 8.4 in the MySQL documentation.
- There must be no foreign key constraint names longer than 64 characters.
- For improved Unicode support, review the following information:
  - Consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated.
  - Consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset. If possible, change `utf8` to `utf8mb4` first, and then upgrade your database.
  - Because older clients can receive an unknown character set error for `utf8mb3`, upgrade your database clients before upgrading your database.

  For more information, see The utf8mb3 character set (3-byte UTF-8 unicode encoding) in the MySQL documentation.

To change the character sets, you can manually perform a backup, restore, and replication of your database. Or you can use Amazon RDS Blue/Green Deployments. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

When you start an upgrade from MySQL 8.0 to 8.4, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.4, see Upgrading MySQL in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.4 by reducing the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation.

Prechecks for upgrades from MySQL 5.7 to 8.0

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan *.frm files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

  For more information, see Keywords and reserved words in the MySQL documentation.
- There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.

- There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters or 1020 bytes in length.
- Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses.
- Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

  For more information, see Features removed in MySQL 8.0 in the MySQL documentation.
- There must be no foreign key constraint names longer than 64 characters.
- For improved Unicode support, review the following information:
  - Consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated.
  - Consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset. If possible, change `utf8` to `utf8mb4` first, and then upgrade your database.
  - Because older clients can receive an unknown character set error for `utf8mb3`, upgrade your database clients before upgrading your database.

  For more information, see The utf8mb3 character set (3-byte UTF-8 unicode encoding) in the MySQL documentation.

  To change the character sets, you can manually perform a backup, restore, and replication of your database. Or you can use Amazon RDS Blue/Green Deployments. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see Upgrading MySQL in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL

8.0 by reducing the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation and Upgrading to MySQL 8.0? Here is what you need to know... on the MySQL Server Blog.

Rollback after failure to upgrade

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0 or from MySQL version 8.0 to 8.4, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 or 8.4 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running the original version:

- MySQL version 8.0 (for a rollback from MySQL 8.4)
- MySQL version 5.7 (for a rollback from MySQL 8.0)

When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the `upgradeFailure.log` file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

- Preparing Your Installation for Upgrade
- Upgrading to MySQL 8.0? Here is what you need to know…

For more information about upgrading to MySQL 8.4, see Preparing Your Installation for Upgrade in the MySQL documentation.

Testing an RDS for MySQL upgrade

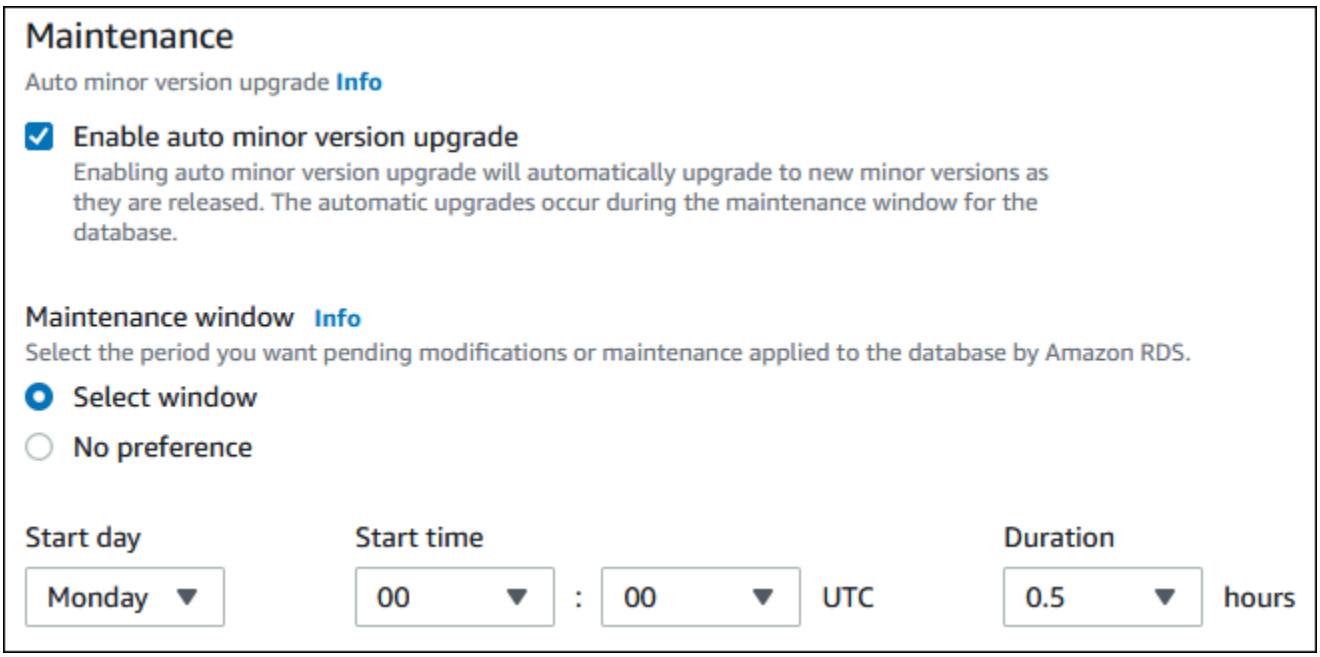
Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
   - Changes in MySQL 5.7
   - Changes in MySQL 8.0
   - Changes in MySQL 8.4
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see Parameter groups for Amazon RDS.
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.
4. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring to a DB instance.
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.

8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a MySQL DB instance



For information about manually or automatically upgrading a MySQL DB instance, see Upgrading a DB instance engine version.

Automatic minor version upgrades for RDS for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.

For more information about these settings, see Settings for DB instances.

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by

Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can run the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version minor_version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version minor_version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
```

```
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 8.0.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  False       |  8.0.15         |
|  False       |  8.0.16         |
|  False       |  8.0.17         |
|  False       |  8.0.19         |
|  False       |  8.0.20         |
|  False       |  8.0.21         |
|  True        |  8.0.23         |
|  False       |  8.0.25         |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version.

Using a read replica to reduce downtime when upgrading an RDS for MySQL database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MySQL DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

If you can't use a blue/green deployment and your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions. You can use the same general steps for upgrades to other major versions.

> **Note**
>
> When you are upgrading from MySQL version 5.7 to MySQL version 8.0, or from MySQL version 8.0 to MySQL version 8.4, complete the prechecks before performing the upgrade. For more information, see Prechecks for upgrades from MySQL 5.7 to 8.0 and Prechecks for upgrades from MySQL 8.0 to 8.4.

To upgrade a MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.

a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.

b. For **Actions**, choose **Create read replica**.

c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.

d. Choose **Create read replica**.

3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

   By default, a read replica is created with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups.

   a. In the console, choose **Databases**, and then choose the read replica that you just created.

   b. Choose **Modify**.

   c. For **Multi-AZ deployment**, choose **Create a standby instance**.

   d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.

   e. For **Scheduling of modifications**, choose **Apply immediately**.

   f. Choose **Modify DB instance**.

4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:

   a. In the console, choose **Databases**, and then choose the read replica that you just created.

   b. Choose **Modify**.

   c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.

   d. For **Scheduling of modifications**, choose **Apply immediately**.

   e. Choose **Modify DB instance** to start the upgrade.

5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. To verify, connect to the read replica and run the `SHOW REPLICA STATUS` command. If the `Seconds_Behind_Master` field is `0`, then replication is up-to-date.

> **Note**
>
> Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

6. (Optional) Create a read replica of your read replica.

   If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

   a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.

   b. For **Actions**, choose **Create read replica**.

   c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.

   d. Choose **Create read replica**.

7. (Optional) Configure a custom DB parameter group for the read replica.

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

   a. Create a custom DB parameter group for MySQL 8.0. For instructions, see Creating a DB parameter group in Amazon RDS.

   b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see Modifying parameters in a DB parameter group in Amazon RDS.

   c. In the console, choose **Databases**, and then choose the read replica.

   d. Choose **Modify**.

   e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.

   f. For **Scheduling of modifications**, choose **Apply immediately**.

   g. Choose **Modify DB instance** to start the upgrade.

8. Make your MySQL 8.0 read replica a standalone DB instance.

> **Important**
>
> When you promote your MySQL 8.0 read replica to a standalone DB instance, it is no longer a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.
> In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
b. For **Actions**, choose **Promote**.
c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see Introduction to backups.
d. Choose **Continue**.
e. Choose **Promote Read Replica**.

9. You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.

Monitoring RDS for MySQL engine upgrades with events

When you upgrade the engine version of a RDS for MySQL database, Amazon RDS emits a specific event during each phase of the process. To track the progress of an upgrade, you can view or subscribe to these events.

For more information about RDS events, see Monitoring Amazon RDS events.

For detailed information about a specific Amazon RDS event that occurs during your engine upgrade, see Amazon RDS event categories and event messages.

Upgrading a MySQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your MySQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your DB instance. You can upgrade the engine version for your DB snapshots.

For RDS for MySQL, you can upgrade a version 5.7 snapshot to version 8.0, or a version 8.0 snapshot to version 8.4. You can upgrade encrypted or unencrypted DB snapshots.

To view the available engine versions for your RDS for MySQL DB snapshot, use the following AWS CLI example.

```
aws rds describe-db-engine-versions --engine mysql --include-all --engine-
version example-engine-version --query "DBEngineVersions[*].ValidUpgradeTarget[*].
{EngineVersion:EngineVersion}" --output text
```

If you don't see results for your snapshot, your engine version might be deprecated. If your engine version is deprecated, we recommend that you upgrade to the newest major version upgrade target or to one of the other available upgrade targets for that version. For more information, see Upgrade options for DB snapshots with unsupported engine versions for RDS for MySQL.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see the section called “Upgrades of the MySQL DB engine”. To learn how to restore a DB snapshot, see the section called “Restoring to a DB instance”.

> **Note**
>
> You can't upgrade automated DB snapshots that were created during the automated backup process.

You can upgrade a DB snapshot using the AWS Management Console, AWS CLI, or RDS API.

Console

To upgrade a DB snapshot engine version using the AWS Management Console, use the following procedure.

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.
4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **Available** to **Upgrading**, and then changes to **Active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **Unavailable**. You can't recover the snapshot from this state.

   > **Note**
   >
   > If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, run the AWS CLI modify-db-snapshot command.

Options

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `--engine-version` – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
```

```
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier my_db_snapshot ^
    --engine-version new_version
```

Amazon RDS API

To upgrade a DB snapshot to a new database engine version, call the RDS API ModifyDBSnapshot operation.

Parameters

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

Upgrade options for DB snapshots with unsupported engine versions for RDS for MySQL

The following table shows which engine versions you can upgrade to from an unsupported engine version for RDS for MySQL DB snapshots.

> **Note**
>
> You might have to upgrade your DB snapshot more than once to upgrade to your chosen engine version.

DB snapshot engine version	Engine versions available for upgrade
5.5.8	5.5.62, 5.6.51
5.5.12	5.5.62, 5.6.51

DB snapshot engine version	Engine versions available for upgrade
5.5.20	5.5.62, 5.6.51
5.5.23	5.5.62, 5.6.51
5.5.25a	5.5.62, 5.6.51
5.5.27	5.5.62, 5.6.51
5.5.31	5.5.62, 5.6.51
5.5.33	5.5.62, 5.6.51
5.5.37	5.5.62, 5.6.51
5.5.38	5.5.62, 5.6.51
5.5.40	5.5.62, 5.6.51
5.5.40a	5.5.62, 5.6.51
5.5.40b	5.5.62, 5.6.51
5.5.41	5.5.62, 5.6.51
5.5.42	5.5.62, 5.6.51
5.5.59	5.5.62, 5.6.51
5.6.12	5.6.51, 5.7.44
5.6.13	5.6.51, 5.7.44
5.6.17	5.6.51, 5.7.44
5.6.19	5.6.51, 5.7.44
5.6.19a	5.6.51, 5.7.44
5.6.19b	5.6.51, 5.7.44

DB snapshot engine version	Engine versions available for upgrade
5.6.21	5.6.51, 5.7.44
5.6.21b	5.6.51, 5.7.44
5.6.22	5.6.51, 5.7.44
5.6.23	5.6.51, 5.7.44
5.6.27	5.6.51, 5.7.44
5.6.27a	5.6.51, 5.7.44
5.7.10	5.7.44, 5.7.44-rds.20240408, 5.7.44-rds.20240529, 5.7.44-rds.20250103, 5.7.44-rds.20250213, 8.0.32, 8.0.33, 8.0.34, 8.0.35, 8.0.36, 8.0.37, 8.0.39, 8.0.40, 8.0.41
5.7.11	5.7.44, 5.7.44-rds.20240408, 5.7.44-rds.20240529, 5.7.44-rds.20250103, 5.7.44-rds.20250213, 8.0.32, 8.0.33, 8.0.34, 8.0.35, 8.0.36, 8.0.37, 8.0.39, 8.0.40, 8.0.41
5.7.12	5.7.44, 5.7.44-rds.20240408, 5.7.44-rds.20240529, 5.7.44-rds.20250103, 5.7.44-rds.20250213, 8.0.32, 8.0.33, 8.0.34, 8.0.35, 8.0.36, 8.0.37, 8.0.39, 8.0.40, 8.0.41

Importing data into an Amazon RDS for MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on a number of factors:

- Source of the data
- Amount of data
- One-time import or ongoing
- Amount of downtime

If you are also migrating an application with the data, the amount of downtime is important to consider.

The following table lists techniques to importing data into an RDS for MySQL DB instance:

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MySQL database on premises or on Amazon EC2	Any	One time	Some	Create a backup of your on-premis es database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.	Restoring a backup into an Amazon RDS for MySQL DB instance
Existing MySQL database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MySQL database as the replication source.	Configuri ng binary log file position replicati on with an

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
					external source instance Importing data to an Amazon RDS for MySQL database with reduced downtime

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	What is AWS Database Migration Service and Using a MySQL-com patible database as a target for AWS DMS in the *AWS Database Migration Service User Guide*
Existing MySQL DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	Working with DB instance read replicas

Source	Amount of data	One time or ongoing	Applicati on downtim	Technique	More informati on
Existing MySQL database	Small	One time	Some	Copy the data directly to your MySQL DB instance using a command-line utility.	Importing data from an external MySQL database to an Amazon RDS for MySQL DB instance
Data not stored in an existing database	Medium	One time	Some	Create flat files and import them using MySQL `LOAD DATA LOCAL INFILE` statements.	Importing data from any source to an Amazon RDS for MySQL DB instance

Note

The `mysql` system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the `mysql` database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI restore-db-instance-

from-db-snapshot command. You can recover the DB instance using the AWS CLI restore-db-instance-to-point-in-time command.

Importing data considerations for MySQL

The following content contains technical information related to loading data into MySQL. This content is aimed at users who are familiar with the MySQL server architecture.

Binary logging

Enabling binary logging reduces data load performance and requires up to four times additional disk space compared to disabled logging. The transaction size used to load the data directly affects system performance and disk space needs—larger transactions require more resources.

Transaction size

Transaction size influences the following aspects of MySQL data loads:

- Resource consumption
- Disk space utilization
- Resume process
- Time to recover
- Input format (flat files or SQL)

This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. You can enable and disable binary logging by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. For more information, see Backup retention period.

This section also describes the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part on the following factors:

- Upload rate
- Other database activity taking place during the load
- Capacity of your Amazon RDS DB instance

The binary logs also consume disk space roughly equal to the amount of data loaded until the logs are backed up and removed. Amazon RDS minimizes this by frequently backing up and removing binary logs.

Large transactions

For large transactions, binary logging triples IOPS and disk usage for the following reasons:

- The binary log cache stores transaction data temporarily on disk.
- This cache grows with the transaction size, which consumes disk space.
- When the transaction (commit or rollback) completes, the system copies the cache to the binary log.

This process creates three copies of the data:

- The original data
- The cache on disk
- The final binary log entry

Each write operation incurs additional IO, further impacting performance.

Because of this, binary logging requires triple the disk space compared to disabled logging. For example, loading 10 GiB of data as a single transaction creates three copies:

- 10 GiB for the table data
- 10 GiB for the binary log cache
- 10 GiB for the binary log file

The total temporary disk space required is 30 GiB.

Important disk space considerations:

- The cache file persists until either the session ends or a new transaction creates another cache.
- The binary log remains until it's backed up, potentially holding 20 GiB (cache and log) for an extended period.

If you use `LOAD DATA LOCAL INFILE` to load the data, data recovery creates a fourth copy in case the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs `LOAD DATA LOCAL INFILE`. Building on the preceding example, this recovery requires a total temporary disk space of 40 GiB, or 10 GiB each for table, cache, log, and local file. Without at least 40 GiB of free disk space, recovery fails.

Optimizing large data loads

For large data loads, disable binary logging to reduce overhead and disk space requirements. You can disable binary logging by setting the backup retention period to 0. After loading completes, restore the backup retention period to the appropriate non-zero value. For more information, see Modifying an Amazon RDS DB instance and Backup retention period in the settings table.

> **Note**
>
> If the DB instance is a source DB instance for read replicas, then you can't set the backup retention period to 0.

Before loading the data, we recommend that you create a DB snapshot. For more information, see Managing manual backups.

InnoDB

The following information about undo logging and recovery options supports keeping InnoDB transactions small to optimize database performance.

Understanding InnoDB undo logging

Undo is a logging mechanism that enables transaction rollback and supports multi-version concurrency control (MVCC).

For MySQL 5.7 and lower versions, undo logs are stored in the InnoDB system tablespace (usually ibdata1) and are retained until the purge thread removes them. As a result, large data load

transactions can cause the system tablespace to become quite large and consume disk space that you can't reclaim unless you recreate the database.

For all MySQL versions, the purge thread must wait to remove any undo logs until the oldest active transaction either commits or rolls back. If the database is processing other transactions during the load, their undo logs also accumulate and can't be removed, even if the transactions commit and no other transaction needs the undo logs for MVCC. In this situation, all transactions—including read-only transactions—slow down. This slowdown occurs because all transactions access all rows that any transaction—not just the load transaction—changes. In effect, transactions must scan through undo logs that long-running load transactions prevented from being purged during an undo log cleanup. This affects performance for any operation accessing modified rows.

InnoDB transaction recovery options

Although InnoDB optimizes commit operations, large transaction rollbacks are slow. For faster recovery, perform a point-in-time recovery or restore a DB snapshot. For more information, see Point-in-time recovery and Restoring to a DB instance.

Data import formats

MySQL supports two data import formats: flat files and SQL. Review the information about each format to determine the best option for your needs.

Flat files

For small transactions, load flat files with `LOAD DATA LOCAL INFILE`. This data import format can provide the following benefits over using SQL:

- Less network traffic
- Lower data transmission costs
- Decreased database processing overhead
- Faster processing

`LOAD DATA LOCAL INFILE` loads the entire flat file as one transaction. Keep the size of the individual files small for the following advantages:

- **Resume capability** – You can keep track of which files have been loaded. If a problem arises during the load, you can pick up where you left off. You might need to retransmit some data to Amazon RDS, but with small files, the amount retransmitted is minimal.

- **Parallel data loading** – If you have sufficient IOPS and network bandwidth for a single file load, loading in parallel could save time.
- **Load rate control** – If your data load has a negative impact on other processes, you can control the load rate by increasing the interval between files.

Large transactions reduce the benefits of using `LOAD DATA LOCAL INFILE` to import data. When you can't break a large amount of data into smaller files, consider using SQL.

SQL

SQL has one main advantage over flat files: you can easily keep transaction sizes small. However, SQL can take significantly longer to load than flat files. Also, after a failure, it can be difficult to determine where to resume—you can't restart mysqldump files. If a failure occurs while loading a mysqldump file, you must modify or replace the file before the load can resume. Or, alternatively, after you correct the cause of the failure, you can restore to the point in time before the load and resend the file. For more information, see Point-in-time recovery.

Using Amazon RDS DB snapshots for database checkpoints

If you load data over long durations—such as hours or days—without binary logging, use DB snapshots to provide periodic checkpoints for data safety. Each DB snapshot creates a consistent copy of your database instance that serves as a recovery point during system failures or data corruption events. Because DB snapshots are fast, frequent checkpointing has minimal impact on load performance. You can delete previous DB snapshots without impacting database durability or recovery capabilities. For more information about DB snapshots, see Managing manual backups.

Reducing database load times

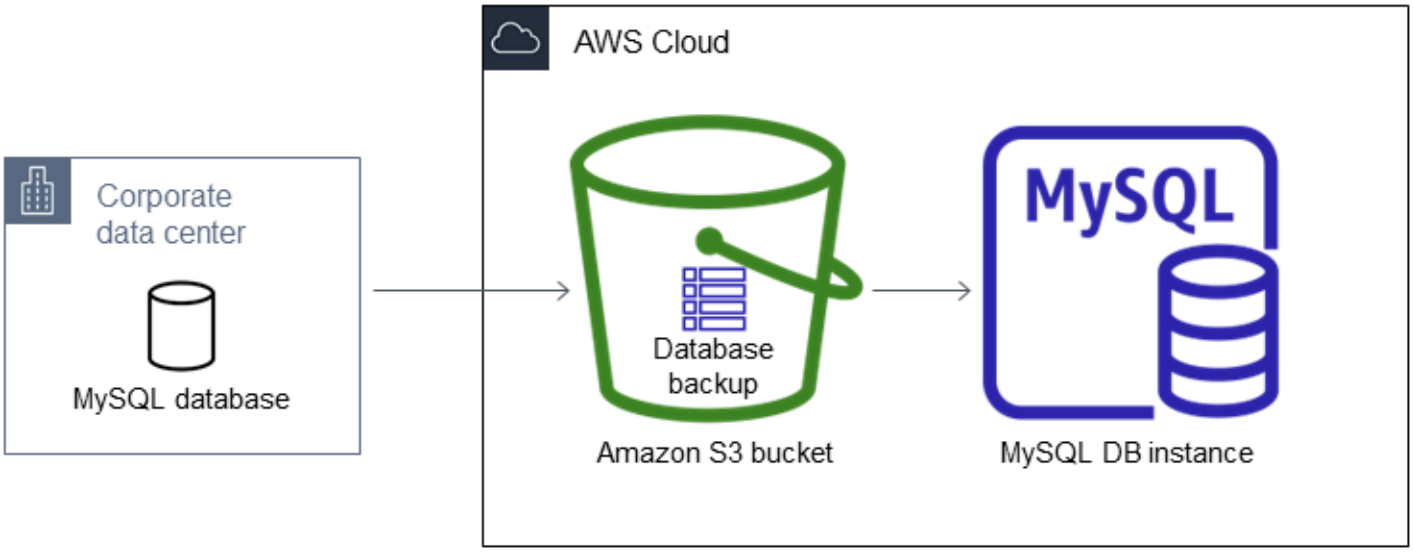
The following items are additional tips to reduce load times:

- Create all secondary indexes before loading data into MySQL databases. Unlike other database systems, MySQL rebuilds the entire table when adding or modifying secondary indexes. This process creates a new table with index changes, copies all data, and drops the original table.
- Load data in primary key order. For InnoDB tables, this can reduce load times by 75%–80% and reduce data file size by 50%.
- Disable foreign key constraints by setting `foreign_key_checks` to `0`. This is often required for flat files loaded with `LOAD DATA LOCAL INFILE`. For any load, disabling foreign key

checks accelerates data loading. After loading completes, re-enable constraints by setting `foreign_key_checks` to 1 and verify the data.

- Load data in parallel unless approaching a resource limit. To enable concurrent loading across multiple table segments, use partitioned tables when appropriate.
- To reduce SQL execution overhead, combine multiple `INSERT` statements into single multi-value `INSERT` operations. `mysqldump` implements this optimization automatically.
- Reduce InnoDB log IO operations by setting `innodb_flush_log_at_trx_commit` to `0`. After loading completes, restore `innodb_flush_log_at_trx_commit` to 1.

> **Warning**
>
> Setting `innodb_flush_log_at_trx_commit` to `0` causes InnoDB to flush its logs every second instead of at each commit. This setting increases performance but can risk transaction loss during system failures.



- If you are loading data into a DB instance that doesn't have read replicas, set `sync_binlog` to `0`. After loading completes, restore `sync_binlog parameterto` 1.
- Load data into a Single-AZ DB instance before converting the DB instance to a Multi-AZ deployment. If the DB instance already uses a Multi-AZ deployment, we don't recommend switching to a Single-AZ deployment for data loading. Doing so only provides marginal improvements.

Restoring a backup into an Amazon RDS for MySQL DB instance

Amazon RDS supports importing MySQL databases with backup files. You can create a backup of your database, store the backup file on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL. Amazon RDS supports importing backup files from Amazon S3 in all AWS Regions.

The scenario described in this section restores a backup of an on-premises database. As long as the database is accessible, you can use this technique for databases in other locations, such as Amazon EC2 or other cloud services.

The following diagram shows the supported scenario.

If your on-premises database can be offline while you create, copy, and restore backup files, then we recommend that you use backup files to import your database to Amazon RDS. If your database can't be offline, then you can use one of the following methods:

- **Binary logs** – First, import backup files from Amazon S3 and to Amazon RDS, as explained in this topic. Then use binary log (binlog) replication to update your database. For more information, see Configuring binary log file position replication with an external source instance.
- **AWS Database Migration Service** – Use AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Overview of setup to import backup files from Amazon S3 to Amazon RDS

To import backup files from Amazon S3 to Amazon RDS, you need the following components:

- An Amazon S3 bucket to store your backup files.

  If you already have an Amazon S3 bucket, you can use that bucket. If you don't have an Amazon S3 bucket, create a new one. For more information, see Creating a bucket.
- A backup of your on-premises database created by Percona XtraBackup.

  For more information, see Creating your database backup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the S3 bucket.

If you already have an IAM role, you can use that role and attach trust and permissions policies to it. For more information, see Creating an IAM role manually.

If you don't have an IAM role, you have two options:

- You can manually create a new IAM role. For more information, see Creating an IAM role manually.
- You can choose for Amazon RDS to create a new IAM role for you. If you want Amazon RDS to create a new IAM role for you, follow the procedure that uses the AWS Management Console in Importing data from Amazon S3 to a new MySQL DB instance section.

Creating your database backup

Use the Percona XtraBackup software to create your backup. We recommend that you use the latest version of Percona XtraBackup. You can install Percona XtraBackup from Software Downloads on the Percona website.

> **Warning**
>
> When creating a database backup, XtraBackup might save credentials in the xtrabackup_info file. Make sure to confirm that the `tool_command` setting in the xtrabackup_info file doesn't contain any sensitive information.

The Percona XtraBackup version that you use depends on the MySQL version that you are backing up.

- **MySQL 8.4** – Use Percona XtraBackup version 8.4.
- **MySQL 8.0** – Use Percona XtraBackup version 8.0.

  > **Note**
  >
  > Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL 8.0. If you are migrating to RDS for MySQL 8.0.32 or higher, you must use Percona XtraBackup 8.0.12 or higher.

- **MySQL 5.7** – Use Percona XtraBackup version 2.4.

You can use Percona XtraBackup to create a full backup of your MySQL database files. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup - Documentation on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that Amazon RDS can restore from Amazon S3, use the Percona XtraBackup utility (`xtrabackup`).

For example, the following command creates a backup of a MySQL database and stores the files in the folder `/on-premises/s3-restore/backup` folder.

```
xtrabackup --backup --user=myuser --password=password --target-dir=/on-premises/s3-restore/backup
```

If you want to compress your backup into a single file—which you can split into multiple files later, if needed—you can save your backup in one of the following formats based on your MySQL version:

- **Gzip (.gz)** – For MySQL 5.7 and lower versions
- **tar (.tar)** – For MySQL 5.7 and lower versions
- **Percona xbstream (.xbstream)** – For all MySQL versions

> **Note**
>
> Percona XtraBackup 8.0 and higher only supports Percona xbstream for compression.

MySQL 5.7 and lower versions

The following command creates a backup of your MySQL database split into multiple Gzip files. Replace values with your own information.

```
xtrabackup --backup --user=my_user --password=password --stream=tar \
   --target-dir=/on-premises/s3-restore/backup | gzip - | split -d --bytes=500MB \
```

```
   - /on-premises/s3-restore/backup/backup.tar.gz
```

MySQL 5.7 and lower versions

The following command creates a backup of your MySQL database split into multiple tar files. Replace values with your own information.

```
xtrabackup --backup --user=my_user --password=password --stream=tar \
   --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup.tar
```

All MySQL versions

The following command creates a backup of your MySQL database split into multiple xbstream files. Replace values with your own information.

```
xtrabackup --backup --user=myuser --password=password --stream=xbstream \
   --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup.xbstream
```

Note

If you see the following error, it might be because you mixed file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

Using incremental backups with Percona XtraBackup

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, to save time, copy your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see Create an incremental backup on the Percona website.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include both the full backup and all incremental backup directories and files. This copy must preserve the directory structure

in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory and to order incremental backups by log sequence number (LSN) range.

Backup considerations for Percona XtraBackup

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format. For example, use `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. To ensure that your backup files are written and named in the proper order, use the `split` option when you issue the `xtrabackup` command.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database:

- `--tables`
- `--tables-exclude`
- `--tables-file`
- `--databases`
- `--databases-exclude`
- `--databases-file`

Creating an IAM role manually

If you don't have an IAM role, you can create a new one manually. However, if you restore the database by using the AWS Management Console, we recommend that you choose to have Amazon RDS create this new IAM role for you. For Amazon RDS to create this role for you, follow the procedure in the Importing data from Amazon S3 to a new MySQL DB instance section.

To create a new IAM role manually for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the following examples. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see Amazon Resource Names (ARNs) and AWS service namespaces.

Example trust policy for importing from Amazon S3

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AssumeRoleForBackup",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Example permissions policy for importing from Amazon S3 — IAM user permissions

In the following example, replace *iam_user_id* with your own value.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3AccessRole",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::111122223333:role/S3Access"
        }
    ]
```

```
}
```

Example permissions policy for importing from Amazon S3 — role permissions

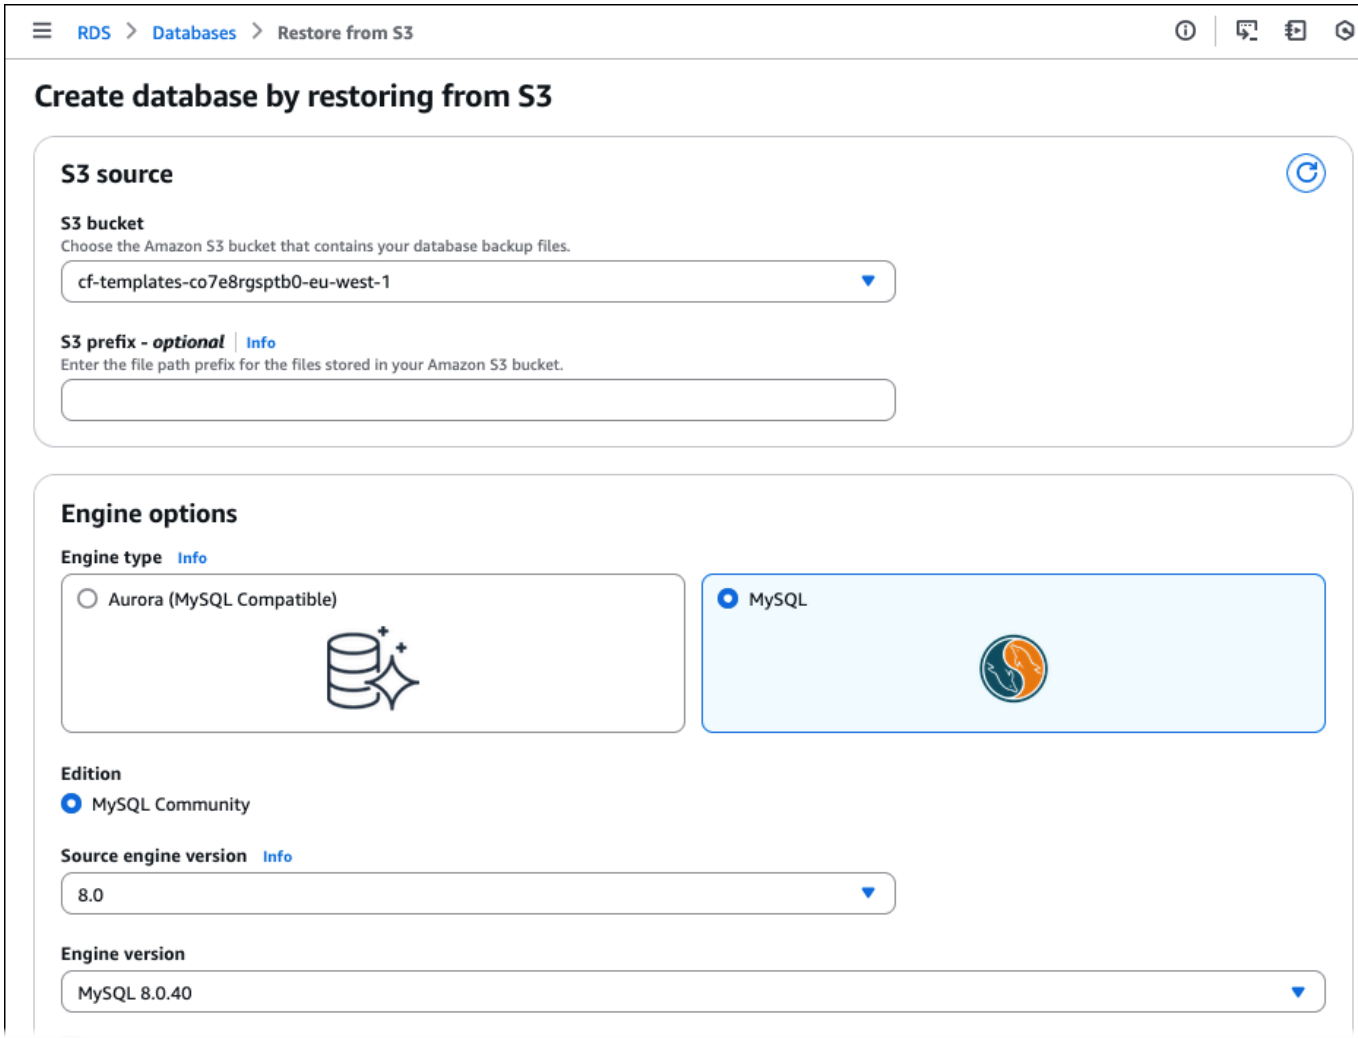
In the following example, replace *amzn-s3-demo-bucket* and *prefix* with your own values.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":
    [
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        {
        "Effect": "Allow",
        "Action":
            [
                "s3:GetObject"
            ],
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix*"
        },
        {
        "Effect": "Allow",
        "Action":
            [
                "kms:Decrypt"
            ],
        "Resource": [
            "arn:aws:kms:us-east-1:111122223333:key/key_id*"
            ]
        }
    ]
}
```

> **Note**
>
> If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

Importing data from Amazon S3 to a new MySQL DB instance



You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose **Databases**.
4. Choose **Restore from S3**.

   The **Create database by restoring from S3** page appears.

5. Under **S3 source**:

   a. Choose the **S3 bucket** that contains the backup.

   b. (Optional) For **S3 prefix**, enter the file path prefix for the files stored in your Amazon S3 bucket.

      If you don't specify a prefix, then Amazon RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then Amazon RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

      For example, you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, to restore from the files in the gzip_backup1 folder, you specify the prefix backups/gzip_backup1.

6. Under **Engine options**:

   a. For **Engine type**, choose **MySQL**.

   b. For **Source engine version**, choose the MySQL major version of your source database.

   c. For **Engine Version**, choose the default minor version of your MySQL major version in your AWS Region.

      In the AWS Management Console, only the default minor version is available. After you complete the import, you can upgrade your DB instance.

7. For **IAM role**, create or choose IAM role with the required trust policy and permissions policy that allows Amazon RDS to access your Amazon S3 bucket. Perform one of the following actions:

   - (Recommended) Choose **Create a new role**, and enter the **IAM role name**. With this option, Amazon RDS automatically creates the role with the trust policy and permissions policy for you.
   - Choose an existing IAM role. Make sure that this role meets all of the criteria in the section called "Creating an IAM role manually".

8. Specify your DB instance information. For information about each setting, see Settings for DB instances.

   > **Note**
   >
   > Be sure to allocate enough storage for your new DB instance so that the restore operation can succeed.
   > To allow for future growth automatically, under **Additional storage configuration**, choose **Enable storage autoscaling**.

9. Choose additional settings as needed.

10. Choose **Create database**.

AWS CLI

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, run the restore-db-instance-from-s3 command with the following options. For information about each setting, see Settings for DB instances.

> **Note**
>
> Be sure to allocate enough storage for your new DB instance so that the restore operation can succeed.
>
> To enable storage autoscaling and allow for future growth automatically, use the `--max-allocated-storage` option.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--manage-master-user-password`
- `--s3-bucket-name`
- `--s3-ingestion-role-arn`
- `--s3-prefix`
- `--source-engine`
- `--source-engine-version`

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-s3 \
    --allocated-storage 250 \
    --db-instance-identifier my_identifier \
    --db-instance-class db.m5.large \
    --engine mysql \
    --master-username admin \
    --manage-master-user-password \
    --s3-bucket-name amzn-s3-demo-bucket \
    --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename \
    --s3-prefix bucket_prefix \
    --source-engine my_sql \
    --source-engine-version 8.0.32 \
```

```
    --max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-from-s3 ^
    --allocated-storage 250 ^
    --db-instance-identifier my_identifier ^
    --db-instance-class db.m5.large ^
    --engine mysql ^
    --master-username admin ^
    --manage-master-user-password ^
    --s3-bucket-name amzn-s3-demo-bucket ^
    --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename ^
    --s3-prefix bucket_prefix ^
    --source-engine mysql ^
    --source-engine-version 8.0.32 ^
    --max-allocated-storage 1000
```

RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the RestoreDBInstanceFromS3 operation.

Limitations and considerations for importing backup files from Amazon S3 to Amazon RDS

The following limitations and considerations apply to importing backup files from Amazon S3 to an RDS for MySQL DB instance:

- You can only migrate your data to a new DB instance, not to an existing DB instance.
- You must use Percona XtraBackup to back up your data to Amazon S3. For more information, see Creating your database backup.
- The Amazon S3 bucket and the RDS for MySQL DB instance must be in the same AWS Region.
- You can't restore from the following sources:
  - A DB instance snapshot export to Amazon S3. You also can't migrate data from a DB instance snapshot export to your Amazon S3 bucket.
  - An encrypted source database. However, you can encrypt the data being migrated. You can also leave the data unencrypted during the migration process.
  - A MySQL 5.5 or 5.6 database.

- RDS for MySQL doesn't support Percona Server for MySQL as a source database because it can contain `compression_dictionary*` tables in the `mysql schema`.
- RDS for MySQL doesn't support backward migration for either major versions or minor versions. For example, you can't migrate from MySQL version 8.0 to RDS for MySQL 5.7, and you can't migrate from MySQL version 8.0.32 to RDS for MySQL version 8.0.26.
- Amazon RDS doesn't support importing on the db.t2.micro DB instance class from Amazon S3. However, you can restore to a different DB instance class, and then change the DB instance class later. For more information about instance classes, see Hardware specifications for DB instance classes.
- Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.
- To provide management services for each DB instance, Amazon RDS creates the `rdsadmin` user when it creates the DB instance. Because `rdsamin` is a reserved user in Amazon RDS, the following limitations apply:
  - Amazon RDS doesn't import functions, procedures, views, events, and triggers with the `'rdsadmin'@'localhost'` definer. For more information, see Stored objects with 'rdsamin'@'localhost' as the definer and Master user account privileges.
  - When creating the DB instance, Amazon RDS creates a master user with the maximum supported privileges. When restoring from backup, Amazon RDS automatically removes any unsupported privileges assigned to users being imported.

    To identify users that might be affected by this, see User accounts with unsupported privileges. For more information on supported privileges in RDS for MySQL, see Role-based privilege model for RDS for MySQL.
- Amazon RDS doesn't migrate user-created tables in the `mysql` schema.
- You must configure the `innodb_data_file_path` parameter with only one data file that uses the default data file name `ibdata1:12M:autoextend`. You can migrate databases with two data files, or with a data file with a different name, using this method.

  The following examples are file names that Amazon RDS doesn't allow:

- `innodb_data_file_path=ibdata1:50M`
- `ibdata2:50M:autoextend`
- `innodb_data_file_path=ibdata01:50M:autoextend`

- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- The maximum supported size for uncompressed backups using this method is limited to 64 TiB. For compressed backups, this limit is lower to account for uncompression space requirements. In such cases, the maximum supported backup size is `64 TiB - compressed backup size`.

  For information about the maximum supported database size that RDS for MySQL supports, see General Purpose SSD storage and Provisioned IOPS SSD storage.
- Amazon RDS doesn't support the importing of MySQL and other external components and plugins.
- Amazon RDS doesn't restore everything from your database. We recommend that you save the database schema and values for the following items from your source MySQL system database, and then add them to your restored RDS for MySQL DB instance after it has been created:
  - User accounts
  - Functions
  - Stored procedures
  - Time zone information. Time zone information is loaded from the local operating system of your RDS for MySQL DB instance. For more information, see Local time zone for MySQL DB instances.

Stored objects with 'rdsamin'@'localhost' as the definer

Amazon RDS doesn't import functions, procedures, views, events, and triggers with `'rdsadmin'@'localhost'` as the definer.

You can use the following SQL script on your source MySQL database to list the stored objects that have the unsupported definer.

```
-- This SQL query lists routines with `rdsadmin`@`localhost` as the definer.

SELECT
    ROUTINE_SCHEMA,
    ROUTINE_NAME
```

```
FROM
    information_schema.routines
WHERE
    definer = 'rdsadmin@localhost';

-- This SQL query lists triggers with `rdsadmin`@`localhost` as the definer.

SELECT
    TRIGGER_SCHEMA,
    TRIGGER_NAME,
    DEFINER
FROM
    information_schema.triggers
WHERE
    DEFINER = 'rdsadmin@localhost';

-- This SQL query lists events with `rdsadmin`@`localhost` as the definer.

SELECT
    EVENT_SCHEMA,
    EVENT_NAME
FROM
    information_schema.events
WHERE
    DEFINER = 'rdsadmin@localhost';

-- This SQL query lists views with `rdsadmin`@`localhost` as the definer.
SELECT
    TABLE_SCHEMA,
    TABLE_NAME
FROM
    information_schema.views
WHERE
    DEFINER = 'rdsadmin@localhost';
```

User accounts with unsupported privileges

User accounts with privileges that RDS for MySQL doesn't supported are imported without the unsupported privileges. For the list of supported privileges, see Role-based privilege model for RDS for MySQL.

You can run the following SQL query on your source database to list the user accounts that have unsupported privileges.

```
SELECT
    user,
    host
FROM
    mysql.user
WHERE
    Shutdown_priv = 'y'
    OR File_priv = 'y'
    OR Super_priv = 'y'
    OR Create_tablespace_priv = 'y';
```

Importing data from an external MySQL database to an Amazon RDS for MySQL DB instance

You can import data from an existing MySQL database to an RDS for MySQL DB instance. You do so by copying the database with mysqldump and piping it directly into the RDS for MySQL DB instance. The `mysqldump` command line utility is commonly used to make backups and transfer data from one MySQL server to another. It's included with MySQL client software.

> **Note**
>
> If you are importing or exporting large amounts of data with a MySQL DB instance, it's more reliable and faster to move data in and out of Amazon RDS by using `xtrabackup` backup files and Amazon S3. For more information, see Restoring a backup into an Amazon RDS for MySQL DB instance.

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following example. Replace values with your own information.

```
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary  \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocal_password | mysql -u RDS_user \
```

```
        --port=port_number \
        --host=host_name \
        -pRDS_password
```

> **Important**
>
> Make sure not to leave a space between the `-p` option and the entered password. As a security best practice, specify credentials other than the prompts shown in this example.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file:
  - `sys`
  - `performance_schema`
  - `information_schema`

  The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups.

The parameters used are as follows:

- `-u` *`local_user`* – Use to specify a user name. In the first usage of this parameter, specify the name of a user account on the local MySQL database that you identify with the `--databases` parameter.
- `--databases` *`database_name`* – Use to specify the name of the database on the local MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.

- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `--routines` – Use if routines such as stored procedures or functions exist in the database that you are copying. Set the parameter to `0`, which excludes the routines during the import process. Then later manually recreate the routines in the Amazon RDS database.
- `--triggers` – Use if triggers exist in the database that you are copying. Set the parameter to `0`, which excludes the triggers during the import process. Then later manually recreate the triggers in the Amazon RDS database.
- `--events` – Use if events exist in the database that you are copying. Set the parameter to `0`, which excludes the events during the import process. Then later manually recreate the events in the Amazon RDS database.
- `-p`*`local_password`* – Use to specify a password. In the first usage of this parameter, specify the password for the user account that you identify with the first `-u` parameter.
- `-u` *`RDS_user`* – Use to specify a user name. In the second usage of this parameter, specify the name of a user account on the default database for the MySQL DB instance that you identify with the `--host` parameter.
- `--port` *`port_number`* – Use to specify the port for your MySQL DB instance. By default, this is 3306 unless you changed the value when creating the DB instance.
- `--host` *`host_name`* – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the DB instance details in the Amazon RDS console.
- `-p`*`RDS_password`* – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command:

- `--routines=0`
- `--triggers=0`
- `--events=0`

Example

The following example copies the `world` sample database on the local host to an RDS for MySQL DB instance. Replace values with your own information.

For Linux, macOS, or Unix:

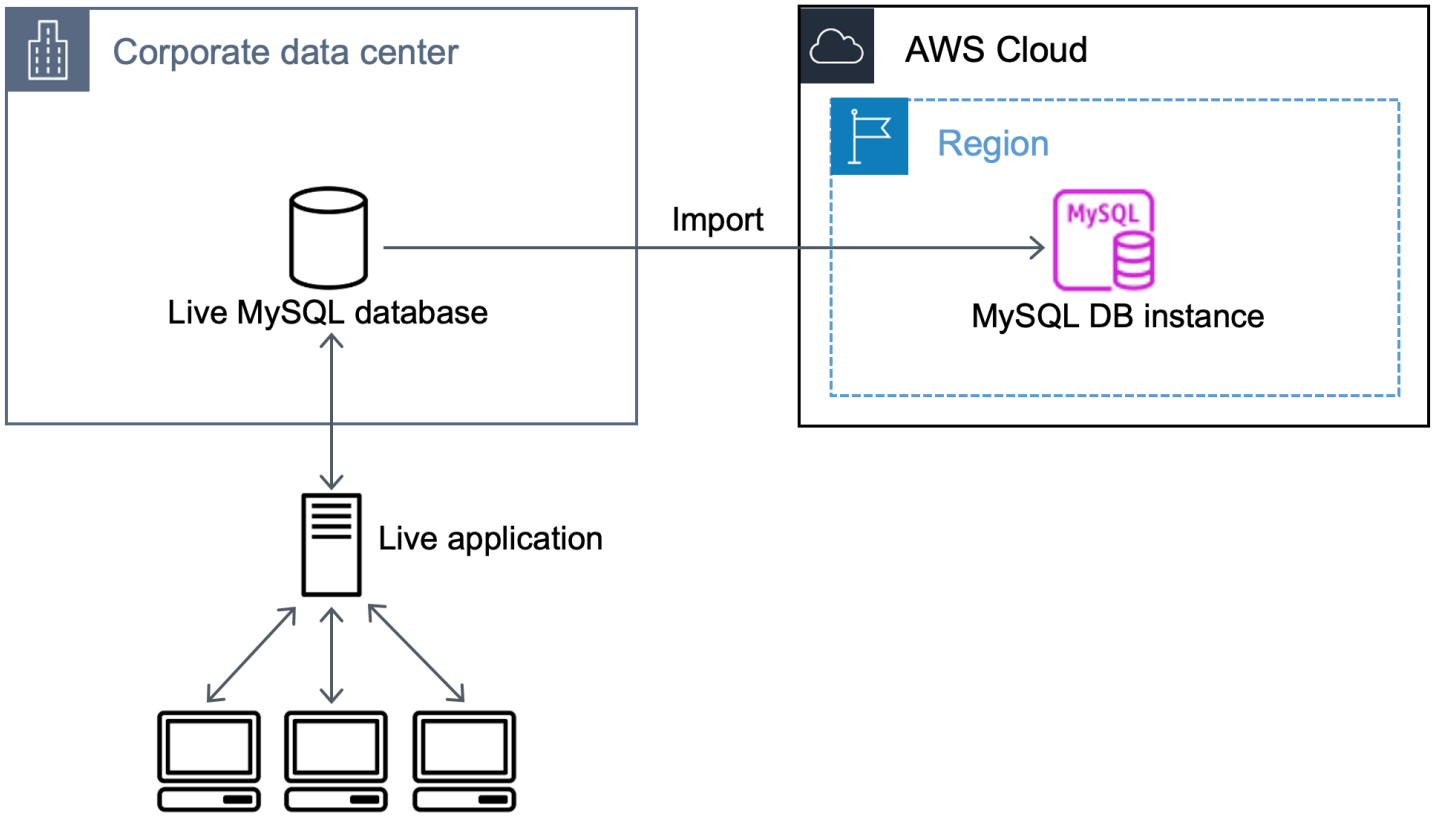
```
sudo mysqldump -u local_user \
    --databases world \
    --single-transaction \
    --compress \
    --order-by-primary  \
    --routines=0 \
    --triggers=0 \
    --events=0 \
    -plocal_password | mysql -u rds_user \
        --port=3306 \
        --host=my_instance.123456789012.us-east-1.rds.amazonaws.com \
        -pRDS_password
```

For Windows:

Run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**. Replace values with your own information.

```
mysqldump -u local_user ^
    --databases world ^
    --single-transaction ^
    --compress ^
    --order-by-primary  ^
    --routines=0 ^
    --triggers=0 ^
    --events=0 ^
    -plocal_password | mysql -u RDS_user ^
        --port=3306 ^
        --host=my_instance.123456789012.us-east-1.rds.amazonaws.com ^
        -pRDS_password
```

> **Note**
>
> As a security best practice, specify credentials other than the prompts shown in the example.

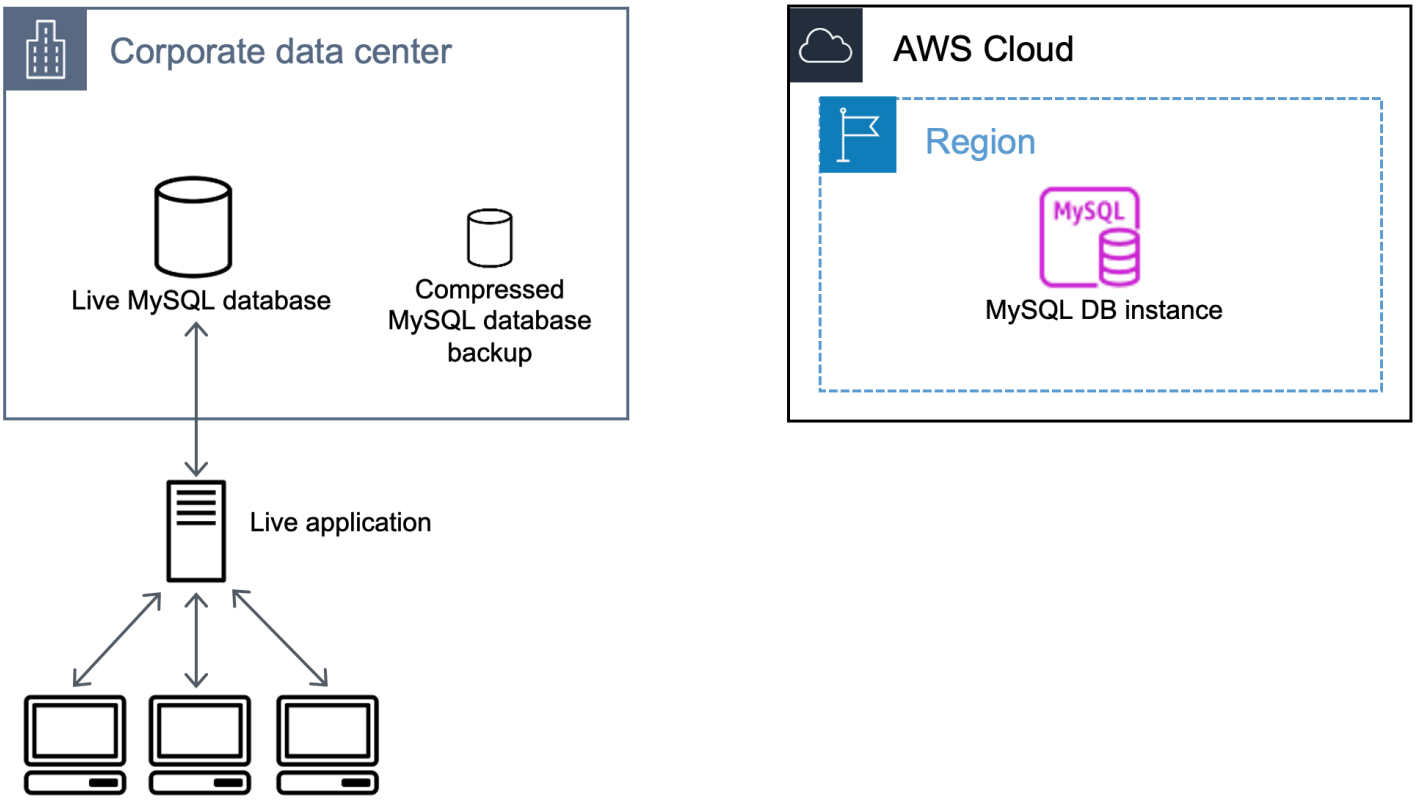


Importing data to an Amazon RDS for MySQL database with reduced downtime

In some cases, you might need to import data from an external MySQL database that supports a live application to an RDS for MySQL DB instance or an RDS for MySQL Multi-AZ DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. Configure replication based on binary log coordinates.

> **Note**
>
> If you want to import data into an RDS for MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into an Amazon RDS for MySQL DB instance.



The following diagram shows importing an external MySQL database into a MySQL database on Amazon RDS.

Task 1: Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MySQL database with minimal downtime is to create a copy of the source data.

The following diagram shows creating a backup of the MySQL database.

You can use the `mysqldump` utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that `mysqldump` runs.

We also recommend that you weigh `mysqldump` performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information, see Step 5: Load the data in the Importing data from any source procedure.

Before you start the backup operation, make sure to set the replication options on the MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

Make sure that you're aware of the following recommendations and considerations:

- Use the `--single-transaction` option with `mysqldump` because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while `mysqldump` is running. You can schedule a maintenance window for these operations.
- Exclude the following schemas from the dump file:
  - `sys`
  - `performance_schema`
  - `information_schema`

  The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the pt-show-grants utility.

To set replication options

1. Edit the `my.cnf` file. This file is usually located under `/etc`.

   ```
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   The following example shows the updated `[mysqld]` section of a `my.cnf` file:

   ```
   [mysqld]
   log-bin=mysql-bin
   server-id=1
   ```

   For more information, see Setting the Replication Source Configuration in the MySQL documentation.
2. For replication with a Multi-AZ DB cluster set the `ENFORCE_GTID_CONSISTENCY` and the `GTID_MODE` parameter to `ON`.

   ```
   mysql> SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
   ```

   ```
   mysql> SET @@GLOBAL.GTID_MODE = ON;
   ```

These settings aren't required for replication with a DB instance.

3. Restart the `mysql` service.

```
sudo service mysqld restart
```

To create a backup copy of your existing database

1. Create a backup of your data using the `mysqldump` utility, specifying either SQL or delimited-text format.

   For MySQL 8.0.25 and lower versions, specify `--master-data=2` to create a backup file that can be used to start replication between servers. For MySQL 8.0.26 and higher versions, specify `--source-data=2` to create a backup file that can be used to start replication between servers. For more information, see the mysqldump — A Database Backup Program in the MySQL documentation.

   To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options for `mysqldump`.

   To avoid including the MySQL system database in the backup, don't use the `--all-databases` option with `mysqldump`. For more information, see Creating a Data Snapshot Using mysqldump in the MySQL documentation.

   Use chmod, if necessary, to make sure that the directory where the backup file is being created is writeable.

   > **Important**
   >
   > On Windows, run the command window as an administrator.

   - To produce SQL output, use the following command:

     For Linux, macOS, or Unix:

     ```
     sudo mysqldump \
         --databases database_name \
         --master-data=2  \
     ```

```
    --single-transaction \
    --order-by-primary \
    -r backup.sql \
    -u local_user \
    -ppassword
```

> **Note**
>
> As a security best practice, specify credentials other than the prompts shown in the example.

For Windows:

```
mysqldump ^
    --databases database_name ^
    --master-data=2  ^
    --single-transaction ^
    --order-by-primary ^
    -r backup.sql ^
    -u local_user ^
    -ppassword
```

> **Note**
>
> As a security best practice, specify credentials other than the prompts shown in the example.

- To produce delimited-text output, use the following command:

  For Linux, macOS, or Unix:

```
sudo mysqldump \
    --tab=target_directory \
    --fields-terminated-by ',' \
    --fields-enclosed-by '"' \
    --lines-terminated-by 0x0d0a \
    database_name \
    --master-data=2 \
    --single-transaction \
```

```
    --order-by-primary \
    -ppassword
```

For Windows:

```
mysqldump ^
    --tab=target_directory ^
    --fields-terminated-by "," ^
    --fields-enclosed-by """ ^
    --lines-terminated-by 0x0d0a ^
    database_name ^
    --master-data=2 ^
    --single-transaction ^
    --order-by-primary ^
    -ppassword
```

Note

As a security best practice, specify credentials other than the prompts shown in the example.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following arguments with your `mysqldump` command:

- `--routines=0`
- `--triggers=0`
- `--events=0`

For MySQL 8.0.22 and lower versions, when you run `mysqldump` and specify the delimited-text format, a `CHANGE MASTER TO` comment is returned. This comment contains the master log file name and position. For MySQL 8.0.23 and higher versions, when you run `mysqldump` using the delimited-text format, a `CHANGE REPLICATION SOURCE TO` comment is returned. This comment contains the source log file name and position. If the external instance is MySQL 8.0.23 and higher versions, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

The following output is returned for MySQL 8.0.22 and lower versions:

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
 MASTER_LOG_POS=107;
```

The following output is returned for MySQL 8.0.23 and higher versions:

```
-- Position to start replication or point-in-time recovery from
--
-- CHANGE SOURCE TO SOURCE_LOG_FILE='mysql-bin-changelog.000031',
 SOURCE_LOG_POS=107;
```

For MySQL 8.0.22 and lower versions, if you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. For MySQL 8.0.23 and higher versions, if you are using SQL format, you can get the source log file name and position in the `CHANGE REPLICATION SOURCE TO` comment in the backup file.

2. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

   - To compress SQL output, use the following command:

     ```
     gzip backup.sql
     ```

   - To compress delimited-text output, use the following command:

     ```
     tar -zcvf backup.tar.gz target_directory
     ```

Task 2: Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.

The following diagram shows copying the database backup to an Amazon EC2 instance.

To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the Amazon RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses—for example, `203.0.113.0/24`—or another VPC security group. You can use the Amazon VPC console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the *Amazon Virtual Private Cloud User Guide*.
2. Open the Amazon EC2 console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 in the *Amazon Elastic Compute Cloud User Guide*.
3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance.

You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Security group rules in the *Amazon Virtual Private Cloud User Guide*.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod`, if necessary, to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or a Secure Shell (SSH) client to copy the file. The following command is an example `scp` command:

```
scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

> **Important**
>
> When copying sensitive data, be sure to use a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands:

```
sudo yum update -y
sudo yum install mysql -y
```

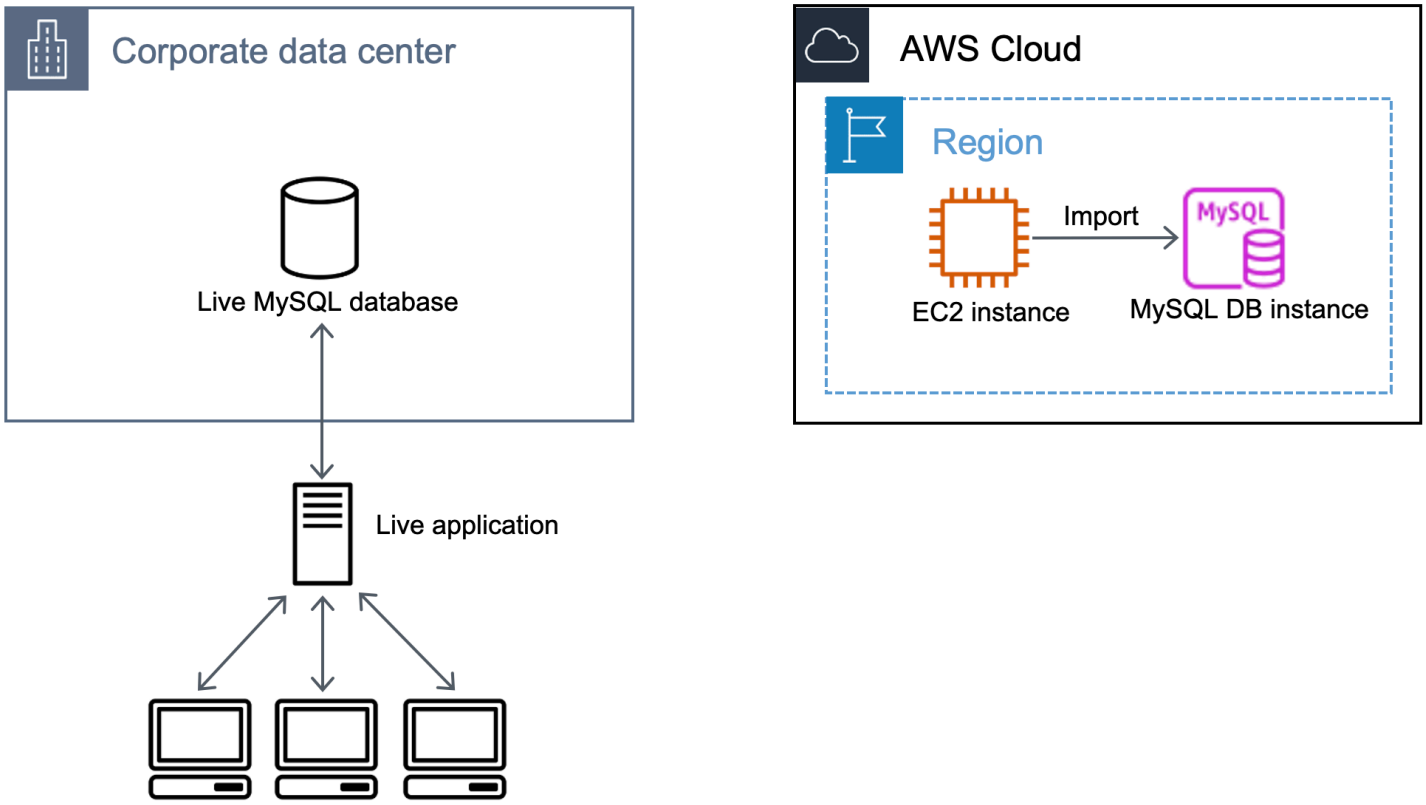
For more information, see Connect to your instance for Linux instances in the *Amazon Elastic Compute Cloud User Guide*.

> **Important**
>
> This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. This example doesn't install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux. For information about installing MySQL, see Installing MySQL in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following commands are examples.

   - To decompress SQL output, use the following command:

```
gzip backup.sql.gz -d
```



- To decompress delimited-text output, use the following command:

```
tar xzvf backup.tar.gz
```

Task 3: Create a MySQL database and import data from your Amazon EC2 instance

By creating an RDS for MySQL DB instance or an RDS for MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from Amazon EC2 faster than over the internet.

The following diagram shows importing the backup from an Amazon EC2 instance into a MySQL database.

To create a MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also, decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MySQL database. For more information, see DB instance classes.
2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.

   To create an RDS for MySQL Multi-AZ DB cluster, follow the instructions in Creating a Multi-AZ DB cluster for Amazon RDS.

   To create an RDS for MySQL DB instance, follow the instructions in Creating an Amazon RDS DB instance and use the following guidelines:

   - Specify a DB engine version that is compatible with your source DB instance.
   - Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described in a following section, your DB instance must be publicly accessible.
   - Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.
3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information about creating a parameter group, see Parameter groups for Amazon RDS.
4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the DB instance. The hostname for the Amazon RDS database is the **Endpoint** value for this DB instance without the port number, for example, `mysampledb.123456789012.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the database details in the Amazon RDS console.
5. Connect to your Amazon EC2 instance. For more information, see Connect to your instance for Linux instances in the *Amazon Elastic Compute Cloud User Guide*.

6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following command is an example:

   ```
   mysql -h host_name -P 3306 -u db_master_user -p
   ```

   The *host_name* is the Amazon RDS database endpoint.

7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file. This command loads the data into the Amazon RDS DB instance.

   - For SQL format, use the following command:

     ```
     mysql> source backup.sql;
     ```

   - For delimited-text format, first create the database, if it isn't the default database that you created when setting up the Amazon RDS database.

     ```
     mysql> create database database_name;
     mysql> use database_name;
     ```

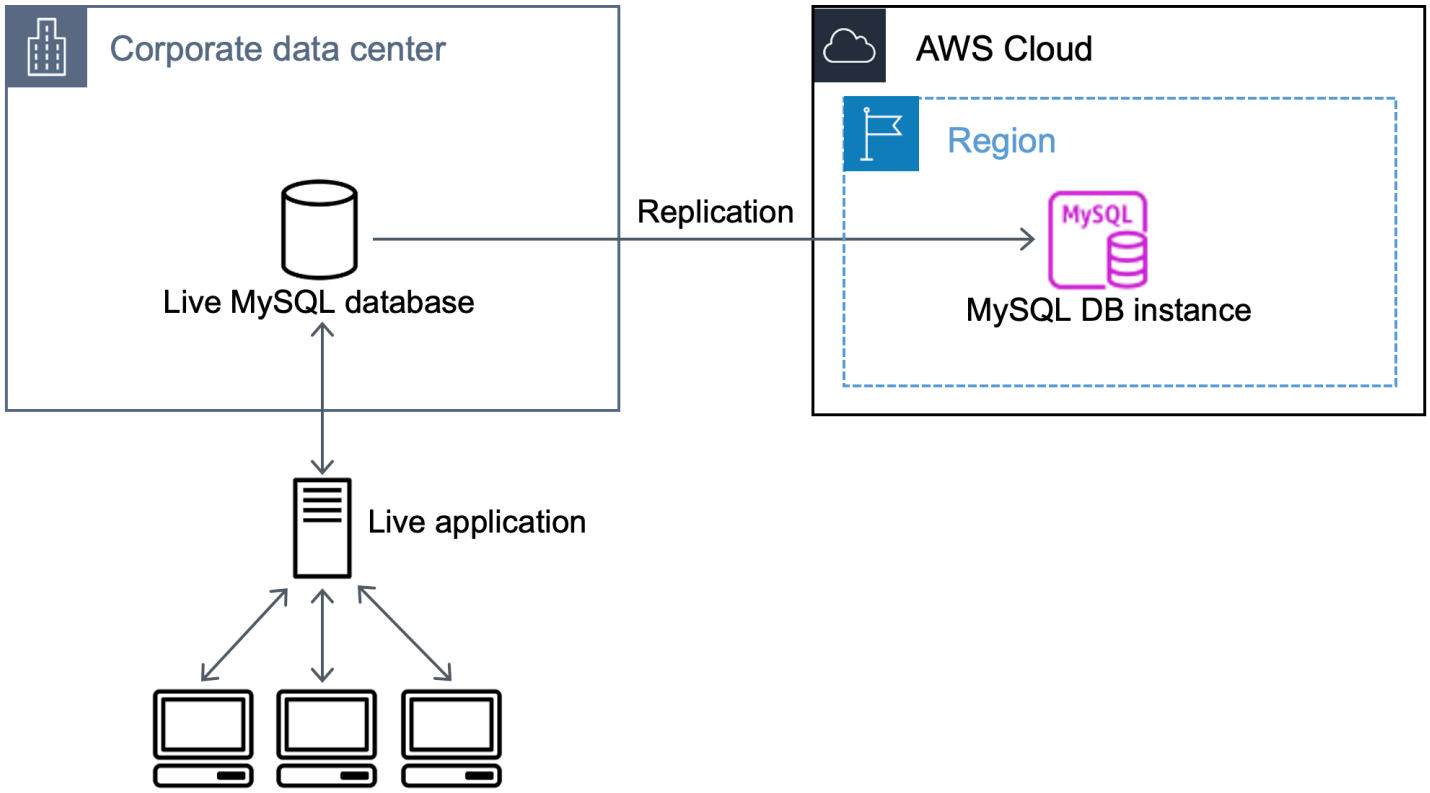
     Then create the tables.

     ```
     mysql> source table1.sql
     mysql> source table2.sql
     etc...
     ```

     Then import the data.

     ```
     mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY
      ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
     mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY
      ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
     etc...
     ```

     To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.



> **Note**
>
> If you used any data-formatting options with `mysqldump` when you initially dumped the table, make sure to use the same options with `LOAD DATA LOCAL INFILE` to ensure proper interpretation of the data file contents.

8. Run a simple `SELECT` query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminate an instance in the *Amazon Elastic Compute Cloud User Guide*.

Task 4: Replicate data from your external database to your new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.

The permissions required to start replication on an Amazon RDS database are restricted and aren't available to your Amazon RDS master user. Because of this, use the appropriate Amazon RDS stored procedure for your major engine version:

- mysql_rds_set_external_master (RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_external_master_gtid to configure replication and mysql.rds_start_replication to start replication

To start replication

In Task 1, when you set replication options, you turned on binary logging and set a unique server ID for your source database. Now, you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on configuring a VPC security group, see Configure security group rules in the *Amazon Virtual Private Cloud User Guide*.

   You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the `host` command:

   ```
   host host_name
   ```

   The *`host_name`* is the DNS name from the Amazon RDS database endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the DB instance details in the Amazon RDS console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following command is an example:

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command:

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

4. Make the Amazon RDS database the replica. Connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the appropriate Amazon RDS stored procedure:

   - mysql_rds_set_external_master (RDS for MySQL major versions 8.0 and lower)
   - mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher)

   If you have a SQL format backup file, use the master log file name and master log position that you determined in Step 4. If you used delimited-text format, use the name and position that you determined when creating the backup files. The following commands are examples:

   MySQL 8.4 and higher versions

```
CALL mysql.rds_set_external_source ('myserver.mydomain.com', 3306,
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
```

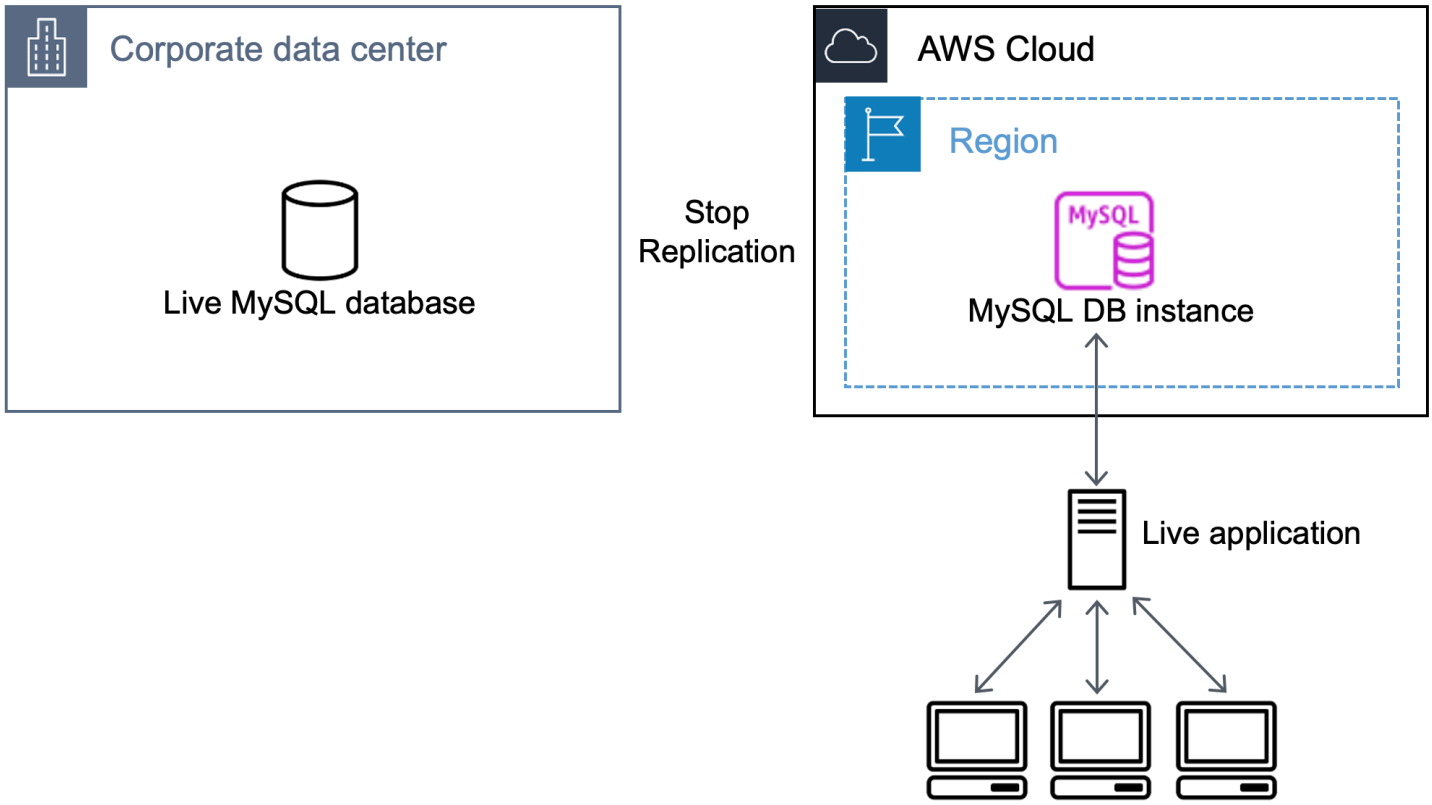
   MySQL 8.0 and lower versions

```
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
```

> **Note**
>
> Specify credentials other than the prompts shown here as a security best practice.

5. On the Amazon RDS database, to start replication, run the following command that uses the mysql.rds_start_replication stored procedure:

```
CALL mysql.rds_start_replication;
```



6. On the Amazon RDS database, to determine when the replica is up to date with the source replication instance, run the SHOW REPLICA STATUS command. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up to date with the source replication instance.

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

7. After the Amazon RDS database is up to date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database by using the Amazon RDS console. For more information, see Introduction to backups.

Task 5: Redirect your live application to your Amazon RDS instance

After the MySQL database is up to date with the source replication instance, you can now update your live application to use the Amazon RDS instance.

To redirect your live application to your MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Configure security group rules in the *Amazon Virtual Private Cloud User Guide*.
2. Verify that the `Seconds_Behind_Master` field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up to date with the source replication instance.

   ```
   SHOW REPLICA STATUS;
   ```

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

3. Close all connections to the source when their transactions complete.
4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.

5. Connect to the DB instance.

   For a Multi-AZ DB cluster, connect to the writer DB instance.

6. Stop replication for the Amazon RDS instance by running the following command that uses the mysql.rds_stop_replication stored procedure:

```
CALL mysql.rds_stop_replication;
```

7. Reset the replication configuration so this instance is no longer identified as a replica by using the appropriate Amazon RDS stored procedure on your Amazon RDS database:
   - mysql_rds_reset_external_master (RDS for MySQL major versions 8.0 and lower)
   - mysql.rds_reset_external_source (RDS for MySQL major versions 8.4 and higher)

   MySQL 8.4 and higher versions

```
CALL mysql.rds_reset_external_source;
```

   MySQL 8.0 and lower versions

```
CALL mysql.rds_reset_external_master;
```

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS and Working with DB instance read replicas.

Importing data from any source to an Amazon RDS for MySQL DB instance

With Amazon RDS, you can migrate existing MySQL data from any source to an RDS for MySQL DB instance. You can transfer data from on-premises databases, other cloud providers, or existing RDS for MySQL DB instances to your target RDS for MySQL DB instance. With this functionality, you can consolidate databases, implement disaster recovery solutions, or transition from self-managed databases. Common scenarios include moving from self-hosted MySQL servers to fully managed Amazon RDS DB instances, consolidating multiple MySQL databases into a single DB instance, or creating test environments with production data. The following sections provide step-by-step instructions for importing your MySQL data using methods such as `mysqldump`, backup files, or replication.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file—you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name could be `sales.csv` or `sales.txt`.

If possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The names of the new files include ascending numerical suffixes. The following command produces files with names such as `sales.part_00` and `sales.part_01`.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

You can store the flat files anywhere. However, when you load the data in Step 5, you must invoke the `mysql` shell from the same location where the files exist, or use the absolute path for the files when you run `LOAD DATA LOCAL INFILE`.

Step 2: Stop any applications from accessing the target DB instance

Before starting a large load, stop all application activity from accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, we recommend that you create DB snapshots of the target Amazon RDS DB instance both before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that you can use to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use DB snapshots after the load to import data into new database instances.

The following example runs the AWS CLI create-db-snapshot command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2" is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2. For more information, see restore-db-instance-from-db-snapshot.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS-2 \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS-2 ^
    --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier. For more information, see delete-db-instance.

The following example also takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
    --db-instance-identifier AcmeRDS \
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot \
    --db-instance-identifier AcmeRDS \
    --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot ^
    --db-instance-identifier AcmeRDS ^
    --db-snapshot-identifier preload
```

Step 4 (Optional): Turn off Amazon RDS automated backups

> **Warning**
>
> Don't turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups is a performance optimization and isn't required for data loads. Turning off automated backups erases all existing backups. As a result, after you turn off automated backups, point-in-time recovery isn't possible. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and then restarts it to turn MySQL logging on or off.

Run the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding. For more information, see modify-db-instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --apply-immediately \
    --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
```

```
    --db-instance-identifier AcmeRDS ^
    --apply-immediately ^
    --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the AcmeRDS DB instance:

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[].
{DBInstanceStatus:DBInstanceStatus}"
```

When the DB instance status is `available`, you're ready to proceed to the next step.

Step 5: Load the data

To read rows from your flat files into the database tables, use the MySQL `LOAD DATA LOCAL INFILE` statement.

> **Note**
>
> You must invoke the `mysql` shell from the same location where your flat files exist, or use the absolute path for the files when you run `LOAD DATA LOCAL INFILE`.

The following example shows how to load data from a file named `sales.txt` into a table named `Sales` in the database:

```
mysql> LOAD DATA LOCAL INFILE 'sales.txt' INTO TABLE Sales FIELDS TERMINATED BY ' '
 ENCLOSED BY '' ESCAPED BY '\\';
Query OK, 1 row affected (0.01 sec)
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

For more information about the `LOAD DATA` statement, see LOAD DATA Statement in the MySQL documentation.

Step 6: Turn back on Amazon RDS automated backups

If you turned off Amazon RDS automated backups in Step 4, after the load is finished, turn automated backups on by setting the backup retention period back to its preload value. As noted in Step 4, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example runs the AWS CLI modify-db-instance command to turn on automated backups for the AcmeRDS DB instance and set the retention period to one day:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier AcmeRDS \
    --backup-retention-period 1 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier AcmeRDS ^
    --backup-retention-period 1 ^
    --apply-immediately
```

Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with DB instance read replicas. For specific information about working with read replicas on Amazon RDS for MySQL, see Working with MySQL read replicas.

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see Using GTID-based replication.

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see Configuring binary log file position replication with an external source instance.

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Configuring RDS for MySQL binary logging for Single-AZ databases.

> **Note**
>
> You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS for MySQL database with reduced downtime and Exporting data from a MySQL DB instance by using replication.

After you restore your DB instance from a snapshot or perform a point-in-time recovery, you can view the last recovered binlog position from the source database in the RDS console. Under **Logs & events**, enter **binlog**. The binlog position appears under **System notes**.

Working with MySQL read replicas

Following, you can find specific information about working with read replicas on RDS for MySQL. For general information about read replicas and instructions for using them, see Working with DB instance read replicas.

For more information about MySQL read replicas, see the following topics.

- Configuring replication filters with MySQL
- Configuring delayed replication with MySQL
- Updating read replicas with MySQL
- Working with Multi-AZ read replica deployments with MySQL
- Using cascading read replicas with RDS for MySQL
- Monitoring replication lag for MySQL read replicas
- Starting and stopping replication with MySQL read replicas
- Troubleshooting a MySQL read replica problem

Configuring read replicas with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported for read replicas running any version of MySQL. You can configure replication based on binary log coordinates for a MySQL DB instance.

You can configure replication using global transaction identifiers (GTIDS) on the following versions:

- RDS for MySQL version 5.7.44 and higher 5.7 versions
- RDS for MySQL version 8.0.28 and higher 8.0 versions
- RDS for MySQL version 8.4.3 and higher 8.4 versions

For more information, see Using GTID-based replication.

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MySQL supports cascading read replicas. To learn how to configure cascading read replicas, see Using cascading read replicas with RDS for MySQL.

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the `DescribeDBInstances` API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

> **Note**
>
> You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Configuring binary log file position replication with an external source instance.

Topics

- Viewing the replication filters for a read replica

Setting replication filtering parameters for RDS for MySQL

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.

- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and _ wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and _ wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see Replica Server Options and Variables.
- For information about how database replication filtering parameters are evaluated, see Evaluation of Database-Level Replication and Binary Logging Options.
- For information about how table replication filtering parameters are evaluated, see Evaluation of Table-Level Replication Options.

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and _ wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see Configuring RDS for MySQL binary logging for Single-AZ databases.

> **Note**
>
> All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for RDS for MySQL

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters for parameter values. In a list of parameters, commas can only be used as value separators. For example, `ParameterValue='`a,b`'` isn't supported, but `ParameterValue='a,b'` is.
- The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

  For more information, see Restrictions on XA Transactions in the MySQL documentation.

Replication filtering examples for RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

> **Note**
>
> You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Parameter groups for Amazon RDS.

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS. When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
- Including tables in replication with wildcard characters
- Excluding databases from replication
- Excluding tables from replication
- Excluding tables from replication using wildcard characters

Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-do-
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-do-
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

Example Including tables in replication

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-do-
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-do-
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `order` and `return` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order
%,mydb.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order
%,mydb.return%',ApplyMethod=immediate"
```

Example Excluding databases from replication

The following example excludes the `mydb5` and `mydb6` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-ignore-
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

Example Excluding tables from replication

The following example excludes tables `table1` in database `mydb5` and `table2` in database `mydb6` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-ignore-
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `order` and `return` in database `mydb7` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order
%,mydb7.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order
%,mydb7.return%',ApplyMethod=immediate"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see Viewing parameter values for a DB parameter group in Amazon RDS.
- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

  In the output, the following fields show the replication filters for the read replica:

  - `Replicate_Do_DB`
  - `Replicate_Ignore_DB`
  - `Replicate_Do_Table`
  - `Replicate_Ignore_Table`
  - `Replicate_Wild_Do_Table`
  - `Replicate_Wild_Ignore_Table`

  For more information about these fields, see Checking Replication Status in the MySQL documentation.

Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the

read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

  Use the mysql.rds_stop_replication stored procedure to stop replication.
- Start replication and specify that replication stops automatically at a log file location.

  You specify a location just before the disaster using the mysql.rds_start_replication_until stored procedure.
- Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

Note

- On RDS for MySQL 8.4, delayed replication is supported for MySQL 8.4.3 and higher. On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.28 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.44 and higher.
- Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
- You can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration for the following versions:
  - RDS for MySQL version 5.7.44 and higher 5.7 versions
  - RDS for MySQL version 8.0.28 and higher 8.0 versions
  - RDS for MySQL version 8.4.3 and higher 8.4 versions

  If you use GTID-based replication, use the mysql.rds_start_replication_until_gtid stored procedure instead of the mysql.rds_start_replication_until stored procedure. For more information about GTID-based replication, see Using GTID-based replication.

Topics

- Configuring delayed replication during read replica creation
- Modifying delayed replication for an existing read replica
- Setting a location to stop replication to a read replica

- Promoting a read replica

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

To configure delayed replication during read replica creation

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.
2. Run the mysql.rds_set_configuration stored procedure with the `target delay` parameter.

   For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

   ```
   call mysql.rds_set_configuration('target delay', 3600);
   ```

   > **Note**
   >
   > After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the mysql.rds_set_source_delay stored procedure.

To modify delayed replication for an existing read replica

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the mysql.rds_stop_replication stored procedure to stop replication.
3. Run the mysql.rds_set_source_delay stored procedure.

   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

```
call mysql.rds_set_source_delay(3600);
```

4. Use the mysql.rds_start_replication stored procedure to start replication.

Setting a location to stop replication to a read replica

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the mysql.rds_start_replication_until stored procedure.

To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the mysql.rds_start_replication_until stored procedure.

   The following example initiates replication and replicates changes until it reaches location `120` in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location `120` is just before the disaster.

```
call mysql.rds_start_replication_until(
  'mysql-bin-changelog.000777',
  120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated: `Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure.`

Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance.

Updating read replicas with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica.

Although you can enable updates by setting the `read_only` parameter to `0` in the DB parameter group for the read replica, we recommend that you don't do so because it can cause problems if the read replica becomes incompatible with the source DB instance. For maintenance operations, we recommend that you use blue/green deployments. For more information, see Using Blue/Green Deployments for database updates.

If you disable read-only on a read replica, change the value of the `read_only` parameter back to `1` as soon as possible.

Working with Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS.

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Using cascading read replicas with RDS for MySQL

RDS for MySQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for MySQL DB instance.

With cascading read replicas, your RDS for MySQL DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MySQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MySQL DB instance. For example, suppose that you have an RDS for MySQL DB instance, `mysql-main`. You can do the following:

- Starting with `mysql-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mysql-main`. A complete series of instances from an RDS for MySQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MySQL DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica, and then modify the read replica to turn on automatic backups. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mysql-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `mysql-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

Monitoring replication lag for MySQL read replicas

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the `read_only` parameter is set to `0` on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag` = -1 is equivalent to `Seconds_Behind_Master` = `NULL`.

Starting and stopping replication with MySQL read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures mysql.rds_stop_replication and mysql.rds_start_replication. You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS for MySQL database with reduced downtime and Exporting data from a MySQL DB instance by using replication.

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MySQL read replica problem

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

Warning

In the parameter group associated with the source DB instance, we recommend keeping these parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These parameters are dynamic. If you don't want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance

class or its storage. The same recommendation applies to creating new read replicas for the source DB instance.
Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see Replication implementation details.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0047. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, review the error number in the MySQL error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. You use `max_allowed_packet` to

specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` value in the DB parameter group associated with a read replica is smaller than the `max_allowed_packet` value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error `Packet bigger than 'max_allowed_packet' bytes` and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the `read_only` parameter to `0` to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping the current replication error for RDS for MySQL. Otherwise, you can first delete the read replica. Then you create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

Using GTID-based replication

The following content explains how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among Amazon RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation.

GTID-based replication is supported for the following versions:

- All RDS for MySQL 8.4 versions

- All RDS for MySQL 8.0 versions
- All RDS for MySQL 5.7 versions

All MySQL DB instances in a replication configuration must meet this version requirement.

Topics

- Overview of global transaction identifiers (GTIDs)
- Parameters for GTID-based replication
- Enabling GTID-based replication for new read replicas for RDS for MySQL
- Enabling GTID-based replication for existing read replicas for RDS for MySQL
- Disabling GTID-based replication for a MySQL DB instance with read replicas

Overview of global transaction identifiers (GTIDs)

Global transaction identifiers (GTIDs) are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with RDS for MySQL read replicas. You can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see Configuring delayed replication with MySQL.

Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

Parameter	Valid values	Description
gtid_mode	OFF, OFF_PERMISSIVE , ON_PERMISSIVE , ON	OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated. OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated. ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated. ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.
enforce_gtid_consistency	OFF, ON, WARN	OFF allows transactions to violate GTID consistency. ON prevents transactions from violating GTID consistency. WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.

Note

In the AWS Management Console, the gtid_mode parameter appears as gtid-mode.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- ON and ON_PERMISSIVE apply only to outgoing replication from an RDS DB instance. Both of these values cause your RDS DB instance to use GTIDs for transactions that are replicated. ON requires that the target database also use GTID-based replication. ON_PERMISSIVE makes GTID-based replication optional on the target database.
- OFF_PERMISSIVE, if set, means that your RDS DB instances can accept incoming replication from a source database. They can do this regardless of whether the source database uses GTID-based replication.
- OFF, if set, means that your RDS DB instance only accepts incoming replication from source databases that don't use GTID-based replication.

For more information about parameter groups, see Parameter groups for Amazon RDS.

Enabling GTID-based replication for new read replicas for RDS for MySQL

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

To enable GTID-based replication for new read replicas

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:

   - gtid_mode – ON or ON_PERMISSIVE
   - enforce_gtid_consistency – ON

   For more information about setting configuration parameters using parameter groups, see Parameter groups for Amazon RDS.
2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see Rebooting a DB instance.
3. Create one or more read replicas of the DB instance. For more information on how to do so, see Creating a read replica.

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the MASTER_AUTO_POSITION. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the MASTER_AUTO_POSITION, see GTID auto-positioning in the MySQL documentation.

Enabling GTID-based replication for existing read replicas for RDS for MySQL

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

To enable GTID-based replication for existing read replicas

1. If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version. All RDS for MySQL 8.4 versions and 5.7 versions support GTID-based replication.

   For more information, see Upgrades of the RDS for MySQL DB engine.
2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:

   a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to `WARN`.

      For more information about setting configuration parameters using parameter groups, see Parameter groups for Amazon RDS.

   b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

      For more information, see Rebooting a DB instance.

   c. Run your DB instance and read replicas with your normal workload and monitor the log files.

      If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.
3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.

   a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

      - `gtid_mode` – `ON_PERMISSIVE`
      - `enforce_gtid_consistency` – `ON`

b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:

   a. Run the following statement on your source DB instance.

      MySQL 8.4

      ```
      SHOW BINARY LOG STATUS;
      ```

      MySQL 5.7 and 8.0

      ```
      SHOW MASTER STATUS;
      ```

      Note the values in the `File` and `Position` columns.

   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

      ```
      SELECT MASTER_POS_WAIT('file', position);
      ```

      For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement.

      ```
      SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
      ```

      If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.

   a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

      - `gtid_mode` – `ON`
      - `enforce_gtid_consistency` – `ON`

   b. Reboot the DB instance and each read replica.

6. On each read replica, run the following procedure.

   MySQL 8.4 and higher major versions

   ```
   CALL mysql.rds_set_source_auto_position(1);
   ```

   MySQL 8.0 and lower major versions

   ```
   CALL mysql.rds_set_master_auto_position(1);
   ```

Disabling GTID-based replication for a MySQL DB instance with read replicas

You can disable GTID-based replication for a MySQL DB instance with read replicas.

To disable GTID-based replication for a MySQL DB instance with read replicas

1. On each read replica, run the following procedure:

   MySQL 8.4 and higher major versions

   ```
   CALL mysql.rds_set_source_auto_position(0);
   ```

   MySQL 8.0 and lower major versions

   ```
   CALL mysql.rds_set_master_auto_position(0);
   ```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `ON_PERMISSIVE`.

      For more information about setting configuration parameters using parameter groups, see Parameter groups for Amazon RDS.

   b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see Rebooting a DB instance.

3. Reset the `gtid_mode` to `OFF_PERMISSIVE`.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `OFF_PERMISSIVE`.

b. Reboot the MySQL DB instance and each read replica.

4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are applied, do the following steps:

   a. On the MySQL DB instance, run the following command:

      MySQL 8.4

      ```
      SHOW BINARY LOG STATUS
      ```

      MySQL 5.7 and 8.0

      ```
      SHOW MASTER STATUS
      ```

      Your output should be similar to the following output.

      ```
      File                        Position
      ------------------------------------
      mysql-bin-changelog.000031      107
      ------------------------------------
      ```

      Note the file and position in your output.

   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query:

      MySQL 8.4 and MySQL 8.0.26 and higher MySQL 8.0 versions

      ```
      SELECT SOURCE_POS_WAIT('file', position);
      ```

      MySQL 5.7

      ```
      SELECT MASTER_POS_WAIT('file', position);
      ```

      For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement:

      MySQL 8.4 and MySQL 8.0.26 and higher MySQL 8.0 versions

```
SELECT SOURCE_POS_WAIT('mysql-bin-changelog.000031', 107);
```

MySQL 5.7

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

5. Reset the GTID parameters to disable GTID-based replication.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:

      - `gtid_mode` – `OFF`
      - `enforce_gtid_consistency` – `OFF`

   b. Reboot the MySQL DB instance and each read replica.

Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

Topics

- Before you begin
- Configuring binary log file position replication with an external source instance

Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) or mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher), and mysql.rds_start_replication commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify the `binlog_format` parameter. In MariaDB and MySQL 8.0 and lower versions, `binlog_format` defaults to `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect. In MySQL 8.4 and higher versions, `binlog_format` defaults to `ROW`.

For information about setting the `binlog_format` parameter, see Configuring RDS for MySQL binary logging for Single-AZ databases. For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up, restoring, and exporting data.

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

```
File                        Position
-------------------------------------
 mysql-bin-changelog.000031      107
-------------------------------------
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS for MySQL database with reduced downtime].

   For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

   For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

   Note

   Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the *Amazon Virtual Private Cloud User Guide*.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher) or mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) command. Use the master log file name and master log position that you determined in step 2. The following commands are examples.

MySQL 8.4

```
CALL mysql.rds_set_external_source ('mysourceserver.mydomain.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
```

MariaDB and MySQL 8.0 and 5.7

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1);
```

> **Note**
>
> On RDS for MySQL, you can choose to use delayed replication by running the mysql.rds_set_external_source_with_delay (RDS for MySQL major versions 8.4

and higher) or mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the mysql.rds_start_replication_until stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the mysql.rds_start_replication command to start replication.

```
CALL mysql.rds_start_replication;
```

Configuring multi-source-replication for Amazon RDS for MySQL

With multi-source replication, you can set up an Amazon RDS for MySQL DB instance as a replica that receives binary log events from more than one RDS for MySQL source DB instance. Multi-source replication is supported for RDS for MySQL DB instances running the following engine versions:

- All MySQL 8.4 versions
- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

For information about MySQL multi-source replication, see MySQL Multi-Source Replication in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the multi-source replication channels on your RDS for MySQL DB instances.

Use cases for multi-source replication

The following cases are good candidates for using multi-source replication on RDS for MySQL:

- Applications that need to merge or combine multiple shards on separate DB instances into a single shard.
- Applications that need to generate reports from data consolidated from multiple sources.

- Requirements to create consolidated long-term backups of data that's distributed among multiple RDS for MySQL DB instances.

Prerequisites for multi-source replication

Before you configure multi-source replication, complete the following prerequisites.

- Make sure that each source RDS for MySQL DB instance has automatic backups enabled. Enabling automatic backups enables binary logging. To learn how to enable automatic backups, see the section called “Enabling automated backups”.
- To avoid replication errors, we recommended that you block write operations to the source DB instances. You can do so by setting the `read-only` parameter to `ON` in a custom parameter group attached to the RDS for MySQL source DB instance. You can use the AWS Management Console or the AWS CLI to create a new custom parameter group or to modify an existing one. For more information, see the section called “Creating a DB parameter group” and the section called “Modifying parameters in a DB parameter group”.
- For each source DB instance, add the IP address of the instance to the Amazon virtual private cloud (VPC) security group for the multi-source DB instance. To identify the IP address of a source DB instance, you can run the command `dig` *`RDS Endpoint`*. Run the command from an Amazon EC2 instance in the same VPC as the destination multi-source DB instance.
- For each source DB instance, use a client to connect to the DB instance and create a database user with the required privileges for replication, as in the following example.

```
CREATE USER 'repl_user' IDENTIFIED BY 'password';
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user';
```

> **Note**
>
> Starting with MySQL 8.4, the `REPLICATION SLAVE` privilege has been deprecated and replaced with `REPLICATION REPLICA`. For MySQL 8.4 and later versions, use the following syntax instead:
>
> ```
> CREATE USER 'repl_user' IDENTIFIED BY 'password';
> GRANT REPLICATION CLIENT, REPLICATION REPLICA ON *.* TO 'repl_user';
> ```

Configuring multi-source replication channels on RDS for MySQL DB instances

Configuring multi-source replication channels is similar to configuring single source replication. For multi-source replication, you first turn on binary logging on the source instance. Then, you import data from the sources to the multi-source replica. Then, you start replication from each source by using the binary log coordinates or by using GTID auto-positioning.

To configure an RDS for MySQL DB instance as a multi-source replica of two or more RDS for MySQL DB instances, perform the following steps.

Topics

- Step 1: Import data from the source DB instances to the multi-source replica
- Step 2: Start replication from the source DB instances to the multi-source replica

Step 1: Import data from the source DB instances to the multi-source replica

Perform the following steps on each source DB instance.

Before you import the data from a source to the multi-source replica, determine the current binary log file and position by running the `SHOW MASTER STATUS` command. Take note of these details for use in the next step. In this example output, the file is `mysql-bin-changelog.000031` and the position is `107`.

> **Note**
>
> Starting with MySQL 8.4, the `SHOW MASTER STATUS` command has been deprecated and replaced with `SHOW BINARY LOG STATUS`. For MySQL 8.4 and later versions, use `SHOW BINARY LOG STATUS` instead.

```
File                        Position
-----------------------------------
mysql-bin-changelog.000031      107
-----------------------------------
```

Now copy the database from the source DB instance to the multi-source replica by using `mysqldump`, as in the following example.

```
mysqldump --databases database_name \
```

```
 --single-transaction \
 --compress \
 --order-by-primary \
 -u RDS_user_name \
 -p RDS_password \
 --host=RDS Endpoint | mysql \
 --host=RDS Endpoint \
 --port=3306 \
 -u RDS_user_name \
-p RDS_password
```

After copying the database, you can set the read-only parameter to OFF on the source DB instance.

Step 2: Start replication from the source DB instances to the multi-source replica

For each source DB instance, use the administrative user credentials to connect to the instance, and run the following two stored procedures. These stored procedures configure replication on a channel and start replication. This example uses the binlog file name and position from the example output in the previous step.

```
CALL mysql.rds_set_external_source_for_channel('mysourcehost.example.com', 3306,
 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 1, 'channel_1');
CALL mysql.rds_start_replication_for_channel('channel_1');
```

For more information about using these stored procedures and others to set up and manage your replication channels, see the section called “Managing multi-source replication”.

Using filters with multi-source replication

You can use replication filters to specify which databases and tables are replicated with in multi-source replica. Replication filters can include databases and tables in replication or exclude them from replication. For more information on replication filters, see the section called “Configuring replication filters”.

With multi-source replication, you can configure replication filters globally or at the channel level. Channel-level filtering is available only with supported DB instances running version 8.0 or version 8.4. The following examples show how to configure filters globally or at the channel level.

Note the following requirements and behavior with filtering in multi-source replication:

- Back quotes (` `) around the channel names are required.

- If you change replication filters in the parameter group, the multi-source replica's `sql_thread` for all channels with updates are restarted to apply the changes dynamically. If an update involves a global filter, then all replication channels in the running state are restarted.
- All global filters are applied before any channel-specific filters.
- If a filter is applied globally and at the channel level, then only the channel-level filter is applied. For example, if the filters are `replicate_ignore_db="db1,`channel_22`:db2"`, then `replicate_ignore_db` set to `db1` is applied to all channels except for `channel_22`, and only `channel_22` ignores changes from `db2`.

Example 1: Setting a global filter

In the following example, the `temp_data` database is excluded from replication in every channel.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "ParameterName=replicate-ignore-
db,ParameterValue='temp_data',ApplyMethod=immediate"
```

Example 2: Setting a channel-level filter

In the following example, changes from the `sample22` database are only included in channel `channel_22`. Similarly, changes from the `sample99` database are only included in channel `channel_99`.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "ParameterName=replicate-do-db,ParameterValue='\`channel_22\`:sample22,
\`channel_99\`:sample99',ApplyMethod=immediate"
```

Monitoring multi-source replication channels

You can monitor individual channels in a multi-source replica by using the following methods:

- To monitor the status of all channels or a specific channel, connect to the multi-source replica and run the `SHOW REPLICA STATUS` or `SHOW REPLICA STATUS FOR CHANNEL`

'*channel_name*' command. For more information, see Checking Replication Status in the MySQL documentation.

- To receive notification when a replication channel is started, stopped, or removed, use RDS event notification. For more information, see the section called "Working with Amazon RDS event notification".
- To monitor the lag for a specific channel, check the `ReplicationChannelLag` metric for it. Data points for this metric have a period of 60 seconds (1 minute) are available for 15 days. To locate the replication channel lag for a channel, use the instance identifier and the replication channel name. To receive notification when this lag exceeds a particular threshold, you can set up a CloudWatch alarm. For more information, see the section called "Monitoring RDS with CloudWatch".

Considerations and best practices for multi-source replication

Before you use multi-source replication on RDS for MySQL, review the following considerations and best practices:

- Make sure that a DB instance configured as a multi-source replica has sufficient resources such as throughput, memory, CPU, and IOPS to handle the workload from multiple source instances.
- Regularly monitor resource utilization on your multi-source replica and adjust the storage or instance configuration to handle the workload without straining resources.
- You can configure multi-threaded replication on a multi-source replica by setting the system variable `replica_parallel_workers` to a value greater than `0`. In this case, the number of threads allocated to each channel is the value of this variable, plus one coordinator thread to manage the applier threads.
- Configure replication filters appropriately to avoid conflicts. To replicate an entire database to another database on a replica, you can use the `--replicate-rewrite-db` option. For example, you can replicate all tables in database A to database B on a replica instance. This approach can be helpful when all source instances are using the same schema naming convention. For information about the `--replicate-rewrite-db` option, see Replica Server Options and Variables in the MySQL documentation.
- To avoid replication errors, avoid writing to the replica. We recommended that you enable the `read_only` parameter on multi-source replicas to block write operations. Doing so helps to eliminate replication issues caused by conflicting write operations.

- To increase the performance of read operations such as sorts and high-load joins that are executed on the multi-source replica, consider using RDS Optimized Reads. This feature can help with queries that depend on large temporary tables or sort files. For more information, see the section called “Improving query performance with RDS Optimized Reads”.
- To minimize replication lag and improve the performance of a multi-source replica, consider enabling optimized writes. For more information, see the section called “Improving write performance with RDS Optimized Writes for MySQL”.
- Perform management operations (such as changing configuration) on one channel at a time, and avoid performing changes to multiple channels from multiple connections. These practices can lead to conflicts in replication operations. For example, simultaneously executing `rds_skip_repl_error_for_channel` and `rds_start_replication_for_channel` procedures from multiple connections can cause skipping of events on a different channel than intended.
- You can enable backups on a multi-source replication instance and export data from that instance to an Amazon S3 bucket to store it for long-term purposes. However, it's important to also configure backups with appropriate retention on the individual source instances. For information about exporting snapshot data to Amazon S3, see the section called “Exporting DB snapshot data to Amazon S3”.
- To distribute the read workload on a multi-source replica, you can create read replicas from a multi-source replica. You can locate these read replicas in different AWS Regions based on your application's requirements. For more information about read replicas, see the section called “MySQL read replicas”.

Limitations for multi-source replication on RDS for MySQL

The following limitations apply to multi-source replication on RDS for MySQL:

- Currently, RDS for MySQL supports configuring a maximum of 15 channels for a multi-source replica.
- A read replica instance can't be configured as a multi-source replica.
- To configure multi-source replication on RDS for MySQL running engine version 5.7, Performance Schema must be enabled on the replica instance. Enabling Performance Schema is optional on RDS for MySQL running engine version 8.0 or 8.4.

- For RDS for MySQL running engine version 5.7, replication filters apply to all replication channels. For RDS for MySQL running engine version 8.0 or 8.4, you can configure filters that apply to all replication channels or to individual channels.
- Restoring an RDS snapshot or performing a Point-in-time-Restore (PITR) doesn't restore multi-source replica channel configurations.
- When you create a read replica of a multi-source replica, it only replicates data from the multi-source instance. It doesn't restore any channel configuration.
- MySQL doesn't support setting up a different number of parallel workers for each channel. Every channel gets the same number of parallel workers based on the `replica_parallel_workers` value.

The following additional limitations apply if your multi-source replication target is a Multi-AZ DB cluster:

- A channel must be configured for a source RDS for MySQL instance before any writes to that instance occur.
- Each source RDS for MySQL instance must have GTID-based replication enabled.
- A failover event on the DB cluster removes the multi-source replication configuration. Restoring that configuration requires repeating the configuration steps.

Configuring active-active clusters for RDS for MySQL

An active-active cluster in Amazon RDS is a database configuration where multiple nodes actively handle read and write operations, distributing the workload across instances to improve availability and scalability. Each node in the cluster is synchronized to maintain data consistency, enabling high availability and faster failover in case of node failure

You can set up an active-active cluster for RDS for MySQL by using the MySQL Group Replication plugin. The Group Replication plugin is supported for RDS for MySQL DB instances running the following versions:

- All MySQL 8.4 versions
- MySQL 8.0.35 and higher minor versions

For information about MySQL Group Replication, see Group Replication in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the plugin on your RDS for MySQL DB instances.

> **Note**
>
> For the sake of brevity, all mentions of "active-active" cluster in this topic refer to active-active clusters using the MySQL Group Replication plugin.

Use cases for active-active clusters

The following cases are good candidates for using active-active clusters:

- Applications that need all of the DB instances in the cluster to support write operations. The Group Replication plugin keeps the data consistent on each DB instance in the active-active cluster. For more information about how this works, see Group Replication in the MySQL documentation.
- Applications that require continuous availability of the database. With an active-active cluster, the data is retained on the all of the DB instances in the cluster. If one DB instance fails, the application can reroute traffic to another DB instance in the cluster.
- Applications that might need to split read and write operations among different DB instances in the cluster for load balancing purposes. With an active-active cluster, your applications can

send read traffic to specific DB instances and write traffic to others. You can also switch which DB instances to send reads or writes to at any time.

Topics

- Limitations and considerations for active-active clusters
- Preparing for a cross-VPC active-active cluster
- Required parameter settings for active-active clusters
- Converting an existing DB instance to an active-active cluster
- Setting up an active-active cluster with new DB instances
- Adding a DB instance to an active-active cluster
- Monitoring active-active clusters
- Stopping Group Replication on a DB instance in an active-active cluster
- Renaming a DB instance in an active-active cluster
- Removing a DB instance from an active-active cluster

Limitations and considerations for active-active clusters

Active-active clusters in Amazon RDS offer enhanced availability and scalability by distributing workloads across multiple instances. However, there are important limitations and considerations to keep in mind when using this architecture.

The following sections outline key factors such as replication delays, conflict resolution, resource allocation, and failover behavior. Understanding these considerations can help ensure optimal performance and reliability in active-active cluster deployments.

Topics

- Limitations for RDS for MySQL active-active clusters
- Considerations and best practices for RDS for MySQL active-active clusters

Limitations for RDS for MySQL active-active clusters

The following limitations apply to active-active clusters for RDS for MySQL:

- The master user name can't be `rdsgrprepladmin` for DB instances in an active-active cluster. This user name is reserved for Group Replication connections.

- For DB instances with read replicas in active-active clusters, a prolonged replication status other than `Replicating` can cause log files to exceed storage limits. For information about the status of read replicas, see Monitoring read replication.
- Blue/green deployments aren't supported for DB instances in an active-active cluster. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.
- Kerberos authentication isn't supported for DB instances in an active-active cluster. For more information, see Using Kerberos authentication for Amazon RDS for MySQL.
- The DB instances in a Multi-AZ DB cluster can't be added to an active-active cluster. However, the DB instances in a Multi-AZ DB instance deployment can be added to an active-active cluster. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS.
- Tables that don't have a primary key aren't replicated in an active-active cluster because writes are rejected by the Group Replication plugin.
- Non-InnoDB tables aren't replicated in an active-active cluster.
- Active-active clusters don't support concurrent DML and DDL statements on different DB instances in the cluster.
- You can't configure an active-active cluster to use single-primary mode for the group's replication mode. For this configuration, we recommend using a Multi-AZ DB cluster instead. For more information, see Multi-AZ DB cluster deployments for Amazon RDS.
- Multi-source replication isn't supported for DB instances in an active-active cluster.
- A cross-Region active-active cluster can't enforce certificate authority (CA) verification for Group Replication connections.

Considerations and best practices for RDS for MySQL active-active clusters

Before you use RDS for MySQL active-active clusters, review the following considerations and best practices:

- Active-active clusters can't have more than nine DB instances.
- With the Group Replication plugin, you can control the transaction consistency guarantees of the active-active cluster. For more information, see Transaction Consistency Guarantees in the MySQL documentation.
- Conflicts are possible when different DB instances update the same row in an active-active cluster. For information about conflicts and conflict resolution, see Group Replication in the MySQL documentation.

- For fault tolerance, include at least three DB instances in your active-active cluster. It is possible to configure an active-active cluster with only one or two DB instances, but the cluster won't be fault tolerant. For information about fault tolerance, see Fault-tolerance in the MySQL documentation.
- When a DB instance joins an existing active-active cluster and is running the same engine version as the lowest engine version in the cluster, the DB instance joins in read-write mode.
- When a DB instance joins an existing active-active cluster and is running a higher engine version than the lowest engine version in the cluster, the DB instance must remain in read-only mode.
- If you enable Group Replication for a DB instance by setting its `rds.group_replication_enabled` parameter to `1` in the DB parameter group, but replication hasn't started or has failed to start, the DB instance is placed in super-read-only mode to prevent data inconsistencies. For information about super-read-only mode, see the MySQL documentation.
- You can upgrade a DB instance in an active-active cluster, but the DB instance is read-only until all of the other DB instances in the active-active cluster are upgraded to same engine version or a higher engine version. When you upgrade a DB instance, the DB instance automatically joins the same active-active cluster when the upgrade completes. To avoid an unintended switch to read-only mode for a DB instance, disable automatic minor version upgrades for it. For information about upgrading a MySQL DB instance, see Upgrades of the RDS for MySQL DB engine.
- You can add a DB instance in a Multi-AZ DB instance deployment to an existing active-active cluster. You can also convert a Single-AZ DB instance in an active-active cluster to a Multi-AZ DB instance deployment. If a primary DB instance in a Multi-AZ deployment fails, that primary instance fails over to the standby instance. The new primary DB instance automatically joins the same cluster after failover completes. For more information about Multi-AZ DB instance deployments, see Multi-AZ DB instance deployments for Amazon RDS.
- We recommend that the DB instances in an active-active cluster have different time ranges for their maintenance windows. This practice avoids multiple DB instances in the cluster going offline for maintenance at the same time. For more information, see Amazon RDS maintenance window.
- Active-active clusters can use SSL for connections between DB instances. To configure SSL connections, set the `group_replication_recovery_use_ssl` and `group_replication_ssl_mode` parameters. The values for these parameters must match for all DB instances in the active-active cluster.

Currently, active-active clusters don't support certificate authority (CA) verification for connections between AWS Regions. So, the group_replication_ssl_mode parameter must be set to DISABLED (the default) or REQUIRED for cross-Region clusters.

- An RDS for MySQL active-active cluster runs in multi-primary mode. The default value of the group_replication_enforce_update_everywhere_checks is ON and the parameter is static. When this parameter is set to ON, applications can't insert into a table that has cascading foreign key constraints.
- An RDS for MySQL active-active cluster uses the MySQL communication stack for connection security instead of XCOM. For more information, see Communication Stack for Connection Security Management in the MySQL documentation.
- When a DB parameter group is associated with a DB instance in an active-active cluster, we recommend only associating this DB parameter group with other DB instances that are in the cluster.
- Active-active clusters only support RDS for MySQL DB instances. These DB instances must be running supported versions of the DB engine.
- When a DB instance in an active-active cluster has an unexpected failure, RDS starts recovery of the DB instance automatically. If the DB instance doesn't recover, we recommend replacing it with a new DB instance by performing a point-in-time recovery with a healthy DB instance in the cluster. For instructions, see Adding a DB instance to an active-active cluster using point-in-time recovery.
- You can delete a DB instance in an active-active cluster without affecting the other DB instances in the cluster. For information about deleting a DB instance, see Deleting a DB instance.
- When a DB instance unintentionally leaves an active-active cluster, by default the group_replication_exit_state_action parameter changes to OFFLINE_MODE. In this state, the DB instance is inaccessible and you must reboot the DB instance to bring it back online and to rejoin the cluster. You can change this behavior by modifying the group_replication_exit_state_action parameter in a custom parameter group. By setting the parameter to READ_ONLY, when the DB instance unintentionally leaves a cluster, it enters a super read-only state rather than going offline.

Preparing for a cross-VPC active-active cluster

You can configure an active-active cluster with Amazon RDS for MySQL DB instances in more than one VPC. The VPCs can be in the same AWS Region or different AWS Regions.

> **Note**
>
> Sending traffic between multiple AWS Regions might incur additional costs. For more information, see Overview of Data Transfer Costs for Common Architectures.

If you are configuring an active-active cluster in a single VPC, you can skip these steps and move on to Setting up an active-active cluster with new DB instances.

To prepare for an active-active cluster with DB instances in more than one VPC

1. Make sure the IPv4 address ranges in the CIDR blocks meet the following requirements:

   - The IPv4 address ranges in the CIDR blocks of the VPCs can't overlap.
   - All of the IPv4 address ranges in the CIDR blocks either must be lower than `128.0.0.0/subnet_mask` or higher than 128.0.0.0/`subnet_mask`.

   The following ranges illustrate these requirements:

   - `10.1.0.0/16` in one VPC and `10.2.0.0/16` in the other VPC is supported.
   - `172.1.0.0/16` in one VPC and `172.2.0.0/16` in the other VPC is supported.
   - `10.1.0.0/16` in one VPC and `10.1.0.0/16` in the other VPC *is not* supported because the ranges overlap.
   - `10.1.0.0/16` in one VPC and `172.1.0.0/16` in the other VPC *is not* supported because one is below `128.0.0.0/subnet_mask` and the other is above `128.0.0.0/subnet_mask`.

   For information about CIDR blocks, see VPC CIDR blocks in the *Amazon VPC User Guide*.
2. In each VPC, make sure DNS resolution and DNS hostnames are both enabled.

   For instructions, see View and update DNS attributes for your VPC in the *Amazon VPC User Guide*.
3. Configure the VPCs so that you can route traffic between them in one of the following ways:

   - Create a VPC peering connection between the VPCs.

     For instructions, see Create a VPC peering connection in the *Amazon VPC Peering Guide*. In each VPC, make sure there are inbound rules for your security groups that reference

security groups in the peered VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the peered VPC. For instructions, see Update your security groups to reference peer security groups in the *Amazon VPC Peering Guide*.

- Create a transit gateway between the VPCs.

  For instructions, see Getting started with transit gateways in *Amazon VPC Transit Gateways*. In each VPC, make sure there are inbound rules for your security groups that allow traffic from the other VPC, such as inbound rules that specify the CIDR of the other VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the active-active cluster. For more information, see Control traffic to your AWS resources using security groups in the *Amazon VPC User Guide*.

Required parameter settings for active-active clusters

Configuring parameters for active-active clusters in Amazon RDS for MySQL is essential for maintaining consistent performance and operational stability. This table details the key parameters that control replication, conflict resolution, and workload distribution. Correct configuration ensures efficient synchronization between nodes, minimizes replication lag, and optimizes resource utilization in distributed or high-traffic environments.

Parameter	Description	Required setting
`binlog_format`	Sets the binary logging format. The default value for RDS for MySQL 8.0 versions and lower is `MIXED`. The default value for RDS for MySQL 8.4 versions is `ROW`. For more information, see the MySQL documentation.	`ROW`
`enforce_gtid_consistency`	Enforces GTID consistency for statement execution. The default value for RDS for MySQL is `OFF`. For more	`ON`

Parameter	Description	Required setting
	information, see the MySQL documentation.	
group_replication_group_name	Sets the Group Replication name to a UUID. The UUID format is 11111111-2222-3333-4444-555555555555. You can generate a MySQL UUID by connecting to a MySQL DB instance and running SELECT UUID(). The value must be the same for all of the DB instances in the active-active cluster. For more information, see the MySQL documentation.	A MySQL UUID
gtid-mode	Controls GTID-based logging. The default value for RDS for MySQL is OFF_PERMISSIVE. For more information, see the MySQL documentation.	ON

Parameter	Description	Required setting
`rds.custom_dns_resolution`	Specifies whether to allow DNS resolution from the Amazon DNS server in your VPC. DNS resolution must be enabled when Group Replication is enabled with the `rds.group_replication_enabled` parameter. DNS resolution can't be enabled when Group Replication is disabled with the `rds.group_replication_enabled` parameter. For more information, see Amazon DNS server in the *Amazon VPC User Guide*.	1
`rds.group_replication_enabled`	Specifies whether Group Replication is enabled for a DB instance. Group Replication must be enabled on a DB instance in an active-active cluster.	1
`replica_preserve_commit_order` (RDS for MySQL 8.4 and higher versions) or `slave_preserve_commit_order` (RDS for MySQL 8.0 versions)	Controls the order that transactions are committed on a replica. The default value for RDS for MySQL is `ON`. For more information, see the MySQL documentation.	`ON`

Converting an existing DB instance to an active-active cluster

The DB engine version of the DB instance you want to migrate to an active-active cluster must be one of the following versions:

- All MySQL 8.4 versions
- MySQL 8.0.35 and higher minor versions

If you need to upgrade the engine version, see Upgrades of the RDS for MySQL DB engine.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in Preparing for a cross-VPC active-active cluster.

Complete the following steps to migrate an existing DB instance to an active-active cluster for RDS for MySQL.

Topics

- Step 1: Set the active-active cluster parameters in one or more custom parameter groups
- Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set
- Step 3: Create the active-active cluster
- Step 4: Create additional RDS for MySQL DB instances for the active-active cluster
- Step 5: Initialize the group on the DB instance you are converting
- Step 6: Start replication on the other DB instances in the active-active cluster
- Step 7: (Recommended) Check the status of the active-active cluster

Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly

recommend that you create a new custom parameter group. The DB instances in an active-active cluster can be associated with the same DB parameter group or with different DB parameter groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see Creating a DB parameter group in Amazon RDS. The following example runs the create-db-parameter-group AWS CLI command to create a custom DB parameter group named *myactivepg* for RDS for MySQL 8.0:

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --db-parameter-group-family mysql8.0 \
  --description "Parameter group for active-active clusters"
```

For Windows:

```
aws rds create-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --db-parameter-group-family mysql8.0 ^
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters for RDS for MySQL 8.0. To use this example with RDS for MySQL 8.4, change `slave_preserve_commit_order` to `replica_preserve_commit_order`.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" \
```

```
 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" \
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" \

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 \

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" ^
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 ^

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set

Associate the DB instance with a parameter group you created or modified in the previous step. For instructions, see Associating a DB parameter group with a DB instance in Amazon RDS.

Reboot the DB instance for the new parameter settings to take effect. For instructions, see Rebooting a DB instance.

Step 3: Create the active-active cluster

In the DB parameter group associated with the DB instance, set the `group_replication_group_seeds` parameter to the endpoint of the DB instance you are converting.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

Step 4: Create additional RDS for MySQL DB instances for the active-active cluster

To create additional DB instances for the active-active cluster, perform point-in-time recovery on the DB instance you are converting. For instructions, see Adding a DB instance to an active-active cluster using point-in-time recovery.

An active-active cluster can have up to nine DB instances. Perform point-in-time recovery on the DB instance until you have the number of DB instances you want for the cluster. When you perform point-in-recovery, make sure you associate the DB instance you are adding with a DB parameter group that has `rds.group_replication_enabled` set to 1. Otherwise, Group Replication won't start on the newly added DB instance.

Step 5: Initialize the group on the DB instance you are converting

Initialize the group and start replication:

1. Connect to that DB instance you are converting in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see Connecting to your MySQL DB instance.
2. In the SQL client, run the following stored procedures and replace *`group_replication_user_password`* with the password for the `rdsgrprepladmin` user. The `rdsgrprepladmin` user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(1);
```

   This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

   This example specifies 1 in the `mysql.rds_group_replication_start` stored procedure to initialize a new group with the current DB instance.

   For more information about the stored procedures called in the example, see Managing active-active clusters.

Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace *group_replication_user_password* with the password for the `rdsgrprepladmin` user.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(0);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies `0` in the `mysql.rds_group_replication_start` stored procedure to join the current DB instance to an existing group.

> **Tip**
>
> Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+---------------
+----------------------------+
```

```
| CHANNEL_NAME               | MEMBER_ID                            | MEMBER_HOST    |
 MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
 |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+---------------
+----------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+---------------
+----------------------------+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER_STATE values, see Group Replication Server States in the MySQL documentation.

Setting up an active-active cluster with new DB instances

Complete the following steps to set up an active-active cluster using new Amazon RDS for MySQL DB instances.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in Preparing for a cross-VPC active-active cluster.

Topics

- Step 1: Set the active-active cluster parameters in one or more custom parameter groups
- Step 2: Create new RDS for MySQL DB instances for the active-active cluster
- Step 3: Specify the DB instances in the active-active cluster
- Step 4: Initialize the group on a DB instance and start replication
- Step 5: Start replication on the other DB instances in the active-active cluster
- Step 6: (Recommended) Check the status of the active-active cluster
- Step 7: (Optional) Import data into a DB instance in the active-active cluster

Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active cluster can be associated with the same DB parameter group or with different DB parameter groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see Creating a DB parameter group in Amazon RDS. The following example runs the create-db-parameter-group AWS CLI command to create a custom DB parameter group named *myactivepg* for RDS for MySQL 8.0:

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --db-parameter-group-family mysql8.0 \
  --description "Parameter group for active-active clusters"
```

For Windows:

```
aws rds create-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --db-parameter-group-family mysql8.0 ^
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters for RDS for MySQL 8.0. To use this example with RDS for MySQL 8.4, change `slave_preserve_commit_order` to `replica_preserve_commit_order`.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" \

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" \
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" \

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \

 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 \

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" ^

 "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" ^
               "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

 "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^
```

```
 "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
 ^

 "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"
```

Step 2: Create new RDS for MySQL DB instances for the active-active cluster

Active-active clusters are supported for the following versions of RDS for MySQL DB instances:

- All MySQL version 8.4 versions
- MySQL version 8.0.35 and higher minor versions

You can create up to nine new DB instances for the cluster.

You can use the AWS Management Console or the AWS CLI to create new DB instances. For more information about creating a DB instance, see Creating an Amazon RDS DB instance. When you create the DB instance, associate it with a DB parameter group that you created or modified in the previous step.

Step 3: Specify the DB instances in the active-active cluster

In the DB parameter group associated with each DB instance, set the `group_replication_group_seeds` parameter to the endpoints of the DB instances you want to include in the cluster.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

The following example runs the modify-db-parameter-group AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myactivepg \
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-
```

```
east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-
east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
 "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-
east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-
east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

Tip

Make sure you set the `group_replication_group_seeds` parameter in each DB parameter group that is associated with a DB instance in the active-active cluster.

Step 4: Initialize the group on a DB instance and start replication

You can choose any new DB to initialize the group and start replication. To do so, complete the following steps:

1. Choose a DB instance in the active-active cluster, and connect to that DB instance in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see Connecting to your MySQL DB instance.
2. In the SQL client, run the following stored procedures and replace *group_replication_user_password* with the password for the `rdsgrprepladmin` user. The `rdsgrprepladmin` user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

   ```
   call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
   call mysql.rds_group_replication_create_user('group_replication_user_password');
   call
    mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   call mysql.rds_group_replication_start(1);
   ```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

This example specifies 1 in the `mysql.rds_group_replication_start` stored procedure to initialize a new group with the current DB instance.

For more information about the stored procedures called in the example, see Managing active-active clusters.

Step 5: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace *`group_replication_user_password`* with the password for the `rdsgrprepladmin` user.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(0);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies `0` in the `mysql.rds_group_replication_start` stored procedure to join the current DB instance to an existing group.

> **Tip**
>
> Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

Step 6: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+-----------------------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST    |
 MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
 |
+---------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+-----------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
+---------------------------+--------------------------------------
+---------------+-------------+-------------+-------------+---------------
+-----------------------------+
3 rows in set (0.00 sec)
```

For information about the possible `MEMBER_STATE` values, see Group Replication Server States in the MySQL documentation.

Step 7: (Optional) Import data into a DB instance in the active-active cluster

You can import data from a MySQL database into a DB instance in the active-active cluster. After the data is imported, Group Replication replicates it to the other DB instances in the cluster.

For information about importing data, see Importing data to an Amazon RDS for MySQL database with reduced downtime.

Adding a DB instance to an active-active cluster

You can add a DB instance to an Amazon RDS for MySQL active-active cluster by restoring a DB snapshot or by restoring a DB instance to a point in time. An active-active cluster can include up to nine DB instances.

When you recover a DB instance to a point in time, it usually includes more recent transactions than a DB instance that was restored from a DB snapshot. When the DB instance has more recent transactions, fewer transactions need to be applied when you start replication. So, using point-in-time recovery to add a DB instance to a cluster is usually faster than restoring from a DB snapshot.

Topics

- Adding a DB instance to an active-active cluster using point-in-time recovery
- Adding a DB instance to an active-active cluster using a DB snapshot

Adding a DB instance to an active-active cluster using point-in-time recovery

You can add a DB instance to an active-active cluster by performing point-in-time recovery on a DB instance in the cluster.

For information about recovering a DB instance to a point in time in a different AWS Region, see Replicating automated backups to another AWS Region.

To add a DB instance to an active-active cluster using point-in-time recovery

1. Create a new DB instance by performing point-in-time recovery on a DB instance in the active-active cluster.

   You can perform point-in-time recovery on any DB instance in the cluster to create the new DB instance. For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

   > **Important**
   >
   > During point-in-time-recovery, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. Otherwise, Group Replication won't start on the new DB instance. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

> **Tip**
>
> If you take a snapshot of the DB instance before you start point-in-time recovery, you might be able to reduce the amount of time required to apply transactions on the new DB instance.

2. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

   For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

3. In a SQL client, connect to the new DB instance, and call the mysql.rds_group_replication_set_recovery_channel stored procedure. Replace *`group_replication_user_password`* with the password for the `rdsgrprepladmin` user.

```
call
 mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
```

4. Using the SQL client, call the mysql.rds_group_replication_start stored procedure to start replication:

```
call mysql.rds_group_replication_start(0);
```

Adding a DB instance to an active-active cluster using a DB snapshot

You can add a DB instance to an active-active cluster by creating a DB snapshot of a DB instance in the cluster and then restoring the DB snapshot.

For information about copying a snapshot to a different AWS Region, see the section called “Cross-Region copying”.

To add a DB instance to an active-active cluster using a DB snapshot

1. Create a DB snapshot of a DB instance in the active-active cluster.

You can create a DB snapshot of any DB instance in the cluster. For instructions, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

2. Restore a DB instance from the DB snapshot.

   During the snapshot restore operation, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. For information about the parameters and the required setting for each one, see Required parameter settings for active-active clusters.

   For information about restoring a DB instance from a DB snapshot, see Restoring to a DB instance.

3. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

   For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

4. In a SQL client, connect to the new DB instance, and call the mysql.rds_group_replication_set_recovery_channel stored procedure. Replace *`group_replication_user_password`* with the password for the `rdsgrprepladmin` user.

   ```
   call
    mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
   ```

5. Using the SQL client, call the mysql.rds_group_replication_start stored procedure to start replication:

   ```
   call mysql.rds_group_replication_start(0);
   ```

Monitoring active-active clusters

Monitoring active-active clusters in Amazon RDS for MySQL is crucial for tracking performance, replication integrity, and node synchronization. You can monitor your active-active cluster by connecting to a DB instance in the cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show ONLINE for the MEMBER_STATE of each DB instance, as in the following sample output:

```
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+---------------
+----------------------------+
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST    |
 MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
 |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+---------------
+----------------------------+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
      3306 | ONLINE       | PRIMARY     | 8.0.35         | MySQL                       |
+---------------------------+--------------------------------------
+---------------+-------------+--------------+-------------+---------------
+----------------------------+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER_STATE values, see Group Replication Server States in the MySQL documentation.

Stopping Group Replication on a DB instance in an active-active cluster

You can stop Group Replication on a DB instance in an active-active cluster. When you stop Group Replication, the DB instance is placed in super-read-only mode until replication is restarted or that DB instance is removed from the active-active cluster. For information about super-read-only mode, see the MySQL documentation.

To stop Group Replication temporarily for an active-active cluster

1. Connect to a DB instance in the active-active cluster using a SQL client.

   For more information about connecting to an RDS for MySQL DB instance, see Connecting to your MySQL DB instance.

2. In the SQL client, call the mysql.rds_group_replication_stop stored procedure:

```
call mysql.rds_group_replication_stop();
```

Renaming a DB instance in an active-active cluster

You can change the name of a DB instance in an active-active cluster. To rename more than one DB instance in an active-active cluster, do so one DB instance at a time. So, rename one DB instance and rejoin it to the cluster before you rename the next DB instance.

To rename a DB instance in an active-active cluster

1. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_stop stored procedure:

   ```
   call mysql.rds_group_replication_stop();
   ```

2. Rename the DB instance by following the instructions in Renaming a DB instance.
3. Modify the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster.

   In the parameter setting, replace the old DB instance endpoint with the new DB instance endpoint. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.
4. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_start stored procedure:

   ```
   call mysql.rds_group_replication_start(0);
   ```

Removing a DB instance from an active-active cluster

When you remove a DB instance from an active-active cluster, it reverts to a standalone DB instance.

To remove a DB instance from an active-active cluster

1. Connect to the DB instance in a SQL client, and call the mysql.rds_group_replication_stop stored procedure:

```
call mysql.rds_group_replication_stop();
```

2. Modify the `group_replication_group_seeds` parameter for the DB instances that will remain in the active-active cluster.

   In the `group_replication_group_seeds` parameter, delete the DB instance that you are removing from the active-active cluster. For more information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.
3. Modify the parameters of the DB instance you are removing from the active-active cluster so that it is no longer part of the cluster.

   You can either associate the DB instance with a different parameter group, or modify the parameters in the DB parameter group associated with the DB instance. The parameters to modify include `group_replication_group_name`, `rds.group_replication_enabled`, and `group_replication_group_seeds`. For more information about active-active cluster parameters, see Required parameter settings for active-active clusters.

   If you modify the parameters in a DB parameter group, make sure the DB parameter group isn't associated with other DB instances in the active-active cluster.
4. Reboot the DB instance you removed from the active-active cluster for the new parameter settings to take effect.

   For instructions, see Rebooting a DB instance.

Exporting data from a MySQL DB instance by using replication

To export data from an RDS for MySQL DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the *source MySQL DB instance*, and the MySQL instance running external to Amazon RDS is the *external MySQL database*.

The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see Setting the Replica Configuration in the MySQL documentation.

4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

   Specify the appropriate egress rules for your environment:

   - If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see Controlling access with security groups.
   - If the external MySQL database is installed on-premises, specify the egress rules in a firewall.
5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:

   - Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
   - Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.

   For more information about Amazon VPC network ACLs, see Network ACLs in *Amazon VPC User Guide.*
6. (Optional) Set the `max_allowed_packet` parameter to the maximum size to avoid replication errors. We recommend this setting.

Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.
2. Connect to the source MySQL DB instance, and create a replication account by following the directions in Creating a User for Replication in the MySQL documentation.
3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows

TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.

4. Specify the egress rules:

   - If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see Controlling access with security groups.

5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:

   - Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
   - Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

   For more information about Amazon VPC network ACLs, see Network ACLs in the *Amazon VPC User Guide.*

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see Introduction to backups.

7. Use the `mysql.rds_set_configuration` stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see Accessing MySQL binary logs.

8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see Creating a read replica.

9. After the Amazon RDS read replica has been created, call the `mysql.rds_stop_replication` stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.

10. (Optional) Set both the `max_allowed_packet` parameter and the `slave_max_allowed_packet` parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Copy the database

Perform the following steps to copy the database.

To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL `SHOW REPLICA STATUS\G` statement. Note the values for the following:

   - `Master_Host`
   - `Master_Port`
   - `Master_Log_File`
   - `Exec_Master_Log_Pos`

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the mysqldump utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Ensure that your client computer has enough space to hold the `mysqldump` files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in Creating a Data Snapshot Using mysqldump in the MySQL documentation.

   The following example runs `mysqldump` on a client and writes the dump to a file.

   For Linux, macOS, or Unix:

   ```
   mysqldump -h source_MySQL_DB_instance_endpoint \
       -u user \
       -ppassword \
       --port=3306 \
       --single-transaction \
       --routines \
       --triggers \
       --databases  database database2 > path/rds-dump.sql
   ```

For Windows:

```
mysqldump -h source_MySQL_DB_instance_endpoint ^
    -u user ^
    -ppassword ^
    --port=3306 ^
    --single-transaction ^
    --routines ^
    --triggers ^
    --databases  database database2 > path\rds-dump.sql
```

You can load the backup file into the external MySQL database. For more information, see Reloading SQL-Format Backups in the MySQL documentation. You can run another utility to load the data into the external MySQL database.

Complete the export

Perform the following steps to complete the export.

To complete the export

1. Use the MySQL `CHANGE MASTER` statement to configure the external MySQL database. Specify the ID and password of the user granted `REPLICATION SLAVE` permissions. Specify the `Master_Host`, `Master_Port`, `Relay_Master_Log_File`, and `Exec_Master_Log_Pos` values that you got from the MySQL `SHOW REPLICA STATUS\G` statement that you ran on the RDS read replica. For more information, see CHANGE MASTER TO Statement in the MySQL documentation.

   > **Note**
   >
   > Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the MySQL `START REPLICA` command to initiate replication from the source MySQL DB instance to the external MySQL database.

Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.

> **Note**
>
> Previous versions of MySQL used `START SLAVE` instead of `START REPLICA`. If you are using a MySQL version before 8.0.23, then use `START SLAVE`.

3. Run the MySQL `SHOW REPLICA STATUS\G` command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see SHOW SLAVE | REPLICA STATUS Statement in the MySQL documentation.
4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL `STOP REPLICA` command to stop replication from the source MySQL DB instance.

> **Note**
>
> Previous versions of MySQL used `STOP SLAVE` instead of `STOP REPLICA`. If you are using a MySQL version before 8.0.23, then use `STOP SLAVE`.

5. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.

Options for MySQL DB instances

Following, you can find a description of options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups.

Amazon RDS supports the following options for MySQL:

Option	Option ID	Engine versions
MariaDB Audit Plugin support for MySQL	`MARIADB_AUDIT_PLUGIN`	All MySQL 8.4 versions MySQL 8.0.28 and higher 8.0 versions All MySQL 5.7 versions
MySQL memcached support	`MEMCACHED`	All MySQL 5.7 and 8.0 versions

MariaDB Audit Plugin support for MySQL

Amazon RDS offers an audit plugin for MySQL database instances based on the open source MariaDB Audit Plugin. For more information, see the Audit Plugin for MySQL Server GitHub repository.

> **Note**
>
> The audit plugin for MySQL is based on the MariaDB Audit Plugin. Throughout this article, we refer to it as MariaDB Audit Plugin.

The MariaDB Audit Plugin records database activity, including users logging on to the database and queries run against the database. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_PATH	/rdsdbdata/log/audit/	/rdsdbdata/log/audit/	The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS . For more information, see Viewing and listing database log files and MySQL database log files.
SERVER_AUDIT_FILE_ROTATE_SIZE	1–1000000000	1000000	The size in bytes that when reached, causes the file to rotate. For more information, see Overview of RDS for MySQL database logs.
SERVER_AUDIT_FILE_ROTATIONS	0–100	9	The number of log rotations to save when server_audit_output_type=file . If set to 0, then the log file never rotates. For more information, see Overview of RDS for

Option setting	Valid values	Default value	Description
			MySQL database logs and Downloading a database log file.
SERVER_AUDIT_EVENTS	CONNECT, QUERY, QUERY_DDL , QUERY_DML , QUERY_DML_NO_SELECT , QUERY_DCL	CONNECT, QUERY	The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged. • CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database. • QUERY: Log the text of all queries run against the database. • QUERY_DDL : Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on). • QUERY_DML : Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT). • QUERY_DML_NO_SELECT : Similar to the QUERY_DML event, but doesn't log SELECT queries. • QUERY_DCL : Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on). For MySQL, TABLE is not supported.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_INCL_USERS	Multiple comma-separated values	None	Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS.
SERVER_AUDIT_EXCL_USERS	Multiple comma-separated values	None	Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS. The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list. **Note** CONNECT activity is always recorded for all users, even if the user is specified for this option setting.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_LOGGING	ON	ON	Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin.
SERVER_AUDIT_QUERY_LOG_LIMIT	0–2147483647	1024	The limit on the length of the query string in a record.

Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
- Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

> **Important**
>
> Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step.

Otherwise, create a custom DB option group. Choose **mysql** for **Engine**, and choose **5.7**, **8.0**, or **8.4** for **Major engine version**. For more information, see Creating an option group.

2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see Audit Plugin option settings.
3. Apply the option group to a new or existing DB instance.

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Audit log format

Log files are represented as comma-separated variable (CSV) files in UTF-8 format.

> **Tip**
>
> Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.
> To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon RDS with Database Activity Streams.

The audit log files include the following comma-delimited information in rows, in the specified order:

Field	Description
timestamp	The `YYYYMMDD` followed by the `HH:MI:SS` (24-hour clock) for the logged event.
serverhost	The name of the instance that the event is logged for.

Field	Description
username	The connected user name of the user.
host	The host that the user connected from.
connectionid	The connection ID number for the logged operation.
queryid	The query ID number, which can be used for finding the relational table events and related queries. For `TABLE` events, multiple lines are added.
operation	The recorded action type. Possible values are: `CONNECT`, `QUERY`, `READ`, `WRITE`, `CREATE`, `ALTER`, `RENAME`, and `DROP`.
database	The active database, as set by the `USE` command.
object	For `QUERY` events, this value indicates the query that the database performed. For `TABLE` events, it indicates the table name.
retcode	The return code of the logged operation.
connection_type	The security state of the connection to the server. Possible values are: • `Undefined` • `TCP/IP` • `Socket` • `Named pipe` • `SSL/TLS` • `Shared memory`

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see Viewing and listing database log files. For information about downloading the log file, see Downloading a database log file.

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see Audit Plugin option settings.

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

> **Note**
>
> The memcached interface is no longer available in MySQL 8.4. When you upgrade your DB instances to MySQL 8.4, you must disable memcached in existing option groups.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see InnoDB integration with memcached.

To enable memcached support for an RDS for MySQL DB instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see Controlling access with security groups
2. Create a custom DB option group, selecting MySQL as the engine type and version. For more information about creating an option group, see Creating an option group.
3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see Adding an option to an option group.
4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see Modifying an option setting.
5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:

- You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see Creating an Amazon RDS DB instance.
- You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named containers in a dedicated database named innodb_memcache. You insert a row into the containers table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the containers table, see InnoDB memcached plugin internals. For an example of mapping an InnoDB table and accessing it through memcached, see Writing applications for the InnoDB memcached plugin.
7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC security group associated with the MySQL instance. For more information about managing security groups, see Controlling access with security groups.

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see Security Considerations for the InnoDB memcached Plugin in the MySQL documentation.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the MEMCACHED option to the option group.

- Ensure that you associate the memcached interface with a VPC security group that limits access to known, trusted client addresses and EC2 instances. For more information about managing security groups, see Controlling access with security groups.

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of my-cache-instance.cg034hpkmmjt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```
<?php

$cache = new Memcache;
$cache->connect('my-cache-instance.cg034hpkmmjt.region.rds.amazonaws.com',11212);
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose the MySQL DB instance name to display its details.
5. In the **Connect** section, note the value of the **Endpoint** field. The DNS name is the same as the endpoint. Also, note that the port in the **Connect** section is not used to access the memcached interface.
6. In the **Details** section, note the name listed in the **Option Group** field.
7. In the navigation pane, choose **Option groups**.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the **Options** section, note the value of the **Port** setting for the **MEMCACHED** option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

MySQL memcached parameters

- DAEMON_MEMCACHED_R_BATCH_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
- DAEMON_MEMCACHED_W_BATCH_SIZE – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
- INNODB_API_BK_COMMIT_INTERVAL – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.
- INNODB_API_DISABLE_ROWLOCK – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- INNODB_API_ENABLE_MDL – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- INNODB_API_TRX_LEVEL – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: DAEMON_MEMCACHED_LIB_NAME, DAEMON_MEMCACHED_LIB_PATH, and INNODB_API_ENABLE_BINLOG. The parameters that MySQL administrators set by using daemon_memcached_options are available as individual MEMCACHED option settings in Amazon RDS.

MySQL daemon_memcached_options parameters

- BINDING_PROTOCOL – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.
- BACKLOG_QUEUE_LIMIT – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.
- CAS_DISABLED – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.
- CHUNK_SIZE – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.
- CHUNK_SIZE_GROWTH_FACTOR – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times CHUNK_SIZE_GROWTH_FACTOR. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.
- ERROR_ON_MEMORY_EXHAUSTED – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.
- MAX_SIMULTANEOUS_CONNECTIONS – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.
- VERBOSITY – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:
  - v – Logs errors and warnings while running the main event loop.
  - vv – In addition to the information logged by v, also logs each client command and the response.

- vvv – In addition to the information logged by vv, also logs internal state transitions.

Amazon RDS configures these MySQL DAEMON_MEMCACHED_OPTIONS parameters, they cannot be modified: DAEMON_PROCESS, LARGE_MEMORY_PAGES, MAXIMUM_CORE_FILE_LIMIT, MAX_ITEM_SIZE, LOCK_DOWN_PAGE_MEMORY, MASK, IDFILE, REQUESTS_PER_EVENT, SOCKET, and USER.

Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see Parameter groups for Amazon RDS.

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the MySQL documentation. For more information about MySQL storage engines, see Supported storage engines for RDS for MySQL.

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see Viewing parameter values for a DB parameter group in Amazon RDS.

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the `describe-engine-default-parameters` command. Specify one of the following values for the `--db-parameter-group-family` option:

- `mysql8.4`
- `mysql8.0`
- `mysql5.7`

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```
{
    "EngineDefaults": {
        "Parameters": [
            {
                "ParameterName": "activate_all_roles_on_login",
                "ParameterValue": "0",
                "Description": "Automatically set all granted roles as active after the
 user has authenticated successfully.",
                "Source": "engine-default",
                "ApplyType": "dynamic",
                "DataType": "boolean",
```

```
                "AllowedValues": "0,1",
                "IsModifiable": true
            },
            {
                "ParameterName": "allow-suspicious-udfs",
                "Description": "Controls whether user-defined functions that have only
 an xxx symbol for the main function can be loaded",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": false
            },
            {
                "ParameterName": "auto_generate_certs",
                "Description": "Controls whether the server autogenerates SSL key and
 certificate files in the data directory, if they do not already exist.",
                "Source": "engine-default",
                "ApplyType": "static",
                "DataType": "boolean",
                "AllowedValues": "0,1",
                "IsModifiable": false
            },
        ...
```

To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 \
   --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 ^
   --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```

Common DBA tasks for MySQL DB instances

In the following content, you can find descriptions of the Amazon RDS-specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see MySQL database log files.

Understanding predefined users

Amazon RDS automatically creates several predefined users with new RDS for MySQL DB instances. Predefined users and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined users. Attempting to do so results in an error.

- **rdsadmin** – A user that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone MySQL database. This user is used internally by RDS for MySQL for many management tasks.
- **rdsrepladmin** – A user that's used internally by Amazon RDS to support replication activities on RDS for MySQL DB instances and clusters.

For information about other common DBA tasks, see the following topics.

Topics

- Role-based privilege model for RDS for MySQL
- Dynamic privileges for RDS for MySQL
- Ending a session or query for RDS for MySQL
- Skipping the current replication error for RDS for MySQL
- Working with InnoDB tablespaces to improve crash recovery times for RDS for MySQL
- Managing the Global Status History for RDS for MySQL
- Configuring buffer pool size and redo log capacity in MySQL 8.4

Role-based privilege model for RDS for MySQL

Starting with RDS for MySQL version 8.0.36, you can't modify the tables in the `mysql` database directly. In particular, you can't create database users by performing data manipulation language

(DML) operations on the `grant` tables. Instead, you use MySQL account-management statements such as `CREATE USER`, `GRANT`, and `REVOKE` to grant role-based privileges to users. You also can't create other kinds of objects such as stored procedures in the `mysql` database. You can still query the `mysql` tables. If you use binary log replication, changes made directly to the `mysql` tables on the source DB instance aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the `mysql` tables. If so, change your application code to use the corresponding statements such as `CREATE USER`.

To export metadata for database users during the migration from an external MySQL database, use one of the following methods:

- Use MySQL Shell's instance dump utility with a filter to exclude users, roles, and grants. The following example shows you the command syntax to use. Make sure that `outputUrl` is empty.

  ```
  mysqlsh user@host -- util.dumpInstance(outputUrl,{excludeSchemas:['mysql'],users:
   true})
  ```

  For more information, see Instance Dump Utility, Schema Dump Utility, and Table Dump Utility in the MySQL Reference Manual.
- Use the `mysqlpump` client utility. This example includes all tables except for tables in the `mysql` system database. It also includes `CREATE USER` and `GRANT` statements to reproduce all MySQL users in the migrated database.

  ```
  mysqlpump --exclude-databases=mysql --users
  ```

  The `mysqlpump` client utility is no longer available with MySQL 8.4. Instead, use `mysqldump`.

To simplify managing permissions for many users or applications, you can use the `CREATE ROLE` statement to create a role that has a set of permissions. Then you can use the `GRANT` and `SET ROLE` statements and the `current_role` function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see Using Roles in the MySQL Reference Manual.

> **Important**
>
> We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Starting with version 8.0.36, RDS for MySQL includes a special role that has all of the following privileges. This role is named `rds_superuser_role`. The primary administrative user for each DB instance already has this role granted. The `rds_superuser_role` role includes the following privileges for all database objects:

- `ALTER`
- `APPLICATION_PASSWORD_ADMIN`
- `ALTER ROUTINE`
- `CREATE`
- `CREATE ROLE`
- `CREATE ROUTINE`
- `CREATE TEMPORARY TABLES`
- `CREATE USER`
- `CREATE VIEW`
- `DELETE`
- `DROP`
- `DROP ROLE`
- `EVENT`
- `EXECUTE`
- `INDEX`
- `INSERT`
- `LOCK TABLES`
- `PROCESS`
- `REFERENCES`
- `RELOAD`
- `REPLICATION CLIENT`

- REPLICATION SLAVE
- ROLE_ADMIN
- SET_USER_ID
- SELECT
- SHOW DATABASES
- SHOW VIEW
- TRIGGER
- UPDATE
- XA_RECOVER_ADMIN

The role definition also includes WITH GRANT OPTION so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the MySQL cluster as the target.

Tip

To see the full details of the permissions, use the following statement.

```
SHOW GRANTS FOR rds_superuser_role@'%';
```

When you grant access by using roles in RDS for MySQL version 8.0.36 and higher, you also activate the role by using the SET ROLE *role_name* or SET ROLE ALL statement. The following example shows how. Substitute the appropriate role name for CUSTOM_ROLE.

```
# Grant role to user
mysql> GRANT CUSTOM_ROLE TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the CUSTOM_ROLE role has not
 been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
+--------------------------+
| CURRENT_ROLE()           |
+--------------------------+
| `rds_superuser_role`@`%` |
+--------------------------+
```

```
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)

# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+-------------------------------------------------+
| CURRENT_ROLE()                                  |
+-------------------------------------------------+
| `CUSTOM_ROLE`@`%`,`rds_superuser_role`@`%` |
+-------------------------------------------------+
```

Dynamic privileges for RDS for MySQL

Dynamic privileges are MySQL privileges that you can explicitly grant by using the GRANT statement. Depending on your version of RDS for MySQL, RDS allows you to grant only specific dynamic privileges. RDS disallows some of these privileges because they can interfere with the specific database operations, such as replication and backup.

The following table shows which of these privileges you can grant for different MySQL versions. If you are upgrading from a MySQL version lower than 8.0.36 to version 8.0.36 or higher, you might have to update your application code if granting a particular privilege is no longer allowed.

Privilege	MySQL 8.0.35 and lower	MySQL 8.0.36 and higher minor versions	MySQL 8.4.3 and higher
ALLOW_NONEXISTENT_DEFINER	Not available	Not available	Disallowed
APPLICATION_PASSWORD_ADMIN	Allowed	Allowed	Allowed
AUDIT_ABORT_EXEMPT	Allowed	Disallowed	Disallowed

Privilege	MySQL 8.0.35 and lower	MySQL 8.0.36 and higher minor versions	MySQL 8.4.3 and higher
AUDIT_ADMIN	Disallowed	Disallowed	Disallowed
AUTHENTICATION_POLICY_ADMIN	Allowed	Disallowed	Disallowed
BACKUP_ADMIN	Allowed	Disallowed	Disallowed
BINLOG_ADMIN	Allowed	Disallowed	Disallowed
BINLOG_ENCRYPTION_ADMIN	Disallowed	Disallowed	Disallowed
CLONE_ADMIN	Disallowed	Disallowed	Disallowed
CONNECTION_ADMIN	Allowed	Disallowed	Disallowed
ENCRYPTION_KEY_ADMIN	Disallowed	Disallowed	Disallowed

Ending a session or query for RDS for MySQL

You can end user sessions or queries on DB instances by using the `rds_kill` and `rds_kill_query` commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see Connecting to your MySQL DB instance.

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

Skipping the current replication error for RDS for MySQL

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data.

> **Note**
>
> First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.

```
SHOW REPLICA STATUS\G
```

For information about the values returned, see the MySQL documentation.
Previous versions of and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

You can skip an error on your read replica in the following ways.

Topics

- Calling the mysql.rds_skip_repl_error procedure
- Setting the slave_skip_errors parameter

Calling the mysql.rds_skip_repl_error procedure

Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see Connecting to your MySQL DB instance.

To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn't encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see mysql.rds_skip_repl_error.

Important

If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error: `ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist`, then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in mysql.rds_skip_repl_error.

Setting the slave_skip_errors parameter

To skip one or more errors, you can set the `slave_skip_errors` static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the MySQL documentation.

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

> **Important**
>
> Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica's data.

Working with InnoDB tablespaces to improve crash recovery times for RDS for MySQL

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a *tablespace*. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a .ibd extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameters controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage

or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time. Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to your MySQL DB instance.

```
ALTER TABLE table_name ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

For MySQL 5.7 DB instances:

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), '` ENGINE=InnoDB,
 ALGORITHM=COPY;') AS Query
```

```
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

For MySQL 8.4 and 8.0 DB instances:

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), '` ENGINE=InnoDB,
 ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available. During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings `read_only = 0` and `innodb_file_per_table = 0`. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

```
ALTER TABLE name ENGINE = InnoDB
```

5. When all of your `ALTER TABLE` statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the `innodb_file_per_table` parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

Managing the Global Status History for RDS for MySQL

> **Tip**
>
> To analyze database performance, you can also use Performance Insights on Amazon RDS. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter `event_scheduler` to `ON`. For MySQL DB instances running MySQL 5.7, also set the parameter `show_compatibility_56` to 1. For information about creating and modifying a DB parameter group, see Parameter groups for Amazon RDS. For information about the side effects of enabling this parameter, see show_compatibility_56 in the *MySQL 5.7 Reference Manual*.

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to your MySQL DB instance. For each procedure, run the following command and replace *procedure-name*:

```
CALL procedure-name;
```

The following table lists all of the procedures that you can use for *procedure-name* in the previous command.

Procedure	Description
mysql.rds_enable_gsh_collector	Enables GoSH to take default snapshots at intervals specified by rds_set_gsh_collector .
mysql.rds_set_gsh_collector	Specifies the interval, in minutes, between snapshots. Default value is 5.
mysql.rds_disable_gsh_collector	Disables snapshots.
mysql.rds_collect_global_status_history	Takes a snapshot on demand.
mysql.rds_enable_gsh_rotation	Enables rotation of the contents of the mysql.rds_global_status_history table to mysql.rds_global_status_history_old at intervals specified by rds_set_gsh_rotation .
mysql.rds_set_gsh_rotation	Specifies the interval, in days, between table rotations. Default value is 7.
mysql.rds_disable_gsh_rotation	Disables table rotation.
mysql.rds_rotate_global_status_history	Rotates the contents of the mysql.rds_global_status_history table to mysql.rds_global_status_history_old on demand.

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the Innodb buffer pool, you would issue the following query:

```
select a.collection_end, a.collection_start, (( a.variable_Delta-b.variable_delta)/
a.variable_delta)*100 as "HitRatio"
    from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b
 on a.collection_end = b.collection_end
    where a. variable_name = 'Innodb_buffer_pool_read_requests' and b.variable_name =
 'Innodb_buffer_pool_reads'
```

Configuring buffer pool size and redo log capacity in MySQL 8.4

In MySQL 8.4, Amazon RDS enables the `innodb_dedicated_server` parameter by default. With the `innodb_dedicated_server` parameter, the database engine calculates the `innodb_buffer_pool_size` and `innodb_redo_log_capacity` parameters. For information about how these parameters are calculated, see Configuring InnoDB Buffer Pool Size and Redo Log in the MySQL documentation.

With `innodb_dedicated_server` enabled, the `innodb_buffer_pool_size` parameter is calculated based on the DB instance class memory. The following table shows the detected server memory and the corresponding buffer pool size.

Detected server memory	Buffer pool size
< 1 GB	Default value of 128 MB
1 GB to 4 GB	*Detected server memory* * 0.5
> 4 GB	*Detected server memory* * 0.75

The `innodb_redo_log_capacity` parameter automatically scales with the instance class to (number of vCPUs / 2) GB up to a maximum of 16 GB. Larger instance classes have a larger redo log capacity, which can improve performance and resilience for write-intensive workloads.

Before upgrading from MySQL 8.0 to MySQL 8.4, be sure to increase your storage space to accommodate a potential increase in the size of the redo logs that might occur after the upgrade completes. For more information, see Increasing DB instance storage capacity.

If you don't want the `innodb_dedicated_server` parameter to calculate the values for the `innodb_buffer_pool_size` and `innodb_redo_log_capacity` parameters, you can override these values by setting specific values for them in a custom parameter group.

Alternatively, you can disable the `innodb_dedicated_server` parameter and set values for the `innodb_buffer_pool_size` and `innodb_redo_log_capacity` parameters in a custom parameter group. For more information, see Default and custom parameter groups.

If you disable the `innodb_dedicated_server` parameter by setting it to `0` and don't set values for the `innodb_buffer_pool_size` and `innodb_redo_log_capacity` parameters, then Amazon RDS sets the latter two parameters to 128 MB and 100 MB, respectively. These defaults result in poor performance on larger instance classes.

Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Parameter groups for Amazon RDS.

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of MySQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MySQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the mysql_tzinfo_to_sql tool in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Asuncion, America/Bogota, America/Buenos_Aires, America/Caracas, America/Chihuahua, America/Cuiaba, America/Denver, America/Fortaleza, America/Guatemala, America/Halifax, America/Manaus, America/Matamoros, America/Monterrey, America/Montevideo, America/Phoenix, America/Santiago, America/Tijuana
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Irkutsk, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Krasnoyarsk, Asia/Magadan, Asia/Muscat, Asia/Novosibirsk, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Hobart, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan, Canda/Yukon
Europe	Europe/Amsterdam, Europe/Athens, Europe/Dublin, Europe/Helsinki, Europe/Istanbul, Europe/Kaliningrad Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Sarajevo
Pacific	Pacific/Auckland, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Samoa
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

Topics

- InnoDB reserved word
- Storage-full behavior for Amazon RDS for MySQL
- Inconsistent InnoDB buffer pool size
- Index merge optimization returns incorrect results
- MySQL parameter exceptions for Amazon RDS DB instances
- MySQL file size limits in Amazon RDS
- MySQL Keyring Plugin not supported
- Custom ports
- MySQL stored procedure limitations
- GTID-based replication with an external source instance
- MySQL default authentication plugin
- Overriding innodb_buffer_pool_size
- Upgrading from MySQL 5.7 to MySQL 8.4
- InnoDB page compression

InnoDB reserved word

`InnoDB` is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the `storage-full` state.

A MySQL DB instance reaches the `storage-full` state in the following cases:

- The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.

- The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.
- The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.

After Amazon RDS stops a DB instance automatically because it reached the `storage-full` state, you can still modify it. To restart the DB instance, complete at least one of the following:

- Modify the DB instance to enable storage autoscaling.

  For more information about storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling.
- Modify the DB instance to increase its storage capacity.

  For more information about increasing storage capacity, see Increasing DB instance storage capacity.

After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Inconsistent InnoDB buffer pool size

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the `innodb_buffer_pool_size` parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent it from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the `innodb_buffer_pool_size` parameter to a multiple of the product of the `innodb_buffer_pool_instances` parameter value and the `innodb_buffer_pool_chunk_size` parameter value. For example, you might set the `innodb_buffer_pool_size` parameter value to a multiple of eight times the product of the `innodb_buffer_pool_instances` and `innodb_buffer_pool_chunk_size` parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, see https://bugs.mysql.com/bug.php?id=79379 in the MySQL documentation.

Index merge optimization returns incorrect results

Queries that use index merge optimization might return incorrect results because of a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes, the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, see http://bugs.mysql.com/bug.php?id=72745 and http://bugs.mysql.com/bug.php?id=68194 in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, because of the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the `optimizer_switch` parameter to `index_merge=off` in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see Parameter groups for Amazon RDS.
- Upgrade your MySQL DB instance to MySQL version 5.7 or 8.0. For more information, see Upgrades of the RDS for MySQL DB engine.
- If you cannot upgrade your instance or change the `optimizer_switch` parameter, you can work around the bug by explicitly identifying an index for the query, for example:

  ```
  SELECT * FROM table1
  USE INDEX covering_index
  WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
  ```

For more information, see Index merge optimization in the MySQL documentation.

MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

lower_case_table_names

Because Amazon RDS uses a case-sensitive file system, setting the value of the `lower_case_table_names` server parameter to 2 (names stored as given but compared in lowercase) is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 (names stored as given and comparisons are case-sensitive) is supported for all RDS for MySQL versions.
- 1 (names stored in lowercase and comparisons are not case-sensitive) is supported for RDS for MySQL version 5.7, version 8.0.28 and higher 8.0 versions, and version 8.4.

Set the `lower_case_table_names` parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the `lower_case_table_names` parameter in the parameter group. Changing it could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 or 8.4 MySQL DB instance, you can't modify the `lower_case_table_names` parameter in the parameter group.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

long_query_time

You can set the `long_query_time` parameter to a floating point value so that you can log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

MySQL file size limits in Amazon RDS

For MySQL versions 8.0 and higher DB instances, the maximum file size is 16 TiB. When using file-per-table tablespaces, the maximum file size limits the size of an InnoDB table to 16 TiB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances. For more information, see InnoDB Limits in the MySQL documentation.

> **Note**
>
> Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see Partitioning in the MySQL documentation.

Because there is no single system table or view that provides the size of all the tables and the InnoDB system tablespace, you must query multiple tables to determine the size of the tablespaces.

To determine the size of the InnoDB system tablespace and the data dictionary tablespace

- Use the following SQL command to determine if any of your tablespaces are too large and are candidates for partitioning.

> **Note**
>
> The data dictionary tablespace is specific to MySQL 8.0 and higher versions.

```
select FILE_NAME,TABLESPACE_NAME, ROUND(((TOTAL_EXTENTS*EXTENT_SIZE)
/1024/1024/1024), 2)  as "File Size (GB)" from information_schema.FILES
where tablespace_name in ('mysql','innodb_system');
```

To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 5.7 versions)

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT SPACE,NAME,ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 8.0 and higher versions)

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT SPACE,NAME,ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_TABLESPACES ORDER BY 3 DESC;
```

To determine the size of non-InnoDB user tables

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH+DATA_FREE)
/ 1024 / 1024/ 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES
```

```
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema')
and ENGINE<>'InnoDB';
```

To enable InnoDB file-per-table tablespaces

- Set the *innodb_file_per_table* parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- Set the *innodb_file_per_table* parameter to `0` in the parameter group for the DB instance.

For information on updating a parameter group, see Parameter groups for Amazon RDS.

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name TABLESPACE=innodb_file_per_table;
```

MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL doesn't support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.

Custom ports

Amazon RDS blocks connections to custom port 33060 for the MySQL engine. Choose a different port for your MySQL engine.

MySQL stored procedure limitations

The mysql.rds_kill and mysql.rds_kill_query stored procedures can't terminate sessions or queries owned by MySQL users with usernames longer than 16 characters on the following RDS for MySQL versions:

- 8.0.32 and lower 8 versions
- 5.7.41 and lower 5.7 versions

GTID-based replication with an external source instance

Amazon RDS supports replication based on global transaction identifiers (GTIDs) from an external MySQL instance into an Amazon RDS for MySQL DB instance that requires setting GTID_PURGED during configuration. However, only RDS for MySQL 8.0.37 and higher versions support this functionality.

MySQL default authentication plugin

RDS for MySQL version 8.0.34 and higher 8.0 versions use the `mysql_native_password` plugin. You can't change the `default_authentication_plugin` setting.

RDS for MySQL version 8.4 and higher versions use the `caching_sha2_password` plugin as the default authentication plugin. You can change the default authentication plugin for MySQL 8.4. The `mysql_native_password` plugin still works with MySQL 8.4, but support of this plugin ends with MySQL 8.4. To change the default authentication plugin, create a custom parameter group and modify the value of the `authentication_policy` parameter. For more information, see the section called “Default and custom parameter groups”.

Overriding innodb_buffer_pool_size

With micro or small DB instance classes, the default value for the `innodb_buffer_pool_size` parameter might differ from the value returned by running the following command:

```
mysql> SELECT @@innodb_buffer_pool_size;
```

This difference can occur when Amazon RDS needs to override the default value as part of managing the DB instance classes. If necessary, you can override the default value and set it to a value that your DB instance class supports. To determine a valid value, add the memory usage and the total memory available on your DB instance. For more information, see Amazon RDS instance types.

If your DB instance has only 4 GB of memory, you can't set `innodb_buffer_pool_size` to 8 GB but you might be able to set it to 3 GB, depending on how much memory you allocated for other parameters.

If the value that you input is too large, Amazon RDS lowers the value to the following limits:

- Micro DB instance classes: 256 MB

- db.t4g.micro DB instance classes: 128 MB

Upgrading from MySQL 5.7 to MySQL 8.4

You can't upgrade directly from MySQL 5.7 to MySQL 8.4. You must first upgrade from MySQL 5.7 to MySQL 8.0, and then upgrade from MySQL 8.0 to MySQL 8.4. For more information, see Major version upgrades for RDS for MySQL.

InnoDB page compression

InnoDB page compression doesn't work with Amazon RDS DB instances that have a file system block size of 16k because the file system block size must be smaller than the InnoDB page size. Starting in February 2024, all newly created DB instances have a file system block size of 16k, which increases throughput and decreases IOPS consumption during page flushes.

RDS for MySQL stored procedure reference

These topics describe system stored procedures that are available for Amazon RDS instances running the MySQL DB engine. The master user must run these procedures.

Topics

- Collecting and maintaining the Global Status History
- Configuring, starting, and stopping binary log (binlog) replication
- Ending a session or query
- Managing active-active clusters
- Managing multi-source replication
- Replicating transactions using GTIDs
- Rotating the query logs
- Setting and showing binary log configuration
- Warming the InnoDB cache

Collecting and maintaining the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see Managing the Global Status History for RDS for MySQL.

The following stored procedures manage how the Global Status History is collected and maintained.

Topics

- mysql.rds_collect_global_status_history
- mysql.rds_disable_gsh_collector
- mysql.rds_disable_gsh_rotation
- mysql.rds_enable_gsh_collector
- mysql.rds_enable_gsh_rotation
- mysql.rds_rotate_global_status_history
- mysql.rds_set_gsh_collector
- mysql.rds_set_gsh_rotation

mysql.rds_collect_global_status_history

Takes a snapshot on demand for the Global Status History.

Syntax

```
CALL mysql.rds_collect_global_status_history;
```

mysql.rds_disable_gsh_collector

Turns off snapshots taken by the Global Status History.

Syntax

```
CALL mysql.rds_disable_gsh_collector;
```

mysql.rds_disable_gsh_rotation

Turns off rotation of the `mysql.global_status_history` table.

Syntax

```
CALL mysql.rds_disable_gsh_rotation;
```

mysql.rds_enable_gsh_collector

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

Syntax

```
CALL mysql.rds_enable_gsh_collector;
```

mysql.rds_enable_gsh_rotation

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

Syntax

```
CALL mysql.rds_enable_gsh_rotation;
```

mysql.rds_rotate_global_status_history

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

Syntax

```
CALL mysql.rds_rotate_global_status_history;
```

mysql.rds_set_gsh_collector

Specifies the interval, in minutes, between snapshots taken by the Global Status History.

Syntax

```
CALL mysql.rds_set_gsh_collector(intervalPeriod);
```

Parameters

intervalPeriod

The interval, in minutes, between snapshots. Default value is 5.

mysql.rds_set_gsh_rotation

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table.

Syntax

```
CALL mysql.rds_set_gsh_rotation(intervalPeriod);
```

Parameters

intervalPeriod

The interval, in days, between table rotations. Default value is 7.

Configuring, starting, and stopping binary log (binlog) replication

The following stored procedures control how transactions are replicated from an external database into RDS for MySQL, or from RDS for MySQL to an external database.

When using these stored procedures to manage replication with a replication user configured with `caching_sha2_password`, you must configure TLS by specifying `SOURCE_SSL=1`. `caching_sha2_password` is the default authentication plugin for RDS for MySQL 8.4 For more information, see Encrypting with SSL/TLS.

For information about configuring, using, and managing read replicas, see the section called "MySQL read replicas".

Topics

- mysql.rds_next_master_log (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)
- mysql.rds_next_source_log (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_reset_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)
- mysql.rds_reset_external_source (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_external_master_with_auto_position (RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_external_source_with_auto_position (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_external_source_with_delay (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_external_source_gtid_purged
- mysql.rds_set_master_auto_position (RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_source_auto_position (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_source_delay
- mysql.rds_skip_repl_error

- mysql.rds_start_replication
- mysql.rds_start_replication_until
- mysql.rds_stop_replication

mysql.rds_next_master_log (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

Syntax

```
CALL mysql.rds_next_master_log(
curr_master_log
);
```

Parameters

curr_master_log

The index of the current master log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.

Warning

Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.
Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred. You can reduce the chance of this happening by setting the source

instance parameters `sync_binlog` and `innodb_support_xa` to 1, even though this might reduce performance. For more information, see Troubleshooting a MySQL read replica problem.

Examples

Assume replication fails on an RDS for MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
*************************** 1. row ***************************
             Replica_IO_State:
                  Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
                  Source_User: MasterUser
                  Source_Port: 3306
                Connect_Retry: 10
              Source_Log_File: mysql-bin-changelog.012345
          Read_Source_Log_Pos: 1219393
               Relay_Log_File: relaylog.012340
                Relay_Log_Pos: 30223388
        Relay_Source_Log_File: mysql-bin-changelog.012345
           Replica_IO_Running: No
          Replica_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Source_Log_Pos: 30223232
              Relay_Log_Space: 5248928866
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Source_SSL_Allowed: No
           Source_SSL_CA_File:
           Source_SSL_CA_Path:
              Source_SSL_Cert:
            Source_SSL_Cipher:
               Source_SSL_Key:
```

```
        Seconds_Behind_Master: NULL
Source_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 1236
                Last_IO_Error: Got fatal error 1236 from master when reading data from
 binary log: 'Client requested master to start replication from impossible position;
 the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
 '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
               Last_SQL_Errno: 0
               Last_SQL_Error:
  Replicate_Ignore_Server_Ids:
             Source_Server_Id: 67285976
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is `12345`. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

mysql.rds_next_source_log (RDS for MySQL major versions 8.4 and higher)

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

Syntax

```
CALL mysql.rds_next_source_log(
curr_source_log
);
```

Parameters

curr_source_log

The index of the current source log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current source log file name, run the `SHOW REPLICA STATUS` command and view the `Source_Log_File` field.

Usage notes

The administrative user must run the `mysql.rds_next_source_log` procedure.

> **Warning**
>
> Call `mysql.rds_next_source_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.
> Calling `mysql.rds_next_source_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred. You can reduce the chance of this happening by setting the source instance parameters `sync_binlog` and `innodb_support_xa` to 1, even though this might reduce performance. For more information, see Troubleshooting a MySQL read replica problem.

Examples

Assume replication fails on an RDS for MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
*************************** 1. row ***************************
             Replica_IO_State:
                  Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
                  Source_User: MasterUser
                  Source_Port: 3306
                Connect_Retry: 10
              Source_Log_File: mysql-bin-changelog.012345
          Read_Source_Log_Pos: 1219393
               Relay_Log_File: relaylog.012340
                Relay_Log_Pos: 30223388
        Relay_Source_Log_File: mysql-bin-changelog.012345
           Replica_IO_Running: No
          Replica_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
```

```
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Source_Log_Pos: 30223232
              Relay_Log_Space: 5248928866
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Source_SSL_Allowed: No
           Source_SSL_CA_File:
           Source_SSL_CA_Path:
              Source_SSL_Cert:
            Source_SSL_Cipher:
               Source_SSL_Key:
        Seconds_Behind_Source: NULL
Source_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 1236
                Last_IO_Error: Got fatal error 1236 from source when reading data from
 binary log: 'Client requested source to start replication from impossible position;
 the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
 '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
               Last_SQL_Errno: 0
               Last_SQL_Error:
  Replicate_Ignore_Server_Ids:
             Source_Server_Id: 67285976
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is `12345`. To resolve the error, you can call `mysql.rds_next_source_log` with the following parameter:

```
CALL mysql.rds_next_source_log(12345);
```

mysql.rds_reset_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)

Reconfigures an RDS for MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_reset_external_master;
```

Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see Configuring binary log file position replication with an external source instance.

mysql.rds_reset_external_source (RDS for MySQL major versions 8.4 and higher)

Reconfigures an RDS for MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_reset_external_source;
```

Usage notes

The administrative user must run the `mysql.rds_reset_external_source` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS.

For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas. For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see Configuring binary log file position replication with an external source instance.

mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Note

You can use the mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) stored procedure to configure an external source database instance and delayed replication.

Syntax

```
CALL mysql.rds_set_external_master (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the mysql.rds_set_external_master procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_master, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and

`replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   MySQL 5.7

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY
    'password';
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   MySQL 5.7

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
    IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```

To use encrypted replication, configure source database instance to use SSL connections.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_master(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  1);
```

mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher)

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The SOURCE_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The administrative user must run the mysql.rds_set_external_source procedure. This procedure must be run on the RDS for MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_source, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and replication_user_password values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the mysql.rds_import_binlog_ssl_material procedure.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_source` to configure an RDS for MySQL DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_source (RDS for MySQL major versions 8.4 and higher) to remove the read replica configuration.

When `mysql.rds_set_external_source` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on an RDS for MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_source(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  1);
```

mysql.rds_set_external_master_with_auto_position (RDS for MySQL major versions 8.0 and lower)

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_master_with_auto_position (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , ssl_encryption
  , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Before you run `mysql.rds_set_external_master_with_auto_position`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored

procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

Before you call `mysql.rds_set_external_master_with_auto_position`, make sure to call the section called "mysql.rds_set_external_source_gtid_purged" to set the `gtid_purged` system variable with a specified GTID range from an external source.

After calling `mysql.rds_set_external_master_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_auto_position(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'SomePassW0rd',
  1,
  3600);
```

mysql.rds_set_external_source_with_auto_position (RDS for MySQL major versions 8.4 and higher)

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_with_auto_position (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , ssl_encryption
  , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `SOURCE_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The administrative user must run the `mysql.rds_set_external_source_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_source_with_auto_position`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify

values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'SomePassW0rd'
```

For more information, see Configuring binary log file position replication with an external source instance.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

Before you call `mysql.rds_set_external_source_with_auto_position`, make sure to call the section called “mysql.rds_set_external_source_gtid_purged” to set the `gtid_purged` system variable with a specified GTID range from an external source.

After calling `mysql.rds_set_external_source_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read

replica to start the replication process. You can call mysql.rds_reset_external_source (RDS for MySQL major versions 8.4 and higher) to remove the read replica configuration.

When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_source_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_source_with_auto_position(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'SomePassW0rd',
  1,
  3600);
```

mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_master_with_delay(
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the `mysql.rds_set_external_master_with_delay` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

For more information, see Configuring binary log file position replication with an external source instance.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to

Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_master_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

The `mysql.rds_set_external_master_with_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_delay(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'SomePassW0rd',
  'mysql-bin-changelog.000777',
  120,
  1,
  3600);
```

mysql.rds_set_external_source_with_delay (RDS for MySQL major versions 8.4 and higher)

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_with_delay (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `SOURCE_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The administrative user must run the `mysql.rds_set_external_source_with_delay` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_source_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'SomePassW0rd'
```

For more information, see Configuring binary log file position replication with an external source instance.

> **Note**
>
> We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with DB instance read replicas.

After calling `mysql.rds_set_external_source_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call mysql.rds_start_replication on the read replica to start the replication process. You can call mysql.rds_reset_external_source (RDS for MySQL major versions 8.4 and higher) to remove the read replica configuration.

When you call `mysql.rds_set_external_source_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_source_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source

database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_source_with_delay(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'SomePassW0rd',
  'mysql-bin-changelog.000777',
  120,
  1,
  3600);
```

mysql.rds_set_external_source_gtid_purged

Sets the gtid_purged system variable with a specified GTID range from an external source. The `gtid_purged` value is required for configuring GTID-based replication to resume the replication using auto positioning.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_gtid_purged(
  server_uuid
  , start_pos
  , end_pos
);
```

Parameters

server_uuid

The universally unique identifier (UUID) of the external server from which the GTID range is being imported.

start_pos

The starting position of the GTID range to be set.

end_pos

The ending position of the GTID range to be set.

Usage notes

The mysql.rds_set_external_source_gtid_purged procedure is only available with MySQL 8.0.37 and higher 8.0 versions.

Call mysql.rds_set_external_source_gtid_purged before you call mysql.rds_set_external_master_with_auto_position (RDS for MySQL major versions 8.0 and lower), mysql.rds_set_external_source_with_auto_position (RDS for MySQL major versions 8.4 and higher), or mysql.rds_set_external_source_with_auto_position_for_channel.

Before you call mysql.rds_set_external_source_gtid_purged, make sure to stop all active replication channels for the database. To check the status of a channel, use the SHOW REPLICA STATUS MySQL statement. To stop replication on a channel, call the section called "mysql.rds_stop_replication_for_channel".

The GTID range that you specify must be a superset of the existing GTID_PURGED value. This stored procedure checks the following values before it sets the GTID_PURGED value:

- The server_uuid is valid.
- The value of start_pos is greater than 0 and less than the value of end_pos.
- The value of end_pos is greater than or equal to the value of start_pos.

If the GTID set on your external server contains multiple ranges of values, consider calling the procedure multiple times with different GTID set values.

When you call mysql.rds_set_external_source_gtid_purged, Amazon RDS records the time, the user, and an action of set gtid_purged in the mysql.rds_history table.

If you don't set the gtid_purged value appropriately for the backup that you use for replication, this can result in missing or duplicated transactions during the replication process. Perform the following steps to set the correct gtid_purged value.

To set the gtid_purged value on the replica

1. Determine the point in time or the specific backup file to use as the starting point for replication. This could be a logical backup (a mysqldump file) or a physical backup (an Amazon RDS snapshot).
2. Determine the `gtid_executed` value. This value represents the set of all GTIDs that were committed on the server. To retrieve this value, on the source instance, do one of the following:
   - Run the SQL statement `SELECT @@GLOBAL.GTID_EXECUTED;` at the time the backup was taken.
   - If any related options are included in the respective backup utility, extract the value from the backup file. For more information, see the set-gtid-purged option in the MySQL documentation.
3. Determine the `gtid_purged` value to use for the call to `mysql.rds_set_external_source_gtid_purged`. The `gtid_purged` value should include all the GTIDs that were executed on the source instance and are no longer needed for replication. Therefore, the `gtid_purged` value should be a subset of the `gtid_executed` value that you retrieved in the previous step.

   To determine the `gtid_purged` value, identify the GTIDs that aren't included in the backup and are no longer needed for replication. You can do so by analyzing the binary logs or by using a tool such as mysqlbinlog to find the GTIDs that were purged from the binary logs.

   Alternatively, if you have a consistent backup that includes all of the binary logs up to the backup point, you can set the `gtid_purged` value to be the same as the `gtid_executed` value at the backup point.
4. After you determine the appropriate `gtid_purged` value that's consistent with your backup, call the `mysql.rds_set_external_source_gtid_purged` stored procedure on your RDS for MySQL DB instance to set the value.

Examples

When run on a MySQL DB instance, the following example sets the GTID range from an external MySQL server with the UUID `12345678-abcd-1234-efgh-123456789abc`, a starting position of 1, and an ending position of `100`. The resulting GTID value is set to `+12345678-abcd-1234-efgh-123456789abc:1-100`.

```
CALL mysql.rds_set_external_source_gtid_purged('12345678-abcd-1234-efgh-123456789abc',
 1, 100);
```

mysql.rds_set_master_auto_position (RDS for MySQL major versions 8.0 and lower)

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_master_auto_position (
auto_position_mode
);
```

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- `0` – Use the replication method based on binary log file position. The default is `0`.
- 1 – Use the GTID-based replication method.

Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions.

mysql.rds_set_source_auto_position (RDS for MySQL major versions 8.4 and higher)

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_source_auto_position (auto_position_mode);
```

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

Usage notes

The administrative user must run the mysql.rds_set_source_auto_position procedure.

mysql.rds_set_source_delay

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

Syntax

```
CALL mysql.rds_set_source_delay(
delay
);
```

Parameters

delay

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the mysql.rds_set_source_delay procedure.

For disaster recovery, you can use this procedure with the mysql.rds_start_replication_until stored procedure or the mysql.rds_start_replication_until_gtid stored procedure.
To roll forward changes to a delayed read replica to the time just before a

disaster, you can run the `mysql.rds_set_source_delay` procedure. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information on GTID-based replication, see Using GTID-based replication.

The `mysql.rds_set_source_delay` procedure is available in these versions of RDS for MySQL:

- All RDS for MySQL 8.4 versions
- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

Examples

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call `mysql.rds_set_source_delay` with the following parameter:

```
CALL mysql.rds_set_source_delay(3600);
```

mysql.rds_skip_repl_error

Skips and deletes a replication error on a MySQL DB read replica.

Syntax

```
CALL mysql.rds_skip_repl_error;
```

Usage notes

The master user must run the `mysql.rds_skip_repl_error` procedure on a read replica. For more information about this procedure, see Calling the mysql.rds_skip_repl_error procedure.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If

there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS\G` to determine the correct course of action for the next error. For information about the values returned, see SHOW REPLICA STATUS statement in the MySQL documentation.

For more information about addressing replication errors with Amazon RDS, see Troubleshooting a MySQL read replica problem.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error because of binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the mysql.rds_set_configuration procedure and specify a configuration parameter of `'binlog retention hours'` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

mysql.rds_start_replication

Initiates replication from an RDS for MySQL DB instance.

> **Note**
>
> You can use the mysql.rds_start_replication_until or mysql.rds_start_replication_until_gtid stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication;
```

Usage notes

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you call mysql.rds_set_external_master (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) or mysql.rds_set_external_source (RDS for MySQL major versions 8.4 and higher) to build the replication configuration. For more information, see Restoring a backup into an Amazon RDS for MySQL DB instance.

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication.

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see Working with DB instance read replicas.

mysql.rds_start_replication_until

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication_until (
replication_log_file
  , replication_stop_point
);
```

Parameters

replication_log_file

The name of the binary log on the source database instance that contains the replication information.

replication_stop_point

The location in the `replication_log_file` binary log at which replication will stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

The `mysql.rds_start_replication_until` procedure is available in these versions of RDS for MySQL:

- All RDS for MySQL 8.4 versions
- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

You can configure delayed replication using the following stored procedures:

- mysql.rds_set_configuration
- mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_external_source_with_delay (RDS for MySQL major versions 8.4 and higher)

- mysql.rds_set_source_delay

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches location `120` in the `mysql-bin-changelog.000777` binary log file.

```
call mysql.rds_start_replication_until(
  'mysql-bin-changelog.000777',
  120);
```

mysql.rds_stop_replication

Stops replication from a MySQL DB instance.

Syntax

```
CALL mysql.rds_stop_replication;
```

Usage notes

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see Restoring a backup into an Amazon RDS for MySQL DB instance.

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication.

You can also use `mysql.rds_stop_replication` to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling mysql.rds_start_replication on the read replica. For more information, see Working with DB instance read replicas.

Ending a session or query

The following stored procedures end a session or query.

Topics

- mysql.rds_kill
- mysql.rds_kill_query

mysql.rds_kill

Ends a connection to the MySQL server.

Syntax

```
CALL mysql.rds_kill(processID);
```

Parameters

processID

The identity of the connection thread to be ended.

Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL SHOW PROCESSLIST command.

For information about limitations, see MySQL stored procedure limitations.

Examples

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

mysql.rds_kill_query

Ends a query running against the MySQL server.

Syntax

```
CALL mysql.rds_kill_query(processID);
```

Parameters

processID

The identity of the process or thread that is running the query to be ended.

Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL INFORMATION_SCHEMA PROCESSLIST table or use the MySQL SHOW PROCESSLIST command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the *processID*.

For information about limitations, see MySQL stored procedure limitations.

Examples

The following example stops a query with a query thread ID of 230040:

```
CALL mysql.rds_kill_query(230040);
```

Managing active-active clusters

The following stored procedures set up and manage RDS for MySQL active-active clusters. For more information, see the section called “Configuring active-active clusters”.

These stored procedures are only available with RDS for MySQL DB instances running the following versions:

- All MySQL 8.4 versions
- MySQL 8.0.35 and higher minor versions

Topics

- mysql.rds_group_replication_advance_gtid
- mysql.rds_group_replication_create_user
- mysql.rds_group_replication_set_recovery_channel
- mysql.rds_group_replication_start
- mysql.rds_group_replication_stop

mysql.rds_group_replication_advance_gtid

Creates placeholder GTIDs on the current DB instance.

Syntax

```
CALL mysql.rds_group_replication_advance_gtid(
begin_id
, end_id
, server_uuid
);
```

Parameters

begin_id

The start transaction ID to be created.

end_id

The end transaction ID to be created.

begin_id

The `group_replication_group_name` for the transaction to be created. The `group_replication_group_name` is specified as a UUID in the DB parameter group associated with the DB instance.

Usage notes

In an active-active cluster, for a DB instance to join a group, all GTID transactions executed on the new DB instance must exist on the other members in the cluster. In unusual cases, a new DB instance might have more transactions when transactions are executed before joining the instance to group. In this case, you can't remove any existing transactions, but you can use this procedure to create the corresponding placeholder GTIDs on the othe DB instances in the group. Before doing so, verify that the transactions *don't affect the replicated data*.

When you call this procedure, GTID transactions of `server_uuid:begin_id-end_id` are created with empty content. To avoid replication issues, don't use this procedure under any other conditions.

> **Important**
>
> Avoid calling this procedure when the active-active cluster is functioning normally. Don't call this procedure unless you understand the possible consequences of the transactions you are creating. Calling this procedure might result in inconsistent data.

Example

The following example creates placeholder GTIDs on current DB instance.:

```
CALL mysql.rds_group_replication_advance_gtid(5, 6,
 '11111111-2222-3333-4444-555555555555');
```

mysql.rds_group_replication_create_user

Creates the replication user `rdsgrprepladmin` for group replication on the DB instance.

Syntax

```
CALL mysql.rds_group_replication_create_user(
```

```
replication_user_password
);
```

Parameters

replication_user_password

The password of the replication user `rdsgrprepladmin`.

Usage notes

- The password of the replication user `rdsgrprepladmin` must be the same on all of the DB instances in an active-active cluster.
- The `rdsgrprepladmin` user name is reserved for group replication connections. No other user, including the master user, can have this user name.

Example

The following example creates the replication user `rdsgrprepladmin` for group replication on the DB instance:

```
CALL mysql.rds_group_replication_create_user('password');
```

mysql.rds_group_replication_set_recovery_channel

Sets the `group_replication_recovery` channel for an active-active cluster. The procedure uses the reserved `rdsgrprepladmin` user to configure the channel.

Syntax

```
CALL mysql.rds_group_replication_set_recovery_channel(
replication_user_password);
```

Parameters

replication_user_password

The password of the replication user `rdsgrprepladmin`.

Usage notes

The password of the replication user `rdsgrprepladmin` must be the same on all of the DB instances in an active-active cluster. A call to the `mysql.rds_group_replication_create_user` specifies the password.

Example

The following example sets the `group_replication_recovery` channel for an active-active cluster:

```
CALL mysql.rds_group_replication_set_recovery_channel('password');
```

mysql.rds_group_replication_start

Starts group replication on the current DB instance.

Syntax

```
CALL mysql.rds_group_replication_start(
bootstrap
);
```

Parameters

`bootstrap`

A value that specifies whether to initialize a new group or join an existing group. `1` initializes a new group with the current DB instance. `0` joins the current DB instance to an existing group by connecting to the endpoints defined in `group_replication_group_seeds` parameter in the of DB parameter group associated with the DB instance.

Example

The following example initializes a new group with the current DB instance:

```
CALL mysql.rds_group_replication_start(1);
```

mysql.rds_group_replication_stop

Stops group replication on the current DB instance.

Syntax

```
CALL mysql.rds_group_replication_stop();
```

Usage notes

When you stop replication on a DB instance, it doesn't affect any other DB instance in the active-active cluster.

Managing multi-source replication

The following stored procedures set up and manage replication channels on a RDS for MySQL multi-source replica. For more information, see the section called "Configuring multi-source replication".

These stored procedures are only available with RDS for MySQL DB instances running the following engine versions:

- All 8.4 versions
- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

When using stored procedures to manage replication with a replication user configured with `caching_sha2_passwword`, you must configure TLS by specifying `SOURCE_SSL=1`. `caching_sha2_password` is the default authentication plugin for RDS for MySQL 8.4.

> **Note**
>
> Although this documentation refers to source DB instances as RDS for MySQL DB instances, these procedures also work for MySQL instances running external to Amazon RDS.

Topics

- mysql.rds_next_source_log_for_channel
- mysql.rds_reset_external_source_for_channel
- mysql.rds_set_external_source_for_channel
- mysql.rds_set_external_source_with_auto_position_for_channel
- mysql.rds_set_external_source_with_delay_for_channel
- mysql.rds_set_source_auto_position_for_channel
- mysql.rds_set_source_delay_for_channel
- mysql.rds_skip_repl_error_for_channel
- mysql.rds_start_replication_for_channel
- mysql.rds_start_replication_until_for_channel
- mysql.rds_start_replication_until_gtid_for_channel

- mysql.rds_stop_replication_for_channel

mysql.rds_next_source_log_for_channel

Changes the source DB instance log position to the start of the next binary log on the source DB instance for the channel. Use this procedure only if you are receiving replication I/O error 1236 on a multi-source replica.

Syntax

```
CALL mysql.rds_next_source_log_for_channel(
curr_master_log,
channel_name
);
```

Parameters

curr_master_log

The index of the current source log file. For example, if the current file is named `mysql-bin-changelog.012345`, then the index is 12345. To determine the current source log file name, run the `SHOW REPLICA STATUS FOR CHANNEL '`*channel_name*`'` command and view the `Source_Log_File` field.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_next_source_log_for_channel` procedure. If there is an IO_Thread error, for example, you can use this procedure to skip all the events in the current binary log file and resume the replication from the next binary log file for the channel specified in `channel_name`.

Example

Assume replication fails on a channel on a multi-source replica. Running `SHOW REPLICA STATUS FOR CHANNEL 'channel_1'\G` on the multi-source replica returns the following result:

```
mysql> SHOW REPLICA STATUS FOR CHANNEL 'channel_1'\G
*************************** 1. row ***************************
             Replica_IO_State: Waiting for source to send event
                  Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
                  Source_User: ReplicationUser
                  Source_Port: 3306
                Connect_Retry: 60
              Source_Log_File: mysql-bin-changelog.012345
          Read_Source_Log_Pos: 1219393
               Relay_Log_File: replica-relay-bin.000003
                Relay_Log_Pos: 30223388
        Relay_Source_Log_File: mysql-bin-changelog.012345
           Replica_IO_Running: No
          Replica_SQL_Running: Yes
              Replicate_Do_DB:.
              .
              .
                Last_IO_Errno: 1236
                Last_IO_Error: Got fatal error 1236 from master when reading data from
 binary log: 'Client requested master to start replication from impossible position;
 the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
 '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
               Last_SQL_Errno: 0
               Last_SQL_Error:
               .
               .
                 Channel_name: channel_1
              .
              .
 -- Some fields are omitted in this example output
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is `12345`. To resolve the error, you can call `mysql.rds_next_source_log_for_channel` with the following parameters:

```
CALL mysql.rds_next_source_log_for_channel(12345,'channel_1');
```

mysql.rds_reset_external_source_for_channel

Stops the replication process on the specified channel, and removes the channel and associated configurations from the multi-source replica.

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_reset_external_source_for_channel (channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_reset_external_source_for_channel` procedure. This procedure deletes all relay logs that belong to the channel being removed.

mysql.rds_set_external_source_for_channel

Configures a replication channel on an RDS for MySQL DB instance to replicate the data from another RDS for MySQL DB instance.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Note

You can use the the section called "mysql.rds_set_external_source_with_delay_for_channel" stored procedure instead to configure this channel with delayed replication.

Syntax

```
CALL mysql.rds_set_external_source_for_channel (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , channel_name
);
```

Parameters

host_name

The host name or IP address of the RDS for MySQL source DB instance.

host_port

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source DB instance that contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW BINARY LOG STATUS` on the source DB instance.

> **Note**
>
> Previous versions of MySQL used `SHOW MASTER STATUS` instead of `SHOW BINARY LOG STATUS`. If you are using a MySQL version before 8.4, then use `SHOW MASTER STATUS`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `SOURCE_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_external_source_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   > **Important**
   >
   > As a security best practice, specify a password other than the placeholder value shown in the following examples.

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
   ```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_for_channel` to configure this replication channel, you can call mysql.rds_start_replication_for_channel on the replica to start the replication process on the channel. You can call the section called "mysql.rds_reset_external_source_for_channel" to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_for_channel`, Amazon RDS records the time, user, and an action of `set channel source` in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306`.

```
call mysql.rds_set_external_source_for_channel(
  'sourcedb.example.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  0,
  'channel_1');
```

mysql.rds_set_external_source_with_auto_position_for_channel

Configures a replication channel on an RDS for MySQL DB instance with an optional replication delay. The replication is based on global transaction identifiers (GTIDs).

> **Important**
>
> To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_with_auto_position_for_channel (
  host_name
  , host_port
```

```
  , replication_user_name
  , replication_user_password
  , ssl_encryption
  , delay
  , channel_name
);
```

Parameters

host_name

The host name or IP address of the RDS for MySQL source DB instance.

host_port

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `SOURCE_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86,400 seconds).

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_external_source_with_auto_position_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `rds_set_external_source_with_auto_position_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   Important

   As a security best practice, specify a password other than the placeholder value shown in the following examples.

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
   ```

To use encrypted replication, configure the source DB instance to use SSL connections.

Before you call `mysql.rds_set_external_source_with_auto_position_for_channel`, make sure to call the section called "mysql.rds_set_external_source_gtid_purged" to set the `gtid_purged` system variable with a specified GTID range from an external source.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure an Amazon RDS DB instance as a read replica on a specific channel, you can call the section called "mysql.rds_start_replication_for_channel" on the read replica to start the replication process on that channel.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure this replication channel, you can call mysql.rds_start_replication_for_channel on the replica to start the replication process on the channel. You can call the section called "mysql.rds_reset_external_source_for_channel" to stop replication on the channel and remove the channel configuration from the replica.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306` It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```
call mysql.rds_set_external_source_with_auto_position_for_channel(
  'sourcedb.example.com',
  3306,
  'repl_user',
  'password',
  1,
  3600,
  'channel_1');
```

mysql.rds_set_external_source_with_delay_for_channel

Configures a replication channel on an RDS for MySQL DB instance with a specified replication delay.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group in Amazon RDS.

Syntax

```
CALL mysql.rds_set_external_source_with_delay_for_channel (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , mysql_binary_log_file_name
  , mysql_binary_log_file_location
  , ssl_encryption
  , delay
  , channel_name
);
```

Parameters

host_name

The host name or IP address of the RDS for MySQL source DB instance.

host_port

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source DB instance contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW BINARY LOG STATUS` on the source database instance.

> **Note**
>
> Previous versions of MySQL used `SHOW MASTER STATUS` instead of `SHOW BINARY LOG STATUS`. If you are using a MySQL version before 8.4, then use `SHOW MASTER STATUS`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

> **Note**
>
> The `SOURCE_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86400 seconds).

channel_name

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_external_source_with_delay_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_with_delay_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

   > **Important**
   >
   > As a security best practice, specify a password other than the placeholder value shown in the following examples.

   ```
   CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
   ```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
   ```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_with_delay_for_channel` to configure this replication channel, you can call mysql.rds_start_replication_for_channel on the replica to start the replication process on the channel. You can call the section called "mysql.rds_reset_external_source_for_channel" to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_with_delay_for_channel`, Amazon RDS records the time, user, and an action of `set channel source` in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306` It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```
call mysql.rds_set_external_source_with_delay_for_channel(
  'sourcedb.example.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.000777',
  120,
  1,
  3600,
  'channel_1');
```

mysql.rds_set_source_auto_position_for_channel

Sets the replication mode for the specified channel to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_source_auto_position_for_channel (
auto_position_mode
 , channel_name
);
```

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- `0` – Use the replication method based on binary log file position. The default is `0`.
- 1 – Use the GTID-based replication method.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_source_auto_position_for_channel` procedure. This procedure restarts replication on the specified channel to apply the specified auto position mode.

Examples

The following example sets the auto position mode for channel_1 to use the GTID-based replication method.

```
call mysql.rds_set_source_auto_position_for_channel(1,'channel_1');
```

mysql.rds_set_source_delay_for_channel

Sets the minimum number of seconds to delay replication from the source database instance to the multi-source replica for the specified channel.

Syntax

```
CALL mysql.rds_set_source_delay_for_channel(delay, channel_name);
```

Parameters

delay

The minimum number of seconds to delay replication from the source DB instance.

The limit for this parameter is one day (86400 seconds).

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_set_source_delay_for_channel` procedure. To use this procedure, first call `mysql.rds_stop_replication_for_channel` to stop the replication. Then, call this procedure to set the replication delay value. When the delay is set, call `mysql.rds_start_replication_for_channel` to restart the replication.

Examples

The following example sets the delay for replication from the source database instance on `channel_1` of the multi-source replica for at least one hour (3,600 seconds).

```
CALL mysql.rds_set_source_delay_for_channel(3600,'channel_1');
```

mysql.rds_skip_repl_error_for_channel

Skips a binary log event and deletes a replication error on a MySQL DB multi-source replica for the specified channel.

Syntax

```
CALL mysql.rds_skip_repl_error_for_channel(channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_skip_repl_error_for_channel` procedure on a read replica. You can use this procedure in a similar way `mysql.rds_skip_repl_error` is used to skip an error on a read replica. For more information, see Calling the mysql.rds_skip_repl_error procedure.

> **Note**
>
> To skip errors in GTID-based replication, we recommend that you use the procedure the section called “mysql.rds_skip_transaction_with_gtid” instead.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error_for_channel` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error_for_channel` deletes the first error on the specified replication channel, then warns that others are present. You can then use `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'\G` to determine the correct course of action for the next error. For information about the values returned, see SHOW REPLICA STATUS statement in the MySQL documentation.

mysql.rds_start_replication_for_channel

Initiates replication from an RDS for MySQL DB instance to a multi-source replica on the specified channel.

> **Note**
>
> You can use the mysql.rds_start_replication_until_for_channel or mysql.rds_start_replication_until_gtid_for_channel stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication_for_channel(channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_start_replication_for_channel` procedure. After you import the data from the source RDS for MySQL DB instance, run this command on the multi-source replica to start replication on the specified channel.

Examples

The following example starts replication on `channel_1` of the multi-source replica.

```
CALL mysql.rds_start_replication_for_channel('channel_1');
```

mysql.rds_start_replication_until_for_channel

Initiates replication from an RDS for MySQL DB instance on the specified channel and stops replication at the specified binary log file location.

Syntax

```
CALL mysql.rds_start_replication_until_for_channel (
replication_log_file
  , replication_stop_point
  , channel_name
);
```

Parameters

replication_log_file

The name of the binary log on the source DB instance contains the replication information.

replication_stop_point

The location in the replication_log_file binary log at which replication will stop.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the mysql.rds_start_replication_until_for_channel procedure. With this procedure, replication starts and then stops when the specified binlog file position is reached. This procedure stops both the SQL_THREAD and IO_THREAD.

The file name specified for the replication_log_file parameter must match the source DB instance binlog file name.

When the replication_stop_point parameter specifies a stop location that's in the past, replication is stopped immediately.

Examples

The following example initiates replication on channel_1, and replicates changes until it reaches location 120 in the mysql-bin-changelog.000777 binary log file.

```
call mysql.rds_start_replication_until_for_channel(
  'mysql-bin-changelog.000777',
  120,
  'channel_1'
  );
```

mysql.rds_start_replication_until_gtid_for_channel

Initiates replication on the specified channel from an RDS for MySQL DB instance and stops replication at the specified global transaction identifier (GTID).

Syntax

```
CALL mysql.rds_start_replication_until_gtid_for_channel(gtid,channel_name);
```

Parameters

gtid

The GTID after which to stop replication.

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid_for_channel` procedure. The procedure starts replication on the specified channel and applies all changes up to the specified GTID value. Then, it stops replication on the channel.

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Before you run this procedure, you must disable multi-threaded replication by setting the value of `replica_parallel_workers` or `slave_parallel_workers` to `0`.

Examples

The following example initiates replication on `channel_1`, and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid_for_channel('3E11FA47-71CA-11E1-9E33-
C80AA9429562:23','channel_1');
```

mysql.rds_stop_replication_for_channel

Stops replication from a MySQL DB instance on the specified channel.

Syntax

```
CALL mysql.rds_stop_replication_for_channel(channel_name);
```

Parameters

channel_name

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

Usage notes

The master user must run the `mysql.rds_stop_replication_for_channel` procedure.

Examples

The following example stops replication on `channel_1` of the multi-source replica.

```
CALL mysql.rds_stop_replication_for_channel('channel_1');
```

Replicating transactions using GTIDs

The following stored procedures control how transactions are replicated using global transaction identifiers (GTIDs) with RDS for MySQL. For more information about replication based on GTIDs with RDS for MySQL, see Using GTID-based replication.

When using stored procedures to manage replication with a replication user configured with `caching_sha2_password`, you must configure TLS by specifying `SOURCE_SSL=1`. `caching_sha2_password` is the default authentication plugin for RDS for MySQL 8.4.

Topics

- mysql.rds_skip_transaction_with_gtid
- mysql.rds_start_replication_until_gtid

mysql.rds_skip_transaction_with_gtid

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (
gtid_to_skip
);
```

Parameters

gtid_to_skip

The GTID of the replication transaction to skip.

Usage notes

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, all RDS for MySQL 8.0 versions, and all RDS for MySQL 8.4 versions.

Examples

The following example skips replication of the transaction with the GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

mysql.rds_start_replication_until_gtid

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).

Syntax

```
CALL mysql.rds_start_replication_until_gtid(gtid);
```

Parameters

gtid

The GTID after which replication is to stop.

Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, all RDS for MySQL 8.0 versions, and all RDS for MySQL 8.4 versions.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

You can configure delayed replication using the following stored procedures:

- mysql.rds_set_configuration
- mysql.rds_set_external_master_with_delay (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower)
- mysql.rds_set_external_source_with_delay (RDS for MySQL major versions 8.4 and higher)
- mysql.rds_set_source_delay

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

Rotating the query logs

The following stored procedures rotate MySQL logs to backup tables. For more information, see MySQL database log files.

Topics

- mysql.rds_rotate_general_log
- mysql.rds_rotate_slow_log

mysql.rds_rotate_general_log

Rotates the `mysql.general_log` table to a backup table.

Syntax

```
CALL mysql.rds_rotate_general_log;
```

Usage notes

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

mysql.rds_rotate_slow_log

Rotates the `mysql.slow_log` table to a backup table.

Syntax

```
CALL mysql.rds_rotate_slow_log;
```

Usage notes

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

Setting and showing binary log configuration

The following stored procedures set and show configuration parameters, such as for binary log file retention.

Topics

- mysql.rds_set_configuration
- mysql.rds_show_configuration

mysql.rds_set_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

```
CALL mysql.rds_set_configuration(name,value);
```

Parameters

name

The name of the configuration parameter to set.

value

The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- binlog retention hours
- source delay
- target delay

The configuration parameters are stored permanently and survive any DB instance reboot or failover.

binlog retention hours

The `binlog retention hours` parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to RDS.

The default value of `binlog retention hours` is `NULL`. For RDS for MySQL, `NULL` means binary logs aren't retained (0 hours).

To specify the number of hours to retain binary logs on a DB instance, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

> **Note**
>
> You can't use the value `0` for `binlog retention hours`.

For MySQL DB instances, the maximum `binlog retention hours` value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

For Multi-AZ DB cluster deployments, you can only configure binary log retention from the writer DB instance, and the setting is propagated to all reader DB instances asynchronously. If binary logs on the DB cluster exceed half of the total local storage space, Amazon RDS automatically moves stale logs to the EBS volume. However, the newest logs remain in local storage, so they're subject to be lost if there's a failure that requires a host replacement, or if you scale the database up or down.

source delay

Use the `source delay` parameter in a read replica to specify the number of seconds to delay replication from the read replica to its source DB instance. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to quickly recover it. The default value of `target delay` is `0` (don't delay replication).

When you use this parameter, it runs mysql.rds_set_source_delay and applies CHANGE primary TO MASTER_DELAY = input value. If successful, the procedure saves the `source delay` parameter to the `mysql.rds_configuration` table.

To specify the number of seconds for Amazon RDS to delay replication to a source DB instance, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. In the following example, the replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('source delay', 3600);
```

The procedure then runs `mysql.rds_set_source_delay(3600)`.

The limit for the `source delay` parameter is one day (86400 seconds).

target delay

Use the `target delay` parameter to specify the number of seconds to delay replication between a DB instance and any future RDS-managed read replicas created from this instance. This parameter is ignored for non-RDS-managed read replicas. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of `target delay` is `0` (don't delay replication).

For disaster recovery, you can use this configuration parameter with the mysql.rds_start_replication_until stored procedure or the mysql.rds_start_replication_until_gtid stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_configuration` procedure with this parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay

replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('target delay', 3600);
```

The limit for the `target delay` parameter is one day (86400 seconds).

mysql.rds_show_configuration

The number of hours that binary logs are retained.

Syntax

```
CALL mysql.rds_show_configuration;
```

Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

Examples

The following example displays the retention period:

```
call mysql.rds_show_configuration;
                name                          value     description
                binlog retention hours        24        binlog retention hours specifies
 the duration in hours before binary logs are automatically deleted.
```

Warming the InnoDB cache

The following stored procedures save, load, or cancel loading the InnoDB buffer pool on RDS for MySQL DB instances. For more information, see InnoDB cache warming for MySQL on Amazon RDS.

Topics

- mysql.rds_innodb_buffer_pool_dump_now
- mysql.rds_innodb_buffer_pool_load_abort
- mysql.rds_innodb_buffer_pool_load_now

mysql.rds_innodb_buffer_pool_dump_now

Dumps the current state of the buffer pool to disk.

Syntax

```
CALL mysql.rds_innodb_buffer_pool_dump_now();
```

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_dump_now` procedure.

mysql.rds_innodb_buffer_pool_load_abort

Cancels a load of the saved buffer pool state while in progress.

Syntax

```
CALL mysql.rds_innodb_buffer_pool_load_abort();
```

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_abort` procedure.

mysql.rds_innodb_buffer_pool_load_now

Loads the saved state of the buffer pool from disk.

Syntax

```
CALL mysql.rds_innodb_buffer_pool_load_now();
```

Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_now` procedure.

Amazon RDS for Oracle

Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)

> **Note**
>
> Oracle Database 11g, Oracle Database 12c, and Oracle Database 18c are legacy versions that are no longer supported in Amazon RDS.

Before creating a DB instance, complete the steps in the Setting up your Amazon RDS environment section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can't use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle Database inside a VPC. You can also add features to your DB instance by enabling various options, such as Oracle Spatial or Oracle Statspack. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

> **Important**
>
> To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need

advanced privileges. You can access your database using standard SQL clients such as Oracle SQL*Plus. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

Overview of Oracle on Amazon RDS

You can read the following sections to get an overview of RDS for Oracle.

Topics

- RDS for Oracle features
- RDS for Oracle releases
- RDS for Oracle licensing options
- RDS for Oracle users and privileges
- RDS for Oracle DB instance classes
- RDS for Oracle database architecture
- RDS for Oracle initialization parameters

- RDS for Oracle character sets
- RDS for Oracle limitations

RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the *Oracle Database Licensing Information User Manual* for the version you're using.

Topics

- New features in RDS for Oracle
- Supported features in RDS for Oracle
- Unsupported features in RDS for Oracle

New features in RDS for Oracle

To see new features in RDS for Oracle, search Document history for the keyword **`Oracle`**.

Supported features in RDS for Oracle

Amazon RDS for Oracle supports the following Oracle Database features:

> **Note**
>
> The following list isn't exhaustive.

- Advanced Compression
- Oracle Application Express (APEX)

  For more information, see Oracle Application Express (APEX).
- Automatic Memory Management
- Automatic Undo Management
- Automatic Workload Repository (AWR)

For more information, see Generating performance reports with Automatic Workload Repository (AWR).

- Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions

  For more information, see Working with read replicas for Amazon RDS for Oracle.
- Blockchain tables (Oracle Database 21c and higher)

  For more information, see Managing Blockchain Tables in the Oracle Database documentation.
- Continuous Query Notification

  For more information, see Using Continuous Query Notification (CQN) in the Oracle documentation.
- Data Redaction
- Continuous Query Notification

  For more information, see Database Change Notification in the Oracle documentation.
- Database In-Memory
- Distributed Queries and Transactions
- Edition-Based Redefinition

  For more information, see Setting the default edition for a DB instance.
- EM Express (12c and higher)

  For more information, see Oracle Enterprise Manager.
- Fine-Grained Auditing
- Flashback Table, Flashback Query, Flashback Transaction Query
- Gradual password rollover for applications (Oracle Database 21c and higher)

  For more information, see Managing Gradual Database Password Rollover for Applications in the Oracle Database documentation.
- HugePages

  For more information, see Turning on HugePages for an RDS for Oracle instance.
- Import/export (legacy and Data Pump) and SQL*Loader

  For more information, see Importing data into Oracle on Amazon RDS.

- Java Virtual Machine (JVM)

  For more information, see Oracle Java virtual machine.
- JavaScript (Oracle Database 21c and higher)

  For more information, see DBMS_MLE in the Oracle Database documentation.
- Label Security

  For more information, see Oracle Label Security.
- Locator

  For more information, see Oracle Locator.
- Materialized Views
- Multitenant

  The Oracle multitenant architecture is supported for all Oracle Database 19c and higher releases. For more information, see Working with CDBs in RDS for Oracle.
- Network encryption

  For more information, see Oracle native network encryption and Oracle Secure Sockets Layer.
- Partitioning
- Real Application Testing

  To use the full capture and replay capabilities, you must use Amazon Elastic File System (Amazon EFS) to access files generated by Oracle Real Application Testing. For more information, see Amazon EFS integration and the blog post Use Oracle Real Application Testing features with Amazon RDS for Oracle.
- Sharding at the application level (but not the Oracle Sharding feature)
- Spatial and Graph

  For more information, see Oracle Spatial.
- Star Query Optimization
- Streams and Advanced Queuing
- Summary Management – Materialized View Query Rewrite
- Text (File and URL data store types are not supported)
- Total Recall

- Transparent Data Encryption (TDE)

  For more information, see Oracle Transparent Data Encryption.
- Unified Auditing, Mixed Mode

  For more information, see Mixed mode auditing in the Oracle documentation.
- XML DB (without the XML DB Protocol Server)

  For more information, see Oracle XML DB.
- Virtual Private Database

Unsupported features in RDS for Oracle

Amazon RDS for Oracle doesn't support the following Oracle Database features:

> **Note**
>
> The following list isn't exhaustive.

- Automatic Storage Management (ASM)
- Database Vault
- Flashback Database

> **Note**
>
> For alternative solutions, see the AWS Database Blog entry Alternatives to the Oracle flashback database feature in Amazon RDS for Oracle.

- FTP and SFTP
- Hybrid partitioned tables
- Messaging Gateway
- Oracle Enterprise Manager Cloud Control Management Repository
- Real Application Clusters (Oracle RAC)
- Real Application Security (RAS)
- Unified Auditing, Pure Mode

- Workspace Manager (WMSYS) schema

> **Warning**
>
> In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYSDBA privileges, you can damage the data dictionary and affect the availability of your DB instance. Use only supported features and schemas that are available in Adding options to Oracle DB instances.

RDS for Oracle releases

RDS for Oracle for Oracle supports multiple Oracle Database releases.

> **Note**
>
> For information about upgrading your releases, see Upgrading the RDS for Oracle DB engine.

Topics

- Oracle Database 21c with Amazon RDS
- Oracle Database 19c with Amazon RDS

Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition 2. Oracle Database 21c (21.0.0.0) includes many new features and updates from the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see Limitations of RDS for Oracle CDBs.

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 21c documentation. For a complete list of features supported by each Oracle Database 21c edition,

see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- New parameters
- Changes for the compatible parameter
- Removed parameters

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).

Name	Range of values	Default value	Modifiable	Description
blockchain_table_max_no_drop	NONE | 0	NONE	Y	Lets you control the maximum amount of idle time that can be specified when creating a blockchain table.
dbnest_enable	NONE | CDB_RESOURCE_PDB_ALL	NONE	N	Allows you to enable or disable dbNest. DbNest provides operating system resource isolation and management, file system isolation, and secure computing for PDBs.
dbnest_pdb_fs_conf	NONE | *pathname*	NONE	N	Specifies the dbNest file system configuration file for a PDB.

Name	Range of values	Default value	Modifiable	Description
diagnostics_control	ERROR | WARNING | IGNORE	IGNORE	Y	Allows you to control and monitor the users who perform potentially unsafe database diagnostic operations.
drcp_dedicated_opt	YES | NO	YES	Y	Enables or disables the use of dedicated optimization with Database Resident Connection Pooling (DRCP).
enable_per_pdb_drcp	true | false	true	N	Controls whether Database Resident Connection Pooling (DRCP) configures one connection pool for the entire CDB or one isolated connection pool for each PDB.
inmemory_deep_vectorization	true | false	true	Y	Enables or disables the deep vectorization framework.
mandatory_user_profile	*profile_name*	N/A	N	Specifies the mandatory user profile for a CDB or PDB.
optimizer_capture_sql_quarantine	true | false	false	Y	Enables or disables the deep vectorization framework.
optimizer_use_sql_quarantine	true | false	false	Y	Enables or disables the automatic creation of SQL Quarantine configurations.

Name	Range of values	Default value	Modifiable	Description
result_cache_execution_threshold	0 to 2147483647	2	Y	Specifies the maximum number of times a PL/SQL function can be executed before its result is stored in the result cache.
result_cache_max_temp_result	0 to 100	5	Y	Specifies the percentage of RESULT_CACHE_MAX_TEMP_SIZE that any single cached query result can consume.
result_cache_max_temp_size	0 to 2199023255552	RESULT_CACHE_SIZE * 10	Y	Specifies the maximum amount of temporary tablespace (in bytes) that can be consumed by the result cache.
sga_min_size	0 to 2199023255552 (maximum value is 50% of sga_target)	0	Y	Indicates a possible minimum value for SGA usage of a pluggable database (PDB).

Name	Range of values	Default value	Modifiable	Description
tablespace_encryption_default_algorithm	GOST256 | SEED128 | ARIA256 | ARIA192 | ARIA128 | 3DES168 | AES256 | AES192 | AES128	AES128	Y	Specifies the default algorithm the database uses when encrypting a tablespace.

Changes for the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

Parameter name	Oracle Database 21c (21.0.0.0) maximum value
compatible	21.0.0

Removed parameters

The following parameters were removed in Oracle Database 21c (21.0.0.0):

- `remote_os_authent`
- `sec_case_sensitive_logon`
- `unified_audit_sga_queue_size`

Oracle Database 19c with Amazon RDS

Amazon RDS supports Oracle Database 19c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two.

Oracle Database 19c (19.0.0.0) includes many new features and updates from the previous version. In this section, you can find the features and changes important to using Oracle Database 19c (19.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 19c documentation. For a complete list of features supported by each Oracle Database 19c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- New parameters
- Changes to the compatible parameter
- Removed parameters

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).

Name	Values	Modifiable	Description
lob_signature_enable	TRUE, FALSE (default)	Y	Enables or disables the LOB locator signature feature.
max_datapump_parallel_per_job	1 to 1024, or AUTO	Y	Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.

Changes to the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

Parameter name	Oracle Database 19c (19.0.0.0) maximum value
compatible	19.0.0

Removed parameters

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- `exafusion_enabled`
- `max_connections`
- `o7_dictionary_access`

RDS for Oracle licensing options

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance.

> **Important**
>
> Make sure that you have the appropriate Oracle Database license, with Software Update License and Support, for your DB instance class and Oracle Database edition. Also make sure that you have licenses for any separately licensed Oracle Database features.

Topics

- License Included model for SE2
- Bring Your Own License (BYOL) for EE and SE2
- Licensing Oracle Multi-AZ deployments

License Included model for SE2

In the License Included model, you don't need to purchase Oracle Database licenses separately. AWS holds the license for the Oracle database software. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition 2 (SE2).

In this model, if you have an AWS Support account with case support, contact Support for both Amazon RDS and Oracle Database service requests. Your use of RDS for Oracle the LI option is subject to Section 10.3.1 of the AWS Service Terms.

Bring Your Own License (BYOL) for EE and SE2

In the BYOL model, you can use your existing Oracle Database licenses to deploy databases on Amazon RDS. Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition 2 (SE2).

Make sure that you have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle's policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle's licensing policy for Amazon EC2, see Licensing Oracle software in the cloud computing environment.

In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact Support for Amazon RDS issues.

Integrating with AWS License Manager

To make it easier to monitor Oracle license usage in the BYOL model, AWS License Manager integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

Filter	Name	Description
Engine Edition	`oracle-ee`	Oracle Database Enterprise Edition (EE)
	`oracle-se2`	Oracle Database Standard Edition 2 (SE2)
License Pack	`data guard`	See Working with read replicas for Amazon RDS for Oracle (Oracle Active Data Guard)
	`olap`	See Oracle OLAP
	`ols`	See Oracle Label Security

Filter	Name	Description
	`diagnostic pack sqlt`	See Oracle SQLT
	`tuning pack sqlt`	See Oracle SQLT

To track license usage of your Oracle DB instances, you can create a self-managed license using AWS License Manager. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the self-managed license. Discovery of Oracle DB instances can take up to 24 hours. You can also track a license across accounts by using AWS Resource Access Manager.

Console

To create a self-managed license in AWS License Manager to track the license usage of your RDS for Oracle DB instances

1. Go to https://console.aws.amazon.com/license-manager/.
2. Choose **Create self-managed license**.

   For instructions, see Create a self-managed license in the *AWS License Manager User Guide*.

   Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

   For more information, see ProductInformation in the *AWS License Manager API Reference*.
3. (Cross-account tracking only) Use AWS Resource Access Manager to share your self-managed licenses with any AWS account or through AWS Organizations. For more information, see Sharing your AWS resources.

AWS CLI

To create a self-managed license by using the AWS CLI, call the create-license-configuration command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.

Example

The following example creates a self-managed license for Oracle Enterprise Edition.

```
aws license-manager create-license-configuration --cli-input-json file://rds-oracle-
ee.json
```

The following is the sample `rds-oracle-ee.json` file used in the example.

```
{
    "Name": "rds-oracle-ee",
    "Description": "RDS Oracle Enterprise Edition",
    "LicenseCountingType": "vCPU",
    "LicenseCountHardLimit": false,
    "ProductInformationList": [
        {
            "ResourceType": "RDS",
            "ProductInformationFilterList": [
                {
                    "ProductInformationFilterName": "Engine Edition",
                    "ProductInformationFilterValue": ["oracle-ee"],
                    "ProductInformationFilterComparator": "EQUALS"
                }
            ]
        }
    ]
}
```

For more information about product information, see Automated discovery of resource inventory in the *AWS License Manager User Guide*.

For more information about the `--cli-input` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the *AWS CLI User Guide*.

Migrating between Oracle Database editions

If you have an unused BYOL Oracle Database license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can't migrate from EE to other editions.

To change your Oracle Database edition and retain your data

1. Create a snapshot of the DB instance.

   For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.

   For more information, see Restoring to a DB instance.

3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.

   For more information, see Deleting a DB instance.

Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS.

If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

RDS for Oracle users and privileges

When you create an Amazon RDS for Oracle DB instance, the default master user has most of the maximum user permissions on the DB instance. Use the master user account for any administrative tasks, such as creating additional user accounts in your database. Because RDS is a managed service, you aren't allowed to log in as SYS and SYSTEM, and thus don't have SYSDBA privileges.

Topics

- Limitations for Oracle DBA privileges
- How to manage privileges on SYS objects

Limitations for Oracle DBA privileges

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security. For more information, see Configuring Privilege and Role Authorization in the Oracle Database documentation.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To

deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- `ALTER DATABASE`
- `ALTER SYSTEM`
- `CREATE ANY DIRECTORY`
- `DROP ANY DIRECTORY`
- `GRANT ANY PRIVILEGE`
- `GRANT ANY ROLE`

For more RDS for Oracle system privilege and role information, see Master user account privileges.

How to manage privileges on SYS objects

You can manage privileges on SYS objects by using the `rdsadmin.rdsadmin_util` package. For example, if you create the database user `myuser`, you could use the `rdsadmin.rdsadmin_util.grant_sys_object` procedure to grant `SELECT` privileges on `V_$SQLAREA` to `myuser`. For more information, see the following topics:

- Granting SELECT or EXECUTE privileges to SYS objects
- Revoking SELECT or EXECUTE privileges on SYS objects
- Granting privileges to non-master users

RDS for Oracle DB instance classes

The computation and memory capacity of an RDS for Oracle DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

Supported RDS for Oracle DB instance classes

The supported RDS for Oracle instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see DB instance classes.

RDS for Oracle preconfigured DB instance classes

RDS for Oracle also offers instance classes that are preconfigured for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention.

```
db.r5b.instance_size.tpcthreads_per_core.memratio
db.r5.instance_size.tpcthreads_per_core.memratio
```

The following is an example of an instance class that is preconfigured for additional memory:

```
db.r5b.4xlarge.tpc2.mem2x
```

The components of the preceding instance class name are as follows:

- `db.r5b.4xlarge` – The name of the instance class.
- `tpc2` – The threads per core. A value of 2 means that multithreading is turned on. A value of 1 means that multithreading is turned off.
- `mem2x` – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard db.r5.4xlarge DB instance.

> **Note**
>
> For the normalization factors of the preconfigured RDS for Oracle DB instance classes, see Hardware specifications for DB instance classes.

Supported edition, instance class, and licensing combinations in RDS for Oracle

If you're using the RDS console, you can find out whether a specific edition, instance class, and license combination is supported by choosing **Create database** and specifying different option. In the AWS CLI, you can run the following command:

```
aws rds describe-orderable-db-instance-options --engine engine-type --license-
model license-type
```

The following table lists all editions, instance classes, and license types supported for RDS for Oracle. For information about the memory attributes of each type, see RDS for Oracle instance types. For information about pricing, see Amazon RDS for Oracle pricing models.

Oracle edition	Oracle Database 19c and higher
Enterprise Edition (EE)	**Standard instance classes**
Bring Your Own License (BYOL)	db.m7i.large–db.m7i.48xlarge, db.m7i.metal-24xl, db.m7i.metal-48xl
	db.m6in.large–db.m6in.32xlarge, db.m6in.metal
	db.m6id.large–db.m6id.32xlarge, db.m6id.metal
	db.m6i.large–db.m6i.32xlarge, db.m6i.metal
	db.m5d.large–db.m5d.24xlarge
	db.m5.large–db.m5.24xlarge
	Memory optimized instance classes
	db.r7i.large–db.r7i.48xlarge, db.r7i.metal-24xl, db.r7i.metal-48xl
	db.r6in.large–db.r6in.32xlarge, db.r6in.metal
	db.r6id.large–db.r6id.32xlarge, db.r6id.metal
	db.r6i.large–db.r6i.32xlarge, db.r6i.metal
	db.r5d.large–db.r5d.24xlarge
	db.r5b.large–db.r5b.24xlarge
	db.r5.large–db.r5.24xlarge
	db.x2iedn.xlarge–db.x2iedn.32xlarge, db.x2iedn.metal
	db.x2iezn.2xlarge–db.x2iezn.12xlarge, db.x2iezn.metal
	db.x2idn.16xlarge–db.x2idn.32xlarge, db.x2idn.metal

Deprecated RDS for Oracle DB instance classes

The following DB instance classes are deprecated for RDS for Oracle:

- db.m1, db.m2, db.m3, db.m4
- db.t1, db.t2
- db.r1, db.r2, db.r3, db.r4
- db.x1, db.x1e

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. If you have DB instances that use deprecated DB instance classes, you have the following options:

- Allow Amazon RDS to modify each DB instance automatically to use a comparable non-deprecated DB instance class. For deprecation timelines, see DB instance class types.
- Change the DB instance class yourself by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring to a DB instance.

RDS for Oracle database architecture

The *Oracle multitenant architecture*, also known as the *CDB architecture*, enables an Oracle database to function as a *multitenant container database (CDB)*. A CDB can include customer-created *pluggable databases (PDBs)*. A *non-CDB* is an Oracle database that uses the traditional architecture, which can't contain PDBs. For more information about the multitenant architecture, see *Oracle Multitenant Administrator's Guide*.

For Oracle Database 19c and higher, you can create an RDS for Oracle DB instance that uses the CDB architecture. In RDS for Oracle, PDBs are referred to as *tenant databases*. Your client applications connect at the tenant database (PDB) level rather than the CDB level. RDS for Oracle supports the following configurations of the CDB architecture:

Multi-tenant configuration

Amazon RDS allows a CDB instance to contain between 1–30 tenant databases, depending on the database edition and any required option licenses. You can use RDS APIs to add, modify, and remove tenant databases. The multi-tenant configuration in RDS for Oracle doesn't support application PDBs or proxy PDBs, which are special types of PDBs. For more information about application PDBs and proxy PDBs, see Types of PDBs in the Oracle Database documentation.

> **Note**
>
> The Amazon RDS configuration is called "multi-tenant" rather than "multitenant" because it is a capability of Amazon RDS, not just the Oracle DB engine. Similarly, the RDS term "tenant" refers to any tenant in an RDS configuration, not just Oracle PDBs. In the RDS documentation, the unhyphenated term "Oracle multitenant" refers exclusively to the Oracle database CDB architecture, which is compatible with both on-premises and RDS deployments.

Single-tenant configuration

Amazon RDS limits an RDS for Oracle CDB instance to 1 tenant database (PDB). You can't add more PDBs using RDS APIs. The single-tenant configuration uses the same RDS APIs as the non-CDB architecture. Thus, the experience of working with a CDB in the single-tenant configuration is mostly the same as working with a non-CDB.

You can convert a CDB that uses the single-tenant configuration to the multi-tenant configuration, thus allowing you to add PDBs to your CDB. This architecture change is permanent and irreversible. For more information, see Converting the single-tenant configuration to multi-tenant.

Note

You can't access the CDB itself.

In Oracle Database 21c and higher, all databases are CDBs. In contrast, you can create an Oracle Database 19c DB instance as either a CDB or non-CDB. You can't upgrade a non-CDB to a CDB, but you convert an Oracle Database 19c non-CDB to a CDB, and then upgrade it. You can't convert a CDB to a non-CDB.

For more information, see the following resources:

- Working with CDBs in RDS for Oracle
- Limitations of RDS for Oracle CDBs
- Creating an Amazon RDS DB instance

RDS for Oracle initialization parameters

In Amazon RDS, you manage parameters using a DB parameter group. Using this group, you can customize initialization parameters. For example, you can configure the sort area size with `sort_area_size`. All RDS for Oracle DB instances associated with a specific DB parameter group use the same parameter settings. For more information, see Parameter groups for Amazon RDS.

Supported initialization parameters in RDS for Oracle

Supported parameters for your DB instance depend on your Oracle Database edition and version. To view the supported initialization parameters for a specific Oracle Database edition and version, run the AWS CLI command `describe-engine-default-parameters`. For example, to list names of the supported initialization parameters for the Enterprise Edition of Oracle Database 19c, run the following command (sample output included).

```
aws rds describe-engine-default-parameters \
```

```
    --db-parameter-group-family oracle-ee-19 \
    --output json | jq -r '.EngineDefaults.Parameters[].ParameterName'

_add_col_optim_enabled
_adg_parselock_timeout
_allow_insert_with_update_check
_allow_level_without_connect_by
_always_semi_join
_autotask_max_window
_awr_disabled_flush_tables
_awr_mmon_cpuusage
_awr_mmon_deep_purge_all_expired
_b_tree_bitmap_plans
_bct_bitmaps_per_file
_bloom_filter_enabled
_buffered_publisher_flow_control_threshold
_bug29394014_allow_triggers_on_vpd_table
_cleanup_rollback_entries
_client_enable_auto_unregister
_clusterwide_global_transactions
_complex_view_merging
_connect_by_use_union_all
_cost_equality_semi_join
_cursor_features_enabled
_cursor_obsolete_threshold
_datafile_write_errors_crash_instance
_db_block_buffers
...
```

To describe a single initialization parameter, use the following command, replacing `sga_max_size` with the name of your parameter (sample output included).

```
aws rds describe-engine-default-parameters \
    --db-parameter-group-family oracle-ee-19 \
    --query 'EngineDefaults.Parameters[?ParameterName==`sga_max_size`]' \
    --output json

[
    {
        "ParameterName": "sga_max_size",
        "Description": "max total SGA size",
        "Source": "engine-default",
        "ApplyType": "static",
```

```
        "DataType": "integer",
        "AllowedValues": "0-2199023255552",
        "IsModifiable": true
    }
]
```

To find general documentation for the Oracle database initialization parameters, see Initialization Parameters in the Oracle Database documentation. Note that the parameter ARCHIVE_LAG_TARGET has special considerations in RDS for Oracle. This parameter forces an online redo log switch after the specified time elapses. In RDS for Oracle, ARCHIVE_LAG_TARGET is set to 300 because the recovery point objective (RPO) is 5 minutes. To honor this objective, RDS for Oracle switches the online redo log every 5 minutes and stores it in an Amazon S3 bucket.

If the frequency of the online redo log switch degrades the performance of your RDS for Oracle database, you can scale your DB instance and storage to use higher IOPS and throughput. Alternatively, if you use RDS Custom for Oracle or deploy an Oracle database on Amazon EC2, you can adjust the setting of the ARCHIVE_LAG_TARGET initialization parameter.

Valid parameter values in RDS for Oracle

In RDS for Oracle, only the following characters are valid for parameter values:

- Letters (A-Z and a-z)
- Numbers (0-9)
- Whitespace (spaces, tabs, and line breaks)
- The following special characters: _ / . : + = ( ) ' * , % $ - (hyphen)

RDS for Oracle character sets

RDS for Oracle supports two types of character sets: the DB character set and national character set.

DB character set

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the *DB character set*.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

Supported DB character sets

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the `--character-set-name` parameter of the AWS CLI create-db-instance command or with the `CharacterSetName` parameter of the Amazon RDS API CreateDBInstance operation.

> **Note**
>
> The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

Value	Description
AL32UTF8	Unicode 5.0 UTF-8 Universal character set (default)
AR8ISO8859P6	ISO 8859-6 Latin/Arabic
AR8MSWIN1256	Microsoft Windows Code Page 1256 8-bit Latin/Arabic
BLT8ISO8859P13	ISO 8859-13 Baltic
BLT8MSWIN1257	Microsoft Windows Code Page 1257 8-bit Baltic
CL8ISO8859P5	ISO 88559-5 Latin/Cyrillic
CL8MSWIN1251	Microsoft Windows Code Page 1251 8-bit Latin/Cyrillic
EE8ISO8859P2	ISO 8859-2 East European
EL8ISO8859P7	ISO 8859-7 Latin/Greek

Value	Description
EE8MSWIN1250	Microsoft Windows Code Page 1250 8-bit East European
EL8MSWIN1253	Microsoft Windows Code Page 1253 8-bit Latin/Greek
IW8ISO8859P8	ISO 8859-8 Latin/Hebrew
IW8MSWIN1255	Microsoft Windows Code Page 1255 8-bit Latin/Hebrew
JA16EUC	EUC 24-bit Japanese
JA16EUCTILDE	Same as JA16EUC except for mapping of wave dash and tilde to and from Unicode
JA16SJIS	Shift-JIS 16-bit Japanese
JA16SJISTILDE	Same as JA16SJIS except for mapping of wave dash and tilde to and from Unicode
KO16MSWIN949	Microsoft Windows Code Page 949 Korean
NE8ISO8859P10	ISO 8859-10 North European
NEE8ISO8859P4	ISO 8859-4 North and Northeast European
TH8TISASCII	Thai Industrial Standard 620-2533-ASCII 8-bit
TR8MSWIN1254	Microsoft Windows Code Page 1254 8-bit Turkish
US7ASCII	ASCII 7-bit American
UTF8	Unicode 3.0 UTF-8 Universal character set, CESU-8 compliant
VN8MSWIN1258	Microsoft Windows Code Page 1258 8-bit Vietnamese

Value	Description
WE8ISO8859P1	Western European 8-bit ISO 8859 Part 1
WE8ISO8859P15	ISO 8859-15 West European
WE8ISO8859P9	ISO 8859-9 West European and Turkish
WE8MSWIN1252	Microsoft Windows Code Page 1252 8-bit West European
ZHS16GBK	GBK 16-bit Simplified Chinese
ZHT16HKSCS	Microsoft Windows Code Page 950 with Hong Kong Supplementary Character Set HKSCS-2001. Character set conversion is based on Unicode 3.0.
ZHT16MSWIN950	Microsoft Windows Code Page 950 Traditional Chinese
ZHT32EUC	EUC 32-bit Traditional Chinese

NLS_LANG environment variable

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS_LANG environment variable in your client's environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more information on NLS_LANG and character sets, see What is a character set or code page? in the Oracle documentation.

NLS initialization parameters

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- NLS_COMP

- NLS_DATE_FORMAT
- NLS_LENGTH_SEMANTICS
- NLS_NCHAR_CONV_EXCP
- NLS_SORT
- NLS_TIME_FORMAT
- NLS_TIME_TZ_FORMAT
- NLS_TIMESTAMP_FORMAT
- NLS_TIMESTAMP_TZ_FORMAT

For information about modifying instance parameters, see Parameter groups for Amazon RDS.

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```

For information about connecting to an Oracle DB instance with a SQL client, see Connecting to your Oracle DB instance.

National character set

The national character set is used in the NCHAR, NVARCHAR2, and NCLOB data types. The national character set is typically referred to as the *NCHAR character set*. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

- AL16UTF16 (default)
- UTF8

You can specify either value with the `--nchar-character-set-name` parameter of the create-db-instance command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the `NcharCharacterSetName` parameter of CreateDBInstance operation. You can't change the national character set after you create the database.

For more information about Unicode in Oracle databases, see Supporting multilingual databases with unicode in the Oracle documentation.

RDS for Oracle limitations

In the following sections, you can find important limitations of using RDS for Oracle. For limitations specific to CDBs, see Limitations of RDS for Oracle CDBs.

> **Note**
>
> This list is not exhaustive.

Topics

- Oracle file size limits in Amazon RDS
- Block size limits in RDS for Oracle
- Public synonyms for Oracle-supplied schemas
- Schemas for unsupported features in RDS for Oracle
- Limitations for DBA privileges in RDS for Oracle
- Deprecation of TLS 1.0 and 1.1 Transport Layer Security in RDS for Oracle

Oracle file size limits in Amazon RDS

The maximum size of a single file on RDS for Oracle DB instances is 16 TiB (tebibytes). This limit is imposed by the ext4 filesystem used by the instance. Thus, Oracle bigfile data files are limited to 16 TiB. If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

```
ORA-01237: cannot extend datafile 6
ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf'
ORA-27059: could not reduce file size
Linux-x86_64 Error: 27: File too large
Additional information: 2
```

Block size limits in RDS for Oracle

RDS for Oracle DB instances are created with a default database block size (`DB_BLOCK_SIZE`) of 8 KB. The default database block size is set at database creation and cannot be changed. The `SYSTEM`

and temporary tablespaces always use the default database block size. You can create additional tablespaces with non-default block sizes by configuring the corresponding DB_nK_CACHE_SIZE parameter (for example, DB_16K_CACHE_SIZE) to allocate a buffer cache for that block size, and then specifying the BLOCKSIZE clause in your CREATE TABLESPACE statement.

Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

Schemas for unsupported features in RDS for Oracle

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in Adding options to Oracle DB instances.

Limitations for DBA privileges in RDS for Oracle

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.

Deprecation of TLS 1.0 and 1.1 Transport Layer Security in RDS for Oracle

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, we strongly recommends that you use TLS 1.2 instead.

Connecting to your Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to log in to your DB instance. Because RDS is a managed service, you can't log in as SYS or SYSTEM. For more information, see RDS for Oracle users and privileges.

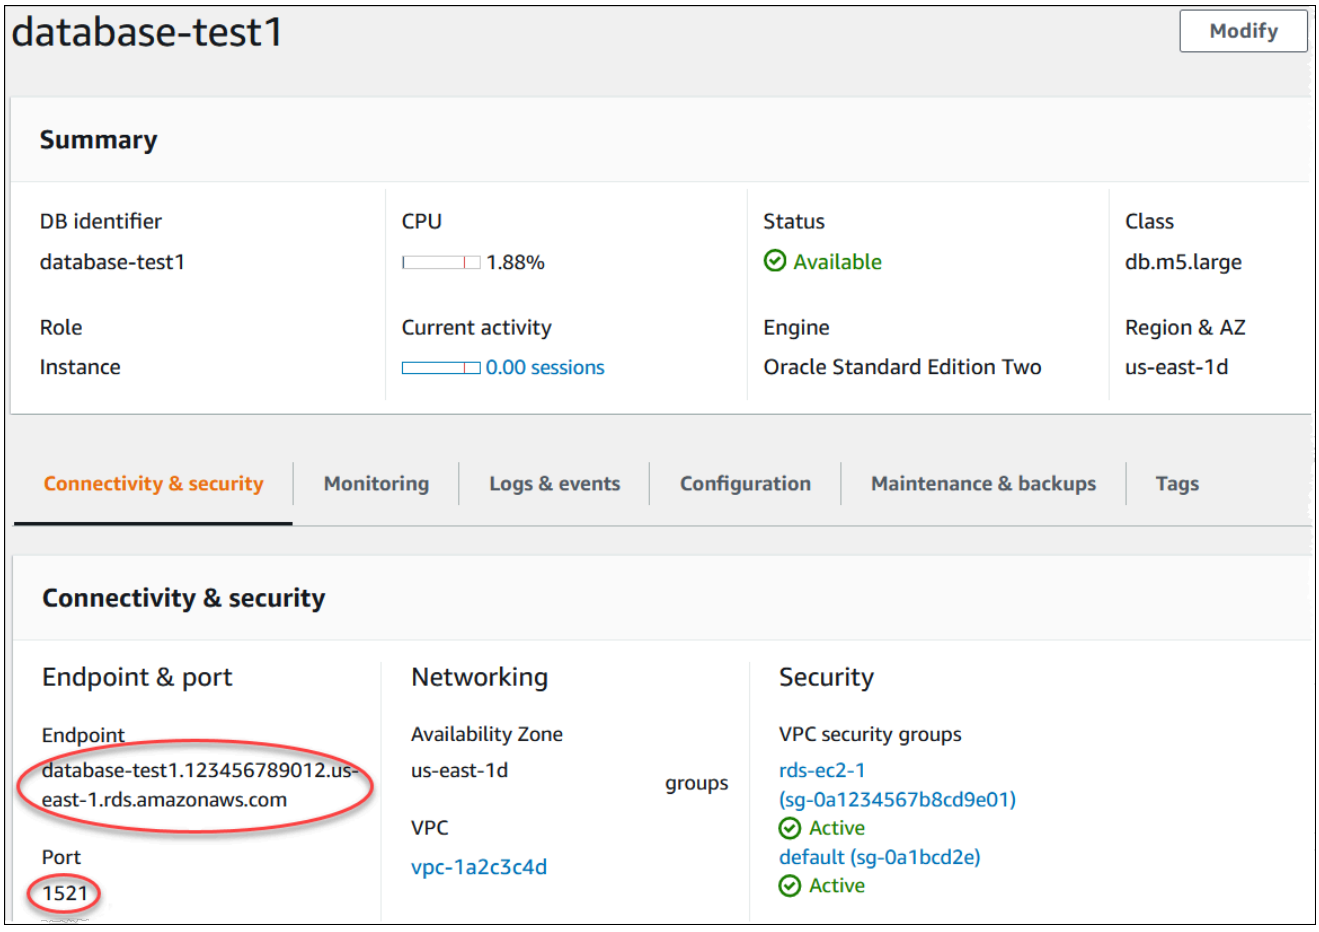
In this topic, you learn how to use Oracle SQL Developer or SQL*Plus to connect to an RDS for Oracle DB instance. For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating and connecting to an Oracle DB instance.

Topics

- Finding the endpoint of your RDS for Oracle DB instance
- Connecting to your DB instance using Oracle SQL developer
- Connecting to your DB instance using SQL*Plus
- Considerations for security groups
- Considerations for process architecture
- Troubleshooting connections to your Oracle DB instance
- Modifying connection properties using sqlnet.ora parameters

Finding the endpoint of your RDS for Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.



You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

> **Note**
>
> If you are using Kerberos authentication, see Connecting to Oracle with Kerberos authentication.

Console

To find the endpoint using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB instance.
   a. Choose **Databases** to display a list of your DB instances.
   b. Choose the Oracle DB instance name to display the instance details.
   c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

AWS CLI

To find the endpoint of an Oracle DB instance by using the AWS CLI, call the describe-db-instances command.

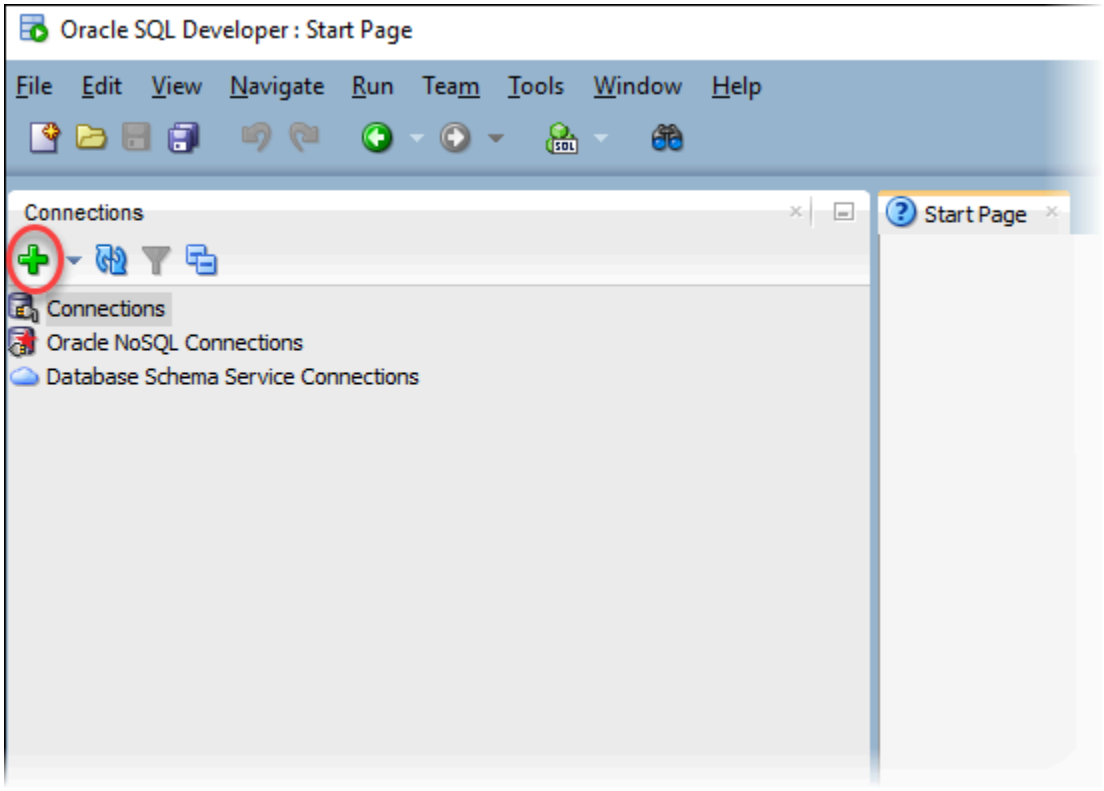
Example To find the endpoint using the AWS CLI

```
aws rds describe-db-instances
```

Search for `Endpoint` in the output to find the DNS name and port number for your DB instance. The `Address` line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```
"Endpoint": {
    "HostedZoneId": "Z1PVIF0B656C1W",
    "Port": 3306,
    "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"
},
```

> **Note**
>
> The output might contain information for multiple DB instances.

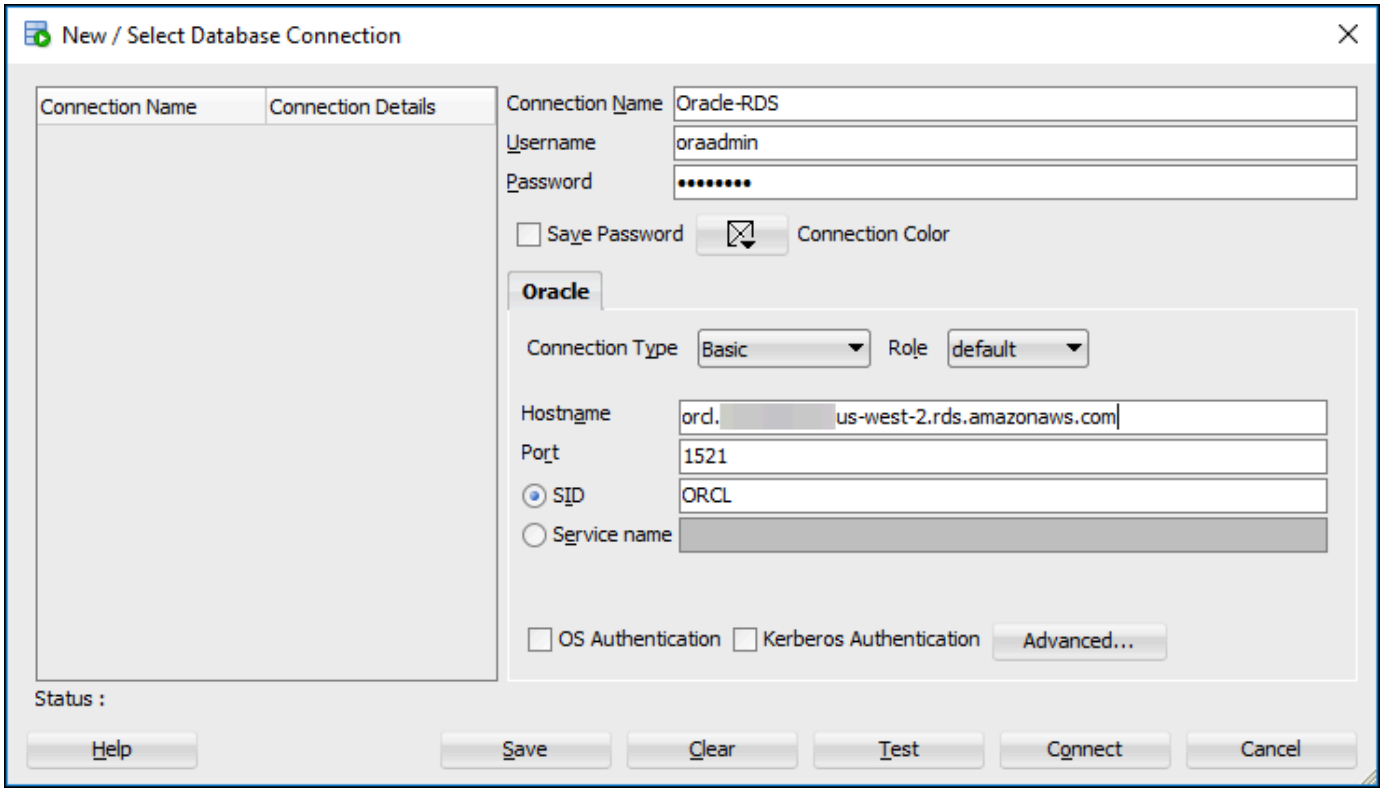


Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the Oracle SQL developer downloads page.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.

To connect to a DB instance using SQL developer

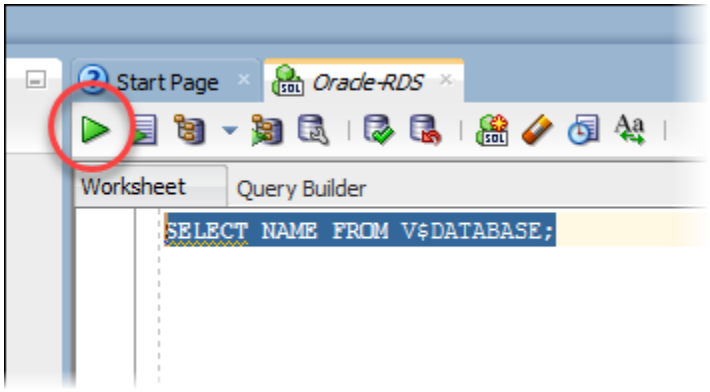


1. Start Oracle SQL Developer.
2. On the **Connections** tab, choose the **add (+)** icon.

3. In the **New/Select Database Connection** dialog box, provide the information for your DB instance:

   - For **Connection Name**, enter a name that describes the connection, such as `Oracle-RDS`.
   - For **Username**, enter the name of the database administrator for the DB instance.
   - For **Password**, enter the password for the database administrator.
   - For **Hostname**, enter the DNS name of the DB instance.
   - For **Port**, enter the port number.
   - For **SID**, enter the DB name. You can find the DB name on the **Configuration** tab of your database details page.

   The completed dialog box should look similar to the following.



4. Choose **Connect**.
5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In the **Worksheet** tab for your connection, enter the following SQL query.

   ```
   SELECT NAME FROM V$DATABASE;
   ```

   b. Choose the **execute** icon to run the query.

   SQL Developer returns the database name.

Connecting to your DB instance using SQL*Plus

You can use a utility like SQL*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.

Example To connect to an Oracle DB instance using SQL*Plus

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))'
```

For Windows:

```
sqlplus user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 12.1.0.2.0 Production on Mon Aug 21 09:42:20 2017
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

> **Note**
>
> The shorter format connection string (EZ Connect), such as `sqlplus USER/PASSWORD@longer-than-63-chars-rds-endpoint-here:1521/database-identifier`, might encounter a maximum character limit, so you we recommend that you don't use it to connect.

Considerations for security groups

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections. For information about creating a new security group, see Controlling access with security groups.

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance.

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Oracle Secure Sockets Layer.

Considerations for process architecture

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see About dedicated and shared server processes in the Oracle documentation. For more information about configuring shared server processes on an RDS for Oracle DB instance, see How do I configure Amazon RDS for Oracle database to work with shared servers? in the Knowledge Center.

Troubleshooting connections to your Oracle DB instance

The following are issues you might encounter when you try to connect to your Oracle DB instance.

Issue	Troubleshooting suggestions
Unable to connect to your DB instance.	For a newly created DB instance, the DB instance has a status of **creating** until it is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.
Unable to connect to your DB instance.	If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the port you specified for your DB instance allows inbound and outbound communication.
Unable to connect to your DB instance.	The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the

Issue	Troubleshooting suggestions
	security group for the DB instance might not match. The problem is most likely the inbound or outbound rules on your firewall. You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser. For more information, see Amazon VPC and Amazon RDS. For more information about security groups, see Controlling access with security groups. To walk through the process of setting up rules for your security group, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).
Connect failed because target host or object does not exist – Oracle, Error: ORA-12545	Make sure that you specified the server name and port number correctly. For **Server name**, enter the DNS name from the console. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your RDS for Oracle DB instance.
Invalid username/ password; logon denied – Oracle, Error: ORA-01017	You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry.
TNS:listener does not currently know of SID given in connect descriptor - Oracle, ERROR: ORA-12505	Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the **Configuration** tab of the **Databases** page for your instance. You can also find the DB name using the AWS CLI: `aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBName]' --output text`

For more information on connection issues, see Can't connect to Amazon RDS DB instance.

Modifying connection properties using sqlnet.ora parameters

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.

For more information about why you might set sqlnet.ora parameters, see Configuring profile parameters in the Oracle documentation.

Setting sqlnet.ora parameters

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The `sqlnetora.` prefix identifies which parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the `default_sdu_size` sqlnet.ora parameter is `sqlnetora.default_sdu_size`.

For information about managing parameter groups and setting parameter values, see Parameter groups for Amazon RDS.

Supported sqlnet.ora parameters

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

Parameter	Valid values	Static/ Dynamic	Description
`sqlnetora.default_sdu_size`	`512` to `20971`	Dynamic	The session data unit (SDU) size, in bytes. The SDU is the amount of data that is put in a buffer and sent across the network at one time.
`sqlnetora.diag_adr_enabled`	`ON`, `OFF`	Dynamic	A value that enables or disables Automatic Diagnostic Repository (ADR) tracing.

Parameter	Valid values	Static/ Dynamic	Description
			ON specifies that ADR file tracing is used. OFF specifies that non-ADR file tracing is used.
sqlnetora.recv_buf_size	8192 to 26843	Dynamic	The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.
sqlnetora.send_buf_size	8192 to 26843	Dynamic	The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.
sqlnetora.sqlnet.allowed_logon_version_client	8, 10, 11, 12	Dynamic	Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.
sqlnetora.sqlnet.allowed_logon_version_server	8, 9, 10, 11, 12, 12a	Dynamic	Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.

Parameter	Valid values	Static/ Dynamic	Description
sqlnetora.sqlnet.expire_time	0 to 1440	Dynamic	Time interval, in minutes, to send a check to verify that client-server connections are active.
sqlnetora.sqlnet.inbound_connect_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.
sqlnetora.sqlnet.outbound_connect_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.
sqlnetora.sqlnet.recv_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a database server to wait for client data after establishing a connection.
sqlnetora.sqlnet.send_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.
sqlnetora.tcp.connect_timeout	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to establish a TCP connection to the database server.

Parameter	Valid values	Static/ Dynamic	Description
sqlnetora.trace_level_server	0, 4, 10, 16, OFF, USER, ADMIN, SUPPOF	Dynamic	For non-ADR tracing, turns server tracing on at a specified level or turns it off.

The default value for each supported sqlnet.ora parameter is the Oracle Database default for the release.

Viewing sqlnet.ora parameters

You can view sqlnet.ora parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

Viewing sqlnet.ora parameters using the console

For information about viewing parameters in a parameter group, see Parameter groups for Amazon RDS.

In Oracle parameter groups, the `sqlnetora.` prefix identifies which parameters are sqlnet.ora parameters.

Viewing sqlnet.ora parameters using the AWS CLI

To view the sqlnet.ora parameters that were configured in an Oracle parameter group, use the AWS CLI describe-db-parameters command.

To view the all of the sqlnet.ora parameters for an Oracle DB instance, call the AWS CLI download-db-log-file-portion command. Specify the DB instance identifier, the log file name, and the type of output.

Example

The following code lists all of the sqlnet.ora parameters for `mydbinstance`.

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
    --db-instance-identifier mydbinstance \
    --log-file-name trace/sqlnet-parameters \
    --output text
```

For Windows:

```
aws rds download-db-log-file-portion ^
    --db-instance-identifier mydbinstance ^
    --log-file-name trace/sqlnet-parameters ^
    --output text
```

Viewing sqlnet.ora parameters using a SQL client

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```
SELECT * FROM TABLE
   (rdsadmin.rds_file_util.read_text_file(
        p_directory => 'BDUMP',
        p_filename  => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see Connecting to your Oracle DB instance.

Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see Oracle native network encryption.

Topics

- Using SSL with an RDS for Oracle DB instance
- Updating applications to connect to Oracle DB instances using new SSL/TLS certificates
- Using native network encryption with an RDS for Oracle DB instance
- Configuring Kerberos authentication for Amazon RDS for Oracle
- Configuring UTL_HTTP access using certificates and an Oracle wallet

Using SSL with an RDS for Oracle DB instance

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see Oracle Secure Sockets Layer.

> **Note**
>
> You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.

Updating applications to connect to Oracle DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

Important

When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.
We recommend that you restart your Oracle DB to prevent any connection errors.

Note

For client applications that use SSL/TLS to connect to your DB instances, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For information about using SSL/TLS with Oracle DB instances, see Oracle Secure Sockets Layer.

Topics

- Finding out whether applications connect using SSL

- Updating your application trust store
- Example Java code for establishing SSL connections

Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in Listing the options and option settings for an option group. For information about the SSL option, see Oracle Secure Sockets Layer.

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program)
(HOST=host)(USER=user))(SID=sid)) *
(ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value `tcps` for an entry, it shows an SSL connection. However, when HOST is `127.0.0.1`, you can ignore the entry. Connections from `127.0.0.1` are a local management agent on the DB instance. These connections aren't external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is `tcps` and HOST is *not* `127.0.0.1`.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.

Updating your application trust store

You can update the trust store for applications that use SQL*Plus or JDBC for SSL/TLS connections.

Updating your application trust store for SQL*Plus

You can update the trust store for applications that use SQL*Plus for SSL/TLS connections.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

To update the trust store for SQL*Plus applications

1. Download the new root certificate that works for all AWS Regions and put the file in the `ssl_wallet` directory.

   For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

2. Run the following command to update the Oracle wallet.

   ```
   prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert
         $ORACLE_HOME/ssl_wallet/ssl-cert.pem -auto_login_only
   ```

   Replace the file name with the one that you downloaded.

3. Run the following command to confirm that the wallet was updated successfully.

   ```
   prompt>orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
   ```

   Your output should contain the following.

   ```
   Trusted Certificates:
   Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services\,
    Inc.,L=Seattle,ST=Washington,C=US
   ```

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
import java.sql.Connection;
```

```
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
    private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-
group>";
    private static final String DB_SID = "<oracle-sid>";
    private static final String DB_USER = "<user name>";
    private static final String DB_PASSWORD = "<password>";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
    private static final String KEY_STORE_PASS = "<keystore-password>";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
                "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=
%d))(CONNECT_DATA=(SID=%s)))",
                DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.J2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString,
 properties);
        // If no exception, that means handshake has passed, and an SSL connection can
 be opened
    }
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Using native network encryption with an RDS for Oracle DB instance

Oracle Database offers two ways to encrypt data over the network: native network encryption (NNE) and Transport Layer Security (TLS). NNE is a proprietary Oracle security feature, whereas TLS is an industry standard. RDS for Oracle supports NNE for all editions of Oracle Database.

NNE has the following advantages over TLS:

- You can control NNE on the client and server using settings in the NNE option:
  - `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS` and `SQLNET.ALLOW_WEAK_CRYPTO`
  - `SQLNET.CRYPTO_CHECKSUM_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_SERVER`
  - `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER`
  - `SQLNET.ENCRYPTION_CLIENT` and `SQLNET.ENCRYPTION_SERVER`
  - `SQLNET.ENCRYPTION_TYPES_CLIENT` and `SQLNET.ENCRYPTION_TYPES_SERVER`
- In most cases, you don't need to configure your client or server. In contrast, TLS requires you to configure both client and server.
- No certificates are required. In TLS, the server requires a certificate (which eventually expires), and the client requires a trusted root certificate for the certificate authority that issued the server's certificate.

To enable NNE encryption for an Oracle DB instance, add the Oracle NNE option to the option group associated with the DB instance. For more information, see Oracle native network encryption.

> **Note**
>
> You can't use both NNE and TLS on the same DB instance.

Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Oracle DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate

with an RDS for Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for Oracle with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

> **Note**
>
> Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Oracle DB instances. For more information, see RDS for Oracle DB instance classes.

Topics

- Setting up Kerberos for Oracle DB instances
- Managing a DB instance in a domain
- Connecting to Oracle with Kerberos authentication

Setting up Kerberos for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

- Step 1: Create a directory using the AWS Managed Microsoft AD
- Step 2: Create a trust
- Step 3: Configure IAM permissions for Amazon RDS
- Step 4: Create and configure users
- Step 5: Enable cross-VPC traffic between the directory and the DB instance
- Step 6: Create or modify an Oracle DB instance

- Step 7: Create Kerberos authentication Oracle logins
- Step 8: Configure an Oracle client

> **Note**
>
> During the setup, RDS creates an Oracle database user named *managed_service_user*@*example.com* with the `CREATE SESSION` privilege, where *example.com* is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

Step 1: Create a directory using the AWS Managed Microsoft AD

Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  > **Note**
  >
  > Be sure to save this password. Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you

created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.

To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the Directory Service console at https://console.aws.amazon.com/directoryservicev2/.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   Directory DNS name

   The fully qualified name for the directory, such as **`corp.example.com`**.

Directory NetBIOS name

The short name for the directory, such as **CORP**.

Directory description

(Optional) A description for the directory.

Admin password

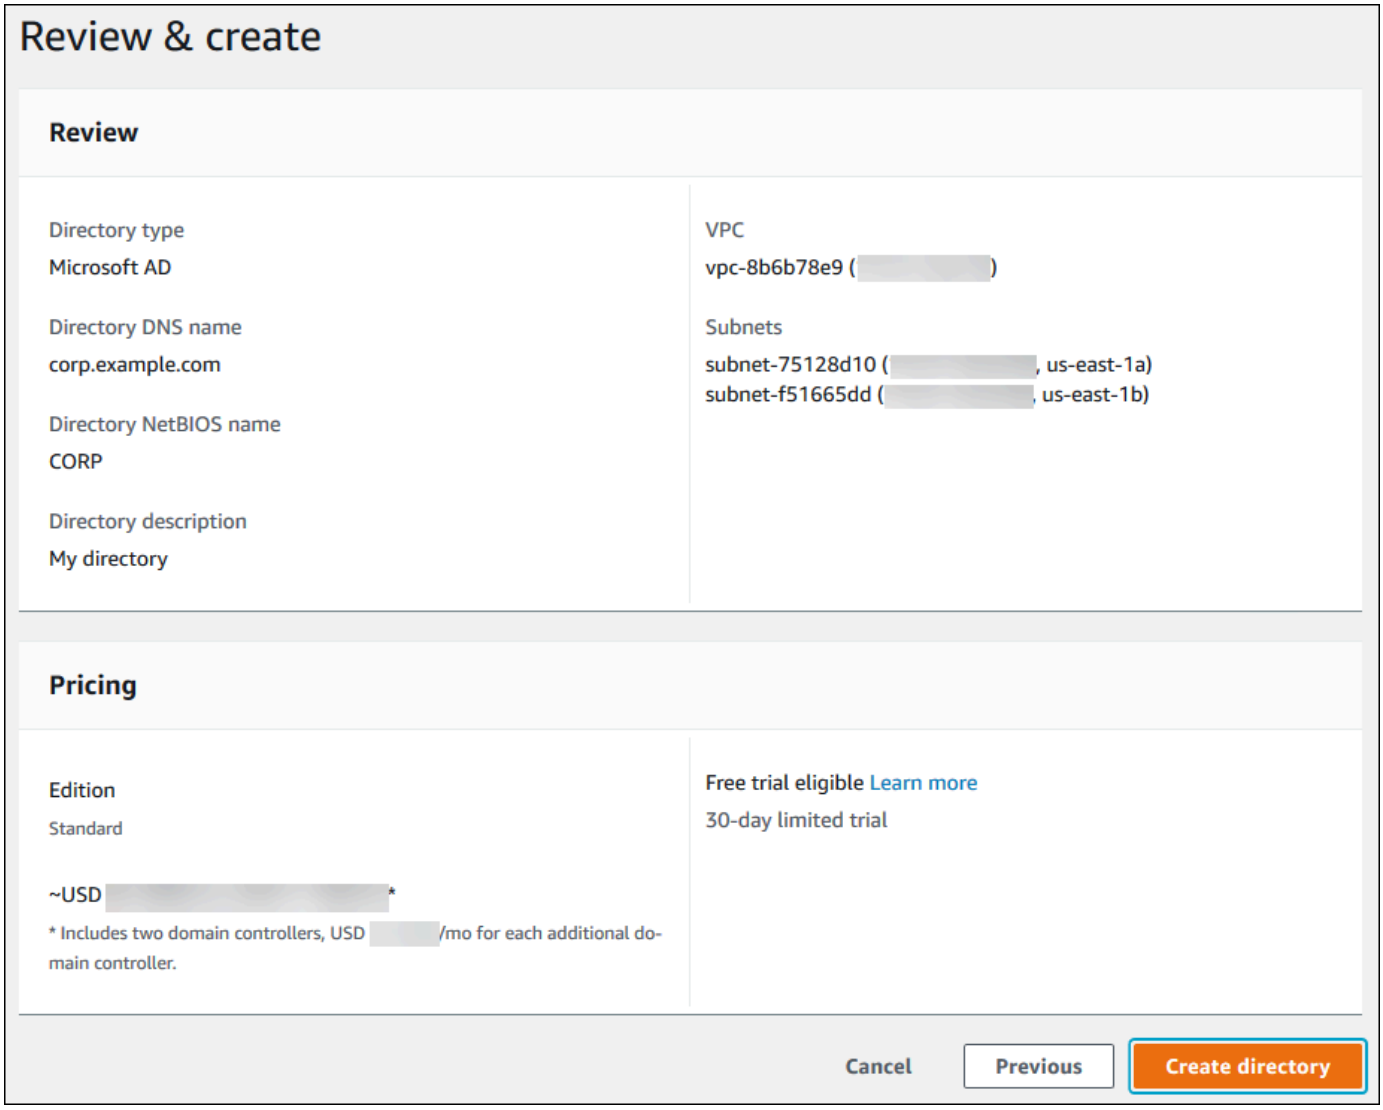
The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

The administrator password retyped.



5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

   VPC

   The VPC for the directory. Create the Oracle DB instance in this same VPC.

   Subnets

   Subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your Oracle DB instance.

Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to Step 3: Configure IAM permissions for Amazon RDS.

To enable Kerberos authentication using your self-managed Active Directory, you must create a forest trust relationship between your self-managed Active Directory and the AWS Managed Microsoft AD created in the previous step. The trust can be one-way, where the AWS Managed Microsoft AD trusts the self-managed Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up forest trusts using

Directory Service, see When to create a trust relationship in the *Directory Service Administration Guide*.

Step 3: Configure IAM permissions for Amazon RDS

To call Directory Service for you, Amazon RDS requires an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to the Directory Service.

> **Note**
>
> For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.

Creating an IAM role

When you create a DB instance using the AWS Management Console, and the console user has the `iam:CreateRole` permission, the console creates `rds-directoryservice-kerberos-access-role` automatically. Otherwise, you must create the IAM role manually. When you create an IAM role manually, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

Creating an IAM trust policy manually

Optionally, you can create resource policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. Specify both `directoryservice.rds.amazonaws.com` and `rds.amazonaws.com` as principals.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies. The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of an Amazon RDS resource. For more information, see Preventing cross-service confused deputy problems.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

For opt-in Regions, you must also include a service principal for that Region in the form of `directoryservice.rds.region_name.amazonaws.com`. For example, in the Africa (Cape Town) Region, use the following trust policy:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "directoryservice.rds.af-south-1.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:af-south-1:123456789012:db:mydbinstance"
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

The role must also have the following IAM policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
```

```
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, *users* are individual people or entities that have access to your directory.

To create users in an Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the *Directory Service Administration Guide*.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify an Oracle DB instance.

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group. For more information, see Best practices for AWS Managed Microsoft AD in the *Directory Service Administration Guide*.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the *Directory Service Administration Guide*.
2. Sign in to the Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new Oracle DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.

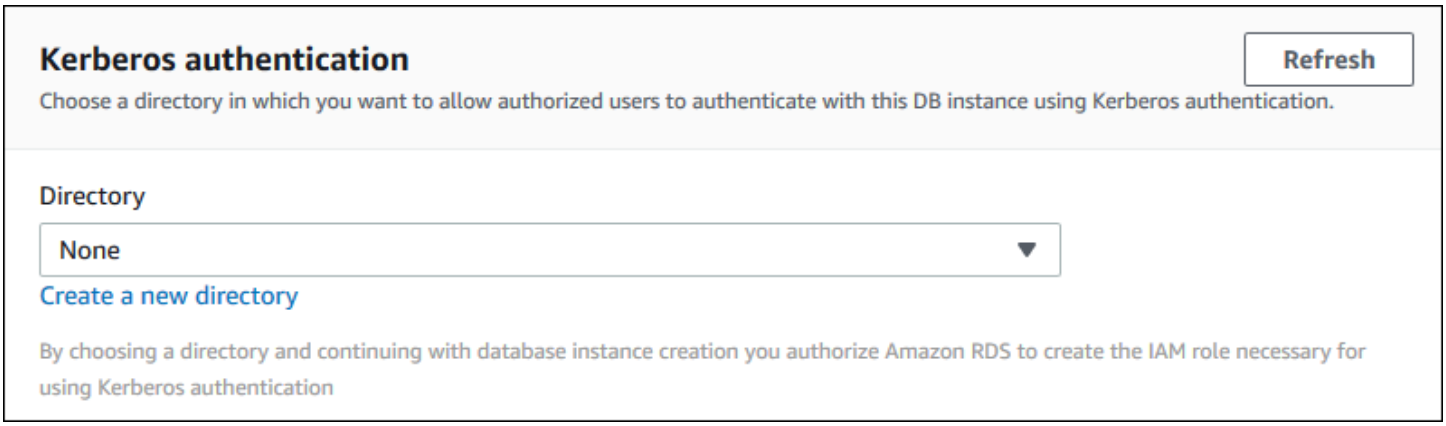
  For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing Oracle DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance.
- Restore an Oracle DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.

  For instructions, see Restoring to a DB instance.
- Restore an Oracle DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.

  For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:



- Provide the domain identifier (d-* identifier) that was generated when you created your directory.

- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the console to modify or restore a DB instance, choose the directory in the **Kerberos authentication** section, or choose **Create a new directory**.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --domain d-ID \
    --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Note

MANAGED_SERVICE_USER is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the `CREATE SESSION` privilege. The Oracle DB user is identified externally as *MANAGED_SERVICE_USER@EXAMPLE.COM*, where *EXAMPLE.COM* is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.

Step 7: Create Kerberos authentication Oracle logins

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

To allow a Microsoft Active Directory user to authenticate with Oracle

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

   In the following example, replace *KRBUSER@CORP.EXAMPLE.COM* with the user name and domain name.

   ```
   CREATE USER "KRBUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;
   GRANT CREATE SESSION TO "KRBUSER@CORP.EXAMPLE.COM";
   ```

   Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.

Step 8: Configure an Oracle client

To configure an Oracle client, meet the following requirements:

- Create a configuration file named krb5.conf (Linux) or krb5.ini (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```
[libdefaults]
 default_realm = EXAMPLE.COM
[realms]
 EXAMPLE.COM = {
```

```
  kdc = example.com
  admin_server = example.com
 }
[domain_realm]
 .example.com = CORP.EXAMPLE.COM
 example.com = CORP.EXAMPLE.COM
```

Following is sample content for on-premise Microsoft AD. In your krb5.conf or krb5.ini file, replace *on-prem-ad-server-name* with the name of your on-premises AD server.

```
[libdefaults]
 default_realm = ONPREM.COM
[realms]
 AWSAD.COM = {
  kdc = awsad.com
  admin_server = awsad.com
 }
 ONPREM.COM = {
  kdc = on-prem-ad-server-name
  admin_server = on-prem-ad-server-name
 }
[domain_realm]
 .awsad.com = AWSAD.COM
 awsad.com= AWSAD.COM
 .onprem.com = ONPREM.COM
 onprem.com= ONPREM.COM
```

Note

After you configure your krb5.ini or krb5.conf file, we recommend that you reboot the server.

The following is sample sqlnet.ora content for a SQL*Plus configuration:

```
SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE,KERBEROS5)
SQLNET.KERBEROS5_CONF=path_to_krb5.conf_file
```

For an example of a SQL Developer configuration, see Document 1609359.1 from Oracle Support.

Managing a DB instance in a domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the modify-db-instance CLI command and specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the modify-db-instance CLI command and specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the modify-db-instance CLI command and specify the domain identifier of the new domain for the `--domain` option.

Viewing the status of domain membership

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.

- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

> **Note**
>
> Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see Setting up a custom DNS server.

Force-rotating Kerberos keys

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

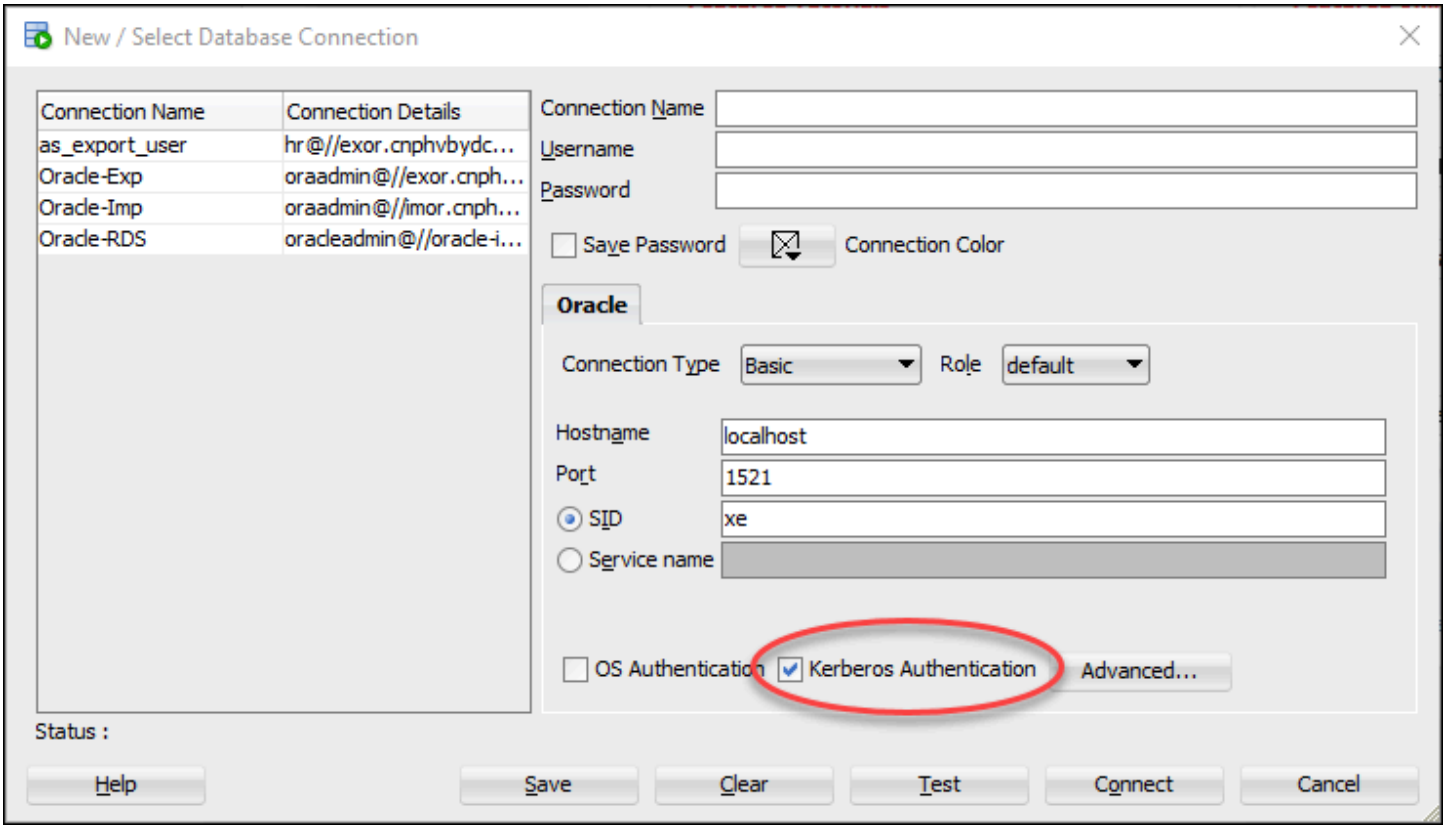
```
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM
 DUAL;
```

> **Note**
>
> In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.

The `SELECT` statement returns the ID of the task in a `VARCHAR2` data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

You can view the result by displaying the task's output file.



```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-
id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

> **Note**
>
> Tasks are executed asynchronously.

Connecting to Oracle with Kerberos authentication

This section assumes that you have set up your Oracle client as described in Step 8: Configure an Oracle client. To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose **Kerberos Authentication** as the authentication type, as shown in the following example.

To connect to Oracle with Kerberos authentication with SQL*Plus:

1. At a command prompt, run the following command:

   ```
   kinit username
   ```

   Replace *username* with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.
2. Open SQL*Plus and connect using the DNS name and port number for the Oracle DB instance.

   For more information about connecting to an Oracle DB instance in SQL*Plus, see Connecting to your DB instance using SQL*Plus.

> **Tip**
>
> If you are using a native Windows cache, you can also set the `SQLNET.KERBEROS5_CC_NAME` parameter to `OSMSFT://` or `MSLSA` in the sqlnet.ora file to use the credentials stored in the Microsoft Active Directory.

Configuring UTL_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your RDS for Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

`UTL_HTTP`

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see UTL_HTTP in the Oracle documentation.

`UTL_TCP`

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see UTL_TCP in the Oracle documentation.

`UTL_SMTP`

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see UTL_SMTP in the Oracle documentation.

By completing the following tasks, you can configure `UTL_HTTP.REQUEST` to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for `UTL_HTTP` access to websites by modifying the Oracle wallet generation commands and the `DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE` procedure. For more information, see DBMS_NETWORK_ACL_ADMIN in the Oracle Database documentation.

> **Note**
>
> You can adapt the following tasks for `UTL_SMTP`, which enables you to send emails over SSL/TLS (including Amazon Simple Email Service).

Topics

- Considerations when configuring UTL_HTTP access
- Step 1: Get the root certificate for a website
- Step 2: Create an Oracle wallet
- Step 3: Download your Oracle wallet to your RDS for Oracle instance
- Step 4: Grant user permissions for the Oracle wallet
- Step 5: Configure access to a website from your DB instance
- Step 6: Test connections from your DB instance to a website

Considerations when configuring UTL_HTTP access

Before configuring access, consider the following:

- You can use SMTP with the UTL_MAIL option. For more information, see Oracle UTL_MAIL.
- The Domain Name Server (DNS) name of the remote host can be any of the following:
  - Publicly resolvable.
  - The endpoint of an Amazon RDS DB instance.
  - Resolvable through a custom DNS server. For more information, see Setting up a custom DNS server.
  - The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the `enableDnsSupport` attribute in the

VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see DNS support in your VPC and Modifying your VPC peering connection.

- To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see Amazon S3 integration.

- You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see Oracle Secure Sockets Layer.

Step 1: Get the root certificate for a website

For the RDS for Oracle DB instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the Amazon trust services repository.

Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.

> **Note**
>
> If you're not using client certificates for authentication, you can skip this step.

The following example converts the client certificate named *client_certificate.p12* to the Java keystore named *client_keystore.jks*. The keystore is then included in the Oracle wallet. The keystore password is *P12PASSWORD*.

```
orapki wallet pkcs12_to_jks -wallet ./client_certificate.p12 -
jksKeyStoreLoc ./client_keystore.jks -jksKeyStorepwd P12PASSWORD
```

3. Create a directory for your Oracle wallet that is different from the certificate directory.

   The following example creates the directory `/tmp/wallet`.

   ```
   mkdir -p /tmp/wallet
   ```

4. Create an Oracle wallet in your wallet directory.

   The following example sets the Oracle wallet password to *P12PASSWORD*, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The `-auto_login` parameter turns on the automatic login feature, so that you don't need to specify a password every time you want to access it.

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

   ```
   orapki wallet create -wallet /tmp/wallet -pwd P12PASSWORD -auto_login
   ```

5. Add the Java keystore to your Oracle wallet.

   > **Note**
   >
   > If you're not using client certificates for authentication, you can skip this step.

The following example adds the keystore *client_keystore.jks* to the Oracle wallet named */tmp/wallet*. In this example, you specify the same password for the Java keystore and the Oracle wallet.

```
orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -
keystore ./client_keystore.jks -jkspwd P12PASSWORD
```

6. Add the root certificate for your target website to the Oracle wallet.

   The following example adds a certificate named *Root_CA.cer*.

   ```
   orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -
   pwd P12PASSWORD
   ```

7. Add any intermediate certificates.

   The following example adds a certificate named *Intermediate.cer*. Repeat this step as many times as need to load all intermediate certificates.

   ```
   orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -
   pwd P12PASSWORD
   ```

8. Confirm that your newly created Oracle wallet has the required certificates.

   ```
   orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
   ```

Step 3: Download your Oracle wallet to your RDS for Oracle instance

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

To download your Oracle wallet to your RDS for Oracle DB instance

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the `S3_INTEGRATION` option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

   For more information, see Amazon S3 integration.

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

   The following example creates an Oracle directory named *WALLET_DIR*.

   ```
   EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
   ```

   For more information, see Creating and dropping directories in the main data storage space.
3. Upload the Oracle wallet to your Amazon S3 bucket.

   You can use any supported upload technique.
4. If you're re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

   The following example removes the existing wallet, which is named *cwallet.sso*.

   ```
   EXEC UTL_FILE.FREMOVE ('WALLET_DIR','cwallet.sso');
   ```
5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

   The following example downloads the wallet named *cwallet.sso* from the Amazon S3 bucket named *my_s3_bucket* to the DB instance directory named *WALLET_DIR*.

   ```
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
         p_bucket_name    =>  'my_s3_bucket',
         p_s3_prefix      =>  'cwallet.sso',
         p_directory_name =>  'WALLET_DIR')
      AS TASK_ID FROM DUAL;
   ```
6. (Optional) Download a password-protected Oracle wallet.

   Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet *ewallet.p12*.

   ```
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
         p_bucket_name    =>  'my_s3_bucket',
         p_s3_prefix      =>  'ewallet.p12',
         p_directory_name =>  'WALLET_DIR')
      AS TASK_ID FROM DUAL;
   ```
7. Check the status of your DB task.

Substitute the task ID returned from the preceding steps for *dbtask-1234567890123-4567.log* in the following example.

```
SELECT TEXT FROM
 TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-4567.log'));
```

8. Check the contents of the directory that you're using to store the Oracle wallet.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

For more information, see Listing files in a DB instance directory.

Step 4: Grant user permissions for the Oracle wallet

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

To grant user permissions for the Oracle wallet

1. Log in your RDS for Oracle DB instance as the master user.
2. If you don't want to configure an existing database user, create a new user. Otherwise, skip to the next step.

   The following example creates a database user named *my-user*.

```
CREATE USER my-user IDENTIFIED BY my-user-pwd;
GRANT CONNECT TO my-user;
```

3. Grant permission to your database user on the directory containing your Oracle wallet.

   The following example grants read access to user *my-user* on directory *WALLET_DIR*.

```
GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
```

4. Grant permission to your database user to use the UTL_HTTP package.

   The following PL/SQL program grants UTL_HTTP access to user *my-user*.

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
  END;
/
```

5. Grant permission to your database user to use the UTL_FILE package.

   The following PL/SQL program grants UTL_FILE access to user *my-user*.

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));
  END;
/
```

Step 5: Configure access to a website from your DB instance

In this step, you configure your Oracle database user so that it can connect to your target website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see Configuring Access Control to an Oracle Wallet in the Oracle Database documentation.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

   The following example configures *my-user* to access *secret.encrypted-website.com* on secure port 443.

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host       => 'secret.encrypted-website.com',
    lower_port => 443,
    upper_port => 443,
    ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                              principal_name => 'my-user',
                              principal_type => xs_acl.ptype_db));
                           -- If the program unit results in PLS-00201, set
                           -- the principal_type parameter to 2 as follows:
                           -- principal_type => 2));
END;
```

```
/
```

Important

The preceding program unit can result in the following error: `PLS-00201: identifier 'XS_ACL' must be declared`. If this error is returned, replace the line that assigns a value to `principal_type` with the following line, and then rerun the program unit:

```
principal_type => 2));
```

For more information about constants in the PL/SQL package XS_ACL, see *Real Application Security Administrator's and Developer's Guide* in the Oracle Database documentation.

For more information, see Configuring Access Control for External Network Services in the Oracle Database documentation.

3. (Optional) Create an ACE for your user and target website on the standard port.

   You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host       => 'secret.encrypted-website.com',
    lower_port => 80,
    upper_port => 80,
    ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                              principal_name => 'my-user',
                              principal_type => xs_acl.ptype_db));
                           -- If the program unit results in PLS-00201, set
                           -- the principal_type parameter to 2 as follows:
                           -- principal_type => 2));
END;
/
```

4. Confirm that the access control entries exist.

```
SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50

SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
  FROM DBA_NETWORK_ACLS
ORDER BY HOST;
```

5. Grant permission to your database user to use the UTL_HTTP package.

   The following PL/SQL program grants UTL_HTTP access to user *my-user*.

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
  END;
/
```

6. Confirm that related access control lists exist.

```
SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10

SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
       TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
       TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
  FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;
```

7. Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.

   Note

   If you're not using client certificates for authentication, you can skip this step.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
```

```
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE(
    wallet_path => 'file:/' || l_wallet_path,
    ace         =>  xs$ace_type(privilege_list => xs
$name_list('use_client_certificates'),
                                principal_name => 'my-user',
                                principal_type => xs_acl.ptype_db));
END;
/
```

Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.

   The following example gets the host address from *secret.encrypted-website.com*.

   ```
   SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com')
     FROM DUAL;
   ```

3. Test a failed connection.

   The following query fails because UTL_HTTP requires the location of the Oracle wallet with the certificates.

   ```
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

4. Test website access by using UTL_HTTP.SET_WALLET and selecting from DUAL.

   ```
   DECLARE
     l_wallet_path all_directories.directory_path%type;
   BEGIN
   ```

```
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  UTL_HTTP.SET_WALLET('file:/' || l_wallet_path);
END;
/

SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
```

5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
  v_webpage_sql VARCHAR2(1000);
  v_results     VARCHAR2(32767);
BEGIN
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
    FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  v_webpage_sql := 'SELECT UTL_HTTP.REQUEST(''secret.encrypted-website.com'', ''''',
 ''file:/' ||l_wallet_path||''''') FROM DUAL';
  DBMS_OUTPUT.PUT_LINE(v_webpage_sql);
  EXECUTE IMMEDIATE v_webpage_sql INTO v_results;
  DBMS_OUTPUT.PUT_LINE(v_results);
END;
/
```

6. (Optional) Find the file system location of your Oracle wallet directory.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

Use the output from the previous command to make an HTTP request. For example, if the directory is *rdsdbdata/userdirs/01*, run the following query.

```
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '',
 'file://rdsdbdata/userdirs/01')
FROM   DUAL;
```

Working with CDBs in RDS for Oracle

In the Oracle multitenant architecture, a container database (CDB) can include customer-created pluggable databases (PDBs). For more information about CDBs, see Introduction to the Multitenant Architecture in the Oracle Database documentation.

Topics

- Overview of RDS for Oracle CDBs
- Configuring an RDS for Oracle CDB
- Backing up and restoring a CDB
- Converting an RDS for Oracle non-CDB to a CDB
- Converting the single-tenant configuration to multi-tenant
- Adding an RDS for Oracle tenant database to your CDB instance
- Modifying an RDS for Oracle tenant database
- Deleting an RDS for Oracle tenant database from your CDB
- Viewing tenant database details
- Upgrading your CDB

Overview of RDS for Oracle CDBs

You can create an RDS for Oracle DB instance as a container database (CDB) when you run Oracle Database 19c or higher. Starting with Oracle Database 21c, all databases are CDBs. A CDB differs from a non-CDB because it can contain pluggable databases (PDBs), which are called *tenant databases* in RDS for Oracle. A PDB is a portable collection of schemas and objects that appears to an application as a separate database.

You create your initial tenant database (PDB) when you create your CDB instance. In RDS for Oracle, your client application interacts with a PDB rather than the CDB. Your experience with a PDB is mostly identical to your experience with a non-CDB.

Topics

- Multi-tenant configuration of the CDB architecture
- Single-tenant configuration of the CDB architecture
- Creation and conversion options for CDBs

- User accounts and privileges in a CDB
- Parameter group families in a CDB
- Limitations of RDS for Oracle CDBs

Multi-tenant configuration of the CDB architecture

RDS for Oracle supports the *multi-tenant configuration* of the Oracle multitenant architecture, also called the *CDB architecture*. In this configuration, your RDS for Oracle CDB instance can contain 1–30 tenant databases, depending on the database edition and any required option licenses. In Oracle database, a tenant database is a PDB. Your DB instance must use Oracle database release 19.0.0.0.ru-2022-01.rur-2022.r1 or higher.

> **Note**
>
> The Amazon RDS configuration is called "multi-tenant" rather than "multitenant" because it is a capability of Amazon RDS, not just the Oracle DB engine. Similarly, the RDS term "tenant" refers to any tenant in an RDS configuration, not just Oracle PDBs. In the RDS documentation, the unhyphenated term "Oracle multitenant" refers exclusively to the Oracle database CDB architecture, which is compatible with both on-premises and RDS deployments.

You can configure the following settings:

- Tenant database name
- Tenant database master username
- Tenant database master password (optionally integrated with Secrets Manager)
- Tenant database character set
- Tenant database national character set

The tenant database character set can be different from the CDB character set. The same applies to the national character set. After you create your initial tenant database, you can create, modify, or delete tenant databases using RDS APIs. The CDB name defaults to RDSCDB and can't be changed. For more information, see Settings for DB instances and Modifying an RDS for Oracle tenant database.

Single-tenant configuration of the CDB architecture

RDS for Oracle supports a legacy configuration of the Oracle multitenant architecture called the *single-tenant configuration*. In this configuration, an RDS for Oracle CDB instance can contain only one tenant (PDB). You can't create more PDBs later.

Creation and conversion options for CDBs

Oracle Database 21c supports only CDBs, whereas Oracle Database 19c supports both CDBs and non-CDBs. All RDS for Oracle CDB instances support both the multi-tenant and single-tenant configurations.

Creation, conversion, and upgrade options for the Oracle database architecture

The following table shows the different architecture options for creating and upgrading RDS for Oracle databases.

Release	Database creation options	Architecture conversion options	Major version upgrade targets
Oracle Database 21c	CDB architecture only	N/A	N/A
Oracle Database 19c	CDB or non-CDB architecture	Non-CDB to CDB architecture (April 2021 RU or higher)	Oracle Database 21c CDB

As shown in the preceding table, you can't directly upgrade a non-CDB to a CDB in a new major database version. But you can convert an Oracle Database 19c non-CDB to an Oracle Database 19c CDB, and then upgrade the Oracle Database 19c CDB to an Oracle Database 21c CDB. For more information, see Converting an RDS for Oracle non-CDB to a CDB.

Conversion options for CDB architecture configurations

The following table shows the different options for converting the architecture configuration of an RDS for Oracle DB instance.

Current architecture and configuration	Conversion to the single-tenant configuration of the CDB architecture	Conversion to the multi-tenant configuration of the CDB architecture	Conversion to the non-CDB architecture
Non-CDB	Supported	Supported*	N/A
CDB using the single-tenant configuration	N/A	Supported	Not supported
CDB using the multi-tenant configuration	Not supported	N/A	Not supported

* You can't convert a non-CDB to the multi-tenant configuration in a single operation. When you convert a non-CDB to a CDB, the CDB is in the single-tenant configuration. You can then convert the single-tenant to the multi-tenant configuration in a separate operation.

User accounts and privileges in a CDB

In the Oracle multitenant architecture, all user accounts are either *common users* or *local users*. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB, which you name when you create your DB instance. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The `rdsadmin` user is a common user account. You can run RDS for Oracle packages that exist in this account, but you can't log in as `rdsadmin`. For more information, see About Common Users and Local Users in the Oracle documentation.

For master users in both the multi-tenant and single-tenant configurations, you can use credentials that are self-managed or managed by AWS Secrets Manager. In the single-tenant configuration, you use instance-level CLI commands such as `create-db-instance` for managed master passwords. In the multi-tenant configuration, you use tenant database commands such as `create-tenant-database` for managed master passwords. For more information about Secrets

Manager integration, see Managing the master user password for an RDS for Oracle tenant database with Secrets Manager.

Parameter group families in a CDB

CDBs have their own parameter group families and default parameter values. The CDB parameter group families are as follows:

- oracle-ee-cdb-21
- oracle-se2-cdb-21
- oracle-ee-cdb-19
- oracle-se2-cdb-19

Limitations of RDS for Oracle CDBs

RDS for Oracle supports a subset of features available in an on-premises CDB.

CDB limitations

The following limitations apply to RDS for Oracle at the CDB level:

- You can't connect to a CDB. You always connect to the tenant database (PDB) rather than the CDB. Specify the endpoint for the PDB just as for a non-CDB. The only difference is that you specify *pdb_name* for the database name, where *pdb_name* is the name you chose for your PDB.
- You can't convert a CDB in the multi-tenant configuration to a CDB in the single-tenant conversion. Conversion to the multi-tenant configuration is one-way and irreversible.
- You can't enable or convert to the multi-tenant configuration if your DB instance uses an Oracle database release lower than 19.0.0.0.ru-2022-01.rur-2022.r1.
- You can't use Database Activity Streams in a CDB.
- You can't enable auditing from within CDB$R00T. You must enable auditing within each PDB individually.

Tenant database (PDB) limitations

The following limitations apply to tenant databases in the RDS for Oracle multi-tenant configuration:

- You can't defer tenant database operations to the maintenance window. All changes occur immediately.
- You can't add a tenant database to a CDB that uses the single-tenant configuration.
- You can't add or modify multiple tenant databases in a single operation. You can only add or modify them one at a time.
- You can't modify a tenant database to be named `CDB$ROOT` or `PDB$SEED`.
- You can't delete a tenant database if it is the only tenant in the CDB.
- Not all DB instance class types have sufficient resources to support multiple PDBs in an RDS for Oracle CDB instance. An increased PDB count affects the performance and stability of the smaller instance classes and increases the time of most instance-level operations, for example, database upgrades.
- You cannot rename a PDB using `rdsadmin.rdsadmin_util.rename_global_name`, You must use the `modify-tenant-database` API instead.
- You can't use multiple AWS accounts to create PDBs in the same CDB. PDBs must be owned by the same account as the DB instance that the PDBs are hosted on.
- All PDBs in a CDB use the same endpoint and database listener.
- The following operations aren't supported at the PDB level but are supported at the CDB level:
  - Backup and recovery
  - Database upgrades
  - Maintenance actions
- The following features aren't supported at the PDB level but are supported at the CDB level:
  - Option groups (options are installed on all PDBs on your CDB instance)
  - Parameter groups (all parameters are derived from the parameter group associated with your CDB instance)
- PDB-level operations that are supported in the on-premises CDB architecture but aren't supported in an RDS for Oracle CDB include the following:

> **Note**
>
> The following list is not exhaustive.

  - Application PDBs

- Proxy PDBs
- Starting and stopping a PDB
- Unplugging and plugging in PDBs

  To move data into or out of your CDB, use the same techniques as for a non-CDB. For more information about migrating data, see Importing data into Oracle on Amazon RDS.
- Setting options at the PDB level

  The PDB inherits options settings from the CDB option group. For more information about setting options, see Parameter groups for Amazon RDS. For best practices, see Working with DB parameter groups.
- Configuring parameters in a PDB

  The PDB inherits parameter settings from the CDB. For more information about setting option, see Adding options to Oracle DB instances.
- Configuring different listeners for PDBs in the same CDB
- Oracle Flashback features

Configuring an RDS for Oracle CDB

Configuring a CDB is similar to configuring a non-CDB.

Topics

- Creating an RDS for Oracle CDB instance
- Connecting to a PDB in your RDS for Oracle CDB

Creating an RDS for Oracle CDB instance

In RDS for Oracle, creating a CDB instance is almost identical to creating a non-CDB instance. The difference is that you choose the Oracle multitenant architecture when creating your DB instance and also choose an architecture configuration: multi-tenant or single-tenant. If you create tags when you create a CDB in the multi-tenant configuration, RDS propagates the tags to the initial tenant database. To create a CDB, use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a CDB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the CDB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. In **Choose a database creation method**, select **Standard Create**.
6. In **Engine options**, choose **Oracle**.
7. For **Database management type**, choose **Amazon RDS**.
8. For **Architecture settings**, choose **Oracle multitenant architecture**.
9. For **Architecture configuration**, do either of the following:
   - Choose **Multi-tenant configuration** and proceed to the next step.
   - Choose **Single-tenant configuration** and skip to Step 11.
10. (Multi-tenant configuration) For **Tenant database settings**, make the following changes:
    - For **Tenant database name**, enter the name of your initial PDB. The PDB name must be different from the CDB name, which defaults to RDSCDB.
    - For **Tenant database master username**, enter the master username of your PDB. You can't use the tenant database master username to log in to the CDB itself.
    - For **Credentials management**, choose either of the following credentials management options:
      - **Managed in AWS Secrets Manager**

        The managed password is for the initial tenant database rather than for the instance. In **Select the encryption key**, choose either a KMS key that Secrets Manager creates or a key that you have created.

> **Note**
>
> We recommend AWS Secrets Manager as the most secure technique for managing credentials. Additional charges apply. For more information, see Password management with Amazon RDS and AWS Secrets Manager.

- **Self managed**

  To specify a password, clear the **Auto generate a password** check box if it is selected. Enter the same password in **Master password** and **Confirm master password**.

- For **Tenant database character set**, choose a character set for the PDB. You can choose a tenant database character set that is different from the CDB character set.

  The default PDB character set is **AL32UTF8**. If you choose a nondefault PDB character set, CDB creation might be slower.

> **Note**
>
> You can't specify multiple tenant databases in the create operation. The CDB has one PDB when it is created. You can add PDBs to an existing CDB in a separate operation.

11. (Single-tenant configuration) Choose the settings that you want based on the options listed in Settings for DB instances:

    - In the **Settings** section, open **Credential Settings**. Then do the following:

      i. For **Master username**, enter the name for a local user in your PDB. You can't use the master username to log in to the CDB root.

      ii. For **Credentials management**, choose either of the following credentials management options:

      - **Managed in AWS Secrets Manager**

        In **Select the encryption key**, choose either a KMS key that Secrets Manager creates or a key that you have created.

> **Note**
>
> We recommend AWS Secrets Manager as the most secure technique for managing credentials. Additional charges apply. For more information, see Password management with Amazon RDS and AWS Secrets Manager.

- **Self managed**

  To specify a password, clear the **Auto generate a password** check box if it is selected. Enter the same password in **Master password** and **Confirm master password**.

12. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.
13. Choose **Create database**.

AWS CLI

To create a CDB in the multi-tenant configuration, use the create-db-instance command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--engine { oracle-ee-cdb | oracle-se2-cdb }`
- `--master-username`
- `--master-user-password` or `--manage-master-user-password`
- `--multi-tenant` (for the single-tenant configuration, either don't specify `multi-tenant` or specify `--no-multi-tenant`)
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see Settings for DB instances.

This following example creates an RDS for Oracle DB instance named *`my-cdb-inst`* in the multi-tenant configuration. If you specify `--no-multi-tenant` or don't specify `--multi-tenant`,

the default CDB configuration is single-tenant. The engine is `oracle-ee-cdb`: a command that specifies `oracle-ee` and `--multi-tenant` fails with an error. The initial tenant database is named *mypdb*.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --engine oracle-ee-cdb \
    --db-instance-identifier my-cdb-inst \
    --multi-tenant \
    --db-name mypdb \
    --allocated-storage 250 \
    --db-instance-class db.t3.large \
    --master-username pdb_admin \
    --manage-master-user-password \
    --backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^
    --engine oracle-ee-cdb ^
    --db-instance-identifier my-cdb-inst ^
    --multi-tenant ^
    --db-name mypdb ^
    --allocated-storage 250 ^
    --db-instance-class db.t3.large ^
    --master-username pdb_admin ^
    --manage-master-user-password \ ^
    --backup-retention-period 3
```

Note

Specify a password other than the prompt shown here as a security best practice.

This command produces output similar to the following. The database name, character set, national character set, master user, and master user secret aren't included in the output. You can view this information by using the CLI command `describe-tenant-databases`.

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "my-cdb-inst",
        "DBInstanceClass": "db.t3.large",
        "MultiTenant": true,
        "Engine": "oracle-ee-cdb",
        "DBResourceId": "db-ABCDEFGJIJKLMNOPQRSTUVWXYZ",
        "DBInstanceStatus": "creating",
        "AllocatedStorage": 250,
        "PreferredBackupWindow": "04:59-05:29",
        "BackupRetentionPeriod": 3,
        "DBSecurityGroups": [],
        "VpcSecurityGroups": [
            {
                "VpcSecurityGroupId": "sg-0a1bcd2e",
                "Status": "active"
            }
        ],
        "DBParameterGroups": [
            {
                "DBParameterGroupName": "default.oracle-ee-cdb-19",
                "ParameterApplyStatus": "in-sync"
            }
        ],
        "DBSubnetGroup": {
            "DBSubnetGroupName": "default",
            "DBSubnetGroupDescription": "default",
            "VpcId": "vpc-1234567a",
            "SubnetGroupStatus": "Complete",
            ...
```

RDS API

To create a DB instance by using the Amazon RDS API, call the CreateDBInstance operation.

For information about each setting, see Settings for DB instances.

Connecting to a PDB in your RDS for Oracle CDB

You can use a utility like SQL*Plus to connect to a PDB. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect SQL*Plus to your PDB, you need the following information:

- PDB name
- Database user name and password
- Endpoint for your DB instance
- Port number

For information about finding the preceding information, see Finding the endpoint of your RDS for Oracle DB instance.

Example To connect to your PDB using SQL*Plus

In the following examples, substitute your master user for *master_user_name*. Also, substitute the endpoint for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the PDB that you specified when you created your DB instance, and not the DB instance identifier.

For Linux, macOS, or Unix:

```
sqlplus 'master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)
(PORT=port))(CONNECT_DATA=(SID=pdb_name)))'
```

For Windows:

```
sqlplus master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)
(PORT=port))(CONNECT_DATA=(SID=pdb_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 19.0.0.0.0 Production on Mon Aug 21 09:42:20 2021
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

> **Note**
>
> The shorter format connection string (Easy connect or EZCONNECT), such as `sqlplus username/password@LONGER-THAN-63-CHARS-RDS-ENDPOINT-`

HERE:1521/*database-identifier*, might encounter a maximum character limit and should not be used to connect.

Backing up and restoring a CDB

You can back up and restore your CDB using either RDS DB snapshots or Recovery Manager (RMAN).

Backing up and restoring a CDB using DB snapshots

DB snapshots work similarly in the CDB and non-CDB architectures. The principal differences are as follows:

- When you restore a DB snapshot of a CDB, you can't rename the CDB. The CDB is named RDSCDB and can't be changed.
- When you restore a DB snapshot of a CDB, you can't rename PDBs. You can modify the PDB name by using the modify-tenant-database command.
- To find tenant databases in a snapshot, use the CLI command describe-db-snapshot-tenant-databases.
- You can't directly interact with the tenant databases in a CDB snapshot that uses the multi-tenant architecture configuration. If you restore the DB snapshot, you restore all its tenant databases.
- RDS for Oracle implicitly copies tags on a tenant database to the tenant database in a DB snapshot. When you restore a tenant database, the tags appear in the restored database.
- If you restore a DB snapshot and specify new tags using the `--tags` parameter, the new tags overwrite all existing tags.
- If you take a DB snapshot of a CDB instance that has tags, and you specify `--copy-tags-to-snapshot`, RDS for Oracle copies tags from the tenant databases to the tenant databases in the snapshot.

For more information, see Oracle Database considerations.

Backing up and restoring a CDB using RMAN

To learn how to back up and restore a CDB or individual tenant database using RMAN, see Performing common RMAN tasks for Oracle DB instances.

Converting an RDS for Oracle non-CDB to a CDB

You can change the architecture of an Oracle database from the non-CDB architecture to the Oracle multitenant architecture, also called the *CDB architecture*, with the `modify-db-instance` command. In most cases, this technique is preferable to creating a new CDB and importing data. The conversion operation incurs downtime.

When you upgrade your database engine version, you can't change the database architecture in the same operation. Therefore, to upgrade an Oracle Database 19c non-CDB to an Oracle Database 21c CDB, you first need to convert the non-CDB to a CDB in one step, and then upgrade the 19c CDB to a 21c CDB in a separate step.

The non-CDB conversion operation has the following requirements:

- You must specify `oracle-ee-cdb` or `oracle-se2-cdb` for the DB engine type. These are the only supported values.
- Your DB engine must use Oracle Database 19c with an April 2021 or later release update (RU).

The operation has the following limitations:

- You can't convert a CDB to a non-CDB. You can only convert a non-CDB to a CDB.
- You can't convert a non-CDB to the multi-tenant configuration in a single `modify-db-instance` call. After you convert a non-CDB to a CDB, your CDB is in the single-tenant configuration. To convert the single-tenant configuration to the multi-tenant configuration, run `modify-db-instance` again. For more information, see Converting the single-tenant configuration to multi-tenant.
- You can't convert a primary or replica database that has Oracle Data Guard enabled. To convert a non-CDB that has read replicas, first delete all read replicas.
- You can't upgrade the DB engine version and convert a non-CDB to a CDB in the same operation.

Before converting your non-CDB, consider the following:

- The considerations for option and parameter groups are the same as for upgrading the DB engine. For more information, see Considerations for Oracle database upgrades.
- You can convert existing non-CDB instances that uses managed master passwords to single-tenant instances in a single operation. The single-tenant instances inherit the managed passwords.

- If your DB instance has the OEMAGENT option installed, a best practice is to remove this option before you convert your non-CDB. After your non-CDB is converted to a CDB, reinstall the option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.
- During the conversion process, RDS resets the online redo log size to the default 128M.

Console

To convert a non-CDB to a CDB

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**. After conversion, your CDB will be in the single-tenant configuration.
6. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Parameter group considerations.
7. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see Option group considerations.
8. (Optional) For **Credentials management**, choose **Managed in AWS Secrets Manager** or **Self-managed**. For more information, see Managing the master user password for a DB instance with Secrets Manager.
9. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
10. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see Using the schedule modifications setting.
11. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance**.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To convert the non-CDB on your DB instance to a CDB in the single-tenant configuration, set `--engine` to `oracle-ee-cdb` or `oracle-se2-cdb` in the AWS CLI command modify-db-instance. For more information, see Settings for DB instances.

The following example converts the DB instance named *my-non-cdb* and specifies a custom option group and parameter group. The command also enables password management with Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my-non-cdb \
    --engine oracle-ee-cdb \
    --option-group-name custom-option-group \
    --db-parameter-group-name custom-parameter-group \
    --manage-master-user-password
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my-non-cdb ^
    --engine oracle-ee-cdb ^
    --option-group-name custom-option-group ^
    --db-parameter-group-name custom-parameter-group ^
    --manage-master-user-password
```

RDS API

To convert a non-CDB to a CDB, specify `Engine` in the RDS API operation ModifyDBInstance.

Converting the single-tenant configuration to multi-tenant

You can modify the architecture of an RDS for Oracle CDB from the single-tenant configuration to the multi-tenant configuration. Before and after the conversion, your CDB contains a single tenant

database (PDB). Tags for the DB instance propagate to the initial tenant database created during the conversion.

Before you begin, make sure that your IAM policy has permission to create a tenant database. During the conversion, RDS for Oracle migrates the following metadata to the new tenant database:

- The master username
- The managed master password (if the source CDB integrates with Secrets Manager)
- The database name
- The character set
- The national character set

Before the conversion, you view the preceding information by using the `describe-db-instances` command. After the conversion, you view the information by using the `describe-tenant-database` command.

The conversion from single-tenant to multi-tenant has the following limitations:

- You can't later convert back to the single-tenant configuration after you convert to the multi-tenant configuration. The conversion is irreversible.
- You can't convert a primary or replica database that has Oracle Data Guard enabled.
- You can't upgrade the DB engine version and convert to the multi-tenant configuration in the same operation.
- You can't enable or disable managed master user passwords during the conversion.

Console

To convert a CDB using the single-tenant configuration to the multi-tenant configuration

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.

4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**.
6. For **Architecture configuration**, select **Multi-tenant configuration**.
7. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance.
8. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance.
9. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
10. Choose **Apply immediately**. This option is required when you switch to a multi-tenant configuration. Note that this option can cause downtime in some cases.
11. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance**.

    Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To convert a CDB using the single-tenant configuration to the multi-tenant configuration, specify `--multi-tenant` in the AWS CLI command modify-db-instance.

The following example converts the DB instance named `my-st-cdb` from the single-tenant configuration to the multi-tenant configuration. The `--apply-immediately` option is required.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --region us-east-1\
    --db-instance-identifier my-st-cdb \
    --multi-tenant \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance --region us-east-1 ^
```

```
    --db-instance-identifier my-st-cdb ^
    --multi-tenant ^
    --apply-immediately
```

The output looks something like the following.

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "my-st-cdb",
        "DBInstanceClass": "db.r5.large",
        "MultiTenant": false,
        "Engine": "oracle-ee-cdb",
        "DBResourceId": "db-AB1CDE2FGHIJK34LMNOPRLXTXU",
        "DBInstanceStatus": "modifying",
        "MasterUsername": "admin",
        "DBName": "ORCL",
        ...
        "EngineVersion": "19.0.0.0.ru-2022-01.rur-2022-01.r1",
        "AutoMinorVersionUpgrade": true,
        "ReadReplicaDBInstanceIdentifiers": [],
        "LicenseModel": "bring-your-own-license",
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "default:oracle-ee-cdb-19",
                "Status": "in-sync"
            }
        ],
        ...
        "PendingModifiedValues": {
            "MultiTenant": "true"
        }
    }
}
```

Adding an RDS for Oracle tenant database to your CDB instance

In the RDS for Oracle multi-tenant configuration, a tenant database is a PDB. To add a tenant database, make sure you meet the following prerequisites:

- Your CDB has the multi-tenant configuration enabled. For more information, see Multi-tenant configuration of the CDB architecture.
- You have the necessary IAM permissions to create the tenant database.

You can add a tenant database using the AWS Management Console, the AWS CLI, or the RDS API. You can't add multiple tenant databases in a single operation: you must add them one at a time. If the CDB has backup retention enabled, Amazon RDS backs up the DB instance before and after it adds a new tenant database. If the CDB has read replicas, you can only add a tenant database to the primary DB instance; Amazon RDS automatically creates the tenant database on the replicas. Replication health is also validated, ensuring all replicas are available and replication lag is less than 5 minutes before the tenant is created.

Console

To add a tenant database to your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the CDB instance to which you want to add a tenant database. Your DB instance must use the multi-tenant configuration of the CDB architecture.
5. Choose **Actions** and then **Add tenant database**.
6. For **Tenant database settings**, do the following:

   - For **Tenant database name**, enter the name of your new PDB.
   - For **Tenant database master username**, enter the name of the master user for your PDB.
   - Choose either of the following credentials management options:
     - **Managed in AWS Secrets Manager**

       In **Select the encryption key**, choose either a KMS key that Secrets Manager creates or a key that you have created.

       > **Note**
       >
       > We recommend AWS Secrets Manager as the most secure technique for managing credentials. Additional charges apply. AWS Secrets Manager is not supported for instances using read replicas. For more information, see Password management with Amazon RDS and AWS Secrets Manager.

- **Self managed**

  To specify a password, clear the **Auto generate a password** check box if it is selected. Enter the same password in **Master password** and **Confirm master password**.

- Under **Additional configuration**, enter the name of your PDB for **Initial database name**. You can't name the CDB, which has the default name RDSCDB.

- For **Tenant database character set**, choose a character set for the PDB. The default is **AL32UTF8**. You can choose a PDB character set that is different from the CDB character set. If the instance has read replicas, tenants cannot be created with a custom character set. You can create your tenants with a custom character set before creating a read replica if needed.
- For **Tenant database national character set**, choose a national character set for the PDB. The default is **AL32UTF8**. The national character set specifies the encoding only for columns that use the NCHAR data type (NCHAR, NVARCHAR2, and NCLOB) and doesn't affect database metadata.

For more information about the preceding settings, see Settings for DB instances.

7. Choose **Add tenant**.

AWS CLI

To add a tenant database to your CDB with the AWS CLI, use the command create-tenant-database with the following required parameters:

- `--db-instance-identifier`
- `--tenant-db-name`
- `--master-username`
- `--master-user-password`

This following example creates a tenant database named *mypdb2* in the RDS for Oracle CDB instance named *my-cdb-inst*. The PDB character set is UTF-16.

Example

For Linux, macOS, or Unix:

```
aws rds create-tenant-database --region us-east-1 \
```

```
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name mypdb2 \
    --master-username mypdb2-admin \
    --master-user-password mypdb2-pwd \
    --character-set-name UTF-16
```

For Windows:

```
aws rds create-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name mypdb2 ^
    --master-username mypdb2-admin ^
    --master-user-password mypdb2-pwd ^
    --character-set-name UTF-16
```

The output looks similar to the following.

```
...}
    "TenantDatabase" :
         {
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac567",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:mypdb2",
            "DBInstanceIdentifier" : "my-cdb-inst",
            "TenantDBName" : "mypdb2",
            "Status" : "creating",
            "MasterUsername" : "mypdb2",
            "CharacterSetName" : "UTF-16",
            ...
        }
}...
```

Modifying an RDS for Oracle tenant database

You can modify only the PDB name and the master user password of a tenant database in your CDB. Note the following requirements and limitations:

- To modify the settings of a tenant database in your DB instance, the tenant database must exist.
- You can't modify multiple tenant databases in a single operation. You can only modify one tenant database at a time.

- You can't change the name of a tenant database to `CDB$ROOT` or `PDB$SEED`.
- If your DB instance has read replicas, you can only modify tenants on the primary DB instance. Replication health is also validated, ensuring the replicas are available and replication lag is less than 5 minutes before the tenant is modified.

You can modify PDBs using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To modify the PDB name or master password of a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the tenant database whose database name or master user password you want to modify.
5. Choose **Modify**.
6. For **Tenant database settings**, do any of the following:
   - For **Tenant database name**, enter the new name of your new PDB.
   - For **Tenant database master password**, enter a new password.
7. Choose **Modify tenant**.

AWS CLI

To modify a tenant database using the AWS CLI, call the modify-tenant-database command with the following parameters:

- `--db-instance-identifier` *value*
- `--tenant-db-name` *value*
- `[--new-tenant-db-name` *value*`]`
- `[--master-user-password` *value*`]`

The following example renames tenant database pdb1 to pdb-hr on DB instance my-cdb-inst.

Example

For Linux, macOS, or Unix:

```
aws rds modify-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name pdb1 \
    --new-tenant-db-name pdb-hr
```

For Windows:

```
aws rds modify-tenant-database --region us-east-1 ^
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name pdb1 ^
    --new-tenant-db-name pdb-hr
```

This command produces output similar to the following.

```
{
    "TenantDatabase" : {
        "DbiResourceId" : "db-abc123",
        "TenantDatabaseResourceId" : "tdb-bac567",
        "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-inst:pdb1",
        "DBInstanceIdentifier" : "my-cdb-inst",
        "TenantDBName" : "pdb1",
        "Status" : "modifying",
        "MasterUsername" : "tenant-admin-user"
        "Port" : "6555",
        "CharacterSetName" : "UTF-16",
        "MaxAllocatedStorage" : "1000",
        "ParameterGroups": [
            {
                "ParameterGroupName": "pdb1-params",
                "ParameterApplyStatus": "in-sync"
            }
        ],
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "pdb1-options",
                "Status": "in-sync"
```

```
            }
        ],
        "PendingModifiedValues": {
            "TenantDBName": "pdb-hr"
        }
    }
}
```

Deleting an RDS for Oracle tenant database from your CDB

You can delete a tenant database (PDB) using the AWS Management Console, the AWS CLI, or the RDS API. Consider the following prerequisites and limitations:

- The tenant database and DB instance must exist.
- For the deletion to succeed, one of the following situations must exist:
  - The tenant database and DB instance are available.

    > **Note**
    >
    > You can take a final snapshot, but only if the tenant database and DB instance were in an available state before you issued the `delete-tenant-database` command. This snapshot will only be taken on the primary instance if the DB instance has read replicas.

  - The tenant database is being created.
  - The DB instance is modifying the tenant database.
  - If the DB instance has read replicas these constraints apply to all replicas.
- You can't delete multiple tenant databases in a single operation.
- You can't delete a tenant database if it is the only tenant in the CDB.
- You can't delete a tenant database on a read replica, you can only delete a tenant on the primary DB instance. Replication health is also validated, ensuring the replication lag is less than 5 minutes before the tenant is deleted.

Console

To delete a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the tenant database that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB instance, choose **Create final snapshot?**.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. Enter **`delete me`** in the box.
7. Choose **Delete**.

AWS CLI

To delete a tenant database using the AWS CLI, call the delete-tenant-database command with the following parameters:

- `--db-instance-identifier` *value*
- `--tenant-db-name` *value*
- `[--skip-final-snapshot | --no-skip-final-snapshot]`
- `[--final-snapshot-identifier` *value*`]`

This following example deletes the tenant database named *pdb-test* from the CDB named *my-cdb-inst*. By default, the operation creates a final snapshot.

Example

For Linux, macOS, or Unix:

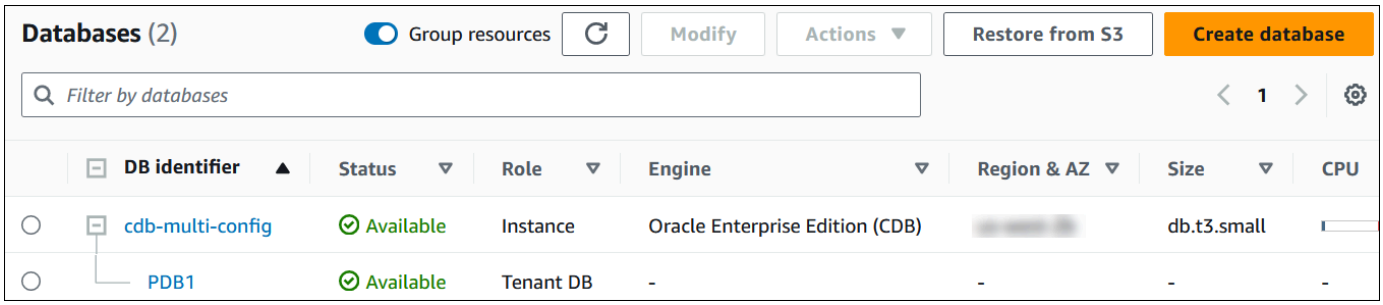
```
aws rds delete-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name pdb-test \
    --final-snapshot-identifier final-snap-pdb-test
```

For Windows:

```
aws rds delete-tenant-database --region us-east-1 ^
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name pdb-test ^
    --final-snapshot-identifier final-snap-pdb-test
```

This command produces output similar to the following.

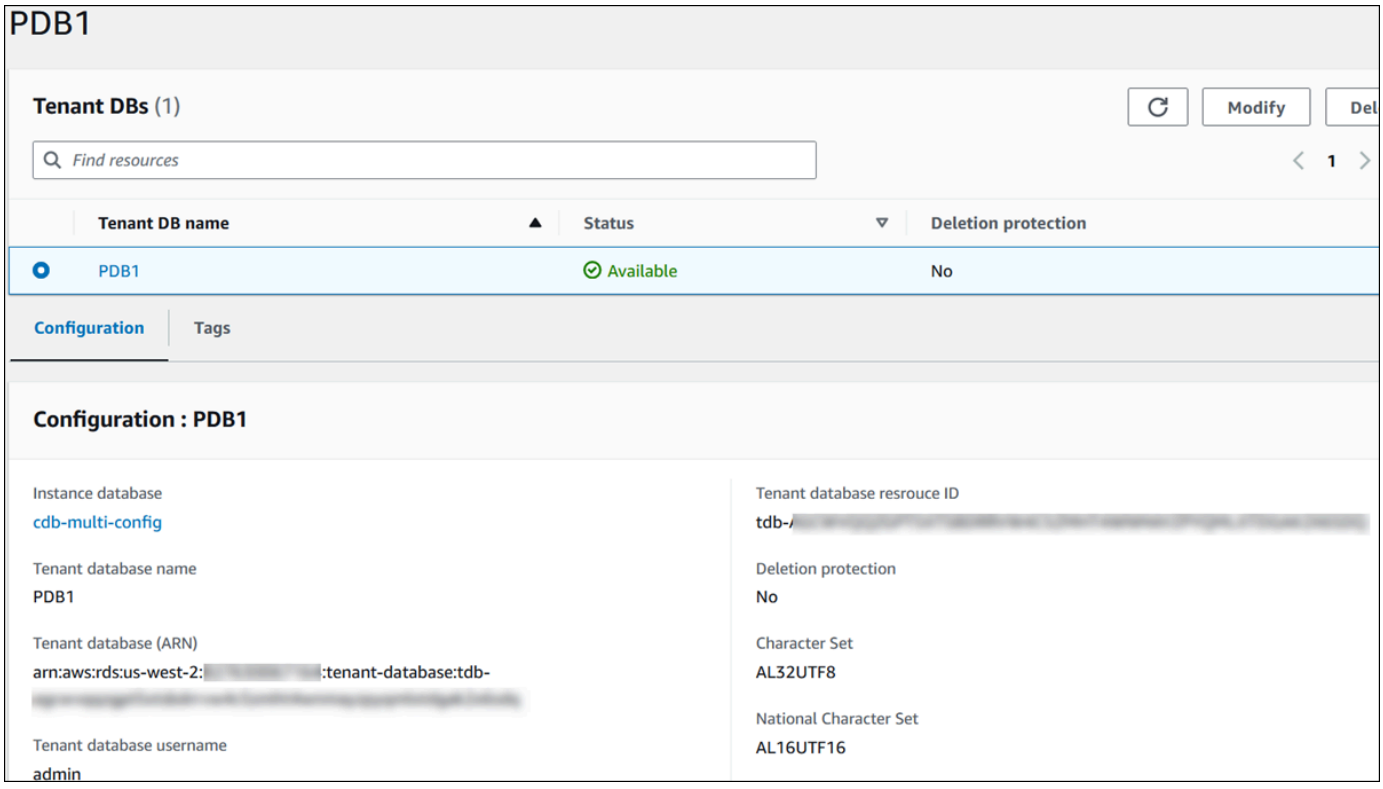
```
{
    "TenantDatabase" : {
        "DbiResourceId" : "db-abc123",
        "TenantDatabaseResourceId" : "tdb-bac456",
        "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-inst:pdb-
test",
        "DBInstanceIdentifier" : "my-cdb-inst",
        "TenantDBName" : "pdb-test",
        "Status" : "deleting",
        "MasterUsername" : "pdb-test-admin"
        "Port" : "6555",
        "CharacterSetName" : "UTF-16",
        "MaxAllocatedStorage" : "1000",
        "ParameterGroups": [
            {
                "ParameterGroupName": "tenant-1-params",
                "ParameterApplyStatus": "in-sync"
            }
        ],
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "tenant-1-options",
                "Status": "in-sync"
            }
        ]
    }
}
```



Viewing tenant database details

You can view details about a tenant database in the same way that you can for a non-CDB or CDB.

Console



To view details about a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**.

In the preceding image, the sole tenant database (PDB) appears as a child of the DB instance.

4. Choose the name of a tenant database.

AWS CLI

To see details about your PDBs, use the AWS CLI command describe-tenant-databases.

This following example describes all tenant databases in the specified Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1
```

This command produces output similar to the following.

```
    "TenantDatabases" : [
         {
            "DBInstanceIdentifier" : "my-cdb-inst",
            "TenantDBName" : "pdb-test",
            "Status" : "available",
            "MasterUsername" : "pdb-test-admin",
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac456",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:pdb-test",
            "CharacterSetName": "AL32UTF8",
            "NcharCharacterSetName": "AL16UTF16",
            "DeletionProtection": false,
            "PendingModifiedValues": {
                 "MasterUserPassword": "****"
            },
            "TagList": []
         },
         {

            "DBInstanceIdentifier" : "my-cdb-inst2",
            "TenantDBName" : "pdb-dev",
            "Status" : "modifying",
            "MasterUsername" : "masterrdsuser"
```

```
            "DbiResourceId" : "db-xyz789",
            "TenantDatabaseResourceId" : "tdb-ghp890",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst2:pdb-dev",
            "CharacterSetName": "AL32UTF8",
            "NcharCharacterSetName": "AL16UTF16",
            "DeletionProtection": false,
            "PendingModifiedValues": {
                 "MasterUserPassword": "****"
            },
            "TagList": []
         },
         ... other truncated data
```

The following example describes the tenant databases on DB instance `my-cdb-inst` in the specified Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 \
    --db-instance-identifier my-cdb-inst
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 ^
    --db-instance-identifier my-cdb-inst
```

This command produces output similar to the following.

```
{
    "TenantDatabase": {
        "TenantDatabaseCreateTime": "2023-10-19T23:55:30.046Z",
        "DBInstanceIdentifier": "my-cdb-inst",
        "TenantDBName": "pdb-hr",
        "Status": "creating",
        "MasterUsername": "tenant-admin-user",
        "DbiResourceId": "db-abc123",
        "TenantDatabaseResourceId": "tdb-bac567",
        "TenantDatabaseARN": "arn:aws:rds:us-west-2:579508833180:pdb-hr:tdb-
abcdefghi1jklmno2p3qrst4uvw5xy6zabc7defghi8jklmn90op",
```

```
        "CharacterSetName": "AL32UTF8",
        "NcharCharacterSetName": "AL16UTF16",
        "DeletionProtection": false,
        "PendingModifiedValues": {
            "MasterUserPassword": "****"
        },
        "TagList": [
            {
                "Key": "TEST",
                "Value": "testValue"
            }
        ]
    }
}
```

The following example describes tenant database pdb1 on DB instance `my-cdb-inst` in the US East (N. Virginia) Region.

Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 \
--db-instance-identifier my-cdb-inst \
--tenant-db-name pdb1
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 ^
--db-instance-identifier my-cdb-inst ^
--tenant-db-name pdb1
```

This command produces output similar to the following.

```
{
    "TenantDatabases" : [
        {
            "DbiResourceId" : "db-abc123",
            "TenantDatabaseResourceId" : "tdb-bac567",
            "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:pdb1"
            "DBInstanceIdentifier" : "my-cdb-inst",
```

```
            "TenantDBName" : "pdb1",
            "Status" : "ACTIVE",
            "MasterUsername" : "masterawsuser"
            "Port" : "1234",
            "CharacterSetName": "UTF-8",
            "ParameterGroups": [
                {
                    "ParameterGroupName": "tenant-custom-pg",
                    "ParameterApplyStatus": "in-sync"
                }
            ],
            {
            "OptionGroupMemberships": [
                {
                    "OptionGroupName": "tenant-custom-og",
                    "Status": "in-sync"
                }
            ]
        }
    ]
}
```

Upgrading your CDB

You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade an Oracle Database 19c CDB to an Oracle Database 21c CDB. You can't change the database architecture during an upgrade. Thus, you can't upgrade a non-CDB to a CDB or upgrade a CDB to a non-CDB.

The procedure for upgrading a CDB to a CDB is the same as for upgrading a non-CDB to a non-CDB. For more information, see Upgrading the RDS for Oracle DB engine.

Administering your RDS for Oracle DB instance

Following are the common management tasks that you perform with an RDS for Oracle DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle Database has special considerations. For example, you connect to an Oracle database using the Oracle clients SQL*Plus and SQL Developer.

Task area	Relevant documentation
Instance classes, storage, and PIOPS If you are creating a production instance, learn how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	RDS for Oracle DB instance classes Amazon RDS storage types
Multi-AZ deployments A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	Configuring and managing a Multi-AZ deployment for Amazon RDS
Amazon VPC If your AWS account has a default virtual private cloud (VPC), then your DB instance is automatically created inside the default VPC. If your account doesn't have a default VPC, and you want the DB instance in a VPC, create the VPC and subnet groups before you create the instance.	Working with a DB instance in a VPC
Security groups By default, DB instances use a firewall that prevents access. Make sure that you create a security group with the correct IP addresses and network configuration to access the DB instance.	Controlling access with security groups
Parameter groups	Parameter groups for Amazon RDS

Task area	Relevant documentation
If your DB instance is going to require specific database parameters, create a parameter group before you create the DB instance.	
Option groups If your DB instance requires specific database options, create an option group before you create the DB instance.	Adding options to Oracle DB instances
Connecting to your DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as Oracle SQL*Plus.	Connecting to your Oracle DB instance
Backup and restore You can configure your DB instance to take automated backups, or take manual snapshots, and then restore instances from the backups or snapshots.	Backing up, restoring, and exporting data
Monitoring You can monitor an Oracle DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing metrics in the Amazon RDS console Viewing Amazon RDS events
Log files You can access the log files for your Oracle DB instance.	Monitoring Amazon RDS log files

Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, RDS restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the `rdsadmin` package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:

- System tasks

Disconnecting a session	Amazon RDS method: `rdsadmin.rdsadmin_util.disconnect` Oracle method: `alter system disconnect session`
Terminating a session	Amazon RDS method: `rdsadmin.rdsadmin_util.kill` Oracle method: `alter system kill session`
Canceling a SQL statement in a session	Amazon RDS method: `rdsadmin.rdsadmin_util.cancel` Oracle method: `alter system cancel sql`
Enabling and disabling restricted sessions	Amazon RDS method: `rdsadmin.rdsadmin_util.restricted_session` Oracle method: `alter system enable restricted session`
Flushing the shared pool	Amazon RDS method: `rdsadmin.rdsadmin_util.flush_shared_pool` Oracle method: `alter system flush shared_pool`
Flushing the buffer cache	Amazon RDS method: `rdsadmin.rdsadmin_util.flush_buffer_cache` Oracle method: `alter system flush buffer_cache`
Granting SELECT or EXECUTE privileges to SYS objects	Amazon RDS method: `rdsadmin.rdsadmin_util.grant_sys_object` Oracle method: `grant`
Revoking SELECT or EXECUTE privileges on SYS objects	Amazon RDS method: `rdsadmin.rdsadmin_util.revoke_sys_object` Oracle method: `revoke`

Managing RDS_X$ views for Oracle DB instances	Amazon RDS method: `rdsadmin.rdsadmin_util.create_sys_x$_view` Oracle method: `CREATE VIEW`
Granting privileges to non-master users	Amazon RDS method: `grant`
Creating custom functions to verify passwords	Amazon RDS method: `rdsadmin.rdsadmin_password_verify.create_verify_function` Amazon RDS method: `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`
Setting up a custom DNS server	—
Listing allowed system diagnostic events	Amazon RDS method: `rdsadmin.rdsadmin_util.list_allowed_system_events` Oracle method: —
Setting system diagnostic events	Amazon RDS method: `rdsadmin.rdsadmin_util.set_allowed_system_events` Oracle method: `ALTER SYSTEM SET EVENTS 'set_event_clause'`
Listing system diagnostic events that are set	Amazon RDS method: `rdsadmin.rdsadmin_util.list_set_system_events` Oracle method: `ALTER SESSION SET EVENTS 'IMMEDIATE EVENTDUMP(SYSTEM)'`
Unsetting system diagnostic events	Amazon RDS method: `rdsadmin.rdsadmin_util.unset_system_event` Oracle method: `ALTER SYSTEM SET EVENTS 'unset_event_clause'`

- Database tasks

Changing the global name of a database	Amazon RDS method: `rdsadmin.rdsadmin_util.rename_global_name` Oracle method: `alter database rename`
Creating and sizing tablespaces in RDS for Oracle	Amazon RDS method: `create tablespace` Oracle method: `alter database`
Setting the default tablespace in RDS for Oracle	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_default_tablespace` Oracle method: `alter database default tablespace`
Setting the default temporary tablespace in RDS for Oracle	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_default_temp_tablespace` Oracle method: `alter database default temporary tablespace`
Creating a temporary tablespace on the instance store	Amazon RDS method: `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace` Oracle method: `create temporary tablespace`
Checkpointing a database	Amazon RDS method: `rdsadmin.rdsadmin_util.checkpoint` Oracle method: `alter system checkpoint`
Setting distributed recovery	Amazon RDS method: `rdsadmin.rdsadmin_util.enable_distr_recovery` Oracle method: `alter system enable distributed recovery`

Setting the database time zone	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_db_time_zone` Oracle method: `alter database set time_zone`
Working with external tables in RDS for Oracle	—
Generating performance reports with Automatic Workload Repository (AWR)	Amazon RDS method: `rdsadmin.rdsadmin_diagnostic_util` procedures Oracle method: `dbms_workload_repository` package
Adjusting database links for use with DB instances in a VPC	—
Setting the default edition for a DB instance	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_default_edition` Oracle method: `alter database default edition`
Enabling auditing for the SYS.AUD$ table	Amazon RDS method: `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table` Oracle method: `audit`
Disabling auditing for the SYS.AUD$ table	Amazon RDS method: `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table` Oracle method: `noaudit`
Cleaning up interrupted online index builds	Amazon RDS method: `rdsadmin.rdsadmin_dbms_repair.online_index_clean` Oracle method: `dbms_repair.online_index_clean`

Skipping corrupt blocks	Amazon RDS method: Several `rdsadmin.rdsadmin_dbms_repair` procedures Oracle method: `dbms_repair` package
Resizing tablespaces, data files, and tempfiles in RDS for Oracle	Amazon RDS method: `rdsadmin.rdsadmin_util.resize_temp_tablespace`, `rdsadmin.rdsadmin_util.resize_tempfile`, or `rdsadmin.rdsadmin_util.autoextend_tempfile` procedures `rdsadmin.rdsadmin_util.resize_datafile` or `rdsadmin.rdsadmin_util.autoextend_datafile` procedure Oracle method: —
Purging the recycle bin	Amazon RDS method: `EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin` Oracle method: `purge dba_recyclebin`
Setting the default displayed values for full redaction	Amazon RDS method: `EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val` Oracle method: `exec dbms_redact.UPDATE_FULL_REDACTION_VALUES`

- Log tasks

Setting force logging	Amazon RDS method: `rdsadmin.rdsadmin_util.force_logging` Oracle method: `alter database force logging`

Setting supplemental logging	Amazon RDS method: `rdsadmin.rdsadmin_util.alter_supplemental_logging` Oracle method: `alter database add supplemental log`
Switching online log files	Amazon RDS method: `rdsadmin.rdsadmin_util.switch_logfile` Oracle method: `alter system switch logfile`
Adding online redo logs	Amazon RDS method: `rdsadmin.rdsadmin_util.add_logfile`
Dropping online redo logs	Amazon RDS method: `rdsadmin.rdsadmin_util.drop_logfile`
Resizing online redo logs	—
Retaining archived redo logs	Amazon RDS method: `rdsadmin.rdsadmin_util.set_configuration`

Downloading archived redo logs from Amazon S3	Amazon RDS method: `rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum` Amazon RDS method: `rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range`
Accessing online and archived redo logs	Amazon RDS method: `rdsadmin.rdsadmin_master_util.create_archivelog_dir` Amazon RDS method: `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`

- RMAN tasks

Validating database files in RDS for Oracle	Amazon RDS method: `rdsadmin_rman_util. procedure` Oracle method: `RMAN VALIDATE`

Enabling and disabling block change tracking	Amazon RDS method: `rdsadmin_rman_util . procedure` Oracle method: `ALTER DATABASE`
Crosschecking archived redo logs	Amazon RDS method: `rdsadmin_rman_util .crosscheck_archivelog` Oracle method: `RMAN BACKUP`
Backing up archived redo log files	Amazon RDS method: `rdsadmin_rman_util . procedure` Oracle method: `RMAN BACKUP`
Performing a full database backup	Amazon RDS method: `rdsadmin_rman_util .backup_database_full` Oracle method: `RMAN BACKUP`
Performing an incremental database backup	Amazon RDS method: `rdsadmin_rman_util .backup_database_incremental` Oracle method: `RMAN BACKUP`

Backing up a tablespace	Amazon RDS method: `rdsadmin_rman_util.backup_database_tablespace` Oracle method: `RMAN BACKUP`

- Oracle Scheduler tasks

Modifying DBMS_SCHEDULER jobs	Amazon RDS method: `dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`
Modifying AutoTask maintenance windows	Amazon RDS method: `dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`
Setting the time zone for Oracle Scheduler jobs	Amazon RDS method: `dbms_scheduler.set_scheduler_attribute` Oracle method: `dbms_scheduler.set_scheduler_attribute`

Turning off Oracle Scheduler jobs owned by SYS	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.disable` Oracle method: `dbms_scheduler.disable`
Turning on Oracle Scheduler jobs owned by SYS	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.enable` Oracle method: `dbms_scheduler.enable`
Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`
Modifying the Oracle Scheduler repeat interval for jobs of NAMED type	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_attribute` Oracle method: `dbms_scheduler.set_attribute`

Turning off autocommit for Oracle Scheduler job creation	Amazon RDS method: `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag` Oracle method: `dbms_isched.set_no_commit_flag`

- Diagnosing problems

Listing incidents	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` Oracle method: ADRCI command `show incident`
Listing problems	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.list_adrci_problem` Oracle method: ADRCI command `show problem`
Creating incident packages	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.create_adrci_package` Oracle method: ADRCI command `ips create package`

Showing trace files	Amazon RDS method: `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` Oracle method: ADRCI command `show tracefile`

- Other tasks

Creating and dropping directories in the main data storage space	Amazon RDS method: `rdsadmin.rdsadmin_util.create_directory` Oracle method: `CREATE DIRECTORY` Amazon RDS method: `rdsadmin.rdsadmin_util.drop_directory` Oracle method: `DROP DIRECTORY`
Listing files in a DB instance directory	Amazon RDS method: `rdsadmin.rds_file_util.listdir` Oracle method: —

Reading files in a DB instance directory	Amazon RDS method: `rdsadmin.rds_file_util.read_text_file` Oracle method: —
Accessing Opatch files	Amazon RDS method: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing` Oracle method: `opatch`
Setting parameters for advisor tasks	Amazon RDS method: `rdsadmin.rdsadmin_util.advisor_task_set_parameter` Oracle method: Various stored package procedures
Disabling AUTO_STATS_ADVISOR_TASK	Amazon RDS method: `rdsadmin.rdsadmin_util.advisor_task_drop` Oracle method: —
Re-enabling AUTO_STATS_ADVISOR_TASK	Amazon RDS method: `rdsadmin.rdsadmin_util.dbms_stats_init` Oracle method: —

You can also use Amazon RDS procedures for Amazon S3 integration with Oracle and for running OEM Management Agent database tasks. For more information, see Amazon S3 integration and Performing database tasks with the Management Agent.

Performing common system tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

- Disconnecting a session
- Terminating a session
- Canceling a SQL statement in a session
- Enabling and disabling restricted sessions
- Flushing the shared pool
- Granting SELECT or EXECUTE privileges to SYS objects
- Revoking SELECT or EXECUTE privileges on SYS objects
- Managing RDS_X$ views for Oracle DB instances
- Granting privileges to non-master users
- Creating custom functions to verify passwords
- Setting up a custom DNS server
- Setting and unsetting system diagnostic events

Disconnecting a session

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The `disconnect` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`sid`	number	—	Yes	The session identifier.

Parameter name	Data type	Default	Required	Description
serial	number	—	Yes	The serial number of the session.
method	varchar	'IMMEDIATE'	No	Valid values are 'IMMEDIATE' or 'POST_TRANSACTION'.

The following example disconnects a session.

```
begin
    rdsadmin.rdsadmin_util.disconnect(
        sid    => sid,
        serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see ALTER SYSTEM in the Oracle documentation.

Terminating a session

To terminate a session, use the Amazon RDS procedure rdsadmin.rdsadmin_util.kill. The kill procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
sid	number	—	Yes	The session identifier.
serial	number	—	Yes	The serial number of the session.

Parameter name	Data type	Default	Required	Description
method	varchar	null	No	Valid values are 'IMMEDIATE' or 'PROCESS' . If you specify IMMEDIATE , it has the same effect as running the following statement: `ALTER SYSTEM KILL SESSION 'sid,serial#' IMMEDIATE` If you specify PROCESS, you terminate the processes associated with a session. Only specify PROCESS if terminating the session using IMMEDIATE was unsuccessful.

To get the session identifier and the session serial number, query the V$SESSION view. The following example gets all sessions for the user *AWSUSER*.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The following example terminates a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid    => sid,
        serial => serial_number,
        method => 'IMMEDIATE');
END;
/
```

The following example terminates the processes associated with a session.

```
BEGIN
    rdsadmin.rdsadmin_util.kill(
        sid    => sid,
        serial => serial_number,
        method => 'PROCESS');
END;
/
```

Canceling a SQL statement in a session

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

> **Note**
>
> This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

The `cancel` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`sid`	number	—	Yes	The session identifier.
`serial`	number	—	Yes	The serial number of the session.
`sql_id`	varchar2	null	No	The SQL identifier of the SQL statement.

The following example cancels a SQL statement in a session.

```
begin
    rdsadmin.rdsadmin_util.cancel(
        sid    => sid,
```

```
        serial => serial_number,
        sql_id => sql_id);
end;
/
```

To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the V$SESSION view. The following example gets all sessions and SQL identifiers for the user AWSUSER.

```
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';
```

Enabling and disabling restricted sessions

To enable and disable restricted sessions, use the Amazon RDS procedure rdsadmin.rdsadmin_util.restricted_session. The restricted_session procedure has the following parameters.

Parameter name	Data type	Default	Yes	Description
p_enable	boolean	true	No	Set to true to enable restricted sessions, false to disable restricted sessions.

The following example shows how to enable and disable restricted sessions.

```
/* Verify that the database is currently unrestricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED

/* Enable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);
```

```
/* Verify that the database is now restricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
----------
RESTRICTED

/* Disable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-------
ALLOWED
```

Flushing the shared pool

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.

The following example flushes the shared pool.

```
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```

Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;
```

Flushing the database smart flash cache

To flush the database smart flash cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_flash_cache`. The `flush_flash_cache` procedure has no parameters. The following example flushes the database smart flash cache.

```
EXEC rdsadmin.rdsadmin_util.flush_flash_cache;
```

For more information about using the database smart flash cache with RDS for Oracle, see Storing temporary data in an RDS for Oracle instance store.

Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.grant_sys_object`. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The `grant_sys_object` procedure has the following parameters.

Important

For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`.

Parameter name	Data type	Default	Required	Description
p_obj_name	varchar2	—	Yes	The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in DBA_OBJEC

Parameter name	Data type	Default	Required	Description
				TS . Most system objects are defined in uppercase , so we recommend that you try that first.
p_grantee	varchar2	—	Yes	The name of the object to grant privileges to. The object can be a schema or a role.
p_privilege	varchar2	null	Yes	—
p_grant_option	boolean	false	No	Set to true to use the with grant option.

The following example grants select privileges on an object named V_$SESSION to a user named USER1.

```
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_grantee   => 'USER1',
        p_privilege => 'SELECT');
end;
/
```

The following example grants select privileges on an object named V_$SESSION to a user named USER1 with the grant option.

```
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name     => 'V_$SESSION',
        p_grantee      => 'USER1',
        p_privilege    => 'SELECT',
        p_grant_option => true);
end;
/
```

To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using `with admin option`. In the most common case, you may want to grant SELECT on a DBA view that has been granted to the SELECT_CATALOG_ROLE role. If that role isn't already directly granted to your user using `with admin option`, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE to USER1. Since the `with admin option` is used, USER1 can now grant access to SYS objects that have been granted to SELECT_CATALOG_ROLE.

```
GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE to USER1 WITH ADMIN OPTION;
```

Objects already granted to PUBLIC do not need to be re-granted. If you use the `grant_sys_object` procedure to re-grant access, the procedure call succeeds.

Revoking SELECT or EXECUTE privileges on SYS objects

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The `revoke_sys_object` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_obj_name	varchar2	—	Yes	The name of the object to revoke privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in DBA_OBJECTS . Most system objects are defined in upper

Parameter name	Data type	Default	Required	Description
				case, so we recommend you try that first.
p_revokee	varchar2	—	Yes	The name of the object to revoke privileges for. The object can be a schema or a role.
p_privilege	varchar2	null	Yes	—

The following example revokes select privileges on an object named V_$SESSION from a user named USER1.

```
begin
    rdsadmin.rdsadmin_util.revoke_sys_object(
        p_obj_name  => 'V_$SESSION',
        p_revokee   => 'USER1',
        p_privilege => 'SELECT');
end;
/
```

Managing RDS_X$ views for Oracle DB instances

You might need to access SYS.X$ fixed tables, which are only accessible by SYS. To create SYS.RDS_X$ views on eligible X$ tables, use the procedures in the rdsadmin.rdsadmin_util package. Your master user is automatically granted the privilege SELECT ... WITH GRANT OPTION on the RDS_X$ views.

The rdsadmin.rdsadmin_util procedures are available in the following cases:

- Existing DB instances that have never been upgraded and use the following releases:
  - 21.0.0.0.ru-2023-10.rur-2023-10.r1 and higher 21c releases
  - 19.0.0.0.ru-2023-10.rur-2023-10.r1 and higher 19c releases
- Any new DB instance that you create
- Any existing DB instance that you have upgraded

> **Important**
>
> Internally, the `rdsadmin.rdsadmin_util` package creates views on X$ tables. The X$ tables are internal system objects that aren't described in the Oracle Database documentation. We recommend that you test specific views in your non-production database and only create views in your production database under the guidance of Oracle Support.

List X$ fixed tables eligible for use in RDS_X$ views

To list X$ tables that are eligible for use in RDS_X$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. This procedure accepts no parameters. The following statements lists all eligible X$ tables (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_allowed_sys_x$_views);

'X$BH'
'X$K2GTE'
'X$KCBWBPD'
'X$KCBWDS'
'X$KGLLK'
'X$KGLOB'
'X$KGLPN'
'X$KSLHOT'
'X$KSMSP'
'X$KSPPCV'
'X$KSPPI'
'X$KSPPSV'
'X$KSQEQ'
'X$KSQRS'
'X$KTUXE'
'X$KQRFP'
```

The list of eligible X$ tables can change over time. To make sure that your list of eligible X$ fixed tables is current, rerun `list_allowed_sys_x$_views` periodically.

Creating SYS.RDS_X$ views

To create an RDS_X$ view on an eligible X$ table, use the RDS procedure `rdsadmin.rdsadmin_util.create_sys_x$_view`. You can only create views for the tables listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `create_sys_x$_view` procedure accepts the following parameters.

Parameter name	Data type	Default	Required	Description
`p_x$_tbl`	varchar2	Null	Yes	A valid X$ table name. The value must be one of the X$ tables reported by `list_allowed_sys_x$_views` .
`p_force_creation`	Boolean	FALSE	No	A value indicating whether to force creation of an RDS_X$ view that already exists for an X$ table. By default, RDS won't create a view if it already exists. To force creation, set this parameter to TRUE.

The following example creates the SYS.RDS_X$KGLOB view on the table X$KGLOB. The format for the view name is RDS_*X$tablename*.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.create_sys_x$_view('X$KGLOB');

PL/SQL procedure successfully completed.
```

The following data dictionary query lists the view SYS.RDS_X$KGLOB and shows its status. Your master user is automatically granted the privilege `SELECT ... WITH GRANT OPTION` on this view.

```
SQL> SET SERVEROUTPUT ON
```

```
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOB';

OWNER                          OBJECT_NAME                    STATUS
------------------------------ ------------------------------
 ------------------------------
SYS                            RDS_X$KGLOB                    VALID
```

Important

X$ tables aren't guaranteed to stay the same before and after an upgrade. RDS for Oracle drops and recreates the RDS_X$ views on X$ tables during an engine upgrade. Then it grants the `SELECT ... WITH GRANT OPTION` privilege to the master user. After an upgrade, grant privileges to database users as needed on the corresponding RDS_X$ views.

Listing SYS.RDS_X$ views

To list existing RDS_X$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_created_sys_x$_views`. The procedure lists only views that were created by the procedure `create_sys_x$_view`. The following example lists X$ tables that have corresponding RDS_X$ views (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL XD_TBL_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_created_sys_x$_views);

XD_TBL_NAME                    STATUS
------------------------------ ------------------------------
X$BH                           VALID
X$K2GTE                        VALID
X$KCBWBPD                      VALID

3 rows selected.
```

Dropping RDS_X$ views

To drop a SYS.RDS_X$ view, use the RDS procedure `rdsadmin.rdsadmin_util.drop_sys_x$_view`. You can only drop views listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `drop_sys_x$_view` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
p_x$_tbl	varchar2	Null	Yes	A valid X$ fixed table name. The value must be one of the X$ fixed tables reported by `list_created_sys_x$_views .`

The following example drops the RDS_X$KGLOB view, which was created on the table X$KGLOB.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.drop_sys_x$_view('X$KGLOB');

PL/SQL procedure successfully completed.
```

The following example shows that the view SYS.RDS_X$KGLOB has been dropped (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOB';

no rows selected
```

Granting privileges to non-master users

You can grant select privileges for many objects in the SYS schema by using the SELECT_CATALOG_ROLE role. The SELECT_CATALOG_ROLE role gives users SELECT privileges on data dictionary views. The following example grants the role SELECT_CATALOG_ROLE to a user named user1.

```
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant EXECUTE privileges for many objects in the SYS schema by using the EXECUTE_CATALOG_ROLE role. The EXECUTE_CATALOG_ROLE role gives users EXECUTE privileges for packages and procedures in the data dictionary. The following example grants the role EXECUTE_CATALOG_ROLE to a user named *user1*.

```
GRANT EXECUTE_CATALOG_ROLE TO user1;
```

The following example gets the permissions that the roles SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE allow.

```
  SELECT *
    FROM ROLE_TAB_PRIVS
   WHERE ROLE IN ('SELECT_CATALOG_ROLE','EXECUTE_CATALOG_ROLE')
ORDER BY ROLE, TABLE_NAME ASC;
```

The following example creates a non-master user named user1, grants the CREATE SESSION privilege, and grants the SELECT privilege on a database named *sh.sales*.

```
CREATE USER user1 IDENTIFIED BY PASSWORD;
GRANT CREATE SESSION TO user1;
GRANT SELECT ON sh.sales TO user1;
```

Creating custom functions to verify passwords

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the SYS schema, use the create_verify_function procedure.
- To use custom verification logic, or to avoid storing your function in the SYS schema, use the create_passthrough_verify_fcn procedure.

The create_verify_function procedure

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_verify_function`. The `create_verify_function` procedure is supported for all versions of RDS for Oracle.

The `create_verify_function` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_verify_function_name`	varchar2	—	Yes	The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.
`p_min_length`	number	8	No	The minimum number of characters required.
`p_max_length`	number	256	No	The maximum number of characters allowed.
`p_min_letters`	number	1	No	The minimum number of letters required.
`p_min_uppercase`	number	0	No	The minimum number of uppercase letters required.
`p_min_lowercase`	number	0	No	The minimum number of lowercase letters required.
`p_min_digits`	number	1	No	The minimum number of digits required.

Parameter name	Data type	Default	Required	Description
p_min_special	number	0	No	The minimum number of special characters required.
p_min_different_chars	number	3	No	The minimum number of different characters required between the old and new password.
p_disallow_username	boolean	true	No	Set to true to disallow the user name in the password.
p_disallow_reverse	boolean	true	No	Set to true to disallow the reverse of the user name in the password.
p_disallow_db_name	boolean	true	No	Set to true to disallow the database or server name in the password.
p_disallow_simple_strings	boolean	true	No	Set to true to disallow simple strings as the password.
p_disallow_whitespace	boolean	false	No	Set to true to disallow white space characters in the password.
p_disallow_at_sign	boolean	false	No	Set to true to disallow the @ character in the password.

You can create multiple password verification functions.

There are restrictions on the name of your custom function. Your custom function can't have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named CUSTOM_PASSWORD_FUNCTION. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```
begin
    rdsadmin.rdsadmin_password_verify.create_verify_function(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_min_length           => 12,
        p_min_uppercase        => 2,
        p_min_digits           => 1,
        p_min_special          => 1,
        p_disallow_at_sign     => true);
end;
/
```

To see the text of your verification function, query DBA_SOURCE. The following example gets the text of a custom password function named CUSTOM_PASSWORD_FUNCTION.

```
COL TEXT FORMAT a150

  SELECT TEXT
    FROM DBA_SOURCE
   WHERE OWNER = 'SYS'
     AND NAME = 'CUSTOM_PASSWORD_FUNCTION'
ORDER BY LINE;
```

To associate your verification function with a user profile, use ALTER PROFILE. The following example associates a verification PL/SQL function named CUSTOM_PASSWORD_FUNCTION with the DEFAULT user profile. PASSWORD_VERIFY_FUNCTION is the Oracle profile resource name.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see which user profiles are associated with which verification functions, query DBA_PROFILES. The following example gets the profiles that are associated with the custom verification function named CUSTOM_PASSWORD_FUNCTION.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION' AND LIMIT =
 'CUSTOM_PASSWORD_FUNCTION';

PROFILE                    RESOURCE_NAME                    RESOURCE  LIMIT
-------------------------  -------------------------------  --------
 ------------------------
DEFAULT                    PASSWORD_VERIFY_FUNCTION         PASSWORD
 CUSTOM_PASSWORD_FUNCTION
```

The following example gets all profiles and the password verification functions that they are associated with.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';

PROFILE                    RESOURCE_NAME                    RESOURCE  LIMIT
-------------------------  -------------------------------  --------
 ------------------------
DEFAULT                    PASSWORD_VERIFY_FUNCTION         PASSWORD
 CUSTOM_PASSWORD_FUNCTION
RDSADMIN                   PASSWORD_VERIFY_FUNCTION         PASSWORD  NULL
```

The create_passthrough_verify_fcn procedure

The `create_passthrough_verify_fcn` procedure is supported for all versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`. The `create_passthrough_verify_fcn` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_verify_function_name`	varchar2	—	Yes	The name for your custom verification function. This is a wrapper function that is created for you in the SYS schema, and

Parameter name	Data type	Default	Required	Description
				it doesn't contain any verification logic. You assign this function to user profiles.
p_target_owner	varchar2	—	Yes	The schema owner for your custom verification function.
p_target_function_name	varchar2	—	Yes	The name of your existing custom function that contains the verification logic. Your custom function must return a boolean. Your function should return `true` if the password is valid and `false` if the password is invalid.

The following example creates a password verification function that uses the logic from the function named PASSWORD_LOGIC_EXTRA_STRONG.

```
begin
    rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_target_owner         => 'TEST_USER',
        p_target_function_name => 'PASSWORD_LOGIC_EXTRA_STRONG');
end;
/
```

To associate the verification function with a user profile, use `alter profile`. The following example associates the verification function with the DEFAULT user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see Configuring UTL_HTTP access using certificates and an Oracle wallet.

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.

  > **Note**
  >
  > The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
- Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.
- Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules.

- Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

  For more information, see Security groups for your VPC and Adding and removing rules.

- The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.
  - If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see What is VPC peering?

Setting and unsetting system diagnostic events

To set and unset diagnostic events at the session level, you can use the Oracle SQL statement `ALTER SESSION SET EVENTS`. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the `rdsadmin.rdsadmin_util` package. The system event procedures are available in the following engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions

  For more information, see Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 in the *Amazon RDS for Oracle Release Notes*

> **Important**
>
> Internally, the `rdsadmin.rdsadmin_util` package sets events by using the `ALTER SYSTEM SET EVENTS` statement. This `ALTER SYSTEM` statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.

Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_allowed_system_events`. This procedure accepts no parameters.

The following example lists all system events that you can set.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;
```

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures `set_system_event` to set these events and `unset_system_event` to unset them.

```
604   - error occurred at recursive SQL level
942   - table or view does not exist
1401  - inserted value too large for column
1403  - no data found
1410  - invalid ROWID
1422  - exact fetch returns more than requested number of rows
1426  - numeric overflow
1427  - single-row subquery returns more than one row
1476  - divisor is equal to zero
1483  - invalid length for DATE or NUMBER bind variable
1489  - result of string concatenation is too long
1652  - unable to extend temp segment by  in tablespace
1858  - a non-numeric character was found where a numeric was expected
4031  - unable to allocate  bytes of shared memory ("","","","")
6502  - PL/SQL: numeric or value error
10027 - Specify Deadlock Trace Information to be Dumped
10046 - enable SQL statement timing
10053 - CBO Enable optimizer trace
10173 - Dynamic Sampling time-out error
10442 - enable trace of kst for ORA-01555 diagnostics
12008 - error in materialized view refresh path
12012 - error on auto execute of job
12504 - TNS:listener was not given the SERVICE_NAME in CONNECT_DATA
14400 - inserted partition key does not map to any partition
31693 - Table data object  failed to load/unload and is being skipped due to error:
```

> **Note**
>
> The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use `rdsadmin.rdsadmin_util.list_allowed_system_events`.

Setting system diagnostic events

To set a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_system_event`. You can only set events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `set_system_event` procedure accepts the following parameters.

Parameter name	Data type	Default	Required	Description
`p_event`	number	—	Yes	The system event number. The value must be one of the event numbers reported by `list_allowed_system_events` .
`p_level`	number	—	Yes	The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values.

The procedure `set_system_event` constructs and runs the required `ALTER SYSTEM SET EVENTS` statements according to the following principles:

- The event type (`context` or `errorstack`) is determined automatically.
- A statement in the form `ALTER SYSTEM SET EVENTS 'event LEVEL event_level'` sets the context events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME CONTEXT FOREVER, LEVEL event_level'`.

- A statement in the form `ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)'` sets the error stack events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'`.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'

PL/SQL procedure successfully completed.
```

Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_set_system_events`. This procedure reports only events set at system level by `set_system_event`.

The following example lists the active system events.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.

```
942 errorstack (3) - set at 2020-11-03 11:42:27
10442 level 10 - set at 2020-11-03 11:42:41

PL/SQL procedure successfully completed.
```

Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.unset_system_event`. You can only unset events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `unset_system_event` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
`p_event`	number	—	Yes	The system event number. The value must be one of the event numbers reported by `list_allowed_system_events` .

The following example unsets events 942 and 10442. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
Unsetting system event 942 with: alter system set events '942 off'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
Unsetting system event 10442 with: alter system set events '10442 off'

PL/SQL procedure successfully completed.
```

Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Amazon RDS also restricts access to some system procedures and tables that require advanced privileges.

Topics

- Changing the global name of a database

- Working with tablespaces in RDS for Oracle
- Working with tempfiles in RDS for Oracle
- Resizing tablespaces, data files, and tempfiles in RDS for Oracle
- Moving data between storage volumes in RDS for Oracle
- Working with external tables in RDS for Oracle

Changing the global name of a database

To change the global name of a database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.rename_global_name`. The `rename_global_name` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_new_global_name	varchar2	—	Yes	The new global name for the database.

The database must be open for the name change to occur. For more information about changing the global name of a database, see ALTER DATABASE in the Oracle documentation.

The following example changes the global name of a database to `new_global_name`.

```
EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');
```

Working with tablespaces in RDS for Oracle

You can use tablespaces with RDS for Oracle, which is a logical storage unit that stores the database's data.

> **Important**
>
> If your DB instance has replicas, we recommend using parameter group settings instead of session-level changes to manage default file locations. Session-level changes to default file locations in the primary instance are not automatically reflected in the replicas. Using parameter group settings ensures consistent file locations across your primary and replica instances.

Topics

- Specifying database file locations in RDS for Oracle
- Creating and sizing tablespaces in RDS for Oracle
- Creating tablespaces on additional storage volumes in RDS for Oracle
- Setting the default tablespace in RDS for Oracle
- Setting the default temporary tablespace in RDS for Oracle
- Creating a temporary tablespace on the instance store

Specifying database file locations in RDS for Oracle

RDS for Oracle uses Oracle Managed Files (OMF) to name database files. When you create database files the database derives the setting based on the current setting of the `DB_CREATE_FILE_DEST` initialization parameter.

The default value of the `DB_CREATE_FILE_DEST` initialization parameter is `/rdsdbdata/db` for standalone databases and `/rdsdbdata/db/pdb` for containerized (CDB/MT) architecture. If your DB instance has additional storage volumes, then you can set `DB_CREATE_FILE_DEST` to your volume locations. For example, if your instance has a volume mounted on `/rdsdbdata/db`, you can set `DB_CREATE_FILE_DEST` to this value.

You can modify the `DB_CREATE_FILE_DEST` parameter at either the session level or Oracle database instance level.

Modifying DB_CREATE_FILE_SET at the instance level

To modify the parameter at the instance level, update the parameter in the parameter group assigned to your DB instance and apply it. For more information, see RDS for Oracle initialization parameters and Modifying parameters in a DB parameter group in Amazon RDS.

Modifying DB_CREATE_FILE_DEST at the session level

You can modify the parameter at the session level by executing an `ALTER SESSION` statement. This approach is useful when you want to create database files in a specific location for a particular session without affecting the entire instance.

The following example shows how to check the current parameter value and modify it for the session:

```
SHOW PARAMETER db_create_file_dest

NAME                                 TYPE        VALUE
------------------------------------ ----------- ------------------------------
db_create_file_dest                  string      /rdsdbdata/db

ALTER SESSION SET db_create_file_dest = '/rdsdbdata2/db';

Session altered.

SHOW PARAMETER db_create_file_dest

NAME                                 TYPE        VALUE
------------------------------------ ----------- ------------------------------
db_create_file_dest                  string      /rdsdbdata2/db
```

Creating and sizing tablespaces in RDS for Oracle

When you create tablespaces, the database creates the data files in the storage volume specified by the DB_CREATE_FILE_DEST initialization parameter at the time of creation. By default, if you don't specify a data file size, tablespaces are created with the default of AUTOEXTEND ON, and no maximum size. In the following example, the tablespace *users1* is autoextensible.

```
CREATE TABLESPACE users1;
```

Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named *users2* with a starting size of 1 gigabyte. Because a data file size is specified, but AUTOEXTEND ON isn't specified, the tablespace isn't autoextensible.

```
CREATE TABLESPACE users2 DATAFILE SIZE 1G;
```

The following example creates a tablespace named *users3* with a starting size of 1 gigabyte, autoextend turned on, and a maximum size of 10 gigabytes.

```
CREATE TABLESPACE users3 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;
```

The following example creates a temporary tablespace named *temp01*.

```
CREATE TEMPORARY TABLESPACE temp01;
```

You can resize a bigfile tablespace by using ALTER TABLESPACE. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T). The following example resizes a bigfile tablespace named *users_bf* to 200 MB.

```
ALTER TABLESPACE users_bf RESIZE 200M;
```

The following example adds an additional data file to a smallfile tablespace named *users_sf*.

```
ALTER TABLESPACE users_sf ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250m
 MAXSIZE UNLIMITED;
```

Creating tablespaces on additional storage volumes in RDS for Oracle

To create a tablespace on an additional storage volume, modify the DB_CREATE_FILE_DEST parameter to the volume location. The following example sets the file location to /rdsdbdata2/db.

```
ALTER SESSION SET db_create_file_dest = '/rdsdbdata2/db';

Session altered.
```

In the following example, you create a tablespace on the additional volume /rdsdbdata2/db.

```
CREATE TABLESPACE new_tablespace DATAFILE SIZE 10G;

Tablespace created.

SELECT tablespace_name,file_id,file_name FROM dba_data_files
WHERE tablespace_name = 'NEW_TABLESPACE';

TABLESPACE_NAME              FILE_ID FILE_NAME
-------------------------- ----------
 --------------------------------------------------------------------------------
NEW_TABLESPACE                     7 /rdsdbdata2/db/ORCL_A/datafile/
o1_mf_newtable_a123b4c5_.dbf
```

To create a smallfile tablespace and spread its data files across different storage volumes, add data files to the tablespace after you create it. In the following example, you create a tablespace with the data files in the default location of `/rdsdbdata/db`. Then you set the default destination to `/rdsdbdata/db2`. When you add a data file to your newly created tablespace, the database stores the file in `/rdsdbdata/db2`.

```
ALTER SESSION SET db_create_file_dest = '/rdsdbdata/db';

Session altered.

CREATE SMALLFILE TABLESPACE smalltbs DATAFILE SIZE 10G;

Tablespace created.

SELECT tablespace_name,file_id,file_name FROM dba_data_files
WHERE tablespace_name = 'SMALLTBS';

TABLESPACE_NAME              FILE_ID FILE_NAME
------------------------- ----------
 --------------------------------------------------------------------------------
SMALLTBS                           8 /rdsdbdata/db/ORCL_A/datafile/
o1_mf_smalltbs_n563yryk_.dbf

ALTER SESSION SET db_create_file_dest = '/rdsdbdata2/db';

Session altered.

ALTER TABLESPACE smalltbs ADD DATAFILE SIZE 10G;

Tablespace altered.

SELECT tablespace_name,file_id,file_name FROM dba_data_files
WHERE tablespace_name = 'SMALLTBS';

TABLESPACE_NAME              FILE_ID FILE_NAME
------------------------- ----------
 --------------------------------------------------------------------------------
SMALLTBS                           8 /rdsdbdata/db/ORCL_A/datafile/
o1_mf_smalltbs_n563yryk_.dbf
SMALLTBS                           9 /rdsdbdata2/db/ORCL_A/datafile/
o1_mf_smalltbs_n564004g_.dbf
```

Setting the default tablespace in RDS for Oracle

To set the default tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_tablespace`. The `alter_default_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`tablespace_name`	varchar	—	Yes	The name of the default tablespace.

The following example sets the default tablespace to *`users2`*:

```
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```

Setting the default temporary tablespace in RDS for Oracle

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`tablespace_name`	varchar	—	Yes	The name of the default temporary tablespace.

The following example sets the default temporary tablespace to *`temp01`*.

```
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

Creating a temporary tablespace on the instance store

To create a temporary tablespace on the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace`. The `create_inst_store_tmp_tblspace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_tablespace_name	varchar	—	Yes	The name of the temporary tablespace.

The following example creates the temporary tablespace *temp01* in the instance store.

```
EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace(p_tablespace_name =>
 'temp01');
```

Important

When you run rdsadmin_util.create_inst_store_tmp_tblspace, the newly created temporary tablespace is not automatically set as the default temporary tablespace. To set it as the default, see Setting the default temporary tablespace in RDS for Oracle.

For more information, see Storing temporary data in an RDS for Oracle instance store.

Working with tempfiles in RDS for Oracle

Adding a tempfile to the instance store on a read replica

When you create a temporary tablespace on a primary DB instance, the read replica doesn't create tempfiles. Assume that an empty temporary tablespace exists on your read replica for either of the following reasons:

- You dropped a tempfile from the tablespace on your read replica. For more information, see Dropping tempfiles on a read replica.
- You created a new temporary tablespace on the primary DB instance. In this case, RDS for Oracle synchronizes the metadata to the read replica.

You can add a tempfile to the empty temporary tablespace, and store the tempfile in the instance store. To create a tempfile in the instance store, use the Amazon RDS procedure rdsadmin.rdsadmin_util.add_inst_store_tempfile. You can use this procedure only on a read replica. The procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_tablespace_name	varchar	—	Yes	The name of the temporary tablespace on your read replica.

In the following example, the empty temporary tablespace *temp01* exists on your read replica. Run the following command to create a tempfile for this tablespace, and store it in the instance store.

```
EXEC rdsadmin.rdsadmin_util.add_inst_store_tempfile(p_tablespace_name => 'temp01');
```

For more information, see Storing temporary data in an RDS for Oracle instance store.

Dropping tempfiles on a read replica

You can't drop an existing temporary tablespace on a read replica. You can change the tempfile storage on a read replica from Amazon EBS to the instance store, or from the instance store to Amazon EBS. To achieve these goals, do the following:

1. Drop the current tempfiles in the temporary tablespace on the read replica.
2. Create new tempfiles on different storage.

To drop the tempfiles, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_replica_tempfiles`. You can use this procedure only on read replicas. The `drop_replica_tempfiles` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_tablespace_name	varchar	—	Yes	The name of the temporary tablespace on your read replica.

Assume that a temporary tablespace named *temp01* resides in the instance store on your read replica. Drop all tempfiles in this tablespace by running the following command.

```
EXEC rdsadmin.rdsadmin_util.drop_replica_tempfiles(p_tablespace_name => 'temp01');
```

For more information, see Storing temporary data in an RDS for Oracle instance store.

Resizing tablespaces, data files, and tempfiles in RDS for Oracle

By default, Oracle tablespaces are created with auto-extend turned on and no maximum size. Because of these default settings, tablespaces can sometimes grow too large. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

Resizing permanent tablespaces

To resize a permanent tablespace in an RDS for Oracle DB instance, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_datafile`
- `rdsadmin.rdsadmin_util.autoextend_datafile`

The `resize_datafile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_data_file_id`	number	—	Yes	The identifier of the data file to resize.
`p_size`	varchar2	—	Yes	The size of the data file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `autoextend_datafile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_data_file_id`	number	—	Yes	The identifier of the data file to resize.

Parameter name	Data type	Default	Required	Description
p_autoextend_state	varchar2	—	Yes	The state of the autoextension feature. Specify ON to extend the data file automatic ally and OFF to turn off autoextension.
p_next	varchar2	—	No	The size of the next data file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).
p_maxsize	varchar2	—	No	The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.

The following example resizes data file 4 to 500 MB.

```
EXEC rdsadmin.rdsadmin_util.resize_datafile(4,'500M');
```

The following example turns off autoextension for data file 4. It also turns on autoextension for data file 5, with an increment of 128 MB and no maximum size.

```
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(4,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(5,'ON','128M','UNLIMITED');
```

Resizing temporary tablespaces

To resize a temporary tablespaces in an RDS for Oracle DB instance, including a read replica, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_temp_tablespace`
- `rdsadmin.rdsadmin_util.resize_tempfile`
- `rdsadmin.rdsadmin_util.autoextend_tempfile`

The `resize_temp_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_temp_tablespace_name`	varchar2	—	Yes	The name of the temporary tablespace to resize.
`p_size`	varchar2	—	Yes	The size of the tablespace. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `resize_tempfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_temp_file_id`	number	—	Yes	The identifier of the temp file to resize.
`p_size`	varchar2	—	Yes	The size of the temp file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `autoextend_tempfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_temp_file_id`	number	—	Yes	The identifier of the temp file to resize.
`p_autoextend_state`	varchar2	—	Yes	The state of the autoextension feature. Specify `ON` to extend the temp file automatically and `OFF` to turn off autoextension.
`p_next`	varchar2	—	No	The size of the next temp file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).
`p_maxsize`	varchar2	—	No	The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify `UNLIMITED` to remove the file size limit.

The following examples resize a temporary tablespace named `TEMP` to the size of 4 GB.

```
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G');
```

```
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000');
```

The following example resizes a temporary tablespace based on the temp file with the file identifier 1 to the size of 2 MB.

```
EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M');
```

The following example turns off autoextension for temp file 1. It also sets the maximum autoextension size of temp file 2 to 10 GB, with an increment of 100 MB.

```
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(1,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(2,'ON','100M','10G');
```

For more information about read replicas for Oracle DB instances see Working with read replicas for Amazon RDS for Oracle.

Moving data between storage volumes in RDS for Oracle

You can move data files and database objects between your primary and additional storage volumes. Before you move data, consider the following points:

- The source and target volumes must have sufficient free space.
- Data movement operations consume I/O on both volumes.
- Large data movements can impact database performance.
- If you restore a snapshot, moving data between storage volumes might be slow if it is affected by EBS lazy loading.

Topics

- Moving data files between volumes in RDS for Oracle
- Moving table data and indexes between volumes in RDS for Oracle
- Managing LOB storage using additional volumes

Moving data files between volumes in RDS for Oracle

To move data files between storage volumes, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.move_datafile`. Note the following requirements:

- You must use Oracle Enterprise Edition to run the `move_datafile` procedure.
- You can't move tablespace `SYSTEM` and `RDSADMIN`.

The `move_datafile` procedure has the following parameters.

Parameter name	Data type	Required	Description
`p_data_file_id`	number	Yes	The ID of the data file to be moved.
`p_location`	varchar2	Yes	The storage volume to which you want to move the data file.

The following example moves a tablespace from the default volume `rdsdbdata` to the additional volume `rdsdbdata2`.

```
SQL> SELECT tablespace_name,file_id,file_name FROM dba_data_files
 WHERE tablespace_name = 'MYNEWTABLESPACE';

TABLESPACE_NAME              FILE_ID FILE_NAME
------------------------- ----------
 --------------------------------------------------------------------------------
MYNEWTABLESPACE                    6 /rdsdbdata/db/ORCL_A/datafile/
o1_mf_mynewtab_n123abcd_.dbf

EXECUTE rdsadmin.rdsadmin_util.move_datafile( 6, 'rdsdbdata2');

PL/SQL procedure successfully completed.

SQL> SELECT tablespace_name,file_id,file_name FROM dba_data_files
  WHERE tablespace_name = 'MYNEWTABLESPACE';

TABLESPACE_NAME              FILE_ID FILE_NAME
------------------------- ----------
 --------------------------------------------------------------------------------
MYNEWTABLESPACE                    6 /rdsdbdata2/db/ORCL_A/datafile/
o1_mf_mynewtab_n356efgh_.dbf
```

Moving table data and indexes between volumes in RDS for Oracle

You can optimize database storage by creating tablespaces on additional storage volumes. Then you can move objects such as tables, indexes, and partitions to these tablespaces using standard

Oracle SQL. This approach is valuable for performance tuning when your database contains data with different access patterns. For example, you could store frequently accessed operational data on high-performance storage volumes while moving rarely accessed historical data to lower-cost storage volumes.

In the following example, you create a new tablespace on high-performance volume `rdsdbdata2`. Then you move a table to your additional storage volume while the table is online. You also move the index to the same volume. Moving tables and rebuilding indexes while online requires Oracle Enterprise Edition.

```
ALTER SESSION SET db_create_file_dest = '/rdsdbdata2/db';
CREATE TABLESPACE perf_tbs DATAFILE SIZE 10G;

ALTER TABLE employees
  MOVE TABLESPACE perf_tbs ONLINE;

ALTER INDEX employees_idx
  REBUILD ONLINE TABLESPACE perf_tbs;
```

In the following example, you create a tablespace on a low-cost volume. Then you move a table partition to your low-cost storage volume using an online operation.

```
ALTER SESSION SET db_create_file_dest = '/rdsdbdata3/db';
CREATE TABLESPACE hist_tbs DATAFILE SIZE 10G;

ALTER TABLE orders
  MOVE PARTITION orders_2022
  TABLESPACE hist_tbs ONLINE;
```

In the following example, you query active sessions long operations.

```
SELECT sid,opname,sofar,totalwork,time_remaining,elapsed_seconds
  FROM v$session_longops
  WHERE time_remaining > 0;
```

You can check your tablespaces usage with the following query.

```
SELECT tablespace_name, used_percent
  FROM dba_tablespace_usage_metrics
  ORDER BY used_percent DESC;
```

Managing LOB storage using additional volumes

Your database might contains tables with BLOB or CLOB objects that consume substantial storage but are infrequently accessed. To optimize storage, you can relocate these LOB segments to a tablespace on an additional storage volume.

In the following example, you create a tablespace for LOB data on a low-cost volume that is intended for low-access data. Then you create a table that stores data on this volume.

```
ALTER SESSION SET db_create_file_dest = '/rdsdbdata3/db';
CREATE TABLESPACE lob_data DATAFILE SIZE 5G AUTOEXTEND ON NEXT 1G;

CREATE TABLE documents (
    doc_id NUMBER PRIMARY KEY,
    doc_date DATE,
    doc_content CLOB
) TABLESPACE user_data
LOB(doc_content) STORE AS (TABLESPACE lob_data);
```

Working with external tables in RDS for Oracle

Oracle external tables are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see Managing external tables in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the DATA_PUMP_DIR directory. For information about creating directory objects, see Creating and dropping directories in the main data storage space. You can query the ALL_DIRECTORIES view to list the directory objects for your Amazon RDS Oracle DB instance.

> **Note**
>
> Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the DBMS_FILE_TRANSFER package or the UTL_FILE package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using DBMS_FILE_TRANSFER, see Importing using Oracle Data Pump.

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the emp_xt_file1.txt file in the USER_DIR1 directory.

```
CREATE TABLE emp_xt (
  emp_id      NUMBER,
  first_name  VARCHAR2(50),
  last_name   VARCHAR2(50),
  user_name   VARCHAR2(20)
)
ORGANIZATION EXTERNAL (
  TYPE ORACLE_LOADER
  DEFAULT DIRECTORY USER_DIR1
  ACCESS PARAMETERS (
    RECORDS DELIMITED BY NEWLINE
    FIELDS TERMINATED BY ','
    MISSING FIELD VALUES ARE NULL
    (emp_id,first_name,last_name,user_name)
  )
  LOCATION ('emp_xt_file1.txt')
)
PARALLEL
REJECT LIMIT UNLIMITED;
```

Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the data from the table in the database. For example, the following SQL statement creates the orders_xt external table by querying the orders table in the database.

```
CREATE TABLE orders_xt
  ORGANIZATION EXTERNAL
   (
     TYPE ORACLE_DATAPUMP
     DEFAULT DIRECTORY DATA_PUMP_DIR
     LOCATION ('orders_xt.dmp')
   )
```

```
   AS SELECT * FROM orders;
```

In this example, the data is populated in the `orders_xt.dmp` file in the DATA_PUMP_DIR directory.

Checkpointing a database

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The `checkpoint` procedure has no parameters.

The following example checkpoints the database.

```
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

Setting distributed recovery

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```

The following example disables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

Setting the database time zone

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- The `Timezone` option

  The `Timezone` option changes the time zone at the host level and affects all date columns and values such as SYSDATE. For more information, see Oracle time zone.
- The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`

The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn't change SYSDATE. There are additional restrictions on setting the time zone listed in the Oracle documentation.

> **Note**
>
> You can also set the default time zone for Oracle Scheduler. For more information, see Setting the time zone for Oracle Scheduler jobs.

The `alter_db_time_zone` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_new_tz	varchar2	—	Yes	The new time zone as a named region or an absolute offset from Coordinated Universal Time (UTC). Valid offsets range from -12:00 to +14:00.

The following example changes the time zone to UTC plus three hours.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => '+3:00');
```

The following example changes the time zone to the Africa/Algiers time zone.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');
```

After you alter the time zone by using the `alter_db_time_zone` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance. For information about upgrading time zones, see Time zone considerations.

Generating performance reports with Automatic Workload Repository (AWR)

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

Working with AWR reports in RDS

To generate AWR reports, you can run scripts such as `awrrpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYS.DBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data

The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see Reading files in a DB instance directory and Amazon S3 integration.

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:

- All Oracle Database 21c versions

- 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions

For a blog that explains how to work with diagnostic reports in a replication scenario, see Generate AWR reports for Amazon RDS for Oracle read replicas.

Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the `rdsadmin_diagnostic_util` package.

Parameter	Data type	Defau	Requi	Description
`begin_snap_id`	NUMBEI	—	Yes	The ID of the beginning snapshot.
`end_snap_id`	NUMBEI	—	Yes	The ID of the ending snapshot.
`dump_directory`	VARCHA	BDUMI	No	The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the `rdsadmin_diagnostic_util` procedures must have write permissions for the directory.
`p_tag`	VARCHA	—	No	A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as `incremental` or `daily`. You can specify up to 30 characters. Valid characters are `a-z`, `A-Z`, `0-9`, an underscore (_), a dash (-), and a period (.). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, RMAN assigns a default tag automatically using the format TAG*YYYYMMDDTHHMMSS*, where *YYYY* is the year, *MM* is the month, *DD* is the day, *HH* is the hour (in 24-hour

Parameter	Data type	Defau	Requi	Description
				format), *MM* is the minutes, and *SS* is the seconds. The date and time indicate when RMAN started the backup. For example, a backup with the default tagTAG20190927T214517 indicates a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following RDS for Oracle DB engine versions: • Oracle Database 21c (21.0.0) • Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 and higher
report_type	VARCHA	HTML	No	The format of the report. Valid values are TEXT and HTML.
dbid	NUMBEF	—	No	A valid database identifier (DBID) shown in the DBA_HIST_DATABASE_INSTANCE view for Oracle. If this parameter is not specified, RDS uses the current DBID, which is shown in the V$DATABASE.DBID view.

You typically use the following parameters when managing ASH with the rdsadmin_diagnostic_util package.

Parameter	Data type	Defaul	Requir	Description
begin_time	DATE	—	Yes	The beginning time of the ASH analysis.
end_time	DATE	—	Yes	The ending time of the ASH analysis.
slot_width	NUMBER	0	No	The duration of the slots (in seconds) used in the "Top Activity" section of the ASH report. If this parameter isn't specified, the time interval between

Parameter	Data type	Defaul	Requir	Description
				`begin_time` and `end_time` uses no more than 10 slots.
`sid`	`NUMBER`	Null	No	The session ID.
`sql_id`	`VARCHAR2`	Null	No	The SQL ID.
`wait_class`	`VARCHAR2`	Null	No	The wait class name.
`service_hash`	`NUMBER`	Null	No	The service name hash.
`module_name`	`VARCHAR2`	Null	No	The module name.
`action_name`	`VARCHAR2`	Null	No	The action name.
`client_id`	`VARCHAR2`	Null	No	The application-specific ID of the database session.
`plsql_entry`	`VARCHAR2`	Null	No	The PL/SQL entry point.

Generating an AWR report

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrrpt_101_106.txt`. You can access this report from the AWS Management Console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');
```

The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named `awrrpt_63_65.html`. The procedure writes the report to the nondefault database directory named `AWR_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');
```

Extracting AWR data into a dump file

To extract AWR data into a dump file, use the `rdsadmin.rdsadmin_diagnostic_util.awr_extract` procedure. You can use this function only at the PDB level.

The following example extracts the snapshot range 101–106. The output dump file is named `awrextract_101_106.dmp`. You can access this file through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);
```

The following example extracts the snapshot range 63–65. The output dump file is named `awrextract_63_65.dmp`. The file is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(63,65,'AWR_RPT_DUMP');
```

Generating an ADDM report

To generate an ADDM report, use the `rdsadmin.rdsadmin_diagnostic_util.addm_report` procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named `addmrpt_101_106.txt`. You can access the report through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);
```

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named `addmrpt_63_65.txt`. The file is stored in the nondefault database directory named `ADDM_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
```

Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrpt`*`begin_time`*`end_time`*`.txt`*, where *`begin_time`* and *`end_time`* use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time     =>     SYSDATE-14/1440,
        end_time       =>     SYSDATE,
        report_type    =>     'TEXT');
END;
/
```

The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
BEGIN
    rdsadmin.rdsadmin_diagnostic_util.ash_report(
        begin_time     =>    TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),
        end_time       =>    TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),
        report_type    =>    'html',
        dump_directory =>    'AWR_RPT_DUMP');
END;
/
```

Accessing AWR reports from the console or CLI

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see Downloading a database log file.

Adjusting database links for use with DB instances in a VPC

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the

valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Updating your security groups to reference peered VPC security groups.

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see Setting up a custom DNS server.

For more information about using database links with Oracle Data Pump, see Importing using Oracle Data Pump.

Setting the default edition for a DB instance

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application's database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_edition`.

The following example sets the default edition for the Amazon RDS Oracle DB instance to `RELEASE_V1`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');
```

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');
```

For more information about Oracle edition-based redefinition, see About editions and edition-based redefinition in the Oracle documentation.

Enabling auditing for the SYS.AUD$ table

To enable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table`. The only supported audit property is ALL. You can't audit or not audit individual statements or operations.

Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The `audit_all_sys_aud_table` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_by_access	boolean	true	No	Set to `true` to audit BY ACCESS. Set to `false` to audit BY SESSION.

The following query returns the current audit configuration for SYS.AUD$ for a database.

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of ALL on SYS.AUD$ BY ACCESS.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;

EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of ALL on SYS.AUD$ BY SESSION.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```

For more information, see AUDIT (traditional auditing) in the Oracle documentation.

Disabling auditing for the SYS.AUD$ table

To disable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table`. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD$ for a database:

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following command disables audit of ALL on SYS.AUD$.

```
EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;
```

For more information, see NOAUDIT (traditional auditing) in the Oracle documentation.

Cleaning up interrupted online index builds

To clean up failed online index builds, use the Amazon RDS procedure `rdsadmin.rdsadmin_dbms_repair.online_index_clean`.

The `online_index_clean` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`object_id`	binary_integer	`ALL_INDEX_ID`	No	The object ID of the index. Typically, you can use the object ID from the ORA-08104 error text.
`wait_for_lock`	binary_integer	`rdsadmin.rdsadmin_dbms_repair.lock_wait`	No	Specify `rdsadmin.rdsadmin_dbms_repair.lock_wait` , the default, to try to get a lock on the underlying object and retry until an

Parameter name	Data type	Default	Required	Description
				internal limit is reached if the lock fails. Specify `rdsadmin.rdsadmin_dbms_repair.lock_nowait` to try to get a lock on the underlying object but not retry if the lock fails.

The following example cleans up a failed online index build:

```
declare
  is_clean boolean;
begin
  is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(
    object_id     => 1234567890,
    wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait
  );
end;
/
```

For more information, see ONLINE_INDEX_CLEAN function in the Oracle documentation.

Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the `rdsadmin.rdsadmin_dbms_repair` package.

The following procedures wrap the functionality of the `sys.dbms_repair.admin_table` procedure and take no parameters:

- `rdsadmin.rdsadmin_dbms_repair.create_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_repair_table`

- `rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table`

The following procedures take the same parameters as their counterparts in the `DBMS_REPAIR` package for Oracle databases:

- `rdsadmin.rdsadmin_dbms_repair.check_object`
- `rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys`
- `rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks`
- `rdsadmin.rdsadmin_dbms_repair.rebuild_freelists`
- `rdsadmin.rdsadmin_dbms_repair.segment_fix_status`
- `rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks`

For more information about handling database corruption, see DBMS_REPAIR in the Oracle documentation.

Example Responding to corrupt blocks

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

> **Important**
>
> Before attempting to repair corrupt blocks, review the DBMS_REPAIR documentation carefully.

To skip corrupt blocks during index and table scans

1. Run the following procedures to create repair tables if they don't already exist.

```
EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;
```

2. Run the following procedures to check for existing records and purge them if appropriate.

```
SELECT COUNT(*) FROM SYS.REPAIR_TABLE;
SELECT COUNT(*) FROM SYS.ORPHAN_KEY_TABLE;
SELECT COUNT(*) FROM SYS.DBA_REPAIR_TABLE;
SELECT COUNT(*) FROM SYS.DBA_ORPHAN_KEY_TABLE;

EXEC rdsadmin.rdsadmin_dbms_repair.purge_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table;
```

3. Run the following procedure to check for corrupt blocks.

```
SET SERVEROUTPUT ON
DECLARE v_num_corrupt INT;
BEGIN
  v_num_corrupt := 0;
  rdsadmin.rdsadmin_dbms_repair.check_object (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    corrupt_count =>  v_num_corrupt
  );
  dbms_output.put_line('number corrupt: '||to_char(v_num_corrupt));
END;
/

COL CORRUPT_DESCRIPTION FORMAT a30
COL REPAIR_DESCRIPTION FORMAT a30

SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
       CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
FROM   SYS.REPAIR_TABLE;

SELECT SKIP_CORRUPT
FROM   DBA_TABLES
WHERE  OWNER = '&corruptionOwner'
AND    TABLE_NAME = '&corruptionTable';
```

4. Use the `skip_corrupt_blocks` procedure to enable or disable corruption skipping for affected tables. Depending on the situation, you may also need to extract data to a new table, and then drop the table containing the corrupt block.

   Run the following procedure to enable corruption skipping for affected tables.

```
begin
```

```
  rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
    flags => rdsadmin.rdsadmin_dbms_repair.skip_flag);
end;
/
select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name
 = '&corruptionTable';
```

Run the following procedure to disable corruption skipping.

```
begin
  rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
    flags => rdsadmin.rdsadmin_dbms_repair.noskip_flag);
end;
/

select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name
 = '&corruptionTable';
```

5. When you have completed all repair work, run the following procedures to drop the repair tables.

```
EXEC rdsadmin.rdsadmin_dbms_repair.drop_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table;
```

Purging the recycle bin

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.purge_dba_recyclebin`. However, this procedure can't purge the recycle bin of `SYS` and `RDSADMIN` objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.

```
EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin;
```

Setting the default displayed values for full redaction

To change the default displayed values for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val`. Note that you create a redaction policy with the `DBMS_REDACT` PL/SQL package, as explained in the Oracle Database documentation. The `dbms_redact_upd_full_rdct_val` procedure specifies the characters to display for different data types affected by an existing policy.

The `dbms_redact_upd_full_rdct_val` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_number_val`	number	Null	No	Modifies the default value for columns of the `NUMBER` data type.
`p_binfloat_val`	binary_float	Null	No	Modifies the default value for columns of the `BINARY_FLOAT` data type.
`p_bindouble_val`	binary_double	Null	No	Modifies the default value for columns of the `BINARY_DOUBLE` data type.
`p_char_val`	char	Null	No	Modifies the default value for columns of the `CHAR` data type.
`p_varchar_val`	varchar2	Null	No	Modifies the default value for columns of the `VARCHAR2` data type.

Parameter name	Data type	Default	Required	Description
p_nchar_val	nchar	Null	No	Modifies the default value for columns of the NCHAR data type.
p_nvarchar_val	nvarchar2	Null	No	Modifies the default value for columns of the NVARCHAR2 data type.
p_date_val	date	Null	No	Modifies the default value for columns of the DATE data type.
p_ts_val	timestamp	Null	No	Modifies the default value for columns of the TIMESTAMP data type.
p_tswtz_val	timestamp with time zone	Null	No	Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE data type.
p_blob_val	blob	Null	No	Modifies the default value for columns of the BLOB data type.
p_clob_val	clob	Null	No	Modifies the default value for columns of the CLOB data type.
p_nclob_val	nclob	Null	No	Modifies the default value for columns of the NCLOB data type.

The following example changes the default redacted value to * for the CHAR data type:

```
EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(p_char_val => '*');
```

The following example changes the default redacted values for NUMBER, DATE, and CHAR data types:

```
BEGIN
rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(
    p_number_val=>1,
    p_date_val=>to_date('1900-01-01','YYYY-MM-DD'),
    p_varchar_val=>'X');
END;
/
```

After you alter the default values for full redaction with the dbms_redact_upd_full_rdct_val procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance.

Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see Amazon RDS for Oracle database log files.

Topics

- Setting force logging
- Setting supplemental logging
- Switching online log files
- Adding online redo logs
- Dropping online redo logs
- Resizing online redo logs
- Retaining archived redo logs
- Accessing online and archived redo logs
- Downloading archived redo logs from Amazon S3

Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (NOLOGGING clauses are ignored). For more information, see Specifying FORCE LOGGING mode in the Oracle documentation.

To set force logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.force_logging`. The `force_logging` procedure has the following parameters.

Parameter name	Data type	Default	Yes	Description
`p_enable`	boolean	true	No	Set to `true` to put the database in force logging mode, `false` to remove the database from force logging mode.

The following example puts the database in force logging mode.

```
EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see Supplemental logging in the Oracle documentation.

Oracle Database doesn't enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_supplemental_logging`. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see Retaining archived redo logs.

The `alter_supplemental_logging` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_action	varchar2	—	Yes	'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.
p_type	varchar2	null	No	The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY KEY', 'UNIQUE', or PROCEDURAL .

The following example enables supplemental logging.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD');
end;
/
```

The following example enables supplemental logging for all fixed-length maximum size columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'PRIMARY KEY');
end;
```

```
/
```

Switching online log files

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.

The following example switches log files.

```
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

Adding online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

> **Note**
>
> The parameters are mutually exclusive.

Parameter name	Data type	Default	Required	Description
`bytes`	positive	null	No	The size of the log file in bytes. Use this parameter only if the size of the log is under 2147483648 bytes (2 GiB). Otherwise, RDS issues an error. For log sizes above this byte value, use the `p_size` parameter instead.

Parameter name	Data type	Default	Required	Description
p_size	varchar2	—	Yes	The size of the log file in kilobytes (K), megabytes (M), or gigabytes (G).

The following command adds a 100 MB log file.

```
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```

Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
grp	positive	—	Yes	The group number of the log.

The following example drops the log with group number 3.

```
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```
SELECT GROUP#, STATUS FROM V$LOG;

GROUP#     STATUS
---------- ----------------
1          CURRENT
2          INACTIVE
3          INACTIVE
4          UNUSED
```

Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

```
/* Query V$LOG to see the logs.          */
/* You start with 4 logs of 128 MB each. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
1          134217728  INACTIVE
2          134217728  CURRENT
3          134217728  INACTIVE
4          134217728  INACTIVE

/* Add four new logs that are each 512 MB */

EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);

/* Query V$LOG to see the logs. */
/* Now there are 8 logs.        */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
1          134217728  INACTIVE
2          134217728  CURRENT
3          134217728  INACTIVE
4          134217728  INACTIVE
5          536870912  UNUSED
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED
```

```
/* Drop each inactive log using the group number. */

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 1);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 4);

/* Query V$LOG to see the logs. */
/* Now there are 5 logs.        */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  CURRENT
5          536870912  UNUSED
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

/* Switch logs so that group 2 is no longer current. */

EXEC rdsadmin.rdsadmin_util.switch_logfile;

/* Query V$LOG to see the logs.        */
/* Now one of the new logs is current. */

SQL>SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  ACTIVE
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

/* If the status of log 2 is still "ACTIVE", issue a checkpoint to clear it to
 "INACTIVE".  */
```

```
EXEC rdsadmin.rdsadmin_util.checkpoint;

/* Query V$LOG to see the logs.            */
/* Now the final original log is inactive. */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
2          134217728  INACTIVE
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED

# Drop the final inactive log.

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 2);

/* Query V$LOG to see the logs.    */
/* Now there are four 512 MB logs. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#     BYTES      STATUS
---------- ---------- ----------------
5          536870912  CURRENT
6          536870912  UNUSED
7          536870912  UNUSED
8          536870912  UNUSED
```

Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (`DBMS_LOGMNR`). After you have retained the redo logs, you can use LogMiner to analyze the logs. For more information, see Using LogMiner to analyze redo log files in the Oracle documentation.

To retain archived redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_configuration`. If you use this procedure on a primary

instance in Oracle Data Guard, RDS changes the archive log retention setting on the primary instance and open read replicas, but not on mounted replicas. RDS retains the latest archive redo logs on mounted replicas for a short period of time. RDS automatically deletes older logs downloaded to mounted replicas.

The `set_configuration` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`name`	varchar	—	Yes	The name of the configuration to update. To change the archived redo log retention hours, set the name to `archivelog retention hours`.
`value`	varchar	—	Yes	The value for the configuration. Set the value the number of hours to retain the logs.

The following example retains 24 hours of redo logs.

```
begin
    rdsadmin.rdsadmin_util.set_configuration(
        name  => 'archivelog retention hours',
        value => '24');
end;
/
commit;
```

Note

The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.show_configuration`.

The following example shows the log retention time.

```
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```

The output shows the current setting for `archivelog retention hours`. The following output shows that archived redo logs are kept for 48 hours.

```
NAME:archivelog retention hours
VALUE:48
DESCRIPTION:ArchiveLog expiration specifies the duration in hours before archive/redo
 log files are automatically deleted.
```

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
  FROM V$ARCHIVED_LOG
 WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see Modifying an Amazon RDS DB instance.

Note

In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.

   Use `rdsadmin.rdsadmin_master_util.create_archivelog_dir` and `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`.
2. Read the files using PL/SQL.

   You can read the files by using PL/SQL. For more information about reading files from directory objects, see Listing files in a DB instance directory and Reading files in a DB instance directory.

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c

The following code creates directories that provide read-only access to your online and archived redo log files:

> **Important**
>
> This code also revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

The following code drops the directories for your online and archived redo log files.

```
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
```

```
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```

Downloading archived redo logs from Amazon S3

You can download archived redo logs on your DB instance using the `rdsadmin.rdsadmin_archive_log_download` package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.

> **Note**
>
> You can't download archived redo logs on read replica instances.

Downloading archived redo logs: basic steps

The availability of your archived redo logs depends on the following retention policies:

- Backup retention policy – Logs inside of this policy are available in Amazon S3. Logs outside of this policy are removed.
- Archived log retention policy – Logs inside of this policy are available on your DB instance. Logs outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use `rdsadmin.rdsadmin_archive_log_download` to download them again. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance.

To download archived redo logs from Amazon S3

1. Configure your retention period to ensure your downloaded archived redo logs are retained for the duration you need them. Make sure to `COMMIT` your change.

   RDS retains your downloaded logs according to the archived log retention policy, starting from the time the logs were downloaded. To learn how to set the retention policy, see Retaining archived redo logs.
2. Wait up to 5 minutes for the archived log retention policy change to take effect.
3. Download the archived redo logs from Amazon S3 using `rdsadmin.rdsadmin_archive_log_download`.

For more information, see Downloading a single archived redo log and Downloading a series of archived redo logs.

> **Note**
>
> RDS automatically checks the available storage before downloading. If the requested logs consume a high percentage of space, you receive an alert.

4. Confirm that the logs were downloaded from Amazon S3 successfully.

   You can view the status of your download task in a bdump file. The bdump files have the path name `/rdsdbdata/log/trace/dbtask-task-id.log`. In the preceding download step, you run a `SELECT` statement that returns the task ID in a `VARCHAR2` data type. For more information, see similar examples in Monitoring the status of a file transfer.

Downloading a single archived redo log

To download a single archived redo log to the `/rdsdbdata/log/arch` directory, use `rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum`. This procedure has the following parameter.

Parameter name	Data type	Default	Required	Description
`seqnum`	number	—	Yes	The sequence number of the archived redo log.

The following example downloads the log with sequence number 20.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20)
       AS TASK_ID
FROM   DUAL;
```

Downloading a series of archived redo logs

To download a series of archived redo logs to the `/rdsdbdata/log/arch` directory, use `download_logs_in_seqnum_range`. Your download is limited to 300 logs per request. The `download_logs_in_seqnum_range` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
start_seq	number	—	Yes	The starting sequence number for the series.
end_seq	number	—	Yes	The ending sequence number for the series.

The following example downloads the logs from sequence 50 to 100.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq
 => 50, end_seq => 100)
       AS TASK_ID
FROM   DUAL;
```

Performing common RMAN tasks for Oracle DB instances

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

Use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archived redo log backups.

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using Amazon S3 integration.

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the `UTL_FILE.FREMOVE` Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle Database documentation.

You can't use the RMAN to restore RDS for Oracle DB instances. However, you can use RMAN to restore a backup to an on-premises or Amazon EC2 instance. For more information, see the blog article Restore an Amazon RDS for Oracle instance to a self-managed instance.

> **Note**
>
> For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see Backing up, restoring, and exporting data.

- Backing up a control file
- Performing block media recovery

Prerequisites for RMAN backups

Before backing up your database using the `rdsadmin.rdsadmin_rman_util` package, make sure that you meet the following prerequisites:

- Make sure that your RDS for Oracle database is in `ARCHIVELOG` mode. To enable this mode, set the backup retention period to a non-zero value.
- When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, and when backing up the database, make sure that redo log retention is set to a nonzero value. Archived redo logs are required to make database files consistent during recovery. For more information, see Retaining archived redo logs.

- Make sure that your DB instance has sufficient free space to hold the backups. When back up your database, you specify an Oracle directory object as a parameter in the procedure call. RMAN places the files in the specified directory. You can use default directories, such as `DATA_PUMP_DIR`, or create a new directory. For more information, see Creating and dropping directories in the main data storage space.

  You can monitor the current free space in an RDS for Oracle instance using the CloudWatch metric `FreeStorageSpace`. We recommend that your free space exceeds the current size of the database, though RMAN backs up only formatted blocks and supports compression.

Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

Parameter name	Data type	Valid values	Defau	Requir	Description
`p_directory_name`	varchar	A valid database directory name.	—	Yes	The name of the directory to contain the backup files.
`p_label`	varchar	`a-z`, `A-Z`, `0-9`, `'_'`, `'-'`, `'.'`	—	No	A unique string that is included in the backup file names. **Note** The limit is 30 characters.
`p_owner`	varchar	A valid owner of the directory specified in	—	Yes	The owner of the directory to contain the backup files.

Parameter name	Data type	Valid values	Defau	Requir	Description
		p_directory_name .			

Parameter name	Data type	Valid values	Defau	Requir	Description
p_tag	varchar	a-z, A-Z, 0-9, '_', '-', '.'	NULL	No	A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups. The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them. Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, then RMAN assigns a default tag automatically using the format TAG*YYYYMMDDT HHMMSS* , where *YYYY* is the year, *MM* is the month, *DD* is the day, *HH* is the hour (in 24-hour format), *MM* is the minutes, and *SS* is the seconds. The date and time refer to when RMAN started the backup. For example, a backup might receive a tag TAG20190927T214517 for a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following Amazon RDS for Oracle DB engine versions: • Oracle Database 21c (21.0.0)

Parameter name	Data type	Valid values	Defau	Requir	Description
					• Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher
p_compress	boolean	TRUE, FALSE	FALSE	No	Specify TRUE to enable BASIC backup compression. Specify FALSE to disable BASIC backup compression.
p_include_archive_logs	boolean	TRUE, FALSE	FALSE	No	Specify TRUE to include archived redo logs in the backup. Specify FALSE to exclude archived redo logs from the backup. If you include archived redo logs in the backup, set retention to one hour or greater using the rdsadmin.rdsadmin_util.set_configuration procedure. Also, call the rdsadmin.rdsadmin_rman_util.crosscheck_archivelog procedure immediately before running the backup. Otherwise, the backup might fail due to missing archived redo log files that have been deleted by Amazon RDS management procedures.
p_include_controlfile	boolean	TRUE, FALSE	FALSE	No	Specify TRUE to include the control file in the backup. Specify FALSE to exclude the control file from the backup.

Parameter name	Data type	Valid values	Defau	Requir	Description
p_optimize	boolear	TRUE, FALSE	TRUE	No	Specify TRUE to enable backup optimization, if archived redo logs are included, to reduce backup size. Specify FALSE to disable backup optimization.
p_parallel	numbe	A valid integer between 1 and 254 for Oracle Database Enterpris e Edition (EE) 1 for other Oracle Database editions	1	No	Number of channels.
p_rman_to _dbms_out put	boolear	TRUE, FALSE	FALSE	No	When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output. When FALSE, the RMAN output is only sent to a file in the BDUMP directory.

Parameter name	Data type	Valid values	Defau	Requir	Description
p_section_size_mb	numbe	A valid integer	NULL	No	The section size in megabytes (MB). Validates in parallel by dividing each file into the specified section size. When NULL, the parameter is ignored.
p_validation_type	varchar	'PHYSICAL' , 'PHYSICAL+LOGICAL'	'PHYS'	No	The level of corruption detection. Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer. Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.

Validating database files in RDS for Oracle

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to validate Amazon RDS for Oracle database files, such as data files, tablespaces, control files, and server parameter files (SPFILEs).

For more information about RMAN validation, see Validating database files and backups and VALIDATE in the Oracle documentation.

Topics

- Validating a database
- Validating a tenant database
- Validating a tablespace
- Validating a control file

- Validating an SPFILE
- Validating an Oracle data file

Validating a database

To validate all of the relevant files used by an Oracle database in RDS for Oracle, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures.

The following example validates the database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_database(
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_rman_to_dbms_output => FALSE);
END;
/
```

When the `p_rman_to_dbms_output` parameter is set to `FALSE`, the RMAN output is written to a file in the `BDUMP` directory.

To view the files in the `BDUMP` directory, run the following `SELECT` statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-
validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tenant database

To validate the data files of the tenant database in a container database (CDB), use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tenant`.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures. This procedure is supported for the following DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example validates the current tenant database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_tenant;
```

The following example validates the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_tenant(
        p_validation_type     => 'PHYSICAL+LOGICAL',
```

```
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_rman_to_dbms_output => FALSE);
END;
/
```

When the p_rman_to_dbms_output parameter is set to FALSE, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following SELECT statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-
validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tablespace

To validate the files associated with a tablespace, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.validate_tablespace.

This procedure uses the following common parameters for RMAN tasks:

- p_validation_type
- p_parallel
- p_section_size_mb
- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_tablespace_name	varchar2	A valid tablespace name	—	Yes	The name of the tablespace.

Validating a control file

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_current_controlfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures.

Validating an SPFILE

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_spfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures.

Validating an Oracle data file

To validate a data file, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_datafile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`

- p_parallel
- p_section_size_mb
- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_datafile	varchar2	A valid datafile ID number or a valid datafile name including complete path	—	Yes	The datafile ID number (from v $datafile.file#) or the full datafile name including the path (from v $datafile.name).
p_from_block	number	A valid integer	NULL	No	The number of the block where the validation starts within the data file. When this is NULL, 1 is used.
p_to_block	number	A valid integer	NULL	No	The number of the block where the validation ends within the data file. When this is NULL, the maximum block in the data file is used.

Enabling and disabling block change tracking

Block changing tracking records changed blocks in a tracking file. This technique can improve the performance of RMAN incremental backups. For more information, see Using Block Change Tracking to Improve Incremental Backup Performance in the Oracle Database documentation.

RMAN features aren't supported in a read replica. However, as part of your high availability strategy, you might choose to enable block tracking in a read-only replica using the procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. If you promote this read-only replica to a source DB instance, block change tracking is enabled for the new source instance. Thus, your instance can benefit from fast incremental backups.

Block change tracking procedures are supported in Enterprise Edition only for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

> **Note**
>
> In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also Limitations of RDS for Oracle CDBs.

To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

Crosschecking archived redo logs

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archivelog`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

> **Note**
>
> Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
`p_delete_expired`	boolean	`TRUE`, `FALSE`	`TRUE`	No	When `TRUE`, delete expired archived redo log records from the control file. When `FALSE`, retain the expired archived redo log records in the control file.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example marks archived redo log records in the control file as expired, but does not delete the records.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
        p_delete_expired      => FALSE,
        p_rman_to_dbms_output => FALSE);
END;
/
```

The following example deletes expired archived redo log records from the control file.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
        p_delete_expired      => TRUE,
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up archived redo log files

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

Topics

- Backing up all archived redo logs
- Backing up an archived redo log from a date range
- Backing up an archived redo log from an SCN range
- Backing up an archived redo log from a sequence number range

Backing up all archived redo logs

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_all`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

The following example backs up all archived redo logs for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from a date range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_date`. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_from_date	date	A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be less than or equal to the value specified	—	Yes	The starting date for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
		for p_to_date .			
p_to_date	date	A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date .	—	Yes	The ending date for the archived log backups.

The following example backs up archived redo logs in the date range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
        p_owner               => 'SYS',
```

```
        p_directory_name      => 'MYDIRECTORY',
        p_from_date           => '03/01/2019 00:00:00',
        p_to_date             => '03/02/2019 00:00:00',
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from an SCN range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_scn`. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
`p_from_scn`	number	An SCN of an archived redo	—	Yes	The starting SCN for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
		log that exists on disk. The value must be less than or equal to the value specified for `p_to_scn`.			
`p_to_scn`	number	An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for `p_from_scn`.	—	Yes	The ending SCN for the archived log backups.

The following example backs up archived redo logs in the SCN range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
        p_owner                => 'SYS',
        p_directory_name       => 'MYDIRECTORY',
        p_from_scn             => 1533835,
        p_to_scn               => 1892447,
        p_parallel             => 4,
        p_tag                  => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up an archived redo log from a sequence number range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence`. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
`p_from_sequence`	number	A sequence	—	Yes	The starting sequence number

Parameter name	Data type	Valid values	Default	Required	Description
		number an archived redo log that exists on disk. The value must be less than or equal to the value specified for `p_to_sequence`.			for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
p_to_sequence	number	A sequence number of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_sequence .	—	Yes	The ending sequence number for the archived log backups.

The following example backs up archived redo logs in the sequence number range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_from_sequence       => 11160,
        p_to_sequence         => 11160,
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing a full database backup

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_full`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a full backup of the DB instance using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_full(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
```

```
END;
/
```

Performing a full backup of a tenant database

You can perform a backup of all data blocks included a tenant database in a container database (CDB). Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_full`. This procedure applies only to the current database backup and uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

The `rdsadmin_rman_util.backup_tenant_full` procedure is supported for the following RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example performs a full backup of the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tenant_full(
        p_owner               => 'SYS',
```

```
        p_directory_name      => 'MYDIRECTORY',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'FULL_TENANT_DB_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing an incremental database backup

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`.

For more information about incremental backups, see Incremental backups in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_level	number	0, 1	0	No	Specify 0 to enable a full incremental backup. Specify 1 to enable a non-cumulative incremental backup.

The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_database_incremental(
        p_owner                => 'SYS',
        p_directory_name       => 'MYDIRECTORY',
        p_level                => 1,
        p_parallel             => 4,
        p_section_size_mb      => 10,
        p_tag                  => 'MY_INCREMENTAL_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing an incremental backup of a tenant database

You can perform an incremental backup of the current tenant database in your CDB. Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_incremental`.

For more information about incremental backups, see Incremental backups in the Oracle Database documentation.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- p_owner

- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_include_controlfile
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_level	number	0, 1	0	No	Specify 0 to enable a full incremental backup. Specify 1 to enable a non-cumulative incremental backup.

The following example performs an incremental backup of the current tenant database using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tenant_incremental(
        p_owner                => 'SYS',
        p_directory_name       => 'MYDIRECTORY',
        p_level                => 1,
        p_parallel             => 4,
        p_section_size_mb      => 10,
        p_tag                  => 'MY_INCREMENTAL_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up a tablespace

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures.

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_tablespace_name	varchar2	A valid tablespace name.	—	Yes	The name of the tablespace to back up.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a tablespace backup using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tablespace(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_tablespace_name     => 'MYTABLESPACE',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'MYTABLESPACE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`

- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example backs up a control file using the specified values for the parameters.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_current_controlfile(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_tag                 => 'CONTROL_FILE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

Performing block media recovery

You can recovery individual data blocks, known as *block media recovery*, using the Amazon RDS procedures rdsadmin.rdsadmin_rman_util.recover_datafile_block. You can use this overloaded procedure to recover either an individual data block or a range of data blocks.

This procedure uses the following common parameter for RMAN tasks:

- p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures.

This procedure uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_datafile	NUMBER	A valid data file ID number.	—	Yes	The data file containing the corrupt blocks. Specify the data file in either of the following ways: • The data file ID number, which is located in V$DATAFILE.FILE# • The full data file name, including the path, located in V$DATAFILE.NAME
p_block	NUMBER	A valid integer.	—	Yes	The number of an individual block to be recovered. The following parameters are mutually exclusive: • p_block • p_from_block and p_to_block
p_from_block	NUMBER	A valid integer.	—	Yes	The first block number in a range of blocks to be recovered. The following parameters are mutually exclusive: • p_block

Parameter name	Data type	Valid values	Default	Required	Description
					• p_from_block and p_to_block
p_to_block	NUMBER	A valid integer.	—	Yes	The last block number in a range of blocks to be recovered. The following parameters are mutually exclusive: • p_block • p_from_block and p_to_block

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example recovers block 100 in data file 5.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.recover_datafile_block(
        p_datafile            => 5,
        p_block               => 100,
        p_rman_to_dbms_output => TRUE);
END;
/
```

The following example recovers blocks 100 to 150 in data file 5.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.recover_datafile_block(
        p_datafile            => 5,
        p_from_block          => 100,
        p_to_block            => 150,
```

```
        p_rman_to_dbms_output => TRUE);
END;
/
```

Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. In such cases, Oracle Support recommends that you modify the schedule. If you need to enable or disable SYS jobs, test the operation on scheduled jobs in a test environment before implementing it in a production environment. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the Amazon RDS for Oracle DB engine versions shown in the following table. When using this package, you can specify the SYS jobs listed in the table.

Database release	Jobs enabled by default	Jobs disabled by default
Oracle Database 19c	BSLN_MAINTAIN_STATS_JOB CLEANUP_NON_EXIST_OBJ CLEANUP_ONLINE_IND_BUILD CLEANUP_ONLINE_PMO CLEANUP_TAB_IOT_PMO CLEANUP_TRANSIENT_PKG CLEANUP_TRANSIENT_TYPE DRA_REEVALUATE_OPEN_FAILU RES FILE_SIZE_UPD ORA$AUTOTASK_CLEAN PMO_DEFERRED_GIDX_MAINT_JO B PURGE_LOG RSE$CLEAN_RECOVERABLE_SC RIPT SM$CLEAN_AUTO_SPLIT_MERGE	FGR$AUTOPURGE_JOB FILE_WATCHER HM_CREATE_OFFLINE_DICTIONARY LOAD_OPATCH_INVENTORY ORA$PREPLUGIN_BACKUP_JOB XMLDB_NFS_CLEANUP_JOB
Oracle Database 21c	BSLN_MAINTAIN_STATS_JOB CLEANUP_NON_EXIST_OBJ CLEANUP_ONLINE_IND_BUILD	FGR$AUTOPURGE_JOB FILE_WATCHER HM_CREATE_OFFLINE_DICTIONARY

Database release	Jobs enabled by default	Jobs disabled by default
	CLEANUP_ONLINE_PMO CLEANUP_TAB_IOT_PMO CLEANUP_TRANSIENT_PKG CLEANUP_TRANSIENT_TYPE DRA_REEVALUATE_OPEN_FAILURES FILE_SIZE_UPD ORA$AUTOTASK_CLEAN PMO_DEFERRED_GIDX_MAINT_JOB PURGE_LOG	LOAD_OPATCH_INVENTORY ORA$PREPLUGIN_BACKUP_JOB ORA$_ATSK_AUTOSTS XMLDB_NFS_CLEANUP_JOB

Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
name	varchar2	The procedures listed in the table in Performing common scheduling tasks for Oracle DB instances	—	Yes	The name of the job to modify.

Parameter name	Data type	Valid values	Default	Required	Description
attribute	varchar2	'REPEAT_INTERVAL' _NAME'	–	Yes	Attribute to modify. To modify the repeat interval for the job, specify 'REPEAT_INTERVAL' . To modify the schedule name for the job, specify 'SCHEDULE_NAME' .
value	varchar2	A valid schedule interval or schedule name, depending on attribute used.	–	Yes	The new value of the attribute.

Modifying DBMS_SCHEDULER jobs

To modify certain components of Oracle Scheduler, use the Oracle procedure dbms_scheduler.set_attribute. For more information, see DBMS_SCHEDULER and SET_ATTRIBUTE procedure in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name SYS to the object name. The following example sets the resource plan attribute for the Monday window object.

```
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE(
        name      => 'SYS.MONDAY_WINDOW',
```

```
        attribute => 'RESOURCE_PLAN',
        value     => 'resource_plan_1');
END;
/
```

Modifying AutoTask maintenance windows

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated maintenance tasks such as optimizer statistics collection run during these windows. By default, the maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the `DBMS_SCHEDULER` package. You might need to modify the maintenance window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For example, if the default maintenance plan is specified, and if the maintenance window opens while the database is under load, you might see wait events such as `resmgr:cpu quantum`. This wait event is related to Database Resource Manager. You have the following options:
  - Ensure that maintenance windows are active during off-peak times for your DB instance.
  - Disable the default maintenance plan by setting the `resource_plan` attribute to an empty string.
  - Set the `resource_manager_plan` parameter to `FORCE:` in your parameter group. If your instance uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

To modify your maintenance window settings

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

   The following example queries the configuration for `MONDAY_WINDOW`.

   ```
   SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
   FROM   DBA_SCHEDULER_WINDOWS
   WHERE  WINDOW_NAME='MONDAY_WINDOW';
   ```

The following output shows that the window is using the default values.

```
ENABLED         RESOURCE_PLAN                  DURATION         REPEAT_INTERVAL
--------------- ------------------------------ ----------------
 ------------------------------
TRUE            DEFAULT_MAINTENANCE_PLAN       +000 04:00:00
 freq=daily;byday=MON;byhour=22
                                                                 ;byminute=0;
 bysecond=0
```

3. Modify the window using the DBMS_SCHEDULER package.

   The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```
BEGIN
  -- disable the window to make changes
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);

  -- specify the empty string to use no plan
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
 attribute=>'RESOURCE_PLAN', value=>'');

  -- re-enable the window
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

   The following example sets the maximum duration of the window to 2 hours.

```
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
 attribute=>'DURATION', value=>'0 2:00:00');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

   The following example sets the repeat interval to every Monday at 10 AM.

```
BEGIN
```

```
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
 attribute=>'REPEAT_INTERVAL',
 value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/
```

Setting the time zone for Oracle Scheduler jobs

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure `dbms_scheduler.set_scheduler_attribute`. For more information about the `dbms_scheduler` package, see DBMS_SCHEDULER and SET_SCHEDULER_ATTRIBUTE in the Oracle documentation.

To modify the current time zone setting

1. Connect to the database using a client such as SQL Developer. For more information, see Connecting to your DB instance using Oracle SQL developer.
2. Set the default time zone as following, substituting your time zone for *`time_zone_name`*.

```
BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
    attribute => 'default_timezone',
    value => 'time_zone_name'
  );
END;
/
```

In the following example, you change the time zone to Asia/Shanghai.

Start by querying the current time zone, as shown following.

```
SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE
 ATTRIBUTE_NAME='DEFAULT_TIMEZONE';
```

The output shows that the current time zone is ETC/UTC.

```
VALUE
```

```
-------
Etc/UTC
```

Then you set the time zone to Asia/Shanghai.

```
BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
    attribute => 'default_timezone',
    value => 'Asia/Shanghai'
  );
END;
/
```

For more information about changing the system time zone, see Oracle time zone.

Turning off Oracle Scheduler jobs owned by SYS

To disable an Oracle Scheduler job owned by the SYS user, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the `name` common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures.

The following example disables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
   rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

Turning on Oracle Scheduler jobs owned by SYS

To turn on an Oracle Scheduler job owned by SYS, use the `rdsadmin.rdsadmin_dbms_scheduler.enable` procedure.

This procedure uses the `name` common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures.

The following example enables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
   rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
```

```
END;
/
```

Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of `CALENDAR` type, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the following common parameters for Oracle Scheduler tasks:

- `name`
- `attribute`
- `value`

For more information, see Common parameters for Oracle Scheduler procedures.

The following example modifies the repeat interval of the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
     rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
          name      => 'SYS.CLEANUP_ONLINE_IND_BUILD',
          attribute => 'repeat_interval',
          value     => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/
```

Modifying the Oracle Scheduler repeat interval for jobs of NAMED type

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard Oracle `sys.dbms_scheduler.create_schedule` procedure to do this. Also, use the `rdsadmin.rdsadmin_dbms_scheduler.set_attribute procedure` to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- `name`
- `attribute`

- `value`

For more information, see Common parameters for Oracle Scheduler procedures.

The following example modifies the repeat interval of the `SYS.BSLN_MAINTAIN_STATS_JOB` Oracle Scheduler job.

```
BEGIN
     DBMS_SCHEDULER.CREATE_SCHEDULE (
          schedule_name   => 'rds_master_user.new_schedule',
          start_date      => SYSTIMESTAMP,
          repeat_interval =>
 'freq=daily;byday=MON,TUE,WED,THU,FRI;byhour=0;byminute=0;bysecond=0',
          end_date        => NULL,
          comments        => 'Repeats daily forever');
END;
/

BEGIN
     rdsadmin.rdsadmin_dbms_scheduler.set_attribute (
          name      => 'SYS.BSLN_MAINTAIN_STATS_JOB',
          attribute => 'schedule_name',
          value     => 'rds_master_user.new_schedule');
END;
/
```

Turning off autocommit for Oracle Scheduler job creation

When `DBMS_SCHEDULER.CREATE_JOB` creates Oracle Scheduler jobs, it creates the jobs immediately and commits the changes. You might need to incorporate the creation of Oracle Scheduler jobs in the user transaction to do the following:

- Roll back the Oracle Schedule job when the user transaction is rolled back.
- Create the Oracle Scheduler job when the main user transaction is committed.

You can use the procedure `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag` to turn on this behavior. This procedure takes no parameters. You can use this procedure in the following RDS for Oracle releases:

- 21.0.0.0.ru-2022-07.rur-2022-07.r1 and higher

- 19.0.0.0.ru-2022-07.rur-2022-07.r1 and higher

The following example turns off autocommit for Oracle Scheduler, creates an Oracle Scheduler job, and then rolls back the transaction. Because autocommit is turned off, the database also rolls back the creation of the Oracle Scheduler job.

```
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag;
  DBMS_SCHEDULER.CREATE_JOB(job_name   => 'EMPTY_JOB',
                            job_type   => 'PLSQL_BLOCK',
                            job_action => 'begin null; end;',
                            auto_drop  => false);
  ROLLBACK;
END;
/

PL/SQL procedure successfully completed.

SELECT * FROM DBA_SCHEDULER_JOBS WHERE JOB_NAME='EMPTY_JOB';

no rows selected
```

Diagnosing problems with RDS for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a *problem* is a critical error such as a code bug or data corruption. An *incident* is the occurrence of a problem. If the same error occurs three times, then the infrastructure shows three incidents of this problem. For more information, see Diagnosing and resolving problems in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate problems and package diagnostic data. An *incident package* includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your RDS for Oracle DB instance, use the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`.

By using the functions in `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of log file that contains the ADRCI output, as in `dbtask-`*`task_id`*`.log`. The log file resides in the BDUMP directory. You can download the log file by following the procedure described in Downloading a database log file.

Common parameters for diagnostic procedures

To perform diagnostic tasks, use functions in the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
`incident_id`	number	A valid incident ID or null	Null	No	If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.
`problem_id`	number	A valid problem ID or null	Null	No	If the value is null, the function shows all problems. If the value isn't null and represents a valid problem ID, the function shows the specified problem.
`last`	number	A valid integer greater than 0 or null	Null	No	If the value is null, then the function displays at most 50 items. If the value isn't null, the function

Parameter name	Data type	Valid values	Default	Required	Description
					displays the specified number.

Listing incidents

To list diagnostic incidents for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents`. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:

- `incident_id`
- `problem_id`
- `last`

If you specify `incident_id` and `problem_id`, then `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures.

This function uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
`detail`	boolean	TRUE or FALSE	FALSE	No	If TRUE, the function lists incidents in detail mode. If FALSE, the function lists incidents in basic mode.

To list all incidents, query the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments. The query returns the task ID.

```
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;
```

```
TASK_ID
------------------
1590786706158-3126
```

Or call the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;

PL/SQL procedure successfully completed.
```

To read the log file, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`.

By default, the function lists the 50 most recent problems.

This function uses the common parameters `problem_id` and `last`. For more information, see Common parameters for diagnostic procedures.

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;

PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file` function, supplying the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

Creating incident packages

You can create incident packages using the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package`. The output is a .zip file that you can supply to Oracle Support.

This function uses the following common parameters:

- `problem_id`
- `incident_id`

Make sure to specify one of the preceding parameters. If you specify both parameters, `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures.

To create a package for a specific incident, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package` with the `incident_id` parameter. The following example creates a package for incident 53523.

```
SQL> EXEC :task_id :=
 rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);

PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file`. You can supply the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212043_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

TEXT
--------------------------------------------------------------------------------
2020-05-29 21:20:43.031 UTC [INFO ] The ADRCI package is being created.

2020-05-29 21:20:47.642 UTC [INFO ] The task finished successfully.
```

To package diagnostic data for a particular problem, specify its ID using the `problem_id` parameter. In the following example, you package data for problem 3 only.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);

PL/SQL procedure successfully completed.
```

To read the task output, call `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212111_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log'));

TEXT
--------------------------------------------------------------------------------
2020-05-29 21:21:11.050 UTC [INFO ] The ADRCI package is being created.
2020-05-29 21:21:15.646 UTC [INFO ] Generated package 2 in file /rdsdbdata/log/trace/
ORA700EVE_20200529212111_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.
2020-05-29 21:21:15.646 UTC [INFO ] The task finished successfully.
```

You can also download the log file. For more information, see Downloading a database log file.

Showing trace files

You can use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` to list trace files under the trace directory and all incident directories under the current ADR home. You can also show the contents of trace files and incident trace files.

This function uses the following parameter.

Parameter name	Data type	Valid values	Default	Required	Description
`filename`	varchar2	A valid trace file name	Null	No	If the value is null, the function shows all trace files. If it isn't null, the function shows the specified file.

To show the trace file, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile`.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;

PL/SQL procedure successfully completed.
```

To list the trace file names, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';

TEXT
--------------------------------------------------------------
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-28
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-27
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-26
     diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-25

You can also download the log file. For more information, see Downloading a database log file.

Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics

- Creating and dropping directories in the main data storage space
- Listing files in a DB instance directory
- Reading files in a DB instance directory
- Accessing Opatch files
- Managing advisor tasks
- Transporting tablespaces

Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_directory`. You can create up to 10,000 directories, all located in your main data storage space. To drop directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_directory`.

The `create_directory` and `drop_directory` procedures have the following required parameter.

Parameter name	Data type	Default	Required	Description
`p_directory_name`	VARCHAR2	—	Yes	The name of the directory.

The following example creates a new directory named PRODUCT_DESCRIPTIONS.

```
EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name =>
 'product_descriptions');
```

The data dictionary stores the directory name in uppercase. You can list the directories by querying DBA_DIRECTORIES. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named PRODUCT_DESCRIPTIONS:

```
SELECT DIRECTORY_PATH
  FROM DBA_DIRECTORIES
 WHERE DIRECTORY_NAME='PRODUCT_DESCRIPTIONS';

DIRECTORY_PATH
--------------------------------------
/rdsdbdata/userdirs/01
```

The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. EXECUTE privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named PRODUCT_DESCRIPTIONS.

```
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

Note

You can also drop a directory by using the Oracle SQL command DROP DIRECTORY.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use UTL_FILE.FREMOVE to remove files from the directory. For more information, see FREMOVE procedure in the Oracle documentation.

Listing files in a DB instance directory

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. This procedure isn't supported on an Oracle replica. The `listdir` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_directory`	varchar2	—	Yes	The name of the directory to list.

The following example grants read/write privileges on the directory `PRODUCT_DESCRIPTIONS` to user `rdsadmin`, and then lists the files in this directory.

```
GRANT READ,WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory =>
 'PRODUCT_DESCRIPTIONS'));
```

Reading files in a DB instance directory

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
`p_directory`	varchar2	—	Yes	The name of the directory that contains the file.
`p_filename`	varchar2	—	Yes	The name of the file to read.

The following example creates the file `rice.txt` in the directory `PRODUCT_DESCRIPTIONS`.

```
declare
  fh sys.utl_file.file_type;
```

```
begin
  fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
 open_mode=>'w');
  utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
  utl_file.fclose(file=>fh);
end;
/
```

The following example reads the file `rice.txt` from the directory `PRODUCT_DESCRIPTIONS`.

```
SELECT * FROM TABLE
    (rdsadmin.rds_file_util.read_text_file(
        p_directory => 'PRODUCT_DESCRIPTIONS',
        p_filename  => 'rice.txt'));
```

Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software. The Oracle mechanism for determining which patches have been applied to a database is the `opatch lsinventory` command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle Support requests the `lsinventory` file and sometimes the `lsinventory_detail` file generated by Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead, the `lsinventory-`*`dbv`*`.txt` in the BDUMP directory contains the patch information related to your current engine version. When you perform a minor or major upgrade, Amazon RDS updates `lsinventory-`*`dbv`*`.txt` within an hour of applying the patch. To verify the applied patches, read `lsinventory-`*`dbv`*`.txt`. This action is similar to running the `opatch lsinventory` command.

> **Note**
>
> The examples in this section assume that the BDUMP directory is named `BDUMP`. On a read replica, the BDUMP directory name is different. To learn how to get the BDUMP name by querying `V$DATABASE.DB_UNIQUE_NAME` on a read replica, see Listing files.

The inventory files use the Amazon RDS naming convention `lsinventory-`*`dbv`*`.txt` and `lsinventory_detail-`*`dbv`*`.txt`, where *`dbv`* is the full name of your DB version.

The `lsinventory-dbv.txt` file is available on all DB versions. The corresponding `lsinventory_detail-dbv.txt` is available on 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later.

For example, if your DB version is 19.0.0.0.ru-2021-07.rur-2021-07.r1, then your inventory files have the following names.

```
lsinventory-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
lsinventory_detail-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
```

Ensure that you download the files that match the current version of your DB engine.

Console

To download an inventory file using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

SQL

To read the `lsinventory-dbv.txt` in a SQL client, you can use a `SELECT` statement. For this technique, use either of the following `rdsadmin` functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace *dbv* with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```
SELECT text
FROM   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-dbv.txt'));
```

PL/SQL

To read the `lsinventory-dbv.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace *dbv* with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```
SET SERVEROUTPUT ON
DECLARE
  v_file              SYS.UTL_FILE.FILE_TYPE;
  v_line              VARCHAR2(1000);
  v_oracle_home_type  VARCHAR2(1000);
  c_directory         VARCHAR2(30) := 'BDUMP';
  c_output_file       VARCHAR2(30) := 'lsinventory-dbv.txt';
BEGIN
  v_file := SYS.UTL_FILE.FOPEN(c_directory, c_output_file, 'r');
  LOOP
    BEGIN
      SYS.UTL_FILE.GET_LINE(v_file, v_line,1000);
      DBMS_OUTPUT.PUT_LINE(v_line);
    EXCEPTION
      WHEN no_data_found THEN
        EXIT;
    END;
  END LOOP;
END;
/
```

Or query `rdsadmin.tracefile_listing`, and spool the output to a file. The following example spools the output to `/tmp/tracefile.txt`.

```
SPOOL /tmp/tracefile.txt
SELECT *
FROM   rdsadmin.tracefile_listing
WHERE  FILENAME LIKE 'lsinventory%';
SPOOL OFF;
```

Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the `rdsadmin.rdsadmin_util` package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions

  For more information, see Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 in the *Amazon RDS for Oracle Release Notes*.

Topics

- Setting parameters for advisor tasks
- Disabling AUTO_STATS_ADVISOR_TASK
- Re-enabling AUTO_STATS_ADVISOR_TASK

Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_set_parameter`. The `advisor_task_set_parameter` procedure has the following parameters.

Parameter name	Data type	Default	Require	Description
`p_task_name`	varchar2	—	Yes	The name of the advisor task whose parameters you want to change. The following values are valid: • `AUTO_STATS_ADVISOR_TASK` • `INDIVIDUAL_STATS_ADVISOR_TASK` • `SYS_AUTO_SPM_EVOLVE_TASK` • `SYS_AUTO_SQL_TUNING_TASK`

Parameter name	Data type	Default	Require	Description

p_parameter	varchar2	—	Yes	The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute *p_task_name* with a valid value for p_task_name :
				`COL PARAMETER_NAME FORMAT a30`
				`COL PARAMETER_VALUE FORMAT a30`
				`SELECT PARAMETER_NAME, PARAMETER_VALUE`
				`FROM DBA_ADVISOR_PARAMETERS`
				`WHERE TASK_NAME='  p_task_name '`
				`AND PARAMETER_VALUE != 'UNUSED'`
				`ORDER BY PARAMETER_NAME;`

p_value	varchar2	—	Yes	The value for a task parameter. To find valid values for task parameters, run the following query. Substitute *p_task_name* with a valid value for p_task_name :
				`COL PARAMETER_NAME FORMAT a30`
				`COL PARAMETER_VALUE FORMAT a30`
				`SELECT PARAMETER_NAME, PARAMETER_VALUE`
				`FROM DBA_ADVISOR_PARAMETERS`
				`WHERE TASK_NAME='  p_task_name '`
				`AND PARAMETER_VALUE != 'UNUSED'`
				`ORDER BY PARAMETER_NAME;`

The following PL/SQL program sets ACCEPT_PLANS to FALSE for SYS_AUTO_SPM_EVOLVE_TASK. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```
BEGIN
  rdsadmin.rdsadmin_util.advisor_task_set_parameter(
```

```
    p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
    p_parameter => 'ACCEPT_PLANS',
    p_value     => 'FALSE');
END;
```

The following PL/SQL program sets EXECUTION_DAYS_TO_EXPIRE to 10 for AUTO_STATS_ADVISOR_TASK. The predefined task AUTO_STATS_ADVISOR_TASK runs automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```
BEGIN
  rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'AUTO_STATS_ADVISOR_TASK',
    p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
    p_value     => '10');
END;
```

Disabling AUTO_STATS_ADVISOR_TASK

To disable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_drop. The advisor_task_drop procedure accepts the following parameter.

Parameter name	Data type	Default	Require	Description
p_task_name	varchar2	—	Yes	The name of the advisor task to be disabled. The only valid value is AUTO_STATS_ADVISOR_TASK .

The following command drops AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.advisor_task_drop('AUTO_STATS_ADVISOR_TASK')
```

You can re-enable AUTO_STATS_ADVISOR_TASK using rdsadmin.rdsadmin_util.dbms_stats_init.

Re-enabling AUTO_STATS_ADVISOR_TASK

To re-enable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_stats_init`. The `dbms_stats_init` procedure takes no parameters.

The following command re-enables AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.dbms_stats_init()
```

Transporting tablespaces

Use the Amazon RDS package `rdsadmin.rdsadmin_transport_util` to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, the transportable tablespace feature incrementally copies source data files and metadata files to your target instance. You can transfer the files using either Amazon EFS or Amazon S3. For more information, see Migrating using Oracle transportable tablespaces.

Topics

- Importing transported tablespaces to your DB instance
- Importing transportable tablespace metadata into your DB instance
- Listing orphaned files after a tablespace import
- Deleting orphaned data files after a tablespace import

Importing transported tablespaces to your DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore tablespaces that you have previously exported from a source DB instance. In the transport phase, you back up your read-only tablespaces, export Data Pump metadata, transfer these files to your target DB instance, and then import the tablespaces. For more information, see Phase 4: Transport the tablespaces.

Syntax

```
FUNCTION import_xtts_tablespaces(
    p_tablespace_list IN CLOB,
    p_directory_name  IN VARCHAR2,
    p_platform_id     IN NUMBER DEFAULT 13,
```

```
    p_parallel        IN INTEGER DEFAULT 0) RETURN VARCHAR2;
```

Parameters

Parameter name	Data type	Default	Required	Description
p_tablespace_list	CLOB	—	Yes	The list of tablespaces to import.
p_directory_name	VARCHAR2	—	Yes	The directory that contains the tablespace backups.
p_platform_id	NUMBER	13	No	Provide a platform ID that matches the one specified during the backup phase. To find a list of platforms, query V$TRANSPORTABLE_PLATFORM . The default platform is Linux x86 64-bit, which is little endian.
p_parallel	INTEGER	0	No	The degree of parallelism. By default, parallelism is disabled.

Examples

The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA_PUMP_DIR*. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying V$TRANSPORTABLE_PLATFORM.

```
VAR task_id CLOB

BEGIN
  :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
        'TBS1,TBS2,TBS3',
        'DATA_PUMP_DIR',
```

```
        p_platform_id => 6);
END;
/

PRINT task_id
```

Importing transportable tablespace metadata into your DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata` to import transportable tablespace metadata into your RDS for Oracle DB instance. During the operation, the status of the metadata import is shown in the table `rdsadmin.rds_xtts_operation_info`. For more information, see Step 5: Import tablespace metadata on your target DB instance.

Syntax

```
PROCEDURE import_xtts_metadata(
    p_datapump_metadata_file IN SYS.DBA_DATA_FILES.FILE_NAME%TYPE,
    p_directory_name         IN VARCHAR2,
    p_exclude_stats          IN BOOLEAN DEFAULT FALSE,
    p_remap_tablespace_list  IN CLOB DEFAULT NULL,
    p_remap_user_list        IN CLOB DEFAULT NULL);
```

Parameters

Parameter name	Data type	Default	Required	Description
p_datapum p_metadat a_file	SYS.DBA_DATA_FILES .FILE_NAME%TYPE	—	Yes	The name of the Oracle Data Pump file that contains the metadata for your transportable tablespaces.
p_directo ry_name	VARCHAR2	—	Yes	The directory that contains the Data Pump file.
p_exclude_stats	BOOLEAN	FALSE	No	Flag that indicates whether to exclude statistics.

Parameter name	Data type	Default	Required	Description
p_remap_tablespace_list	CLOB	NULL	No	A list of tablespaces to be remapped during the metadata import. Use the format *from_tbs*:*to_tbs*. For example, specify users:user_data .
p_remap_user_list	CLOB	NULL	No	A list of user schemas to be remapped during the metadata import. Use the format *from_schema_name* :*to_schema_name* . For example, specify hr:human_resources .

Examples

The example imports the tablespace metadata from the file *xttdump.dmp*, which is located in directory *DATA_PUMP_DIR*.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
END;
/
```

Listing orphaned files after a tablespace import

Use the rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files procedure to list data files that were orphaned after a tablespace

import. After you identify the data files, you can delete them by calling `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

Syntax

```
FUNCTION list_xtts_orphan_files RETURN xtts_orphan_files_list_t PIPELINED;
```

Examples

The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`. The output shows two data files that are orphaned.

```
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);

FILENAME       FILESIZE
-------------- ---------
datafile_7.dbf 104865792
datafile_8.dbf 104865792
```

Deleting orphaned data files after a tablespace import

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete data files that were orphaned after a tablespace import. Running this command generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-`*`YYYY-MM-DD.HH24-MI-SS.FF`*`.log` in the BDUMP directory. Use the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import` to find the orphaned files. You can read the log file by calling the procedure `rdsadmin.rds_file_util.read_text_file`. For more information, see Phase 6: Clean up leftover files.

Syntax

```
PROCEDURE cleanup_incomplete_xtts_import(
    p_directory_name IN VARCHAR2);
```

Parameters

Parameter name	Data type	Default	Required	Description
p_directory_name	VARCHAR2	—	Yes	The directory that contains the orphaned data files.

Examples

The following example deletes the orphaned data files in *DATA_PUMP_DIR*.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The following example reads the log file generated by the previous command.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
       p_directory => 'BDUMP',
       p_filename  => 'rds-xtts-
delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));

TEXT
--------------------------------------------------------------------------------
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```

Working with storage in RDS for Oracle

Every RDS for Oracle instance has a primary storage volume. To increase storage capacity, you can attach up to three additional storage volumes to your DB instance. Depending on your workload requirements, choose between gp3 and io2 storage for each volume. For example, you might put frequently accessed data on an io2 volume and historical data on a gp3 volume.

Use additional storage volumes to enable the following benefits:

- **Enhanced capacity** – Scale your total storage up to 256 TiB per DB instance by attaching up to three additional storage volumes.
- **Flexible storage configuration and performance optimization** – Mix different storage types (gp3 and io2) to optimize for both cost and performance based on your data access patterns. Separate frequently accessed data on high-performance io2 storage from archival data on cost-effective gp3 storage.
- **Expand and reduce storage capacity as needed** – Attach a volume when you need additional storage, as during data migration, and then later delete the volume. In this way, you can expand and reduce the total DB instance storage.
- **Online data movement** – Use the built-in capabilities of Oracle database to move data between volumes without downtime.

> **Note**
>
> You can remove additional storage volumes, but you can't remove the primary volume.

Topics

- Considerations for using additional storage volumes with RDS for Oracle
- Limitations of using additional storage volumes with RDS for Oracle
- Database management operations with additional storage volumes in RDS for Oracle
- Add, remove, or modify storage volumes with RDS for Oracle
- Backing up and restoring data with additional storage volumes in RDS for Oracle
- Use cases for additional storage volumes in RDS for Oracle

Considerations for using additional storage volumes with RDS for Oracle

Consider the following when using additional storage volumes with RDS for Oracle:

- You can add up to 3 additional storage volumes per instance.
- Additional storage volumes must use the following volume names:
  - rdsdbdata2
  - rdsdbdata3
  - rdsdbdata4
- You can only add General Purpose SSD (gp3) and Provisioned IOPS SSD (io2) storage types.
- You can use Oracle's online relocation capabilities to move data between volumes while your applications continue running.
- When you create an additional storage volume by modifying the DB instance, RDS immediately creates the storage volume regardless of the schedule modifications setting. Adding a storage volume is an online operation and does not impact your database performance. See Using the schedule modifications setting.

For optimal performance, check the following when you are using additional storage volumes:

- Data movement planning
  - Schedule large movements during off-peak hours
  - Break large operations into smaller chunks
  - Monitor system resources during moves
- Resource management
  - Keep sufficient free space on both volumes
  - Monitor I/O patterns using AWR or Statspack
  - Watch for storage-full scenarios
- Best practices
  - Use online datafile relocation operations where possible
  - Maintain appropriate indexes
  - Regularly monitor space usage

When using additional storage volumes with replicas:

- When you are creating an RDS for Oracle replica for a DB instance that has additional storage volumes, RDS automatically configures additional storage volumes on the replica. However, any subsequent modifications made in storage volumes of your primary DB instance are not automatically applied to the replica.
- When managing datafile locations across volumes, we recommend using parameter group settings instead of session-level changes to ensure consistent behavior between primary and replica instances.

Limitations of using additional storage volumes with RDS for Oracle

The following limitations apply to using additional storage volumes with RDS for Oracle:

- You can’t add a storage volume to the instance types with less than 64GiB memory because they don’t have sufficient memory to support large storage volumes.
- The minimum storage size is 200GiB for additional storage volumes. The primary storage volume of your DB instance should be equal to or larger than 200GiB to attach additional storage volumes. The maximum storage size for your DB instance is 256 TiB total across all volumes.
- The following capabilities aren’t supported for DB instances with additional storage volumes:
  - Cross-region automated backups
  - Storage autoscaling (for additional storage volumes)
  - Cross-account snapshot copy
  - Public snapshots
- You can't delete the primary storage volume (`rdsdbdata`), but you can delete other additional storage volumes as long as they're empty.
- You can't store the online redo logs, archived redo logs, and control files in additional storage volumes. These files can only be stored in the primary storage volume (`rdsdbdata`).

Database management operations with additional storage volumes in RDS for Oracle

You can perform database management operations such as creating tablespaces or moving data between storage volumes while using additional storage volumes in RDS for Oracle. For more

information about database management operations with additional storage volumes, see the following sections:

- Specifying database file locations in RDS for Oracle
- Creating and sizing tablespaces in RDS for Oracle
- Moving data files between volumes in RDS for Oracle

Add, remove, or modify storage volumes with RDS for Oracle

You can add, modify, and remove additional storage volumes using the AWS Management Console or AWS CLI. All operations use the `modify-db-instance` command with the `additional-storage-volumes` parameter.

> **Important**
>
> Adding or removing additional storage volumes creates a backup pending action and a blackout window. The blackout window closes when the backup workflow completes.

Adding storage volumes

You can add up to three storage volumes beyond the primary storage volume. To add a new storage volume to your RDS for Oracle DB instance, use the `modify-db-instance` command with the `additional-storage-volumes` parameter.

The following code snippet adds a mew 5,000 GiB general purpose SSD (gp3) volume with 4000 provision IOPS name `rdsdbdata3`.

```
aws rds modify-db-instance \
  --db-instance-identifier my-oracle-instance \
  --region us-east-1 \
  --additional-storage-volumes '[
        {
            "VolumeName":"rdsdbdata3",
            "StorageType":"gp3",
            "AllocatedStorage":5000
            "IOPS":4000}
```

```
    ]' \
  --apply-immediately
```

Modifying storage volumes

You can modify storage type, allocated storage size, IOPS, and storage throughput settings of your additional storage volume. The following code snippet modifies the IOPS setting for the `rdsdbdata2` volume.

```
aws rds modify-db-instance \
  --db-instance-identifier my-oracle-instance \
  --region us-east-1 \
  --additional-storage-volumes '[
        {
            "VolumeName":"rdsdbdata2",
            "IOPS":8000}
    ]' \
  --apply-immediately
```

Note

You can't reduce the storage allocation for an additional storage volume once you've added it to the instance.

Removing storage volumes

You can remove additional storage volumes from RDS for Oracle DB instances when they are no longer needed. Before removing a volume, make sure that you have moved all database files from the volume and no database objects are referencing it. Verify that the volume status is `Not-in-use`. You can remove additional storage volumes, but you can't remove the primary storage volume.

Warning

Before you remove an additional storage volume, make sure that no database files are stored on the volume. Removing a volume with active database files causes database corruption.

The following example removes the `rdsdbdata4` volume.

```
aws rds modify-db-instance \
  --db-instance-identifier my-oracle-instance \
  --region us-east-1 \
  --additional-storage-volumes '[
        {
            "VolumeName":"rdsdbdata2",
            "SetForDelete":true}
    ]' \
  --apply-immediately
```

Backing up and restoring data with additional storage volumes in RDS for Oracle

You can use automated backups and create a DB snapshot with your DB instance with additional storage volumes. All backup operations include both the primary volume and additional storage volumes. You can also use point-in-time recovery for your DB instance with additional storage volumes. When you restore your database, you can add storage volumes. You can also modify the storage settings of existing volumes. You cannot delete additional storage volumes when you restore your database from a snapshot.

Topics

- Creating manual snapshots
- Restoring manual snapshots
- Point-in-time recovery

Creating manual snapshots

The following example creates a manual snapshot of your database with additional storage volumes:

```
aws rds create-db-snapshot \
--db-instance-identifier my-oracle-asv-instance \
--db-snapshot-identifier my-snapshot
```

Restoring manual snapshots

When restoring from a snapshot, you can add new additional storage volumes or modify the IOPS or throughput settings of existing volumes. The following example restores a DB instance from a snapshot and modifies the IOPS setting for the `rdsdbdata2` volume:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier my-restored-instance \
  --db-snapshot-identifier my-snapshot \
  --region us-east-1 \
  --additional-storage-volumes '[
        {
            "VolumeName":"rdsdbdata2",
            "IOPS":5000
        }
    ]'
```

Point-in-time recovery

During point-in-time recovery (PITR), you can add new additional storage volumes with custom configurations. The following example performs PITR and adds a new 5,000 GiB General Purpose SSD (gp3) with 5000 IOPS and 200 MB/s storage throughput for the `rdsdbdata2` volume:

```
aws rds restore-db-instance-to-point-in-time \
  --source-db-instance-identifier my-source-instancemy-source-instance \
  --target-db-instance my-pitr-instance\
  --use-latest-restorable-time \
  --region us-east-1 \
  --additional-storage-volumes '[
        {
            "VolumeName":"rdsdbdata2",
            "StorageType":"gp3",
            "AllocatedStorage":5000,
            "IOPS":5000,
            "StorageThroughput":200
        }
    ]'
```

Use cases for additional storage volumes in RDS for Oracle

Additional storage volumes support various database management scenarios. The following sections describe common use cases and implementation approaches.

Topics

- Extending storage capacity beyond 64 TiB
- Storage tiering of frequently and infrequently accessed data on separate volumes
- Temporary storage for data loading and unloading
- Using Oracle transportable tablespaces with an additional storage volume

Extending storage capacity beyond 64 TiB

You can use additional storage volumes when your primary storage volume approaches the 64 TiB limit but need more storage space in your database. You can attach additional storage volumes to your DB instance, each up to 64TiB, using the `modify-db-instance` command. After attaching additional storage volumes, you can create tablespaces on additional storage volumes and move objects such as tables, indexes, and partitions to these tablespaces using standard Oracle SQL. For more information, see Database management operations with additional storage volumes in RDS for Oracle.

Storage tiering of frequently and infrequently accessed data on separate volumes

You can use additional storage volumes to optimize cost and performance by configuring different storage types between volumes. For example, you can use high-performance Provisioned IOPS SSD storage (io2) volumes for frequently accessed data while storing historical data on cost-effective General Purpose (gp3) storage volumes. You can move specific database objects (tables, indexes, and partitions) to these tablespaces using standard Oracle commands. For more information, see Database management operations with additional storage volumes in RDS for Oracle.

Temporary storage for data loading and unloading

You can use additional storage volumes as temporary storage for large data loads or exports with the following steps:

- Create a directory on an additional storage volume with the following command:

```
BEGIN
```

```
rdsadmin.rdsadmin_util.create_directory(
            p_directory_name => 'DATA_PUMP_DIR2',
            p_database_volume_name => 'rdsdbdata2');
END;
/
```

- After the creation of the directory, follow the steps described in Importing using Oracle Data Pump to export and import your data to the new directory.
- After the completion of the operation, remove files and optionally delete the volume to save the storage costs. You can remove the additional storage volume only when the volume is empty.

Using Oracle transportable tablespaces with an additional storage volume

You can use additional storage volumes to move datafiles to an additional storage volume using Oracle transportable tablespaces with the following steps:

- Set db_create_file_dest parameter at session level before importing transportable tablespaces into the target database with an additional storage volume.

```
ALTER SESSION SET db_create_file_dest = '/rdsdbdata2/db';

VAR x CLOB;

BEGIN
:x := rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
p_tablespace_list => 'TBTEST1',
p_directory_name => 'XTTS_DIR_DATA2',
p_platform_id => 13);
END;
/

PRINT :x;
```

- Check the transportable tablespace import status:

```
ALTER SESSION SET nls_date_format = 'DD.MM.YYYY HH24:MI:SS';

COL xtts_operation_start_utc FORMAT A30
COL xtts_operation_end_utc FORMAT A30
COL xtts_operation_state FORMAT A30
COL xtts_operation_type FORMAT A30
```

```
SELECT xtts_operation_start_utc, xtts_operation_type, xtts_operation_state
FROM rdsadmin.rds_xtts_operation_info;
```

- When transportable tablespace import completes, import transportable tablespace metadata.

```
BEGIN
rdsadmin.rdsadmin_transport_util.import_xtts_metadata(
p_datapump_metadata_file => 'xttdump.dmp',
p_directory_name => 'XTTS_DIR_DATA2');
END;
/
```

Configuring advanced RDS for Oracle features

RDS for Oracle supports various advanced features, including HugePages, an instance store, and extended data types.

Topics

- Storing temporary data in an RDS for Oracle instance store
- Turning on HugePages for an RDS for Oracle instance
- Turning on extended data types in RDS for Oracle

Storing temporary data in an RDS for Oracle instance store

Use an instance store for the temporary tablespaces and the Database Smart Flash Cache (the flash cache) on supported RDS for Oracle DB instance classes.

Topics

- Overview of the RDS for Oracle instance store
- Turning on an RDS for Oracle instance store
- Configuring an RDS for Oracle instance store
- Working with an instance store on an Oracle read replica
- Configuring a temporary tablespace group on an instance store and Amazon EBS
- Removing an RDS for Oracle instance store

Overview of the RDS for Oracle instance store

An *instance store* provides temporary block-level storage for an RDS for Oracle DB instance. You can use an instance store for temporary storage of information that changes frequently.

An instance store is based on Non-Volatile Memory Express (NVMe) devices that are physically attached to the host computer. The storage is optimized for low latency, random I/O performance, and sequential read throughput.

The size of the instance store varies by DB instance type. For more information about the instance store, see Amazon EC2 instance store in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

Topics

- Types of data in the RDS for Oracle instance store
- Benefits of the RDS for Oracle instance store
- Supported instance classes for the RDS for Oracle instance store
- Supported engine versions for the RDS for Oracle instance store
- Supported AWS Regions for the RDS for Oracle instance store
- Cost of the RDS for Oracle instance store

Types of data in the RDS for Oracle instance store

You can place the following types of RDS for Oracle temporary data in an instance store:

A temporary tablespace

Oracle Database uses temporary tablespaces to store intermediate query results that don't fit in memory. Larger queries can generate large amounts of intermediate data that needs to be cached temporarily, but doesn't need to persist. In particular, a temporary tablespace is useful for sorts, hash aggregations, and joins. If your RDS for Oracle DB instance uses the Enterprise Edition or Standard Edition 2, you can place a temporary tablespace in an instance store.

The flash cache

The flash cache improves the performance of single-block random reads in the conventional path. A best practice is to size the cache to accommodate most of your active data set. If your RDS for Oracle DB instance uses the Enterprise Edition, you can place the flash cache in an instance store.

By default, an instance store is configured for a temporary tablespace but not for the flash cache. You can't place Oracle data files and database log files in an instance store.

Benefits of the RDS for Oracle instance store

You might consider using an instance store to store temporary files and caches that you can afford to lose. If you want to improve DB performance, or if an increasing workload is causing performance problems for your Amazon EBS storage, consider scaling to an instance class that supports an instance store.

By placing your temporary tablespace and flash cache on an instance store, you get the following benefits:

- Lower read latencies
- Higher throughput
- Reduced load on your Amazon EBS volumes
- Lower storage and snapshot costs because of reduced Amazon EBS load
- Less need to provision high IOPS, possibly lowering your overall cost

By placing your temporary tablespace on the instance store, you deliver an immediate performance boost to queries that use temporary space. When you place the flash cache on the instance store, cached block reads typically have much lower latency than Amazon EBS reads. The flash cache needs to be "warmed up" before it delivers performance benefits. The cache warms up by itself because the database writes blocks to the flash cache as they age out of the database buffer cache.

> **Note**
>
> In some cases, the flash cache causes performance overhead because of cache management. Before you turn on the flash cache in a production environment, we recommend that you analyze your workload and test the cache in a test environment.

Supported instance classes for the RDS for Oracle instance store

Amazon RDS supports the instance store for the following DB instance classes:

- db.m5d
- db.m6id
- db.r5d
- db.r6id
- db.x2idn
- db.x2iedn

RDS for Oracle supports the preceding DB instance classes for the BYOL licensing model only. For more information, see Supported RDS for Oracle DB instance classes and Bring Your Own License (BYOL) for EE and SE2.

To see the total instance storage for the supported DB instance types, run the following command in the AWS CLI.

Example

```
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=*5d.*large*,*6id.*large*" \
  --query "InstanceTypes[?contains(InstanceType,'m5d')||contains(InstanceType,'r5d')||
contains(InstanceType,'m6id')||contains(InstanceType,'r6id')][InstanceType,
 InstanceStorageInfo.TotalSizeInGB]" \
  --output table
```

The preceding command returns the raw device size for the instance store. RDS for Oracle uses a small portion of this space for configuration. The space in the instance store that is available for temporary tablespaces or the flash cache is slightly smaller.

Supported engine versions for the RDS for Oracle instance store

The instance store is supported for the following RDS for Oracle engine versions:

- 21.0.0.0.ru-2022-01.rur-2022-01.r1 or higher Oracle Database 21c versions
- 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher Oracle Database 19c versions

Supported AWS Regions for the RDS for Oracle instance store

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see DB instance classes. For more information on the instance classes supported by Amazon RDS for Oracle, see RDS for Oracle DB instance classes.

Cost of the RDS for Oracle instance store

The cost of the instance store is built into the cost of the instance-store turned on instances. You don't incur additional costs by enabling an instance store on an RDS for Oracle DB instance. For more information about instance-store turned on instances, see Supported instance classes for the RDS for Oracle instance store.

Turning on an RDS for Oracle instance store

To turn on the instance store for RDS for Oracle temporary data, do one of the following:

- Create an RDS for Oracle DB instance using a supported instance class. For more information, see Creating an Amazon RDS DB instance.

- Modify an existing RDS for Oracle DB instance to use a supported instance class. For more information, see Modifying an Amazon RDS DB instance.

Configuring an RDS for Oracle instance store

By default, 100% of instance store space is allocated to the temporary tablespace. To configure the instance store to allocate space to the flash cache and temporary tablespace, set the following parameters in the parameter group for your instance:

db_flash_cache_size={DBInstanceStore*{0,2,4,6,8,10}/10}

This parameter specifies the amount of storage space allocated for the flash cache. This parameter is valid only for Oracle Database Enterprise Edition. The default value is `{DBInstanceStore*0/10}`. If you set a nonzero value for `db_flash_cache_size`, your RDS for Oracle instance enables the flash cache after you restart the instance.

rds.instance_store_temp_size={DBInstanceStore*{0,2,4,6,8,10}/10}

This parameter specifies the amount of storage space allocated for the temporary tablespace. The default value is `{DBInstanceStore*10/10}`. This parameter is modifiable for Oracle Database Enterprise Edition and read-only for Standard Edition 2. If you set a nonzero value for `rds.instance_store_temp_size`, Amazon RDS allocates space in the instance store for the temporary tablespace.

You can set the `db_flash_cache_size` and `rds.instance_store_temp_size` parameters for DB instances that don't use an instance store. In this case, both settings evaluate to `0`, which turns off the feature. In this case, you can use the same parameter group for different instance sizes and for instances that don't use an instance store. If you modify these parameters, make sure to reboot the associated instances so that the changes can take effect.

> **Important**
>
> If you allocate space for a temporary tablespace, Amazon RDS doesn't create the temporary tablespace automatically. To learn how to create the temporary tablespace on the instance store, see Creating a temporary tablespace on the instance store.

The combined value of the preceding parameters must not exceed 10/10, or 100%. The following table illustrates valid and invalid parameter settings.

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
db_flash_cache_size={DBInstanceStore*0/10}	rds.instance_store_temp_size={DBInstanceStore*10/10}	This is a valid configuration for all editions of Oracle Database. Amazon RDS allocates 100% of instance store space to the temporary tablespace. This is the default.
db_flash_cache_size={DBInstanceStore*10/10}	rds.instance_store_temp_size={DBInstanceStore*0/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 100% of instance store space to the flash cache.
db_flash_cache_size={DBInstanceStore*2/10}	rds.instance_store_temp_size={DBInstanceStore*8/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
		the flash cache, and 80% of instance store space to the temporary tablespace.
db_flash_cache_size={DBInstanceStore*6/10}	rds.instance_store_temp_size={DBInstanceStore*4/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 60% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
db_flash_cache_size={DBInstanceStore*2/10}	rds.instance_store_temp_size={DBInstanceStore*4/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.
db_flash_cache_size={DBInstanceStore*8/10}	rds.instance_store_temp_size={DBInstanceStore*8/10}	This is an invalid configuration because the combined percentage of instance store space exceeds 100%. In such cases, Amazon RDS fails the attempt.

Considerations when changing the DB instance type

If you change your DB instance type, it can affect the configuration of the flash cache or the temporary tablespace on the instance store. Consider the following modifications and their effects:

You scale up or scale down the DB instance that supports the instance store.

The following values increase or decrease proportionally to the new size of the instance store:

- The new size of the flash cache.
- The space allocated to the temporary tablespaces that reside in the instance store.

For example, the setting `db_flash_cache_size={DBInstanceStore*6/10}` on a db.m5d.4xlarge instance provides around 340 GB of flash cache space. If you scale up the instance type to db.m5d.8xlarge, the flash cache space increases to around 680 GB.

You modify a DB instance that doesn't use an instance store to an instance that does use an instance store.

If `db_flash_cache_size` is set to a value larger than `0`, the flash cache is configured. If `rds.instance_store_temp_size` is set to a value larger than `0`, the instance store space is allocated for use by a temporary tablespace. RDS for Oracle doesn't move tempfiles to the instance store automatically. For information about using the allocated space, see Creating a temporary tablespace on the instance store or Adding a tempfile to the instance store on a read replica.

You modify a DB instance that uses an instance store to an instance that doesn't use an instance store.

In this case, RDS for Oracle removes the flash cache. RDS re-creates the tempfile that is currently located on the instance store on an Amazon EBS volume. The maximum size of the new tempfile is the former size of the `rds.instance_store_temp_size` parameter.

Working with an instance store on an Oracle read replica

Read replicas support the flash cache and temporary tablespaces on an instance store. While the flash cache works the same way as on the primary DB instance, note the following differences for temporary tablespaces:

- You can't create a temporary tablespace on a read replica. If you create a new temporary tablespace on the primary instance, RDS for Oracle replicates the tablespace information without tempfiles. To add a new tempfile, use either of the following techniques:
  - Use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. RDS for Oracle creates a tempfile in the instance store on your read replica, and adds it to the specified temporary tablespace.

- Run the `ALTER TABLESPACE ... ADD TEMPFILE` command. RDS for Oracle places the tempfile on Amazon EBS storage.

> **Note**
>
> The tempfile sizes and storage types can be different on the primary DB instance and the read replica.

- You can manage the default temporary tablespace setting only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.
- You can configure the temporary tablespace groups only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

Configuring a temporary tablespace group on an instance store and Amazon EBS

You can configure a temporary tablespace group to include temporary tablespaces on both an instance store and Amazon EBS. This technique is useful when you want more temporary storage than is allowed by the maximum setting of `rds.instance_store_temp_size`.

When you configure a temporary tablespace group on both an instance store and Amazon EBS, the two tablespaces have significantly different performance characteristics. Oracle Database chooses the tablespace to serve queries based on an internal algorithm. Therefore, similar queries can vary in performance.

Typically, you create a temporary tablespace in the instance store as follows:

1. Create a temporary tablespace in the instance store.
2. Set the new tablespace as the database default temporary tablespace.

If the tablespace size in the instance store is insufficient, you can create additional temporary storage as follows:

1. Assign the temporary tablespace in the instance store to a temporary tablespace group.
2. Create a new temporary tablespace in Amazon EBS if one doesn't exist.
3. Assign the temporary tablespace in Amazon EBS to the same tablespace group that includes the instance store tablespace.
4. Set the tablespace group as the default temporary tablespace.

The following example assumes that the size of the temporary tablespace in the instance store doesn't meet your application requirements. The example creates the temporary tablespace `temp_in_inst_store` in the instance store, assigns it to tablespace group `temp_group`, adds the existing Amazon EBS tablespace named `temp_in_ebs` to this group, and sets this group as the default temporary tablespace.

```
SQL> EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace('temp_in_inst_store');

PL/SQL procedure successfully completed.

SQL> ALTER TABLESPACE temp_in_inst_store TABLESPACE GROUP temp_group;

Tablespace altered.

SQL> ALTER TABLESPACE temp_in_ebs TABLESPACE GROUP temp_group;

Tablespace altered.

SQL> EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace('temp_group');

PL/SQL procedure successfully completed.

SQL> SELECT * FROM DBA_TABLESPACE_GROUPS;

GROUP_NAME                     TABLESPACE_NAME
------------------------------ ------------------------------
TEMP_GROUP                     TEMP_IN_EBS
TEMP_GROUP                     TEMP_IN_INST_STORE

SQL> SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE
 PROPERTY_NAME='DEFAULT_TEMP_TABLESPACE';

PROPERTY_VALUE
--------------
TEMP_GROUP
```

Removing an RDS for Oracle instance store

To remove the instance store, modify your RDS for Oracle DB instance to use an instance type that doesn't support instance store, such as db.m5 or db.r5.

Turning on HugePages for an RDS for Oracle instance

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see Overview of HugePages in the Oracle documentation.

You can use HugePages with all supported versions and editions of RDS for Oracle.

The `use_large_pages` parameter controls whether HugePages are turned on for a DB instance. The possible settings for this parameter are `ONLY`, `FALSE`, and `{DBInstanceClassHugePagesDefault}`. The `use_large_pages` parameter is set to `{DBInstanceClassHugePagesDefault}` in the default DB parameter group for Oracle.

To control whether HugePages are turned on for a DB instance automatically, you can use the `DBInstanceClassHugePagesDefault` formula variable in parameter groups. The value is determined as follows:

- For the DB instance classes mentioned in the table following, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE` by default, and `use_large_pages` evaluates to `FALSE`. You can turn on HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.
- For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE`. Also, `use_large_pages` evaluates to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, `DBInstanceClassHugePagesDefault` evaluates to `TRUE` by default. Also, `use_large_pages` evaluates to `ONLY`. You can turn off HugePages manually by setting `use_large_pages` to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `TRUE`. Also, `use_large_pages` evaluates to `ONLY` and HugePages can't be disabled.

HugePages are not turned on by default for the following DB instance classes.

DB instance class family	DB instance classes with HugePages not turned on by default
db.m5	db.m5.large
db.m4	db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge, db.m4.10xlarge
db.t3	db.t3.micro, db.t3.small, db.t3.medium, db.t3.large

For more information about DB instance classes, see Hardware specifications for DB instance classes.

To turn on HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to `ONLY`. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to `ONLY`, then you must also set both `memory_target` and `memory_max_target` to `0`. For more information about setting DB parameters for your DB instance, see Parameter groups for Amazon RDS.

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from your available instance memory (`DBInstanceClassMemory`) to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see Rebooting a DB instance.

Note

The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose **Reboot** but *do not* choose **Reboot with failover**. In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.

```
memory_target            = 0
memory_max_target        = 0
pga_aggregate_target     = {DBInstanceClassMemory*1/8}
sga_target               = {DBInstanceClassMemory*3/4}
sga_max_size             = {DBInstanceClassMemory*3/4}
use_large_pages          = ONLY
```

Assume the following parameters values are set in a parameter group.

```
memory_target            = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = {DBInstanceClassHugePagesDefault}
```

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and `use_large_pages` set to `{DBInstanceClassHugePagesDefault}`, HugePages are turned on for the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

```
memory_target           = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
memory_max_target       = IF({DBInstanceClassHugePagesDefault}, 0,
 {DBInstanceClassMemory*3/4})
pga_aggregate_target    = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*1/8}, 0)
sga_target              = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
sga_max_size            = IF({DBInstanceClassHugePagesDefault},
 {DBInstanceClassMemory*3/4}, 0)
use_large_pages         = FALSE
```

The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are turned off on the db.r4 and db.r5 instance.

> **Note**
>
> If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the `FALSE` setting for `use_large_pages` is overridden and set to `ONLY`. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring.

Turning on extended data types in RDS for Oracle

Amazon RDS for Oracle supports extended data types. With extended data types, the maximum size is 32,767 bytes for the `VARCHAR2`, `NVARCHAR2`, and `RAW` data types. To use extended data types, set the `MAX_STRING_SIZE` parameter to `EXTENDED`. For more information, see Extended data types in the Oracle documentation.

If you don't want to use extended data types, keep the `MAX_STRING_SIZE` parameter set to `STANDARD` (the default). In this case, the size limits are 4,000 bytes for the `VARCHAR2` and `NVARCHAR2` data types, and 2,000 bytes for the RAW data type.

You can turn on extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you turn on extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

Considerations for extended data types

Consider the following when you enable extended data types for your DB instance:

- When you turn on extended data types for a new or existing DB instance, you must reboot the instance for the change to take effect.
- After you turn on extended data types, you can't change the DB instance back to use the standard size for data types. If you set the `MAX_STRING_SIZE` parameter back to `STANDARD` it results in the `incompatible-parameters` status.

- When you restore a DB instance that uses extended data types, you must specify a parameter group with the `MAX_STRING_SIZE` parameter set to `EXTENDED`. During restore, if you specify the default parameter group or any other parameter group with `MAX_STRING_SIZE` set to `STANDARD` it results in the `incompatible-parameters` status.
- When the DB instance status is `incompatible-parameters` because of the `MAX_STRING_SIZE` setting, the DB instance remains unavailable until you set the `MAX_STRING_SIZE` parameter to `EXTENDED` and reboot the DB instance.

Turning on extended data types for a new DB instance

When you create a DB instance with `MAX_STRING_SIZE` set to `EXTENDED`, the instance shows `MAX_STRING_SIZE` set to the default `STANDARD`. Reboot the instance to enable the change.

To turn on extended data types for a new DB instance

1. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Parameter groups for Amazon RDS.
2. Create a new RDS for Oracle DB instance.

   For more information, see Creating an Amazon RDS DB instance.
3. Associate the parameter group with `MAX_STRING_SIZE` set to `EXTENDED` with the DB instance.

   For more information, see Creating an Amazon RDS DB instance.
4. Reboot the DB instance for the parameter change to take effect.

   For more information, see Rebooting a DB instance.

Turning on extended data types for an existing DB instance

When you modify a DB instance to turn on extended data types, RDS converts the data in the database to use the extended sizes. The conversion and downtime occur when you next reboot the database after the parameter change. The DB instance is unavailable during the conversion.

The amount of time it takes to convert the data depends on the DB instance class, the database size, and the time of the last DB snapshot. To reduce downtime, consider taking a snapshot immediately before rebooting. This shortens the time of the backup that occurs during the conversion workflow.

> **Note**
>
> After you turn on extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

To turn on extended data types for an existing DB instance

1. Take a snapshot of the database.

   If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

   For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.
2. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

   To set the parameter, you can either create a new parameter group or modify an existing parameter group.

   For more information, see Parameter groups for Amazon RDS.
3. Modify the DB instance to associate it with the parameter group with `MAX_STRING_SIZE` set to `EXTENDED`.

   For more information, see Modifying an Amazon RDS DB instance.
4. Reboot the DB instance for the parameter change to take effect.

   For more information, see Rebooting a DB instance.

Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS for Oracle DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, you can use the following tools, depending on your requirements:

- Oracle SQL Developer – Import a simple, 20 MB database.
- Oracle Data Pump – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. For example, you can transport tablespaces from an on-premises database to your RDS for Oracle DB instance. You can use Amazon S3 or Amazon EFS to transfer the data files and metadata. For more information, see Migrating using Oracle transportable tablespaces, Amazon EFS integration, and Amazon S3 integration.
- AWS Database Migration Service (AWS DMS) – Migrate databases without downtime. For more information about AWS DMS, see What is AWS Database Migration Service and the blog post Migrating Oracle databases with near-zero downtime using AWS DMS.

> **Important**
>
> Before you use the preceding migration techniques, we recommend that you back up your database. After you import the data, you can back up your RDS for Oracle DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see Backing up, restoring, and exporting data.

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can use AWS DMS to migrate to RDS for Oracle from either the same database engine or a different engine. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that AWS DMS doesn't migrate.

Topics

- Importing using Oracle SQL Developer
- Migrating using Oracle transportable tablespaces

- Importing using Oracle Data Pump
- Importing using Oracle Export/Import
- Importing using Oracle SQL*Loader
- Migrating with Oracle materialized views

Importing using Oracle SQL Developer

Oracle SQL Developer is a graphical Java tool distributed without cost by Oracle. SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to an Oracle database. This tool is best for migrating small databases.

You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. After you install SQL Developer, you can use it to connect to your source and target databases. Use the **Database Copy** command on the Tools menu to copy your data to your RDS for Oracle DB instance.

To download SQL Developer, go to http://www.oracle.com/technetwork/developer-tools/sql-developer.

We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data. Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see http://www.oracle.com/technetwork/database/migration in the Oracle documentation.

Migrating using Oracle transportable tablespaces

You can use the Oracle transportable tablespaces feature to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, you transfer source data files and metadata files to your target DB instance using either Amazon EFS or Amazon S3. The transportable tablespaces feature uses the `rdsadmin.rdsadmin_transport_util` package. For syntax and semantics of this package, see Transporting tablespaces.

For blog posts that explain how to transport tablespaces, see Migrate Oracle Databases to AWS using transportable tablespace and Amazon RDS for Oracle Transportable Tablespaces using RMAN.

Topics

- Overview of Oracle transportable tablespaces
- Phase 1: Set up your source host
- Phase 2: Prepare the full tablespace backup
- Phase 3: Make and transfer incremental backups
- Phase 4: Transport the tablespaces
- Phase 5: Validate the transported tablespaces
- Phase 6: Clean up leftover files

Overview of Oracle transportable tablespaces

A transportable tablespace set consists of data files for the set of tablespaces being transported and an export dump file containing tablespace metadata. In a physical migration solution such as transportable tablespaces, you transfer physical files: data files, configuration files, and Data Pump dump files.

Topics

- Advantages and disadvantages of transportable tablespaces
- Limitations for transportable tablespaces
- Prerequisites for transportable tablespaces

Advantages and disadvantages of transportable tablespaces

We recommend that you use transportable tablespaces when you need to migrate one or more large tablespaces to RDS with minimum downtime. Transportable tablespaces offer the following advantages over logical migration:

- Downtime is lower than most other Oracle migration solutions.
- Because the transportable tablespace feature copies only physical files, it avoids the data integrity errors and logical corruption that can occur in logical migration.
- No additional license is required.
- You can migrate a set of tablespaces across different platforms and endianness types, for example, from an Oracle Solaris platform to Linux. However, transporting tablespaces to and from Windows servers isn't supported.

> **Note**
>
> Linux is fully tested and supported. Not all UNIX variations have been tested.

If you use transportable tablespaces, you can transport data using either Amazon S3 or Amazon EFS:

- When you use EFS, your backups remain in the EFS file system for the duration of the import. You can remove the files afterward. In this technique, you don't need to provision EBS storage for your DB instance. For this reason, we recommend using Amazon EFS instead of S3. For more information, see Amazon EFS integration.
- When you use S3, you download RMAN backups to EBS storage attached to your DB instance. The files remain in your EBS storage during the import. After the import, you can free up this space, which remains allocated to your DB instance.

The primary disadvantage of transportable tablespaces is that you need relatively advanced knowledge of Oracle Database. For more information, see Transporting Tablespaces Between Databases in the *Oracle Database Administrator's Guide*.

Limitations for transportable tablespaces

Oracle Database limitations for transportable tablespaces apply when you use this feature in RDS for Oracle. For more information, see Limitations on Transportable Tablespaces and General Limitations on Transporting Data in the *Oracle Database Administrator's Guide*. Note the following additional limitations for transportable tablespaces in RDS for Oracle:

- Neither the source or target database can use Standard Edition 2 (SE2). Only Enterprise Edition is supported.
- You can't use an Oracle Database 11g database as a source. The RMAN cross-platform transportable tablespaces feature relies on the RMAN transport mechanism, which Oracle Database 11g doesn't support.
- You can't migrate data from an RDS for Oracle DB instance using transportable tablespaces. You can only use transportable tablespaces to migrate data to an RDS for Oracle DB instance.
- The Windows operating system isn't supported.

- You can't transport tablespaces into a database at a lower release level. The target database must be at the same or later release level as the source database. For example, you can't transport tablespaces from Oracle Database 21c into Oracle Database 19c.
- You can't transport administrative tablespaces such as SYSTEM and SYSAUX.
- You can't transport non-data objects such as PL/SQL packages, Java classes, views, triggers, sequences, users, roles, and temporary tables. To transport non-data objects, create them manually or use Data Pump metadata export and import. For more information, see My Oracle Support Note 1454872.1.
- You can't transport tablespaces that are encrypted or use encrypted columns.
- If you transfer files using Amazon S3, the maximum supported file size is 5 TiB.
- If the source database uses Oracle options such as Spatial, you can't transport tablespaces unless the same options are configured on the target database.
- You can't transport tablespaces into an RDS for Oracle DB instance in an Oracle replica configuration. As a workaround, you can delete all replicas, transport the tablespaces, and then recreate the replicas.

Prerequisites for transportable tablespaces

Before you begin, complete the following tasks:

- Review the requirements for transportable tablespaces described in the following documents in My Oracle Support:
  - Reduce Transportable Tablespace Downtime using Cross Platform Incremental Backup (Doc ID 2471245.1)
  - Transportable Tablespace (TTS) Restrictions and Limitations: Details, Reference, and Version Where Applicable (Doc ID 1454872.1)
  - Primary Note for Transportable Tablespaces (TTS) -- Common Questions and Issues (Doc ID 1166564.1)
- Plan for endianness conversion. If you specify the source platform ID, RDS for Oracle converts the endianness automatically. To learn how to find platform IDs, see Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration (Doc ID 413484.1).
- Make sure that the transportable tablespace feature is enabled on your target DB instance. The feature is enabled only if you don't get an ORA-20304 error when you run the following query:

```
SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
```

If the transportable tablespace feature isn't enabled, reboot your DB instance. For more information, see Rebooting a DB instance.

- Make sure that the time zone file is the same in the source and target databases.
- Make sure that the database character sets on the source and target databases meet either of the following requirements:
  - The character sets are the same.
  - The character sets are compatible. For a list of compatibility requirements, see General Limitations on Transporting Data in the Oracle Database documentation.
- If you plan to transfer files using Amazon S3, do the following:
  - Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as your DB instance. For instructions, see Create a bucket in the *Amazon Simple Storage Service Getting Started Guide*.
  - Prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3.
- If you plan to transfer files using Amazon EFS, make sure that you have configured EFS according to the instructions in Amazon EFS integration.
- We strongly recommend that you turn on automatic backups in your target DB instance. Because the metadata import step can potentially fail, it's important to be able to restore your DB instance to its state before the import, thereby avoiding the necessity to back up, transfer, and import your tablespaces again.

Phase 1: Set up your source host

In this step, you copy the transport tablespaces scripts provided by My Oracle Support and set up necessary configuration files. In the following steps, the *source host* is running the database that contains the tablespaces to be transported to your *target instance*.

To set up your source host

1. Log in to your source host as the owner of your Oracle home.
2. Make sure that your `ORACLE_HOME` and `ORACLE_SID` environment variables point to your source database.

3. Log in to your database as an administrator, and verify that the time zone version, DB character set, and national character set are the same as in your target database.

```
SELECT * FROM V$TIMEZONE_FILE;
SELECT * FROM NLS_DATABASE_PARAMETERS
  WHERE PARAMETER IN ('NLS_CHARACTERSET','NLS_NCHAR_CHARACTERSET');
```

4. Set up the transportable tablespace utility as described in Oracle Support note 2471245.1.

   The setup includes editing the `xtt.properties` file on your source host. The following sample `xtt.properties` file specifies backups of three tablespaces in the `/dsk1/backups` directory. These are the tablespaces that you intend to transport to your target DB instance. It also specifies the source platform ID to convert the endianness automatically.

   > **Note**
   >
   > For valid platform IDs, see Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration (Doc ID 413484.1).

```
#linux system
platformid=13
#list of tablespaces to transport
tablespaces=TBS1,TBS2,TBS3
#location where backup will be generated
src_scratch_location=/dsk1/backups
#RMAN command for performing backup
usermantransport=1
```

Phase 2: Prepare the full tablespace backup

In this phase, you back up your tablespaces for the first time, transfer the backups to your target host, and then restore them using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. When this phase is complete, the initial tablespace backups reside on your target DB instance and can be updated with incremental backups.

Topics

- Step 1: Back up the tablespaces on your source host
- Step 2: Transfer the backup files to your target DB instance
- Step 3: Import the tablespaces on your target DB instance

Step 1: Back up the tablespaces on your source host

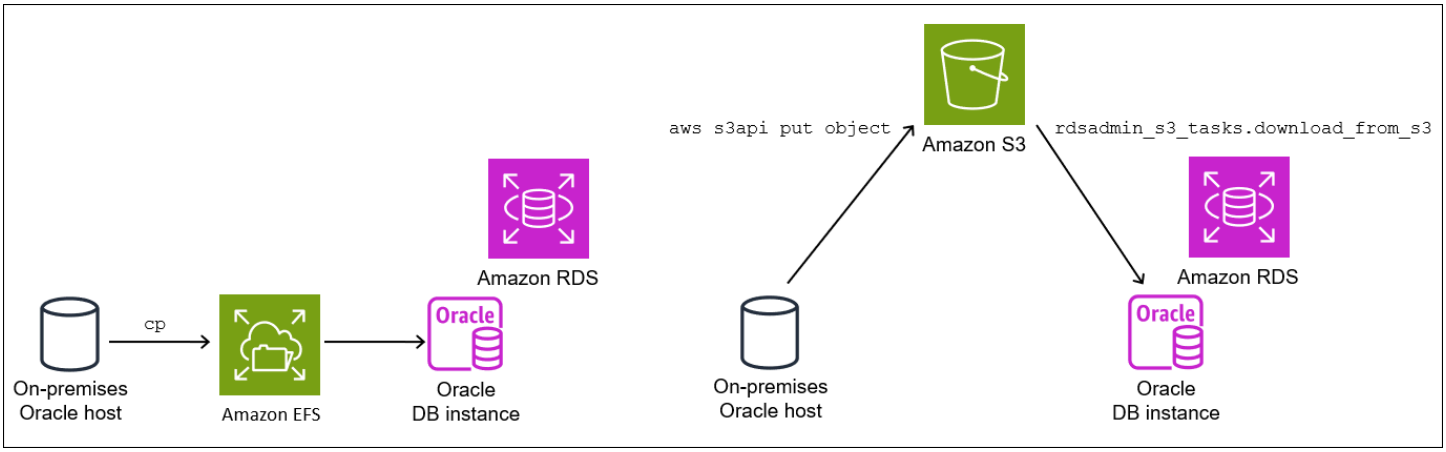
In this step, you use the `xttdriver.pl` script to make a full backup of your tablespaces. The output of `xttdriver.pl` is stored in the `TMPDIR` environment variable.

To back up your tablespaces

1. If your tablespaces are in read-only mode, log in to your source database as a user with the `ALTER TABLESPACE` privilege, and place your tablespaces in read/write mode. Otherwise, skip to the next step.

   The following example places `tbs1`, `tbs2`, and `tbs3` in read/write mode.

   ```
   ALTER TABLESPACE tbs1 READ WRITE;
   ALTER TABLESPACE tbs2 READ WRITE;
   ALTER TABLESPACE tbs3 READ WRITE;
   ```



2. Back up your tablespaces using the `xttdriver.pl` script. Optionally, you can specify `--debug` to run the script in debug mode.

   ```
   export TMPDIR=location_of_log_files
   cd location_of_xttdriver.pl
   $ORACLE_HOME/perl/bin/perl xttdriver.pl --backup
   ```

Step 2: Transfer the backup files to your target DB instance

In this step, copy the backup and configuration files from your scratch location to your target DB instance. Choose one of the following options:

- If the source and target hosts share an Amazon EFS file system, use an operating system utility such as `cp` to copy your backup files and the `res.txt` file from your scratch location to a shared directory. Then skip to Step 3: Import the tablespaces on your target DB instance.
- If you need to stage your backups to an Amazon S3 bucket, complete the following steps.

Step 2.2: Upload the backups to your Amazon S3 bucket

Upload your backups and the `res.txt` file from your scratch directory to your Amazon S3 bucket. For more information, see Uploading objects in the *Amazon Simple Storage Service User Guide*.

Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups to your RDS for Oracle DB instance.

To download your backups from your Amazon S3 bucket

1. Start SQL*Plus or Oracle SQL Developer and log in to your RDS for Oracle DB instance.
2. Download the backups from the Amazon S3 bucket to your target DB instance by using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to d. The following example downloads all of the files from an Amazon S3 bucket named *`amzn-s3-demo-bucket`* to the *`DATA_PUMP_DIR`* directory.

```
EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'res.txt');
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
  p_bucket_name    =>  'amzn-s3-demo-bucket',
  p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

   The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance.

Step 3: Import the tablespaces on your target DB instance

To restore your tablespaces to your target DB instance, use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. This procedure automatically converts the data files to the correct endian format.

If you import from a platform other than Linux, specify the source platform using the parameter `p_platform_id` when you call `import_xtts_tablespaces`. Make sure that the platform ID that you specify matches the one specified in the `xtt.properties` file in Step 2: Export tablespace metadata on your source host.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

   The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA_PUMP_DIR*. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying `V$TRANSPORTABLE_PLATFORM`.

   ```
   VAR task_id CLOB

   BEGIN
     :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
           'TBS1,TBS2,TBS3',
           'DATA_PUMP_DIR',
           p_platform_id => 6);
   END;
   /

   PRINT task_id
   ```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value `EXECUTING`, `COMPLETED`, or `FAILED`.

   ```
   SELECT * FROM rdsadmin.rds_xtts_operation_info;
   ```

> **Note**
>
> For long-running operations, you can also query V$SESSION_LONGOPS, V$RMAN_STATUS, and V$RMAN_OUTPUT.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||'&task_id'||'.log'));
```

Make sure that the import succeeded before continuing to the next step.

Phase 3: Make and transfer incremental backups

In this phase, you make and transfer incremental backups periodically while the source database is active. This technique reduces the size of your final tablespace backup. If you take multiple incremental backups, you must copy the `res.txt` file after the last incremental backup before you can apply it on the target instance.

The steps are the same as in Phase 2: Prepare the full tablespace backup, except that the import step is optional.

Phase 4: Transport the tablespaces

In this phase, you back up your read-only tablespaces and export Data Pump metadata, transfer these files to your target host, and import both the tablespaces and the metadata.

Topics

- Step 1: Back up your read-only tablespaces
- Step 2: Export tablespace metadata on your source host
- Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance
- Step 4: Import the tablespaces on your target DB instance
- Step 5: Import tablespace metadata on your target DB instance

Step 1: Back up your read-only tablespaces

This step is identical to Step 1: Back up the tablespaces on your source host, with one key difference: you place your tablespaces in read-only mode before backing up your tablespaces for the last time.

The following example places `tbs1`, `tbs2`, and `tbs3` in read-only mode.

```
ALTER TABLESPACE tbs1 READ ONLY;
ALTER TABLESPACE tbs2 READ ONLY;
ALTER TABLESPACE tbs3 READ ONLY;
```

Step 2: Export tablespace metadata on your source host

Export your tablespace metadata by running the `expdb` utility on your source host. The following example exports tablespaces *`TBS1`*, *`TBS2`*, and *`TBS3`* to dump file *`xttdump.dmp`* in directory *`DATA_PUMP_DIR`*.

```
expdp username/pwd \
dumpfile=xttdump.dmp \
directory=DATA_PUMP_DIR \
statistics=NONE \
transport_tablespaces=TBS1,TBS2,TBS3 \
transport_full_check=y \
logfile=tts_export.log
```

If *`DATA_PUMP_DIR`* is a shared directory in Amazon EFS, skip to Step 4: Import the tablespaces on your target DB instance.

Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance

If you are using Amazon S3 to stage your tablespace backups and Data Pump export file, complete the following steps.

Step 3.1: Upload the backups and dump file from your source host to your Amazon S3 bucket

Upload your backup and dump files from your source host to your Amazon S3 bucket. For more information, see Uploading objects in the *Amazon Simple Storage Service User Guide*.

Step 3.2: Download the backups and dump file from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups and dump file to your RDS for Oracle DB instance. Follow the steps in Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance.

Step 4: Import the tablespaces on your target DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore the tablespaces. For syntax and semantics of this procedure, see Importing transported tablespaces to your DB instance

> **Important**
>
> After you complete your final tablespace import, the next step is importing the Oracle Data Pump metadata. If the import fails, it's important to return your DB instance to its state before the failure. Thus, we recommend that you create a DB snapshot of your DB instance by following the instructions in Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS. The snapshot will contain all imported tablespaces, so if the import fails, you don't need to repeat the backup and import process.
> If your target DB instance has automatic backups turned on, and Amazon RDS doesn't detect that a valid snapshot was initiated before you import the metadata, RDS attempts to create a snapshot. Depending on your instance activity, this snapshot might or might not succeed. If a valid snapshot isn't detected or a snapshot can't be initiated, the metadata import exits with errors.

Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

   The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA_PUMP_DIR*.

   ```
   BEGIN
   ```

```
 :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3','DATA_
END;
/
PRINT task_id
```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value `EXECUTING`, `COMPLETED`, or `FAILED`.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

> **Note**
>
> For long-running operations, you can also query `V$SESSION_LONGOPS`, `V$RMAN_STATUS`, and `V$RMAN_OUTPUT`.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
 'dbtask-'||'&task_id'||'.log'));
```

   Make sure that the import succeeded before continuing to the next step.

5. Take a manual DB snapshot by following the instructions in Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

Step 5: Import tablespace metadata on your target DB instance

In this step, you import the transportable tablespace metadata into your RDS for Oracle DB instance using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata`. For syntax and semantics of this procedure, see Importing transportable tablespace metadata into your DB instance. During the operation, the status of the import is shown in the table `rdsadmin.rds_xtts_operation_info`.

> **Important**
>
> Before you import metadata, we strongly recommend that you confirm that a DB snapshot was successfully created after you imported your tablespaces. If the import step fails, restore your DB instance, address the import errors, and then attempt the import again.

Import the Data Pump metadata into your RDS for Oracle DB instance

1. Start your Oracle SQL client and log in to your target DB instance as the master user.
2. Create the users that own schemas in your transported tablespaces, if these users don't already exist.

```
CREATE USER tbs_owner IDENTIFIED BY password;
```

3. Import the metadata, specifying the name of the dump file and its directory location.

```
BEGIN

 rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp','DATA_PUMP_DIR');
END;
/
```

4. (Optional) Query the transportable tablespace history table to see the status of the metadata import.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

   When the operation completes, your tablespaces are in read-only mode.

5. (Optional) View the log file.

   The following example lists the contents of the BDUMP directory and then queries the import log.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'BDUMP'));

SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file(
  p_directory => 'BDUMP',
```

```
  p_filename => 'rds-xtts-
import_xtts_metadata-2023-05-22.01-52-35.560858000.log'));
```

Phase 5: Validate the transported tablespaces

In this optional step, you validate your transported tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`, and then place your tablespaces in read/write mode.

To validate the transported data

1. Start SQL*Plus or SQL Developer and log in to your target DB instance as the master user.
2. Validate the tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

```
SET SERVEROUTPUT ON
BEGIN
    rdsadmin.rdsadmin_rman_util.validate_tablespace(
        p_tablespace_name     => 'TBS1',
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_rman_to_dbms_output => TRUE);
    rdsadmin.rdsadmin_rman_util.validate_tablespace(
        p_tablespace_name     => 'TBS2',
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_rman_to_dbms_output => TRUE);
    rdsadmin.rdsadmin_rman_util.validate_tablespace(
        p_tablespace_name     => 'TBS3',
        p_validation_type     => 'PHYSICAL+LOGICAL',
        p_rman_to_dbms_output => TRUE);
END;
/
```

3. Place your tablespaces in read/write mode.

```
ALTER TABLESPACE TBS1 READ WRITE;
ALTER TABLESPACE TBS2 READ WRITE;
ALTER TABLESPACE TBS3 READ WRITE;
```

Phase 6: Clean up leftover files

In this optional step, you remove any unneeded files. Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import, and then use `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete them. For syntax and semantics of these procedures, see Listing orphaned files after a tablespace import and Deleting orphaned data files after a tablespace import.

To clean up leftover files

1. Remove old backups in *DATA_PUMP_DIR* as follows:

   a. List the backup files by running `rdsadmin.rdsadmin_file_util.listdir`.

   ```
   SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory =>
    'DATA_PUMP_DIR'));
   ```

   b. Remove the backups one by one by calling `UTL_FILE.FREMOVE`.

   ```
   EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'backup_filename');
   ```

2. If you imported tablespaces but didn't import metadata for these tablespaces, you can delete the orphaned data files as follows:

   a. List the orphaned data files that you need to delete. The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`.

   ```
   SQL> SELECT * FROM
    TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);

   FILENAME       FILESIZE
   -------------- ---------
   datafile_7.dbf 104865792
   datafile_8.dbf 104865792
   ```

   b. Delete the orphaned files by running the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

   ```
   BEGIN
   ```

```
 rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The cleanup operation generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log` in the BDUMP directory.

c. Read the log file generated in the previous step. The following example reads log `rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log`.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
       p_directory => 'BDUMP',
       p_filename  => 'rds-xtts-
delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));

TEXT
--------------------------------------------------------------------------------
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```

3. If you imported tablespaces and imported metadata for these tablespaces, but you encountered compatibility errors or other Oracle Data Pump issues, clean up the partially transported data files as follows:

a. List the tablespaces that contain partially transported data files by querying DBA_TABLESPACES.

```
SQL> SELECT TABLESPACE_NAME FROM DBA_TABLESPACES WHERE PLUGGED_IN='YES';

TABLESPACE_NAME
--------------------------------------------------------------------------------
TBS_3
```

b. Drop the tablespaces and the partially transported data files.

```
DROP TABLESPACE TBS_3 INCLUDING CONTENTS AND DATAFILES;
```

Importing using Oracle Data Pump

Oracle Data Pump is a utility that allows you to export Oracle data to a dump file and import it into another Oracle database. It is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the recommended way to move large amounts of data from an Oracle database to an Amazon RDS DB instance.

The examples in this section show one way to import data into an Oracle database, but Oracle Data Pump supports other techniques. For more information, see the Oracle Database documentation.

The examples in this section use the `DBMS_DATAPUMP` package. You can accomplish the same tasks using the Oracle Data Pump command line utilities `impdp` and `expdp`. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client. For more information, see How do I use Oracle Instant Client to run Data Pump Import or Export for my Amazon RDS for Oracle DB instance?

Topics

- Overview of Oracle Data Pump
- Importing data with Oracle Data Pump and an Amazon S3 bucket
- Importing data with Oracle Data Pump and a database link

Overview of Oracle Data Pump

Oracle Data Pump is made up of the following components:

- Command-line clients `expdp` and `impdp`
- The `DBMS_DATAPUMP` PL/SQL package
- The `DBMS_METADATA` PL/SQL package

You can use Oracle Data Pump for the following scenarios:

- Import data from an Oracle database, either on-premises or on an Amazon EC2 instance, to an RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database, either on-premises or on an Amazon EC2 instance.
- Import data between RDS for Oracle DB instances, for example, to migrate data from EC2-Classic to VPC.

To download Oracle Data Pump utilities, see Oracle database software downloads on the Oracle Technology Network website. For compatibility considerations when migrating between versions of Oracle Database, see the Oracle Database documentation.

Oracle Data Pump workflow

Typically, you use Oracle Data Pump in the following stages:

1. Export your data into a dump file on the source database.
2. Upload your dump file to your destination RDS for Oracle DB instance. You can transfer using an Amazon S3 bucket or by using a database link between the two databases.
3. Import the data from your dump file into your RDS for Oracle DB instance.

Oracle Data Pump best practices

When you use Oracle Data Pump to import data into an RDS for Oracle instance, we recommend the following best practices:

- Perform imports in `schema` or `table` mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in `full` mode or import schemas for system-maintained components.

  Because RDS for Oracle doesn't allow access to SYS or SYSDBA administrative users, these actions might damage the Oracle data dictionary and affect the stability of your database.
- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

  If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.
- Don't import dump files that were created using the Oracle Data Pump export parameters `TRANSPORT_TABLESPACES`, `TRANSPORTABLE`, or `TRANSPORT_FULL_CHECK`. RDS for Oracle DB instances don't support importing these dump files.
- Don't import dump files that contain Oracle Scheduler objects in SYS, `SYSTEM`, `RDSADMIN`, `RDSSEC`, and `RDS_DATAGUARD`, and belong to the following categories:

- Jobs
- Programs
- Schedules
- Chains
- Rules
- Evaluation contexts
- Rule sets

RDS for Oracle DB instances don't support importing these dump files.

- To exclude unsupported Oracle Scheduler objects, use additional directives during the Data Pump export. If you use DBMS_DATAPUMP, you can add an additional METADATA_FILTER before the DBMS_METADATA.START_JOB:

```
DBMS_DATAPUMP.METADATA_FILTER(
  v_hdnl,
  'EXCLUDE_NAME_EXPR',
  q'[IN (SELECT NAME FROM SYS.OBJ$
         WHERE TYPE# IN (66,67,74,79,59,62,46)
         AND OWNER# IN
           (SELECT USER# FROM SYS.USER$
            WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
            )
        )
  ]',
  'PROCOBJ'
);
```

If you use expdp, create a parameter file that contains the exclude directive shown in the following example. Then use PARFILE=*parameter_file* with your expdp command.

```
exclude=procobj:"IN
  (SELECT NAME FROM sys.OBJ$
   WHERE TYPE# IN (66,67,74,79,59,62,46)
   AND OWNER# IN
     (SELECT USER# FROM SYS.USER$
      WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
     )
  )"
```

Importing data with Oracle Data Pump and an Amazon S3 bucket

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The steps are as follows:

1. Export data on the source database using the Oracle DBMS_DATAPUMP package.
2. Place the dump file in an Amazon S3 bucket.
3. Download the dump file from the Amazon S3 bucket to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the package `DBMS_DATAPUMP`.

Topics

- Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket
- Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance
- Step 2: Export data into a dump file using DBMS_DATAPUMP
- Step 3: Upload the dump file to your Amazon S3 bucket
- Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance
- Step 5: Import your dump file into your target DB instance using DBMS_DATAPUMP
- Step 6: Clean up

Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket

The process has the following requirements:

- Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as the DB instance. For instructions, see Create a bucket in the *Amazon Simple Storage Service Getting Started Guide*.
- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see Amazon Simple Storage Service User Guide.

> **Note**
>
> If you dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.

- You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for RDS for Oracle integration with Amazon S3.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

> **Note**
>
> This process imports a dump file into the `DATA_PUMP_DIR` directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the `DATA_PUMP_DIR` directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance

In this step, you create the schemas into which you plan to import data and grant the users necessary privileges.

To create users and grant necessary privileges on the RDS for Oracle target instance

1. Use SQL*Plus or Oracle SQL Developer to log in as the master user to the RDS for Oracle DB instance into which the data will be imported. For information about connecting to a DB instance, see Connecting to your Oracle DB instance.
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces in RDS for Oracle.

3. Create the user account and grant the necessary permissions and roles if the user account into which the data is imported doesn't exist. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

   For example, the following SQL statements create a new user and grant the necessary permissions and roles to import the data into the schema owned by this user. Replace *schema_1* with the name of your schema in this step and in the following steps.

   ```
   CREATE USER schema_1 IDENTIFIED BY my_password;
   GRANT CREATE SESSION, RESOURCE TO schema_1;
   ALTER USER schema_1 QUOTA 100M ON users;
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

   The preceding statements grant the new user the `CREATE SESSION` privilege and the `RESOURCE` role. You might need additional privileges and roles depending on the database objects that you import.

Step 2: Export data into a dump file using DBMS_DATAPUMP

To create a dump file, use the `DBMS_DATAPUMP` package.

To export Oracle data into a dump file

1. Use SQL Plus or Oracle SQL Developer to connect to the source RDS for Oracle DB instance with an administrative user. If the source database is an RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Export the data by calling `DBMS_DATAPUMP` procedures.

   The following script exports the *SCHEMA_1* schema into a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory. Replace *SCHEMA_1* with the name of the schema that you want to export.

   ```
   DECLARE
     v_hdnl NUMBER;
   ```

```
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl         ,
    filename  => 'sample.dmp'   ,
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM SYS.OBJ$
           WHERE TYPE# IN (66,67,74,79,59,62,46)
           AND OWNER# IN
             (SELECT USER# FROM SYS.USER$
              WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
             )
          )
    ]',
    'PROCOBJ'
  );
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

Note

Data Pump starts jobs asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation.

3. (Optional) View the contents of the export log by calling the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

Step 3: Upload the dump file to your Amazon S3 bucket

Use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the `DATA_PUMP_DIR` directory to an Amazon S3 bucket named *amzn-s3-demo-bucket*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
  p_bucket_name    =>  'amzn-s3-demo-bucket',
  p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket.

Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance

Perform this step using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. When you download a file to a directory, the procedure `download_from_s3` skips the download if an identically named file already exists in the directory. To remove a file from the download directory, use UTL_FILE.FREMOVE, found on the Oracle website.

To download your dump file

1. Start SQL*Plus or Oracle SQL Developer and log in as the master on your Amazon RDS target Oracle DB instance
2. Download the dump file using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

   The following example downloads all files from an Amazon S3 bucket named *amzn-s3-demo-bucket* to the directory `DATA_PUMP_DIR`.

   ```
   SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
     p_bucket_name    =>  'amzn-s3-demo-bucket',
     p_directory_name =>  'DATA_PUMP_DIR')
   ```

```
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance.

Step 5: Import your dump file into your target DB instance using DBMS_DATAPUMP

Use DBMS_DATAPUMP to import the schema into your RDS for Oracle DB instance. Additional options such as METADATA_REMAP might be required.

To import data into your target DB instance

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. Import the data by calling DBMS_DATAPUMP procedures.

   The following example imports the *SCHEMA_1* data from `sample_copied.dmp` into your target DB instance.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

> **Note**
>
> Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

3. Verify the data import by listing the schema tables on your target DB instance.

   For example, the following query returns the number of tables for *SCHEMA_1*.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 6: Clean up

After the data has been imported, you can delete the files that you don't want to keep.

To remove unneeded files

1. Start SQL*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. List the files in `DATA_PUMP_DIR` using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY
 MTIME;
```

3. Delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','filename');
```

   For example, the following command deletes the file named `sample_copied.dmp`.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing data with Oracle Data Pump and a database link

The following import process uses Oracle Data Pump and the Oracle DBMS_FILE_TRANSFER package. The steps are as follows:

1. Connect to a source Oracle database, which can be an on-premises database, Amazon EC2 instance, or an RDS for Oracle DB instance.
2. Export data using the DBMS_DATAPUMP package.
3. Use `DBMS_FILE_TRANSFER.PUT_FILE` to copy the dump file from the Oracle database to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance that is connected using a database link.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the `DBMS_DATAPUMP` package.

The import process using Oracle Data Pump and the `DBMS_FILE_TRANSFER` package has the following steps.

Topics

- Requirements for importing data with Oracle Data Pump and a database link
- Step 1: Grant privileges to the user on the RDS for Oracle target DB instance
- Step 2: Grant privileges to the user on the source database
- Step 3: Create a dump file using DBMS_DATAPUMP
- Step 4: Create a database link to the target DB instance
- Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER
- Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP
- Step 7: Clean up

Requirements for importing data with Oracle Data Pump and a database link

The process has the following requirements:

- You must have execute privileges on the `DBMS_FILE_TRANSFER` and `DBMS_DATAPUMP` packages.
- You must have write privileges to the `DATA_PUMP_DIR` directory on the source DB instance.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

> **Note**
>
> This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

Step 1: Grant privileges to the user on the RDS for Oracle target DB instance

To grant privileges to the user on the RDS for Oracle target DB instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance into which you intend to import the data. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see Connecting to your Oracle DB instance.
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces in RDS for Oracle.
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

   For example, the following commands create a new user named *schema_1* and grant the necessary permissions and roles to import the data into the schema for this user.

   ```
   CREATE USER schema_1 IDENTIFIED BY my-password;
   GRANT CREATE SESSION, RESOURCE TO schema_1;
   ALTER USER schema_1 QUOTA 100M ON users;
   ```

   > **Note**
   >
   > Specify a password other than the prompt shown here as a security best practice.

The preceding example grants the new user the `CREATE SESSION` privilege and the `RESOURCE` role. Additional privileges and roles might be required depending on the database objects that you import.

> **Note**
>
> Replace *schema_1* with the name of your schema in this step and in the following steps.

Step 2: Grant privileges to the user on the source database

Use SQL*Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.

> **Note**
>
> If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```
CREATE USER export_user IDENTIFIED BY my-password;
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;
ALTER USER export_user QUOTA 100M ON users;
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;
GRANT SELECT_CATALOG_ROLE TO export_user;
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 3: Create a dump file using DBMS_DATAPUMP

To create a dump file, do the following:

1. Use SQL*Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Create a dump file using the Oracle Data Pump utility.

   The following script creates a dump file named *sample.dmp* in the DATA_PUMP_DIR directory.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT' ,
    job_mode  => 'SCHEMA' ,
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample.dmp'    ,
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl           ,
    filename  => 'sample_exp.log' ,
    directory => 'DATA_PUMP_DIR'  ,
    filetype  => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl              ,
    'SCHEMA_EXPR'       ,
    'IN (''SCHEMA_1'')'
  );
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdnl,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM sys.OBJ$
           WHERE TYPE# IN (66,67,74,79,59,62,46)
           AND OWNER# IN
             (SELECT USER# FROM SYS.USER$
              WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
             )
         )
    ]',
```

```
    'PROCOBJ'
  );
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

> **Note**
>
> Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the export log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

Step 4: Create a database link to the target DB instance

Create a database link between your source DB instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peered VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Adjusting database links for use with DB instances in a VPC.

The following command creates a database link named `to_rds` that connects to the Amazon RDS master user at the target DB instance.

```
CREATE DATABASE LINK to_rds
  CONNECT TO <master_user_account> IDENTIFIED BY <password>
  USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)
         (PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```

Step 5: Copy the exported dump file to the target DB instance using DBMS_FILE_TRANSFER

Use DBMS_FILE_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named sample.dmp from the source instance to a target database link named *to_rds* (created in the previous step).

```
BEGIN
  DBMS_FILE_TRANSFER.PUT_FILE(
    source_directory_object       => 'DATA_PUMP_DIR',
    source_file_name              => 'sample.dmp',
    destination_directory_object  => 'DATA_PUMP_DIR',
    destination_file_name         => 'sample_copied.dmp',
    destination_database          => 'to_rds' );
END;
/
```

Step 6: Import the data file to the target DB instance using DBMS_DATAPUMP

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
```

```
END;
/
```

> **Note**
>
> Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see Reading files in a DB instance directory.

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for *schema_1*.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 7: Clean up

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in `DATA_PUMP_DIR` using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');
```

For example, the following command deletes the file named `"sample_copied.dmp"`.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing using Oracle Export/Import

You might consider Oracle Export/Import utilities for migrations in the following conditions:

- Your data size is small.
- Data types such as binary float and double aren't required.

The import process creates the necessary schema objects. Thus, you don't need to run a script to create the objects beforehand.

The easiest way to install the Oracle the export and import utilities is to install the Oracle Instant Client. To download the software, go to https://www.oracle.com/database/technologies/instant-client.html. For documentation, see Instant Client for SQL*Loader, Export, and Import in the *Oracle Database Utilities* manual.

To export tables and then import them

1. Export the tables from the source database using the `exp` command.

   The following command exports the tables named `tab1`, `tab2`, and `tab3`. The dump file is `exp_file.dmp`.

   ```
   exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
   ```

   The export creates a binary dump file that contains both the schema and data for the specified tables.
2. Import the schema and data into a target database using the `imp` command.

   The following command imports the tables `tab1`, `tab2`, and `tab3` from dump file `exp_file.dmp`.

   ```
   imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \
   TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
   ```

Export and Import have other variations that might be better suited to your requirements. See the Oracle Database documentation for full details.

Importing using Oracle SQL*Loader

You might consider Oracle SQL*Loader for large databases that contain a limited number of objects. Because the process of exporting from a source database and loading to a target database is specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads the data into a target database.

The easiest way to install Oracle SQL*Loader is to install the Oracle Instant Client. To download the software, go to https://www.oracle.com/database/technologies/instant-client.html. For

documentation, see Instant Client for SQL*Loader, Export, and Import in the *Oracle Database Utilities* manual.

To import data using Oracle SQL*Loader

1. Create a sample source table using the following SQL statement.

```
CREATE TABLE customer_0 TABLESPACE users
   AS (SELECT ROWNUM id, o.*
       FROM   ALL_OBJECTS o, ALL_OBJECTS x
       WHERE  ROWNUM <= 1000000);
```

2. On the target RDS for Oracle DB instance, create a destination table for loading the data. The clause `WHERE 1=2` ensures that you copy the structure of `ALL_OBJECTS`, but don't copy any rows.

```
CREATE TABLE customer_1 TABLESPACE users
  AS (SELECT 0 AS ID, OWNER, OBJECT_NAME, CREATED
      FROM   ALL_OBJECTS
      WHERE  1=2);
```

3. Export the data from the source database to a text file. The following example uses SQL*Plus. For your data, you will likely need to generate a script that does the export for all the objects in the database.

```
ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY/MM/DD HH24:MI:SS'

SET LINESIZE 800 HEADING OFF FEEDBACK OFF ARRAY 5000 PAGESIZE 0
SPOOL customer_0.out
SET MARKUP HTML PREFORMAT ON
SET COLSEP ','

SELECT id, owner, object_name, created
FROM   customer_0;

SPOOL OFF
```

4. Create a control file to describe the data. You might need to write a script to perform this step.

```
cat << EOF > sqlldr_1.ctl
load data
infile customer_0.out
```

```
into table customer_1
APPEND
fields terminated by "," optionally enclosed by '"'
(
  id           POSITION(01:10)    INTEGER EXTERNAL,
  owner        POSITION(12:41)    CHAR,
  object_name  POSITION(43:72)    CHAR,
  created      POSITION(74:92)    date "YYYY/MM/DD HH24:MI:SS"
)
```

If needed, copy the files generated by the preceding code to a staging area, such as an Amazon EC2 instance.

5. Import the data using SQL*Loader with the appropriate user name and password for the target database.

```
sqlldr cust_dba@targetdb CONTROL=sqlldr_1.ctl BINDSIZE=10485760 READSIZE=10485760
 ROWS=1000
```

Migrating with Oracle materialized views

To migrate large datasets efficiently, you can use Oracle materialized view replication. With replication, you can keep the target tables synchronized with the source tables. Thus, you can switch over to Amazon RDS later, if needed.

Before you can migrate using materialized views, make sure that you meet the following requirements:

- Configure access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the RDS for Oracle target database to connect to the source over SQL*Net.
- Create a database link from the RDS for Oracle DB instance to the source database.

To migrate data using materialized views

1. Create a user account on both source and RDS for Oracle target instances that can authenticate with the same password. The following example creates a user named `dblink_user`.

```
CREATE USER dblink_user IDENTIFIED BY my-password
  DEFAULT TABLESPACE users
  TEMPORARY TABLESPACE temp;

GRANT CREATE SESSION TO dblink_user;

GRANT SELECT ANY TABLE TO dblink_user;

GRANT SELECT ANY DICTIONARY TO dblink_user;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

2. Create a database link from the RDS for Oracle target instance to the source instance using your newly created user.

```
CREATE DATABASE LINK remote_site
  CONNECT TO dblink_user IDENTIFIED BY my-password
  USING '(description=(address=(protocol=tcp) (host=my-host)
    (port=my-listener-port)) (connect_data=(sid=my-source-db-sid)))';
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

3. Test the link:

```
SELECT * FROM V$INSTANCE@remote_site;
```

4. Create a sample table with primary key and materialized view log on the source instance.

```
CREATE TABLE customer_0 TABLESPACE users
  AS (SELECT ROWNUM id, o.*
      FROM   ALL_OBJECTS o, ALL_OBJECTS x
      WHERE  ROWNUM <= 1000000);

ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
```

```
CREATE MATERIALIZED VIEW LOG ON customer_0;
```

5. On the target RDS for Oracle DB instance, create a materialized view.

```
CREATE MATERIALIZED VIEW customer_0
  BUILD IMMEDIATE REFRESH FAST
  AS (SELECT *
      FROM   cust_dba.customer_0@remote_site);
```

6. On the target RDS for Oracle DB instance, refresh the materialized view.

```
EXEC DBMS_MVIEW.REFRESH('CUSTOMER_0', 'f');
```

7. Drop the materialized view and include the `PRESERVE TABLE` clause to retain the materialized view container table and its contents.

```
DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;
```

   The retained table has the same name as the dropped materialized view.

Working with read replicas for Amazon RDS for Oracle

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see Overview of Amazon RDS read replicas. For a summary of the differences between Oracle replicas and other DB engines, see Differences between read replicas for DB engines.

Topics

- Overview of RDS for Oracle replicas
- Requirements and considerations for RDS for Oracle replicas
- Preparing to create an Oracle replica
- Creating an RDS for Oracle replica in mounted mode
- Modifying the RDS for Oracle replica mode
- Working with RDS for Oracle replica backups
- Performing an Oracle Data Guard switchover
- Troubleshooting RDS for Oracle replicas
- Redo transport compression with RDS for Oracle

Overview of RDS for Oracle replicas

An *Oracle replica* database is a physical copy of your primary database. An Oracle replica in read-only mode is called a *read replica*. An Oracle replica in mounted mode is called a *mounted replica*. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of RDS for Oracle disaster recovery.

For more information, see the blog post Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 1 and Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 2.

Topics

- Read-only and mounted replicas
- Read replicas of CDBs

- Archived redo log retention
- Outages during Oracle replication

Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.

You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see Working with DB instance read replicas. For information about Oracle Data Guard, see Oracle Data Guard concepts and administration in the Oracle documentation.

Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

Read replicas of CDBs

RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c CDBs in both single-tenant and multi-tenant configurations. You can create, manage, and promote read replicas in a CDB just as you can in a non-CDB. Mounted replicas are also supported. You get the following benefits:

- Managed disaster recovery, high availability, and read-only access to your replicas
- The ability to create read replicas in a different AWS Region.
- Integration with the existing RDS read replica APIs: CreateDBInstanceReadReplica, PromoteReadReplica, and SwitchoverReadReplica

To use this feature, you need an Active Data Guard license and an Oracle Database Enterprise Edition license for both the replica and primary DB instances. There are no additional costs related to using CDB architecture. You pay only for your DB instances.

For more information about the single-tenant and multi-tenant configurations of the CDB architecture, see Overview of RDS for Oracle CDBs.

Archived redo log retention

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of archived redo logs on the source DB instance. This is true regardless of the setting for `archivelog retention hours` in `rdsadmin.rdsadmin_util.set_configuration`.

RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about `rdsadmin.rdsadmin_util.set_configuration`, see Retaining archived redo logs.

Outages during Oracle replication

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. The source DB instance experiences a very brief I/O suspension when the DB snapshot operation begins. The I/O suspension typically lasts about one second. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

The DB snapshot becomes the Oracle replica. Amazon RDS sets the necessary parameters and permissions for the source database and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

Requirements and considerations for RDS for Oracle replicas

Before creating an Oracle replica, familiarize yourself with the following requirements and considerations.

Topics

- Version and licensing requirements for RDS for Oracle replicas
- Option group limitations for RDS for Oracle replicas
- Backup and restore considerations for RDS for Oracle replicas
- Oracle Data Guard requirements and limitations for RDS for Oracle replicas
- Multi-tenant configuration limitations for RDS for Oracle replicas
- Miscellaneous considerations for RDS for Oracle replicas

Version and licensing requirements for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.
- Oracle replicas are supported only for Oracle Enterprise Edition (EE).
- Oracle replicas of non-CDBs are supported only for DB instances created using non-CDB instances running Oracle Database 19c.
- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.small instance class.
- The Oracle DB engine version of the source DB instance and all its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.

  For more information about upgrading the DB engine version, see Upgrading the RDS for Oracle DB engine.

Option group limitations for RDS for Oracle replicas

When working with option groups for your RDS for Oracle replica, consider the following:

- You can't use a replica option group different from the source DB instance option group when the source and replica are in the same AWS Region.

  Modifications to the source option group or source option group membership propagate to Oracle replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window. For more information about option groups, see Working with option groups.
- You can't remove an RDS for Oracle cross-Region replica from its dedicated option group, which is automatically created for the replica.
- You can't add the dedicated option group for an RDS for Oracle cross-Region replica to a different DB instance.
- You can't add or remove nonreplicated options from a dedicated option group for an RDS for Oracle cross-Region replica, with the exception of the following options:
  - `NATIVE_NETWORK_ENCRYPTION`
  - `OEM`
  - `OEM_AGENT`
  - `SSL`

  To add other options to an RDS for Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

  When you promote an RDS for Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

  For more information about option groups, see Working with option groups.
- You can't add the `EFS_INTEGRATION` option to RDS for Oracle cross-Region replicas.

Backup and restore considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- To create snapshots of RDS for Oracle replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.

- When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The *database time* refers to the latest applied transaction time of the data in the backup. The difference is significant because a replica can lag behind the primary for minutes or hours.

  To find the difference, use the `describe-db-snapshots` command. Compare the `snapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database.

Oracle Data Guard requirements and limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, note the following requirements and limitations:

- If your primary DB instance uses the single-tenant or multi-tenant configuration of the multitenant architecture, consider the following:
  - You must use Oracle Database 19c or higher with the Enterprise Edition.
  - Your primary CDB instance must be in an `ACTIVE` lifecycle.
  - You can't convert a non-CDB primary instance to a CDB instance and convert its replicas in the same operation. Instead, delete the non-CDB replicas, convert the primary DB instance to a CDB, and then create new replicas
- Make sure that a logon trigger on a primary DB instance permits access to the `RDS_DATAGUARD` user and to any user whose `AUTHENTICATED_IDENTITY` value is `RDS_DATAGUARD` or `rdsdb`. Also, the trigger must not set the current schema for the `RDS_DATAGUARD` user.
- To avoid blocking connections from the Data Guard broker process, don't enable restricted sessions. For more information about restricted sessions, see Enabling and disabling restricted sessions.

Multi-tenant configuration limitations for RDS for Oracle replicas

When using the multi-tenant configuration on an RDS for Oracle replica, note the following limitations:

- You can only create, delete, or modify tenant databases on the primary DB instance. These changes automatically propagate to the replicas.

- Tenant databases on an RDS for Oracle primary, source, or replica cannot be created with a custom character set. If you require a custom character set, create the tenant databases before creating read replicas for the DB instance.

Miscellaneous considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- When you are creating an RDS for Oracle replica for a DB instance that has additional storage volumes, RDS automatically configure additional storage volumes on the replica. However, any subsequent modifications made in storage volumes of your primary DB instance are not automatically applied to the replica.
- If you add additional storage volumes in your primary DB instance, RDS does not automatically add additional storage volumes to the replica. You need to modify your replica to add additional storage volumes.
- If you modify storage volumes configuration such as storage size and IOPS in your primary DB instance, RDS does not automatically modify storage volumes in the replica. You need to modify your replica to update storage volume configurations.
- When managing datafile locations across volumes, note that changes made on your primary instance don't automatically sync to replicas.
  - For read-only replicas: You can either use parameter group settings to control default file locations, or manually move files after they're created.
  - For mounted replicas: Manual changes to datafile locations in the primary database require recreating the mounted replica to reflect those changes. To avoid this, we recommend using parameter group settings to manage default file locations.
- If your DB instance is a source for one or more cross-Region replicas, the source DB retains its archived redo log files until they are applied on all cross-Region replicas. The archived redo logs might result in increased storage consumption.
- To avoid disrupting RDS automation, system triggers must permit specific users to log on to the primary and replica database. System triggers include DDL, logon, and database role triggers. We recommend that you add code to your triggers to exclude the users listed in the following sample code:

```
-- Determine who the user is
SELECT SYS_CONTEXT('USERENV','AUTHENTICATED_IDENTITY') INTO CURRENT_USER FROM DUAL;
```

```
-- The following users should always be able to login to either the Primary or
 Replica
IF CURRENT_USER IN ('master_user', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'rdsdb') THEN
RETURN;
END IF;
```

- Block change tracking is supported for read-only replicas, but not for mounted replicas. You can change a mounted replica to a read-only replica, and then enable block change tracking. For more information, see Enabling and disabling block change tracking.
- You can't create an Oracle read replica when the source database manages master user credentials with Secrets Manager.

Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

Topics

- Enabling automatic backups
- Enabling force logging mode
- Changing your logging configuration
- Setting the MAX_STRING_SIZE parameter
- Planning compute and storage resources

Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see Enabling automated backups.

Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when `NOLOGGING` is used with data definition language (DDL) statements.

To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.

```
exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

For more information about this procedure, see Setting force logging.

Changing your logging configuration

For *n* online redo logs of size *m*, RDS automatically creates *n*+1 standby logs of size *m* on the primary DB instance and all replicas. Whenever you change the logging configuration on the primary, the changes propagate automatically to the replicas.

If you change your logging configuration, consider the following guidelines:

- We recommend that you complete the changes before making a DB instance the source for replicas. RDS for Oracle also supports updating the instance after it becomes a source.
- Before you change the logging configuration on the primary DB instance, check that each replica has enough storage to accommodate the new configuration.

You can modify the logging configuration for a DB instance by using the Amazon RDS procedures `rdsadmin.rdsadmin_util.add_logfile` and `rdsadmin.rdsadmin_util.drop_logfile`. For more information, see Adding online redo logs and Dropping online redo logs.

Setting the MAX_STRING_SIZE parameter

Before you create an Oracle replica, ensure that the setting of the `MAX_STRING_SIZE` parameter is the same on the source DB instance and the replica. You can do this by associating them with the same parameter group. If you have different parameter groups for the source and the replica, you can set `MAX_STRING_SIZE` to the same value. For more information about setting this parameter, see Turning on extended data types for a new DB instance.

Planning compute and storage resources

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource capacity, the replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn't intervene to mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and CPU resources of a replica independently from its source and other replicas.

Creating an RDS for Oracle replica in mounted mode

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS CLI, or the RDS API.

Console

To create a mounted replica from a source Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For **Actions**, choose **Create replica**.
5. For **Replica mode**, choose **Mounted**.
6. Choose the settings that you want to use. For **DB instance identifier**, enter a name for the read replica. Adjust other settings as needed.
7. For **Regions**, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
9. For **Multi-AZ deployment**, choose **Create a standby instance** to create a standby of your replica in another Availability Zone for failover support for the mounted replica. Creating your mounted replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Choose the other settings that you want to use.
11. Choose **Create replica**.

In the **Databases** page, the mounted replica has the role Replica.

AWS CLI

To create an Oracle replica in mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command create-db-instance-read-replica.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --source-db-instance-identifier mydbinstance \
    --replica-mode mounted
```

For Windows:

```
aws rds create-db-instance-read-replica ^
    --db-instance-identifier myreadreplica ^
    --source-db-instance-identifier mydbinstance ^
    --replica-mode mounted
```

To change a read-only replica to a mounted state, set `--replica-mode` to `mounted` in the AWS CLI command modify-db-instance. To place a mounted replica in read-only mode, set `--replica-mode` to `open-read-only`.

RDS API

To create an Oracle replica in mounted mode, specify `ReplicaMode=mounted` in the RDS API operation CreateDBInstanceReadReplica.

Modifying the RDS for Oracle replica mode

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to **modifying**. For more information about status changes, see Viewing Amazon RDSDB instance status.

Console

To change the replica mode of an Oracle replica from mounted to read-only

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the mounted replica database.

4. Choose **Modify**.
5. For **Replica mode**, choose **Read-only**.
6. Choose the other settings that you want to change.
7. Choose **Continue**.
8. For **Scheduling of modifications**, choose **Apply immediately**.
9. Choose **Modify DB instance**.

AWS CLI

To change a read replica to mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command modify-db-instance. To change a mounted replica to read-only mode, set `--replica-mode` to `open-read-only`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myreadreplica \
    --replica-mode mode
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myreadreplica ^
    --replica-mode mode
```

RDS API

To change a read-only replica to mounted mode, set `ReplicaMode=mounted` in ModifyDBInstance. To change a mounted replica to read-only mode, set `ReplicaMode=read-only`.

Working with RDS for Oracle replica backups

You can create and restore backups of an RDS for Oracle replica. Both automatic backups and manual snapshots are supported. For more information, see Backing up, restoring, and exporting

data. The following sections describe the key differences between managing backups of a primary and an RDS for Oracle replica.

Turning on RDS for Oracle replica backups

An Oracle replica doesn't have automated backups turned on by default. You turn on automated backups by setting the backup retention period to a positive nonzero value.

Console

To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose a positive nonzero value, for example three days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI modify-db-instance or modify-db-cluster command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier my_db_instance  \
    --backup-retention-period 3 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier my_db_instance  ^
    --backup-retention-period 3 ^
    --apply-immediately
```

RDS API

To enable automated backups, use the RDS API ModifyDBInstance or ModifyDBCluster operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

Restoring an RDS for Oracle replica backup

You can restore an Oracle replica backup just as you can restore a backup of the primary instance. For more information, see the following:

- Restoring to a DB instance
- Restoring a DB instance to a specified time for Amazon RDS

The main consideration when you restore a replica backup is determining the point in time to which you are restoring. The *database time* refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup completed. The difference is significant because an RDS for Oracle replica can lag behind the primary by minutes or hours. Thus, the database time of a replica backup, and thus the point in time to which you restore it, might be much earlier than the backup creation time.

To find the difference between database time and creation time, use the `describe-db-snapshots` command. Compare the `SnapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database. The following example shows the difference between the two times:

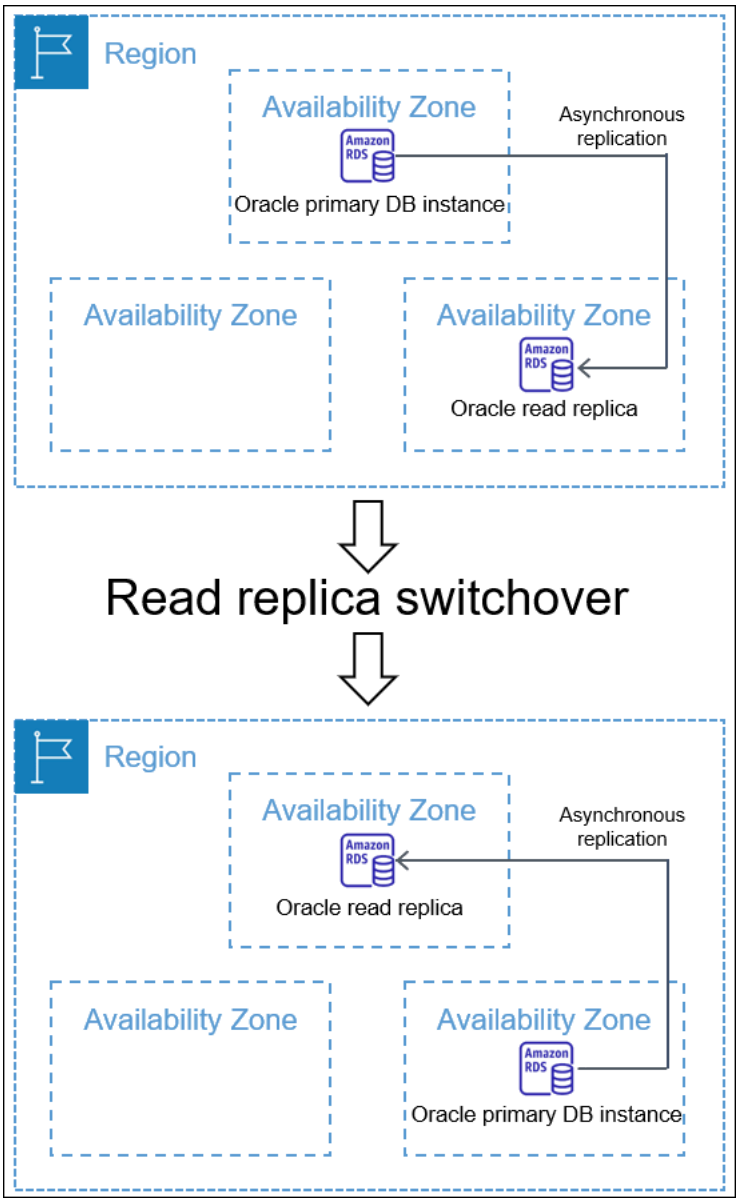
```
aws rds describe-db-snapshots \
    --db-instance-identifier my-oracle-replica
    --db-snapshot-identifier my-replica-snapshot

{
    "DBSnapshots": [
        {
            "DBSnapshotIdentifier": "my-replica-snapshot",
            "DBInstanceIdentifier": "my-oracle-replica",
            "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
            ...
            "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
        }
    ]
}
```

Performing an Oracle Data Guard switchover

A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

In an Oracle Data Guard environment, a primary database supports one or more standby databases. You can perform a managed, switchover-based role transition from a primary database to a standby database. A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.



Topics

- Overview of Oracle Data Guard switchover
- Requirements for the Oracle Data Guard switchover
- Initiating the Oracle Data Guard switchover
- Monitoring the Oracle Data Guard switchover

Overview of Oracle Data Guard switchover

Amazon RDS supports a fully managed, switchover-based role transition for Oracle Database replicas. You can only initiate a switchover to a standby database that is mounted or open read-only.

The replicas can reside in separate AWS Regions or in different Availability Zones (AZs) of a single Region. All AWS Regions are supported.

A switchover differs from a read replica promotion. In a switchover, the source and replica DB instances change roles. In a promotion, a read replica becomes a source DB instance, but the source

DB instance doesn't become a replica. For more information, see Promoting a read replica to be a standalone DB instance.

Topics

- Benefits of Oracle Data Guard switchover
- Supported Oracle Database versions
- Cost of Oracle Data Guard switchover
- How Oracle Data Guard switchover works

Benefits of Oracle Data Guard switchover

Just as for RDS for Oracle read replicas, a managed switchover relies on Oracle Data Guard. The operation is designed to have zero data loss. Amazon RDS automates the following aspects of the switchover:

- Reverses the roles of your primary database and specified standby database, putting the new standby database in the same state (mounted or read-only) as the original standby
- Ensures data consistency
- Maintains your replication configuration after the transition
- Supports repeated reversals, allowing your new standby database to return to its original primary role

Supported Oracle Database versions

Oracle Data Guard switchover is supported for Oracle Database 19c and higher releases.

Cost of Oracle Data Guard switchover

The Oracle Data Guard switchover feature doesn't incur additional costs. Oracle Database Enterprise Edition includes support for standby databases in mounted mode. To open standby databases in read-only mode, you need the Oracle Active Data Guard option.

How Oracle Data Guard switchover works

Oracle Data Guard switchover is a fully managed operation. You initiate the switchover for a standby database by issuing the CLI command `switchover-read-replica`. Then Amazon RDS modifies the primary and standby roles in your replication configuration.

The *original standby* and *original primary* are the roles that exist before the switchover. The *new standby* and *new primary* are the roles that exist after the switchover. A *bystander replica* is a replica database that serves as a standby database in the Oracle Data Guard environment but is not switching roles.

Topics

- Stages of the Oracle Data Guard switchover
- After the Oracle Data Guard switchover

Stages of the Oracle Data Guard switchover

To perform the switchover, Amazon RDS must take the following steps:

1. Block new transactions on the original primary database. During the switchover, Amazon RDS interrupts replication for all databases in your Oracle Data Guard configuration. During the switchover, the original primary database can't process write requests.
2. Ship unapplied transactions to the original standby database, and apply them.
3. Restart the new standby database in read-only or mounted mode. The mode depends on the open state of the original standby database before the switchover.
4. Open the new primary database in read/write mode.

After the Oracle Data Guard switchover

Amazon RDS switches the roles of the primary and standby database. You are responsible for reconnecting your application and performing any other desired configuration.

Topics

- Success criteria
- Connection to the new primary database
- Configuration of the new primary database

Success criteria

The Oracle Data Guard switchover is successful when the original standby database does the following:

- Transitions to its role as new primary database

- Completes its reconfiguration

To limit downtime, your new primary database becomes active as soon as possible. Because Amazon RDS configures bystander replicas asynchronously, these replicas might become active after the original primary database.

Connection to the new primary database

Amazon RDS won't propagate your current database connections to the new primary database after the switchover. After the Oracle Data Guard switchover completes, reconnect your application to the new primary database.

Configuration of the new primary database

To perform a switchover to the new primary database, Amazon RDS changes the mode of the original standby database to open. The change in role is the only change to the database. Amazon RDS doesn't set up features such as Multi-AZ replication.

If you perform a switchover to a cross-Region replica with different options, the new primary database keeps its own options. Amazon RDS won't migrate the options on the original primary database. If the original primary database had options such as SSL, NNE, OEM, and OEM_AGENT, Amazon RDS doesn't propagate them to the new primary database.

Requirements for the Oracle Data Guard switchover

Before initiating the Oracle Data Guard switchover, make sure that your replication environment meets the following requirements:

- The original standby database is mounted or open read-only.
- Automatic backups are enabled on the original standby database.
- The original primary database and the original standby database are in the `available` state.
- The original primary database and the original standby database don't have pending maintenance actions in any of the following states: `required`, `next window`, or `in progress`. Actions in these states block switchover. To learn how to check the status of pending maintenance updates, see Viewing pending maintenance updates.

  Pending maintenance actions in the `available` state don't block switchover. RDS for Oracle frequently releases operating system (OS) updates in the `available` state. These pending OS

updates won't block a switchover unless you schedule them for the next maintenance window, which puts them in the `next window` state.

> **Note**
>
> If you want to defer a scheduled maintenance action so that you can execute a switchover, choose **Actions** and then **Defer upgrade** in the RDS console. You can also prevent a switchover from being blocked by applying a pending maintenance action or moving the maintenance window to an interval before your switchover. For more information, see the re:Post article How to remove RDS pending maintenance items.

- The original standby database is in the replicating state.
- You aren't attempting to initiate a switchover when either the primary database or standby database is currently in a switchover lifecycle. If a replica database is reconfiguring after a switchover, Amazon RDS prevents you from initiating another switchover.

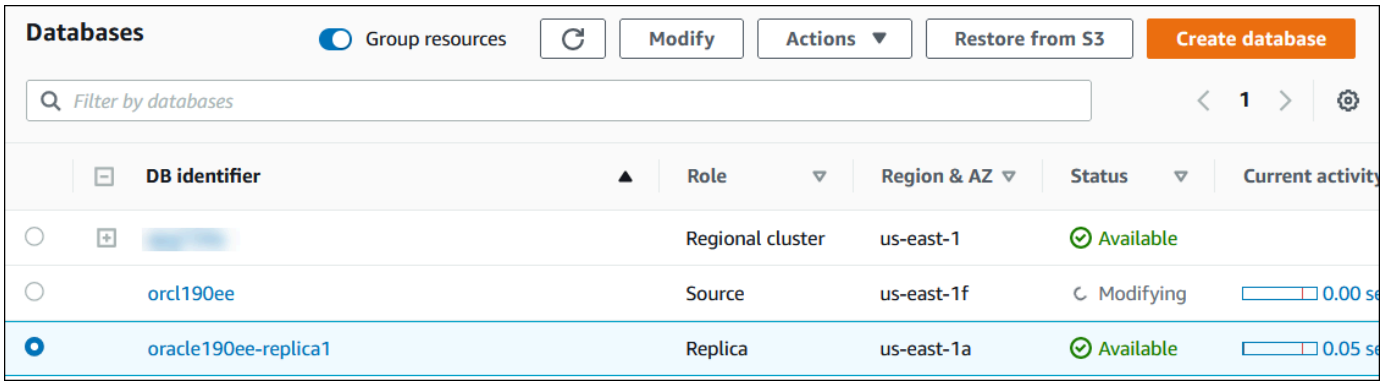
> **Note**
>
> A *bystander replica* is a replica in the Oracle Data Guard configuration that isn't the target of the switchover. Bystander replicas can be in any state during the switchover.

- The original standby database has a configuration that is as close as desired to the original primary database. Assume a scenario where the original primary and original standby databases have different options. After the switchover completes, Amazon RDS doesn't automatically reconfigure the new primary database to have the same options as the original primary database.
- You configure your desired Multi-AZ deployment before initiating a switchover. Amazon RDS doesn't manage Multi-AZ as part of the switchover. The Multi-AZ deployment remains as it is.

  Assume that db_maz is the primary database in a Multi-AZ deployment, and db_saz is a Single-AZ replica. You initiate a switchover from db_maz to db_saz. Afterward, db_maz is a Multi-AZ replica database, and db_saz is a Single-AZ primary database. The new primary database is now unprotected by a Multi-AZ deployment.
- In preparation for a cross-Region switchover, the primary database doesn't use the same option group as a DB instance outside of the replication configuration. For a cross-Region switchover to succeed, the current primary database and its read replicas must be the only DB instances

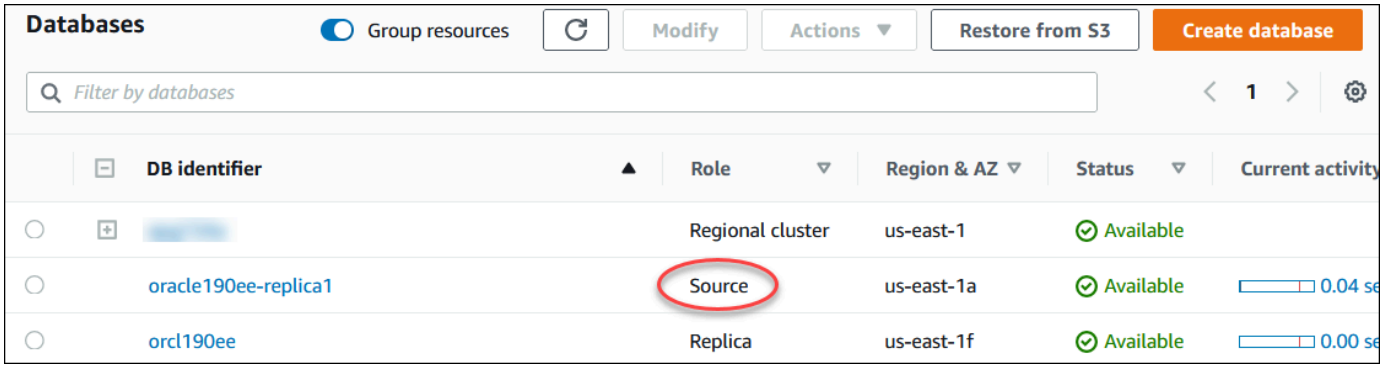
to use the option group of the current primary database. Otherwise, Amazon RDS prevents the switchover.

Initiating the Oracle Data Guard switchover



You can switch over an RDS for Oracle read replica to the primary role, and the former primary DB instance to a replica role.

Console



To switch over an Oracle read replica to the primary DB role

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, choose **Databases**.

   The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.
3. Choose the read replica that you want to switch over to the primary role.
4. For **Actions**, choose **Switch over replica**.
5. Choose **I acknowledge**. Then choose **Switch over replica**.
6. On the **Databases** page, monitor the progress of the switchover.

When the switchover completes, the role of the switchover target changes from **Replica** to **Source**.

AWS CLI

To switch over an Oracle replica to the primary DB role, use the AWS CLI `switchover-read-replica` command. The following examples make the Oracle replica named *`replica-to-be-made-primary`* into the new primary database.

Example

For Linux, macOS, or Unix:

```
aws rds switchover-read-replica \
    --db-instance-identifier replica-to-be-made-primary
```

For Windows:

```
aws rds switchover-read-replica ^
    --db-instance-identifier replica-to-be-made-primary
```

RDS API

To switch over an Oracle replica to the primary DB role, call the Amazon RDS API `SwitchoverReadReplica` operation with the required parameter `DBInstanceIdentifier`. This parameter specifies the name of the Oracle replica that you want to assume the primary DB role.

Monitoring the Oracle Data Guard switchover

To check the status of your instances, use the AWS CLI command `describe-db-instances`. The following command checks the status of the DB instance *`orcl2`*. This database was a standby database before the switchover, but is the new primary database after the switchover.

```
aws rds describe-db-instances \
```

```
    --db-instance-identifier orcl2
```

To confirm that the switchover completed successfully, query `V$DATABASE.OPEN_MODE`. Check that the value for the new primary database is `READ WRITE`.

```
SELECT OPEN_MODE FROM V$DATABASE;
```

To look for switchover-related events, use the AWS CLI command `describe-events`. The following example looks for events on the *orcl2* instance.

```
aws rds describe-events \
    --source-identifier orcl2 \
    --source-type db-instance
```

Troubleshooting RDS for Oracle replicas

This section describes possible replication problems and solutions.

Topics

- Monitoring Oracle replication lag
- Troubleshooting Oracle replication failure after adding or modifying triggers

Monitoring Oracle replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS `ReplicaLag` metric. For more information about replication lag time, see Monitoring read replication and Amazon CloudWatch metrics for Amazon RDS.

For a read replica, if the lag time is too long, query the following views:

- `V$ARCHIVED_LOG` – Shows which commits have been applied to the read replica.
- `V$DATAGUARD_STATS` – Shows a detailed breakdown of the components that make up the `ReplicaLag` metric.
- `V$DATAGUARD_STATUS` – Shows the log output from Oracle's internal replication processes.

For a mounted replica, if the lag time is too long, you can't query the `V$` views. Instead, do the following:

- Check the `ReplicaLag` metric in CloudWatch.
- Check the alert log file for the replica in the console. Look for errors in the recovery messages. The messages include the log sequence number, which you can compare to the primary sequence number. For more information, see Amazon RDS for Oracle database log files.

Troubleshooting Oracle replication failure after adding or modifying triggers

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- `SYS`
- `SYSTEM`
- `RDS_DATAGUARD`
- `rdsdb`

For more information, see Miscellaneous considerations for RDS for Oracle replicas.

Redo transport compression with RDS for Oracle

Use RDS for Oracle redo transport compression to improve the replication performance between your primary DB instance and standby replicas. This is particularly useful in environments that have limited network bandwidth or high-latency connections.

Obtaining a license for redo transport compression

Redo transport compression is part of the Oracle Advanced Compression option. To use redo transport compression, you need a valid license for the Oracle Advanced Compression option. For licensing information, contact your Oracle representative.

Configuring redo transport compression

To configure redo transport compression, you can use the `rds.replica.redo_compression` parameter. This parameter is available for Oracle versions 19c and 21c.

The `rds.replica.redo_compression` parameter accepts the following values:

- `DISABLE` – Default value that disables redo transport compression.
- `ENABLE` – Value that enables redo transport compression through the default algorithm ZLIB.
- `ZLIB` – Value that explicitly enables redo transport compression using the ZLIB algorithm, which provides good compression ratios.
- `LZO` – Value that explicitly enables redo transport compression using the LZO algorithm, which optimizes compression speed, particularly during decompression.

Performance considerations for redo transport compression

Compression and decompression operations consume CPU resources on both the primary and standby instances. If you use redo transport compression, consider instance resource usage and network conditions.

Related topics for redo transport compression

For more information on configuring redo transport compression, see the following resources:

- DB parameter groups for Amazon RDS DB instances
- RedoCompression in the Oracle Database 19c release notes

Adding options to Oracle DB instances

In Amazon RDS, an *option* is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

Topics

- Overview of Oracle DB options
- Amazon S3 integration
- Oracle Application Express (APEX)
- Amazon EFS integration
- Oracle Java virtual machine
- Oracle Enterprise Manager
- Oracle Label Security
- Oracle Locator
- Oracle native network encryption

- Oracle time zone
- Oracle time zone file autoupgrade
- Oracle Transparent Data Encryption
- Oracle UTL_MAIL
- Oracle XML DB

Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups.

Topics

- Summary of Oracle Database options
- Options supported for different editions
- Memory requirements for specific options

Summary of Oracle Database options

You can add the following options for Oracle DB instances.

Option	Option ID
Amazon S3 integration	S3_INTEGRATION
Oracle Application Express (APEX)	APEX APEX-DEV
Oracle Enterprise Manager	OEM OEM_AGENT
Oracle Java virtual machine	JVM
Oracle Label Security	OLS
Oracle Locator	LOCATOR
Oracle native network encryption	NATIVE_NETWORK_ENCRYPTION
Oracle OLAP	OLAP
Oracle Secure Sockets Layer	SSL
Oracle Spatial	SPATIAL
Oracle SQLT	SQLT
Oracle Statspack	STATSPACK
Oracle time zone	Timezone

Option	Option ID
Oracle time zone file autoupgrade	TIMEZONE_FILE_AUTOUPGRADE
Oracle Transparent Data Encryption	TDE
Oracle UTL_MAIL	UTL_MAIL
Oracle XML DB	XMLDB

Options supported for different editions

RDS for Oracle prevents you from adding options to an edition if they aren't supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```
aws rds describe-option-group-options \
    --engine-name oracle-ee \
    --major-engine-version 19
```

For more information, see describe-option-group-options in the *AWS CLI Command Reference*.

Memory requirements for specific options

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.

Amazon S3 integration

You can transfer files between your RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle Database features such as Oracle Data Pump. For example, you can download Data Pump files from Amazon S3 to your RDS for Oracle DB instance. For more information, see Importing data into Oracle on Amazon RDS.

> **Note**
>
> Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

Topics

- Configuring IAM permissions for RDS for Oracle integration with Amazon S3
- Adding the Amazon S3 integration option
- Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket
- Troubleshooting Amazon S3 integration
- Removing the Amazon S3 integration option

Configuring IAM permissions for RDS for Oracle integration with Amazon S3

For RDS for Oracle to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket. The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

RDS for Oracle supports transferring files between a DB instance in one account and an Amazon S3 bucket in a different account. Where additional steps are required, they are noted in the following sections.

Topics

- Step 1: Create an IAM policy for your Amazon RDS role
- Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket
- Step 3: Create an IAM role for your DB instance and attach your policy
- Step 4: Associate your IAM role with your RDS for Oracle DB instance

Step 1: Create an IAM policy for your Amazon RDS role

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files between your Amazon S3 bucket and your RDS DB instance. This step assumes that you have already created an S3 bucket.

Before you create the policy, note the following pieces of information:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS KMS key, if your bucket uses SSE-KMS or SSE-S3 encryption

> **Note**
>
> An RDS for Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

For more information, see Protecting data using server-side encryption in the *Amazon Simple Storage Service User Guide*.

Console

To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Open the IAM Management Console.
2. Under **Access management**, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.
5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:
   - Expand **List**, and then select **ListBucket**.
   - Expand **Read**, and then select **GetObject**.
   - Expand **Write**, and then select **PutObject**, **DeleteObject**, **AbortMultipartUpload**, and **ListMultipartUploadParts**. The multipart upload permissions are required when uploading large files (100 MB or larger) to Amazon S3.

- Expand **Permissions management**, and then select **PutObjectAcl**. This permission is necessary if you plan to upload files to a bucket owned by a different account, and this account needs full control of the bucket contents.

Object permissions are permissions for object operations in Amazon S3. You must grant them for objects in a bucket, not the bucket itself. For more information, see Permissions for object operations.

6. Choose **Resources**, and then do the following:

   a. Choose **Specific**.

   b. For **bucket**, choose **Add ARN**. Enter your bucket ARN. The bucket name is filled in automatically. Then choose **Add**.

   c. If the **object** resource is shown, either choose **Add ARN** to add resources manually or choose **Any**.

   > **Note**
   >
   > You can set **Amazon Resource Name (ARN)** to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

7. (Optional) Choose **Add additional permissions** to add resources to the policy. For example, do the following:

   a. If your bucket is encrypted with a custom KMS key, select **KMS** for the service.

   b. For **Manual actions**, select the following:

      - **Encrypt**
      - **ReEncrypt from** and **ReEncrypt to**
      - **Decrypt**
      - **DescribeKey**
      - **GenerateDataKey**

   c. For **Resources**, choose **Specific**.

d. For **key**, choose **Add ARN**. Enter the ARN of your custom key as the resource, and then choose **Add**.

   For more information, see Protecting Data Using Server-Side Encryption with KMS keys Stored in AWS Key Management Service (SSE-KMS) in the *Amazon Simple Storage Service User Guide*.

e. If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.

8. Choose **Next: Tags** and then **Next: Review**.
9. For **Name**, enter a name for your IAM policy, for example `rds-s3-integration-policy`. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional **Description** value.
10. Choose **Create policy**.

AWS CLI

Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket. After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step.

Include the appropriate actions in the policy based on the type of access required:

- `GetObject` – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- `ListBucket` – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- `PutObject` – Required to transfer files from Amazon RDS to an Amazon S3 bucket.
- `AbortMultipartUpload` – Required for multipart uploads when transferring large files (100 MB or larger) from Amazon RDS to an Amazon S3 bucket.
- `ListMultipartUploadParts` – Required for multipart uploads when transferring large files (100 MB or larger) from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named *`rds-s3-integration-policy`* with these options. It grants access to a bucket named *`amzn-s3-demo-bucket`*.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
   --policy-name rds-s3-integration-policy \
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3integration",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket",
           "s3:PutObject",
           "s3:AbortMultipartUpload",
           "s3:ListMultipartUploadParts"
         ],
         "Effect": "Allow",
         "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket",
           "arn:aws:s3:::amzn-s3-demo-bucket/*"
         ]
       }
     ]
   }'
```

The following example includes permissions for custom KMS keys.

```
aws iam create-policy \
   --policy-name rds-s3-integration-policy \
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3integration",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket",
           "s3:PutObject",
           "kms:Decrypt",
           "kms:Encrypt",
           "kms:ReEncrypt*",
           "kms:GenerateDataKey",
           "kms:DescribeKey",
         ],
         "Effect": "Allow",
```

```
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*",
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }'
```

For Windows:

```
aws iam create-policy ^
   --policy-name rds-s3-integration-policy ^
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3integration",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket",
           "s3:PutObject",
           "s3:AbortMultipartUpload",
           "s3:ListMultipartUploadParts"
         ],
         "Effect": "Allow",
         "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket",
           "arn:aws:s3:::amzn-s3-demo-bucket/*"
         ]
       }
     ]
   }'
```

The following example includes permissions for custom KMS keys.

```
aws iam create-policy ^
   --policy-name rds-s3-integration-policy ^
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3integration",
```

```
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject",
          "kms:Decrypt",
          "kms:Encrypt",
          "kms:ReEncrypt",
          "kms:GenerateDataKey",
          "kms:DescribeKey",
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*",
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }'
```

Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket

This step is necessary only in the following conditions:

- You plan to upload files to an Amazon S3 bucket from one account (account A) and access them from a different account (account B).
- Account B owns the bucket.
- Account B needs full control of objects loaded into the bucket.

If the preceding conditions don't apply to you, skip to Step 3: Create an IAM role for your DB instance and attach your policy.

To create your bucket policy, make sure you have the following:

- The account ID for account A
- The user name for account A
- The ARN value for the Amazon S3 bucket in account B

Console

To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
3. Choose **Permissions**.
4. Under **Bucket policy**, choose **Edit**. This opens the Edit bucket policy page.
5. On the **Edit bucket policy** page, explore **Policy examples** in the *Amazon S3 User Guide*, choose **Policy generator** to generate a policy automatically, or edit the JSON in the **Policy** section.

   If you choose **Policy generator**, the AWS Policy Generator opens in a new window:

   a. On the **AWS Policy Generator** page, in **Select Type of Policy**, choose **S3 Bucket Policy**.

   b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat for as many statements as you would like to add. For more information about these fields, see the IAM JSON policy elements reference in the *IAM User Guide*.

   > **Note**
   >
   > For convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

   c. After you finish adding statements, choose **Generate Policy**.

   d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.
6. In the **Policy** box, edit the existing policy or paste the bucket policy from the Policy generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

   JSON

```
{
```

```
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "ExamplePermissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/account-A-user"
      },
      "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-destination-bucket",
        "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      ]
    }
  ]
}
```

7. Choose **Save changes**, which returns you to the Bucket Permissions page.

Step 3: Create an IAM role for your DB instance and attach your policy

This step assumes that you have created the IAM policy in Step 1: Create an IAM policy for your Amazon RDS role. In this step, you create a role for your RDS for Oracle DB instance and then attach your policy to the role.

Console

To create an IAM role to allow Amazon RDS to access an Amazon S3 bucket

1. Open the IAM Management Console.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service**.
5. For **Use cases for other AWS services:**, choose **RDS** and then **RDS – Add Role to Database**. Then choose **Next**.

6. For **Search** under **Permissions policies**, enter the name of the IAM policy you created in Step 1: Create an IAM policy for your Amazon RDS role, and select the policy when it appears in the list. Then choose **Next**.
7. For **Role name**, enter a name for your IAM role, for example, `rds-s3-integration-role`. You can also add an optional **Description** value.
8. Choose **Create role**.

AWS CLI

To create a role and attach your policy to it

1. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.

   We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

   You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

   - Use `aws:SourceArn` if you want cross-service access for a single resource.
   - Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

   In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

   The following AWS CLI command creates the role named *`rds-s3-integration-role`* for this purpose.

   Example

   For Linux, macOS, or Unix:

```
aws iam create-role \
   --role-name rds-s3-integration-role \
```

```
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": "my_account_ID",
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For Windows:

```
aws iam create-role ^
   --role-name rds-s3-integration-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": "my_account_ID",
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

2. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.
3. Attach the policy you created to the role you created.

   The following AWS CLI command attaches the policy to the role named *rds-s3-integration-role*.

   Example

   For Linux, macOS, or Unix:

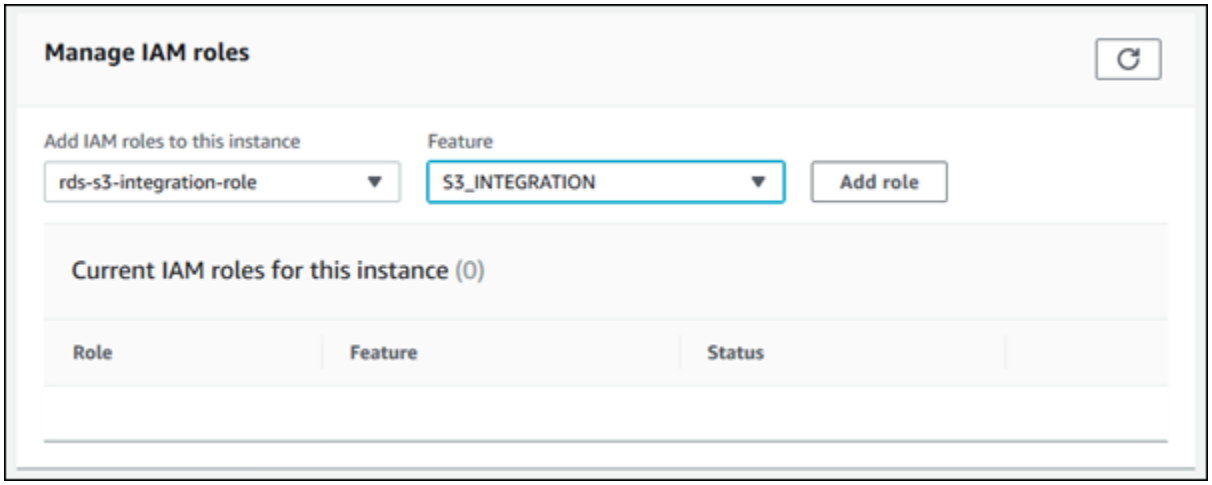
```
aws iam attach-role-policy \
   --policy-arn your-policy-arn \
   --role-name rds-s3-integration-role
```

   For Windows:

```
aws iam attach-role-policy ^
   --policy-arn your-policy-arn ^
   --role-name rds-s3-integration-role
```

   Replace *your-policy-arn* with the policy ARN that you noted in a previous step.

Step 4: Associate your IAM role with your RDS for Oracle DB instance



The last step in configuring permissions for Amazon S3 integration is associating your IAM role with your DB instance. Note the following requirements:

- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Oracle DB instance at a time.
- Your DB instance must be in the **Available** state.

Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** from the navigation pane.
3. Choose the RDS for Oracle DB instance name to display its details.
4. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
5. For **Add IAM roles to this instance**, choose the role that you created in Step 3: Create an IAM role for your DB instance and attach your policy.
6. For **Feature**, choose **S3_INTEGRATION**.

7. Choose **Add role**.

AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier mydbinstance \
   --feature-name S3_INTEGRATION \
   --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name S3_INTEGRATION ^
   --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. `S3_INTEGRATION` must be specified for the `--feature-name` option.

Adding the Amazon S3 integration option

To integrate Amazon RDS for Oracle with Amazon S3, your DB instance must be associated with an option group that includes the `S3_INTEGRATION` option.

Console

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the `S3_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.
2. Add the `S3_INTEGRATION` option to the option group.

   For information about adding an option to an option group, see Adding an option to an option group.
3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the `S3_INTEGRATION` option.

For information about creating an option group, see Creating an option group.

2. Add the S3_INTEGRATION option to the option group.

   For example, the following AWS CLI command adds the S3_INTEGRATION option to an option group named **myoptiongroup**.

   Example

   For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
   --option-group-name myoptiongroup \
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

   For Windows:

```
aws rds add-option-to-option-group ^
   --option-group-name myoptiongroup ^
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying an RDS for Oracle DB instance, see Modifying an Amazon RDS DB instance.

Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket

To transfer files between an RDS for Oracle DB instance and an Amazon S3 bucket, you can use the Amazon RDS package rdsadmin_s3_tasks. You can compress files with GZIP when uploading them, and decompress them when downloading.

Topics

- Requirements and limitations for file transfers
- Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket
- Downloading files from an Amazon S3 bucket to an Oracle DB instance

- Monitoring the status of a file transfer

Requirements and limitations for file transfers

Before transferring files between your DB instance and an Amazon S3 bucket, note the following:

- The `rdsadmin_s3_tasks` package transfers files located in a single directory. You can't include subdirectories in a transfer.
- The maximum object size in an Amazon S3 bucket is 5 TB.
- Tasks created by `rdsadmin_s3_tasks` run asynchronously.
- You can upload files from the Data Pump directory, such as `DATA_PUMP_DIR`, or any user-created directory. You can't upload files from a directory used by Oracle background processes, such as the `adump`, `bdump`, or `trace` directories.
- The download limit is 2000 files per procedure call for `download_from_s3`. If you need to download more than 2000 files from Amazon S3, split your download into separate actions, with no more than 2000 files per procedure call.
- If a file exists in your download folder, and you attempt to download a file with the same name, `download_from_s3` skips the download. To remove a file from the download directory, use the PL/SQL procedure UTL_FILE.FREMOVE.

Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket

To upload files from your DB instance to an Amazon S3 bucket, use the procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3`. For example, you can upload Oracle Recovery Manager (RMAN) backup files or Oracle Data Pump files. For more information about working with objects, see Amazon Simple Storage Service User Guide. For more information about performing RMAN backups, see Performing common RMAN tasks for Oracle DB instances.

The `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_bucket_name	VARCHAR2	–	required	The name of the Amazon S3 bucket to upload files to.

Parameter name	Data type	Default	Required	Description
p_directory_name	VARCHAR2	–	required	The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR . You can't upload files from a directory used by background processes, such as adump, bdump, and trace. **Note** You can only upload files from the specified directory. You can't upload files in subdirectories in the specified directory.

Parameter name	Data type	Default	Required	Description
p_s3_prefix	VARCHAR2	–	required	An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names. For example, if the prefix is folder_1/oradb , files are uploaded to folder_1. In this case, the oradb prefix is added to each file.
p_prefix	VARCHAR2	–	required	A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.
p_compression_level	NUMBER	0	optional	The level of GZIP compression. Valid values range from 0 to 9: • 0 – No compression • 1 – Fastest compression • 9 – Highest compression

Parameter name	Data type	Default	Required	Description
p_bucket_owner_full_control	VARCHAR2	–	optional	The access control setting for the bucket. The only valid values are null or FULL_CONTROL . This setting is required only if you upload files from one account (account A) into a bucket owned by a different account (account B), and account B needs full control of the files.

The return value for the rdsadmin.rdsadmin_s3_tasks.upload_to_s3 procedure is a task ID.

The following example uploads all of the files in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files aren't compressed.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_prefix         =>  '',
      p_s3_prefix      =>  '',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

The following example uploads all of the files with the prefix *db* in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. Amazon RDS applies the highest level of GZIP compression to the files.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name       =>  'amzn-s3-demo-bucket',
      p_prefix            =>  'db',
      p_s3_prefix         =>  '',
      p_directory_name    =>  'DATA_PUMP_DIR',
      p_compression_level =>  9)
```

```
   AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files are uploaded to a `dbfiles` folder. In this example, the GZIP compression level is *1*, which is the fastest level of compression.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name       =>  'amzn-s3-demo-bucket',
      p_prefix            =>  '',
      p_s3_prefix         =>  'dbfiles/',
      p_directory_name    =>  'DATA_PUMP_DIR',
      p_compression_level =>  1)
   AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the *DATA_PUMP_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files are uploaded to a `dbfiles` folder and `ora` is added to the beginning of each file name. No compression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_prefix         =>  '',
      p_s3_prefix      =>  'dbfiles/ora',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

The following example assumes that the command is run in account A, but account B requires full control of the bucket contents. The command `rdsadmin_s3_tasks.upload_to_s3` transfers all files in the *DATA_PUMP_DIR* directory to the bucket named *s3bucketOwnedByAccountB*. Access control is set to `FULL_CONTROL` so that account B can access the files in the bucket. The GZIP compression level is *6*, which balances speed and file size.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
      p_bucket_name               =>  's3bucketOwnedByAccountB',
      p_prefix                    =>  '',
      p_s3_prefix                 =>  '',
      p_directory_name            =>  'DATA_PUMP_DIR',
      p_bucket_owner_full_control =>  'FULL_CONTROL',
      p_compression_level         =>  6)
   AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

> **Note**
>
> Tasks are executed asynchronously.

Downloading files from an Amazon S3 bucket to an Oracle DB instance

To download files from an Amazon S3 bucket to an RDS for Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

The `download_from_s3` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_bucket_name	VARCHAR	–	Required	The name of the Amazon S3 bucket to download files from.
p_directory_name	VARCHAR	–	Required	The name of the Oracle directory object to download files to. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR .
p_error_on_zero_downloads	VARCHAR	FALSE	Optional	A flag that determines whether the task raises an error when no objects in the Amazon S3 bucket match the prefix. If this parameter is not set or set to FALSE (default), the task prints a message that no objects were found,

Parameter name	Data type	Default	Required	Description
				but doesn't raise an exception or fail. If this parameter is TRUE, the task raises an exception and fails. Examples of prefix specifications that can fail match tests are spaces in prefixes, as in `' import/test9.log'` , and case mismatches, as in `test9.log` and `test9.LOG` .

Parameter name	Data type	Default	Required	Description
p_s3_prefix	VARCHAR	–	Required	A file name prefix that file names must match to be downloaded. An empty prefix downloads all of the top level files in the specified Amazon S3 bucket, but not the files in folders in the bucket. The procedure downloads Amazon S3 objects only from the first level folder that matches the prefix. Nested directory structures matching the specified prefix are not downloaded. For example, suppose that an Amazon S3 bucket has the folder structure folder_1/folder_2/folder_3 . You specify the 'folder_1/folder_2/' prefix. In this case, only the files in folder_2 are downloaded, not the files in folder_1 or folder_3. If, instead, you specify the 'folder_1/folder_2' prefix, all files in folder_1 that match the 'folder_2' prefix are downloaded, and no files in folder_2 are downloaded.
p_decompression_format	VARCHAR	–	Optional	The decompression format. Valid values are NONE for no decompression and GZIP for decompression.

The return value for the rdsadmin.rdsadmin_s3_tasks.download_from_s3 procedure is a task ID.

The following example downloads all files in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. The files aren't compressed, so no decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

The following example downloads all of the files with the prefix *db* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. The files are compressed with GZIP, so decompression is applied. The parameter `p_error_on_zero_downloads` turns on prefix error checking, so if the prefix doesn't match any files in the bucket, the task raises and exception and fails.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name               =>  'amzn-s3-demo-bucket',
      p_s3_prefix                 =>  'db',
      p_directory_name            =>  'DATA_PUMP_DIR',
      p_decompression_format      =>  'GZIP',
      p_error_on_zero_downloads   =>  'TRUE')
   AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder *myfolder/* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. Use the `p_s3_prefix` parameter to specify the Amazon S3 folder. The uploaded files are compressed with GZIP, but aren't decompressed during the download.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
      p_bucket_name          =>  'amzn-s3-demo-bucket',
      p_s3_prefix            =>  'myfolder/',
      p_directory_name       =>  'DATA_PUMP_DIR',
      p_decompression_format =>  'NONE')
   AS TASK_ID FROM DUAL;
```

The following example downloads the file *mydumpfile.dmp* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA_PUMP_DIR* directory. No decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
```

```
      p_bucket_name    =>  'amzn-s3-demo-bucket',
      p_s3_prefix      =>  'mydumpfile.dmp',
      p_directory_name =>  'DATA_PUMP_DIR')
   AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

> **Note**
>
> Tasks are executed asynchronously.
> You can use the UTL_FILE.FREMOVE Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle documentation.

Monitoring the status of a file transfer

File transfer tasks publish Amazon RDS events when they start and when they complete. The event message contains the task ID for the file transfer. For information about viewing events, see Viewing Amazon RDS events.

You can view the status of an ongoing task in a bdump file. The bdump files are located in the /rdsdbdata/log/trace directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

Replace *task-id* with the ID of the task that you want to monitor.

> **Note**
>
> Tasks are executed asynchronously.

You can use the `rdsadmin.rds_file_util.read_text_file` stored procedure to view the contents of bdump files. For example, the following query returns the contents of the *dbtask-1234567890123-1234.log* bdump file.

```
SELECT text FROM
 table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-1234.log'));
```

The following sample shows the log file for a failed transfer.

```
TASK_ID

                                                
```

Troubleshooting Amazon S3 integration

For troubleshooting tips, see the AWS re:Post article How do troubleshoot issues when I integrate Amazon RDS for Oracle with Amazon S3?.

Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the `S3_INTEGRATION` option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- To remove the Amazon S3 integration option from a single DB instance, modify the instance and specify a different option group that doesn't include the `S3_INTEGRATION` option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the `APEX` and `APEX-DEV` options. You can deploy Oracle APEX as a runtime environment or as a full development environment for web-based applications. Using Oracle APEX, you can build applications entirely within the web browser. For more information, see Oracle application Express in the Oracle documentation.

Topics

- Oracle APEX components
- Requirements and limitations
- Setting up Oracle APEX and Oracle Rest Data Services (ORDS)
- Configuring Oracle Rest Data Services (ORDS)
- Upgrading and removing Oracle APEX

Oracle APEX components

Oracle APEX consists of the following main components:

- A *repository* that stores the metadata for Oracle APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.
- A *listener* that manages HTTP communications with Oracle APEX clients. The listener resides on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers.

  RDS for Oracle supports the following types of listeners:

  - For Oracle APEX version 5.0 and later, use Oracle REST Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
  - For Oracle APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.
  - You can use Oracle HTTP Server and `mod_plsql` listeners.

> **Note**
>
> Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway as a listener for Oracle APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

For more information about these listener types, see About choosing a web listener in the Oracle documentation.

When you add the APEX and APEX-DEV options to your RDS for Oracle DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host.

Requirements and limitations

The following topic lists the requirements and limitations for Oracle APEX and ORDS.

Oracle APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.

Oracle APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 24.2.v1	114 MiB	All	This version includes patch 37885097: PSE BUNDLE FOR APEX 24.2 (PSES ON TOP OF 24.2.0), PATCH_VERSION 4.
Oracle APEX version 24.1.v1	112 MiB	All	This version includes patch 36695709: PSE BUNDLE FOR APEX 24.1 (PSES ON TOP OF 24.1.0), PATCH_VERSION 3. If you need exactly the same APEX images version to install on your EC2 instance, download patch 37544819: 24.1.3 PSE BUNDLE FOR APEX 24.1 (PSES ON TOP OF 24.1.0).

Oracle APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 23.2.v1	110 MiB	All	This version includes patch 35895964: PSE BUNDLE FOR APEX 23.2 (PSES ON TOP OF 23.2.0), PATCH_VERSION 6. If you need exactly the same APEX images version to install on your EC2 instance, download patch 37593125: 23.2.6 PSE BUNDLE FOR APEX 23.2 (PSES ON TOP OF 23.2.0).
Oracle APEX version 23.1.v1	106 MiB	All	This version includes patch 35283657: PSE BUNDLE FOR APEX 23.1 (PSES ON TOP OF 23.1.0), PATCH_VERSION 2.
Oracle APEX version 22.2.v1	106 MiB	All	This version includes patch 34628174: PSE BUNDLE FOR APEX 22.2 (PSES ON TOP OF 22.2.0), PATCH_VERSION 4.
Oracle APEX version 22.1.v1	124 MiB	All	This version includes patch 34020981: PSE BUNDLE FOR APEX 22.1 (PSES ON TOP OF 22.1.0), PATCH_VERSION 6.
Oracle APEX version 21.2.v1	125 MiB	All	This version includes patch 33420059: PSE BUNDLE FOR APEX 21.2 (PSES ON TOP OF 21.2.0), PATCH_VERSION 8.
Oracle APEX version 21.1.v1	125 MiB	All	This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1, PATCH_VERSION 3.

Oracle APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 20.2.v1	148 MiB	All except Oracle Database 21c	This version includes patch 32006852: PSE BUNDLE FOR APEX 20.2, PATCH_VERSION 2020.11.12. You can see the patch number and date by running the following query: `SELECT PATCH_VERSION, PATCH_NUMBER FROM APEX_PATCHES;`
Oracle APEX version 20.1.v1	173 MiB	All except Oracle Database 21c	This version includes patch 30990551: PSE BUNDLE FOR APEX 20.1, PATCH_VERSION 2020.07.15.
Oracle APEX version 19.2.v1	149 MiB	All except Oracle Database 21c	
Oracle APEX version 19.1.v1	148 MiB	All except Oracle Database 21c	

For downloadable Oracle APEX .zip files, see Oracle APEX Prior Release Archives on the Oracle website.

Oracle APEX and ORDS prerequisites

Note the following prerequisites for using Oracle APEX and ORDS:

- Your system must use the Java Runtime Environment (JRE).
- Your Oracle client installation must include the following:

- SQL*Plus or SQL Developer for administration tasks
- Oracle Net Services for configuring connections to your RDS for Oracle DB instance

Oracle APEX limitations
