You can't modify the APEX_*version* user account, which is managed by Amazon RDS. Thus, you can't apply database profiles or enforce password rules on this user. The profiles and password settings for APEX_*version* are predefined by Oracle and AWS and are designed to meet the security requirements for Amazon RDS.

Setting up Oracle APEX and Oracle Rest Data Services (ORDS)

The following topic lists the steps required to set up Oracle APEX and ORDS

Topics

- Adding the APEX and APEX-DEV options to your DB instance
- Unlocking the public user account on your DB instance
- Configuring RESTful services for Oracle APEX
- Preparing to install ORDS on a separate host
- Setting up Oracle APEX listener

Adding the APEX and APEX-DEV options to your DB instance

To add the APEX and APEX-DEV options to your RDS for Oracle DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the APEX and APEX-DEV options to the option group.
3. Associate the option group with your DB instance.

When you add the APEX and APEX-DEV options, a brief outage occurs while your DB instance is automatically restarted.

> **Note**
>
> APEX_MAIL is available when the APEX option is installed. The execute privilege for the APEX_MAIL package is granted to PUBLIC so you don't need the APEX administrative account to use it.

To add the APEX and APEX-DEV options to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the Oracle edition that you want to use. The APEX and APEX-DEV options are supported on all editions.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.

2. Add the options to the option group. If you want to deploy only the Oracle APEX runtime environment, add only the APEX option. To deploy the full development environment, add both the APEX and APEX-DEV options.

   For **Version**, choose the version of Oracle APEX that you want to use.

   > **Important**
   >
   > If you add the APEX or APEX-DEV options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group.

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX or APEX-DEV options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

Unlocking the public user account on your DB instance

After you have installed the APEX or APEX-DEV options your DB instance, make sure to do the following:

1. Change the password for the APEX_PUBLIC_USER account.
2. Unlock the account.

You can do this by using the Oracle SQL*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace new_password with a password of your choice.

```
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```

Configuring RESTful services for Oracle APEX

To configure RESTful services in Oracle APEX (not needed for Oracle APEX 4.1.1.V1), use SQL*Plus to connect to your DB instance as the master user. After you do this, run the rdsadmin.rdsadmin_run_apex_rest_config stored procedure. When you run the stored procedure, you provide passwords for the following users:

- APEX_LISTENER
- APEX_REST_PUBLIC_USER

The stored procedure runs the apex_rest_config.sql script, which creates new database accounts for these users.

> **Note**
>
> Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password',
 'apex_rest_public_user_password');
```

Preparing to install ORDS on a separate host

Install ORDS on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The examples in this section,assume that your host runs Linux and is named `myapexhost.example.com`.

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the Oracle APEX installation file.

To prepare for ORDS installation

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named *apexuser*.

   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the Oracle APEX installation file from Oracle to your `/home/apexuser` directory:

   - http://www.oracle.com/technetwork/developer-tools/apex/downloads/index.html
   - Oracle application Express prior release archives

4. Unzip the file in the `/home/apexuser` directory.

   ```
   unzip apex_version.zip
   ```

   After you unzip the file, there is an `apex` directory in the `/home/apexuser` directory.

5. While you are still logged into `myapexhost.example.com` as `apexuser`, download the Oracle REST Data Services file from Oracle to your `/home/apexuser` directory: http://www.oracle.com/technetwork/developer-tools/apex-listener/downloads/index.html.

Setting up Oracle APEX listener

> **Note**
>
> Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support Oracle APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

Preparing to install Oracle APEX listener

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the Oracle APEX installation file.

To prepare for Oracle APEX listener installation

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named *apexuser*.

   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the Oracle APEX installation file from Oracle to your `/home/apexuser` directory:

   - http://www.oracle.com/technetwork/developer-tools/apex/downloads/index.html

- Oracle application Express prior release archives

4. Unzip the file in the /home/apexuser directory.

```
unzip apex_<version>.zip
```

After you unzip the file, there is an apex directory in the /home/apexuser directory.

5. While you are still logged into myapexhost.example.com as apexuser, download the Oracle APEX Listener file from Oracle to your /home/apexuser directory.

Installing and configuring Oracle APEX listener

Before you can use Oracle APEX, you need to download the apex.war file, use Java to install Oracle APEX Listener, and then start the listener.

To install and configure Oracle APEX listener

1. Create a new directory based on Oracle APEX Listener and open the listener file.

Run the following code:

```
mkdir /home/apexuser/apexlistener
cd /home/apexuser/apexlistener
unzip ../apex_listener.version.zip
```

2. Run the following code.

```
java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -
jar ./apex.war
```

3. Enter information for the program prompts following:

- The APEX Listener Administrator user name. The default is *adminlistener*.
- A password for the APEX Listener Administrator.
- The APEX Listener Manager user name. The default is *managerlistener*.
- A password for the APEX Listener Administrator.

The program prints a URL that you need to complete the configuration, as follows.

```
INFO: Please complete configuration at: http://localhost:8080/apex/
listenerConfigure
Database is not yet configured
```

4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.
5. From your web browser, go to the URL provided by the Oracle APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:

   - **Username** – `APEX_PUBLIC_USER`
   - **Password** – the password for *APEX_PUBLIC_USER*. This password is the one that you specified earlier when you configured the Oracle APEX repository. For more information, see Unlocking the public user account on your DB instance.
   - **Connection type** – Basic
   - **Hostname** – the endpoint of your Amazon RDS DB instance, such as `mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com`.
   - **Port** – 1521
   - **SID** – the name of the database on your Amazon RDS DB instance, such as `mydb`.
6. Choose **Apply**. The Oracle APEX administration window appears.
7. Set a password for the Oracle APEX `admin` user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

   ```
   EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
   grant APEX_ADMINISTRATOR_ROLE to master;
   @/home/apexuser/apex/apxchpwd.sql
   ```

   Replace *`master`* with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.
8. Return to the Oracle APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

   - **User name** – `admin`
   - **Password** – the password you set using the `apxchpwd.sql` script

Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

Configuring Oracle Rest Data Services (ORDS)

The following topic lists the configuration options for ORDS 21 and 22:

Topics

- Installing and configuring ORDS 21 and lower
- Installing and configuring ORDS 22 and higher

Installing and configuring ORDS 21 and lower

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For Oracle APEX version 5.0 and later, use ORDS versions 19.1 to 21. To learn how to install ORDS 22 and higher, see Installing and configuring ORDS 22 and higher.

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

To install and configure ORDS 21 and lower for use with Oracle APEX

1. Go to Oracle REST data services, and examine the Readme. Make sure that you have the required version of Java installed.
2. Create a new directory for your ORDS installation.

   ```
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

3. Download the file `ords.version.number.zip` from Oracle REST data services.
4. Unzip the file into the `/home/apexuser/ORDS` directory.
5. If you're installing ORDS in a multitenant database, add the following line to the file `/home/apexuser/ORDS/params/ords_params.properties`:

```
pdb.disable.lockdown=false
```

6. Grant the master user the required privileges to install ORDS.

   After the options for Oracle APEX are installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace *MASTER_USER* with the uppercase name of your master user.

   > **Important**
   >
   > When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`. For more information, see Granting SELECT or EXECUTE privileges to SYS objects.

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE',
 true);
```

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER',
 'EXECUTE', true);
```

> **Note**
>
> These commands apply to ORDS version 19.1 and later.

7. Install the ORDS schema using the downloaded ords.war file.

```
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see Introduction to Oracle REST data services in the Oracle documentation.

- Enter the location to store configuration data:

  Enter */home/apexuser/ORDS*. This is the location of the ORDS configuration files.

- Specify the database connection type to use. Enter number for [1] Basic [2] TNS [3] Custom URL [1]:

  Choose the desired connection type.

- Enter the name of the database server [localhost]: *DB_instance_endpoint*

  Choose the default or enter the correct value.

- Enter the database listener port [1521]: *DB_instance_port*

  Choose the default or enter the correct value.

- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:

  Choose 2 to specify the database SID.

- Database SID [xe]

  Choose the default or enter the correct value.

- Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:

Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS_PUBLIC_USER.

- Enter the database password for ORDS_PUBLIC_USER:

  Enter the password, and then confirm it.

- Requires to login with administrator privileges to verify Oracle REST Data Services schema.

  Enter the administrator user name: *master_user*

  Enter the database password for *master_user*: *master_user_password*

  Confirm the password: *master_user_password*

  > **Note**
  >
  > Specify a password other than the prompt shown here as a security best practice.

- Enter the default tablespace for ORDS_METADATA [SYSAUX].

  Enter the temporary tablespace for ORDS_METADATA [TEMP].

  Enter the default tablespace for ORDS_PUBLIC_USER [USERS].

  Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].

- Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod_plsql, you must enter 1 [1].

  Choose the default.

- Enter the PL/SQL Gateway database user name [APEX_PUBLIC_USER]

  Choose the default.

- Enter the database password for APEX_PUBLIC_USER:

  Enter the password, and then confirm it.

- Enter 1 to specify passwords for Application Express RESTful Services database users (APEX_LISTENER, APEX_REST_PUBLIC_USER) or 2 to skip this step [1]:

  Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.

- [Not needed for APEX 4.1.1.v1] Database password for APEX_LISTENER

  Enter the password (if required), and then confirm it.

- [Not needed for APEX 4.1.1.v1] Database password for APEX_REST_PUBLIC_USER

  Enter the password (if required), and then confirm it.

- Enter a number to select a feature to enable:

  Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.

- Enter 1 if you wish to start in standalone mode or 2 to exit [1]:

  Enter 1.

- Enter the APEX static resources location:

  If you unzipped APEX installation files into `/home/apexuser`, enter `/home/apexuser/apex/images`. Otherwise, enter *`unzip_path`*`/apex/images`, where *`unzip_path`* is the directory where you unzipped the file.

- Enter 1 if using HTTP or 2 if using HTTPS [1]:

  If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:

  - Enter 1 to use the self-signed certificate.
  - Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.

8. Set a password for the APEX `admin` user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

   Replace *`master`* with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.

9. Start the ORDS listener. Run the following code.

```
java -jar ords.war
```

The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the `/apex/images` directory in the installation directory for APEX.

10. Return to the Oracle APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

    - **User name** – `admin`
    - **Password** – the password you set using the `apxchpwd.sql` script

    Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

Installing and configuring ORDS 22 and higher

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For the examples in this section, we assume that the name of your separate host is `myapexhost.example.com`, and that your host is running Linux. The instructions for ORDS 22 differ from the instructions for previous releases.

To install and configure ORDS 22 and higher for use with Oracle APEX

1. Go to Oracle REST data services, and examine the Readme for the ORDS version that you plan to download. Make sure that you have the required version of Java installed.
2. Create a new directory for your ORDS installation.

   ```
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

3. Download the file `ords.`*`version.number`*`.zip` or `ords-latest.zip` from Oracle REST data services.
4. Unzip the file into the `/home/apexuser/ORDS` directory.
5. Grant the master user the required privileges to install ORDS.

After the APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by logging in to the database and running the following commands. Replace *MASTER_USER* with the uppercase name of your master user.

> **Important**
>
> When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`. For more information, see Granting SELECT or EXECUTE privileges to SYS objects.

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER',
 'EXECUTE', true);
```

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_LOB', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_ASSERT', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_OUTPUT', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SCHEDULER', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('HTP', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('OWA', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPG_DOCLOAD', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_CRYPTO', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_METADATA', 'MASTER_USER',
 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SQL', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('UTL_SMTP', 'MASTER_USER', 'EXECUTE',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_NETWORK_ACL_ADMIN',
 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('SESSION_PRIVS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_USERS', 'MASTER_USER', 'SELECT',
 true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_NETWORK_ACL_PRIVILEGES',
 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_NETWORK_ACLS', 'MASTER_USER',
 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_REGISTRY', 'MASTER_USER',
 'SELECT', true);
```

> **Note**
>
> The preceding commands apply to ORDS 22 and later.

6. Install the ORDS schema using the downloaded `ords` script. Specify directories to contain configuration files and log files. Oracle Corporation recommends not placing these directories inside the directory that contains the ORDS product software.

```
mkdir -p /home/apexuser/ords_config /home/apexuser/ords_logs

/home/apexuser/ORDS/bin/ords \
  --config /home/apexuser/ords_config \
  install --interactive --log-folder /home/apexuser/ords_logs
```

For DB instances running the container database (CDB) architecture, use ORDS 23.3 or higher and pass the `--pdb-skip-disable-lockdown` argument when installing ORDS.

```
/home/apexuser/ORDS/bin/ords \
  --config /home/apexuser/ords_config \
  install --interactive --log-folder /home/apexuser/ords_logs --pdb-skip-disable-
lockdown
```

The program prompts you for the following information. The default values are in brackets. For more information, see Introduction to Oracle REST data services in the Oracle documentation.

- `Choose the type of installation:`

  Choose **2** to install ORDS schemas in the database and create a database connection pool in the local ORDS configuration files.

- `Specify the database connection type to use. Enter number for [1] Basic [2] TNS [3] Custom URL:`

  Choose the desired connection type. This example assumes that you choose **1**.

- `Enter the name of the database server [localhost]:` ***`DB_instance_endpoint`***

  Choose the default or enter the correct value.

- `Enter the database listener port [1521]:` ***`DB_instance_port`***

  Choose the default **1521** or enter the correct value.

- `Enter the database service name [orcl]:`

  Enter the database name used by your RDS for Oracle DB instance.

- `Provide database user name with administrator privileges`

Enter the master user name for your RDS for Oracle DB instance.

- `Enter the database password for [username]:`

  Enter the master user password for your RDS for Oracle DB instance.

- `Enter the default tablespace for ORDS_METADATA and ORDS_PUBLIC_USER [SYSAUX]:`
- `Enter the temporary tablespace for ORDS_METADATA [TEMP]. Enter the default tablespace for ORDS_PUBLIC_USER [USERS]. Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].`
- `Enter a number to select additional feature(s) to enable [1]:`
- `Enter a number to configure and start ORDS in standalone mode [1]:`

  Choose **2** to skip starting ORDS immediately in standalone mode.

- `Enter a number to select the protocol [1] HTTP`
- `Enter the HTTP port [8080]:`
- `Enter the APEX static resources location:`

  Enter the path to the Oracle APEX installation files (`/home/apexuser/apex/images`).

7. Set a password for the Oracle APEX `admin` user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

   Replace *`master`* with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.

8. Run ORDS in standalone mode using the `ords` script with the `serve` command. For production deployments, consider using supported Java EE application servers such as Apache Tomcat or Oracle WebLogic Server. For more information, see Deploying and Monitoring Oracle REST Data Services in the Oracle Database documentation.

```
/home/apexuser/ORDS/bin/ords \
  --config /home/apexuser/ords_config serve \
  --port 8193 \
```

```
  --apex-images /home/apexuser/apex/images
```

If ORDS is running but unable to access the Oracle APEX installation, you might see the following error, particularly on non-CDB instances.

```
The procedure named apex_admin could not be accessed, it may not be declared,
 or the user executing this request may not have been granted execute privilege
 on the procedure, or a function specified by security.requestValidationFunction
 configuration property has prevented access.
```

To fix this error, change the request validation function used by ORDS by running the `ords` script with the `config` command. By default, ORDS uses the `ords_util.authorize_plsql_gateway` procedure, which is only supported on CDB instances. For non-CDB instances, you can change this procedure to the `wwv_flow_epg_include_modules.authorize` package. See the Oracle Database documentation and Oracle Support for best practices on configuring the proper request validation function for your use case.

9. Return to the Oracle APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

   - **User name** – `admin`
   - **Password** – the password you set using the `apxchpwd.sql` script

   Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

Upgrading and removing Oracle APEX

To upgrade or remove Oracle APEX, follow the instructions in this topic:

Topics

- Upgrading the Oracle APEX version
- Removing the APEX and APEX-DEV options

Upgrading the Oracle APEX version

> **Important**
>
> Back up your DB instance before you upgrade Oracle APEX. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS and Testing an Oracle DB upgrade.

To upgrade Oracle APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of the `APEX` and `APEX-DEV` options to the new option group. Be sure to include any other options that your DB instance uses. For more information, see Option group considerations.
- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of Oracle APEX, the Oracle APEX schema for the previous version might still exist in your database. If you don't need it anymore, you can drop the old Oracle APEX schema from your database after you upgrade.

If you upgrade the Oracle APEX version and RESTful services were not configured in the previous Oracle APEX version, we recommend that you configure RESTful services. For more information, see Configuring RESTful services for Oracle APEX.

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you're using an Oracle APEX version that isn't compatible with your target database version. In these cases, you can upgrade your version of Oracle APEX before you upgrade your DB instance. Upgrading Oracle APEX first can reduce the amount of time that it takes to upgrade your DB instance.

> **Note**
>
> After upgrading Oracle APEX, install and configure a listener for use with the upgraded version. For instructions, see Setting up Oracle APEX listener.

Removing the APEX and APEX-DEV options

You can remove the APEX and APEX-DEV options from a DB instance. To remove these options from your DB instance, do one of the following:

- To remove the APEX and APEX-DEV options from multiple DB instances, remove the options from the option group they belong to. This change affects all DB instances that use the option group. When you remove the options from an option group that is attached to multiple DB instances, a brief outage occurs while the DB instances are restarted.

  For more information, see Removing an option from an option group.
- To remove the APEX and APEX-DEV options from a single DB instance, modify the DB instance and specify a different option group that doesn't include these options. You can specify the default (empty) option group, or a different custom option group. When you remove the options, a brief outage occurs while your DB instance is automatically restarted.

  For more information, see Modifying an Amazon RDS DB instance.

When you remove the APEX and APEX-DEV options from a DB instance, the APEX schema is removed from your database.

Amazon EFS integration

Amazon Elastic File System (Amazon EFS) provides serverless, fully elastic file storage so that you can share file data without provisioning or managing storage capacity and performance. With Amazon EFS, you can create a file system and then mount it in your VPC through the NFS versions 4.0 and 4.1 (NFSv4) protocol. Then you can use the EFS file system like any other POSIX-compliant file system. For general information, see What is Amazon Elastic File System? and the AWS blog Integrate Amazon RDS for Oracle with Amazon EFS.

Topics

- Overview of Amazon EFS integration
- Configuring network permissions for RDS for Oracle integration with Amazon EFS
- Configuring IAM permissions for RDS for Oracle integration with Amazon EFS
- Adding the EFS_INTEGRATION option
- Configuring Amazon EFS file system permissions
- Transferring files between RDS for Oracle and an Amazon EFS file system
- Removing the EFS_INTEGRATION option
- Troubleshooting Amazon EFS integration

Overview of Amazon EFS integration

With Amazon EFS, you can transfer files between your RDS for Oracle DB instance and an EFS file system. For example, you can use EFS to support the following use cases:

- Share a file system between applications and multiple database servers.
- Create a shared directory for migration-related files, including transportable tablespace data files. For more information, see Migrating using Oracle transportable tablespaces.
- Store and share archived redo log files without allocating additional storage space on the server.
- Use Oracle Database utilities such as `UTL_FILE` to read and write files.

Advantages to Amazon EFS integration

When you choose an EFS file system over alternative data transfer solutions, you get the following benefits:

- You can transfer Oracle Data Pump files between Amazon EFS and your RDS for Oracle DB instance. You don't need to copy these files locally because Data Pump imports directly from the EFS file system. For more information, see Importing data into Oracle on Amazon RDS.
- Data migration is faster than using a database link.
- You avoid allocating storage space on your RDS for Oracle DB instance to hold the files.
- An EFS file systems can automatically scale storage without requiring you to provision it.
- Amazon EFS integration has no minimum fees or setup costs. You pay only for what you use.
- Amazon EFS integration supports two forms of encryption: encryption of data in transit and encryption at rest. Encryption of data in transit is enabled by default using TLS version 1.2. You can enable encryption of data at rest when creating an Amazon EFS file system. For more information, see Encrypting data at rest in the *Amazon Elastic File System User Guide*.

Requirements for Amazon EFS integration

Make sure that you meet the following requirements:

- Your database must run database version 19.0.0.0.ru-2022-07.rur-2022-07.r1 or higher.
- Your DB instance and your EFS file system must be in the same AWS Region, VPC, and AWS account. RDS for Oracle doesn't support cross-account and cross-Region access for EFS.
- Your VPC must have both **DNS Resolution** and **DNS Hostnames** enabled. For more information, see DNS attributes in your VPC in the *Amazon Virtual Private Cloud User Guide*.
- If you use a DNS name in the `mount` command, make sure your VPC configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.
- You must use non-RDS solutions to back up your EFS file system. RDS for Oracle doesn't support automated backups or manual DB snapshots of an EFS file system. For more information, see Backing up your Amazon EFS file systems.

Configuring network permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, make sure that your DB instance has network access to an EFS file system. For more information, see Controlling network access to Amazon EFS file systems for NFS clients in the *Amazon Elastic File System User Guide*.

Topics

- Controlling network access with security groups

- Controlling network access with file system policies

Controlling network access with security groups

You can control your DB instance access to EFS file systems using network layer security mechanisms such as VPC security groups. To allow access to an EFS file system for your DB instance, make sure that your EFS file system meets the following requirements:

- An EFS mount target exists in every Availability Zone used by an RDS for Oracle DB instance.

  An *EFS mount target* provides an IP address for an NFSv4 endpoint at which you can mount an EFS file system. You mount your file system using its DNS name, which resolves to the IP address of the EFS mount target in the used by the Availability Zone of your DB instance.

  You can configure DB instances in different AZs to use the same EFS file system. For Multi-AZ, you need a mount point for each AZ in your deployment. You might need to move a DB instance to a different AZ. For these reasons, we recommend that you create an EFS mount point in each AZ in your VPC. By default, when you create a new EFS file system using the console, RDS creates mount targets for all AZs.
- A security group is attached to the mount target.
- The security group has an inbound rule to allow the network subnet or security group of the RDS for Oracle DB instance on TCP/2049 (Type NFS).

For more information, see Creating Amazon EFS file systems and Creating and managing EFS mount targets and security groups in the *Amazon Elastic File System User Guide*.

Controlling network access with file system policies

Amazon EFS integration with RDS for Oracle works with the default (empty) EFS file system policy. The default policy doesn't use IAM to authenticate. Instead, it grants full access to any anonymous client that can connect to the file system using a mount target. The default policy is in effect whenever a user-configured file system policy isn't in effect, including at file system creation. For more information, see Default EFS file system policy in the *Amazon Elastic File System User Guide*.

To strengthen access to your EFS file system for all clients, including RDS for Oracle, you can configure IAM permissions. In this approach, you create a file system policy. For more information, see Creating file system policies in the *Amazon Elastic File System User Guide*.

Configuring IAM permissions for RDS for Oracle integration with Amazon EFS

By default, Amazon EFS integration feature doesn't use an IAM role: the `USE_IAM_ROLE` option setting is `FALSE`. To integrate RDS for Oracle with Amazon EFS and an IAM role, your DB instance must have IAM permissions to access an Amazon EFS file system.

Topics

- Step 1: Create an IAM role for your DB instance and attach your policy
- Step 2: Create a file system policy for your Amazon EFS file system
- Step 3: Associate your IAM role with your RDS for Oracle DB instance

Step 1: Create an IAM role for your DB instance and attach your policy

In this step, you create a role for your RDS for Oracle DB instance to allow Amazon RDS to access your EFS file system.

Console

To create an IAM role to allow Amazon RDS access to an EFS file system

1. Open the IAM Management Console.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **AWS service**, choose **RDS**.
5. For **Select your use case**, choose **RDS – Add Role to Database**.
6. Choose **Next**.
7. Don't add any permissions policies. Choose **Next**.
8. Set **Role name** to a name for your IAM role, for example `rds-efs-integration-role`. You can also add an optional **Description** value.
9. Choose **Create role**.

AWS CLI

To limit the service's permissions to a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named *`rds-efs-integration-role`* for this purpose.

Example

For Linux, macOS, or Unix:

```
aws iam create-role \
   --role-name rds-efs-integration-role \
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": my_account_ID,
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For Windows:

```
aws iam create-role ^
   --role-name rds-efs-integration-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                 "aws:SourceAccount": my_account_ID,
                 "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
             }
         }
       }
     ]
   }'
```

For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

Step 2: Create a file system policy for your Amazon EFS file system

In this step, you create a file system policy for your EFS file system.

To create or edit an EFS file system policy

1. Open the EFS Management Console.
2. Choose **File Systems**.
3. On the **File systems** page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.
4. Choose the **File system policy** tab.

   If the policy is empty, then the default EFS file system policy is in use. For more information, see Default EFS file system policy in the *Amazon Elastic File System User Guide*.
5. Choose **Edit**. The **File system policy** page appears.
6. In **Policy editor**, enter a policy such as the following, and then choose **Save**.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "ExamplePolicy01",
    "Statement": [
        {
            "Sid": "ExampleStatement01",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/rds-efs-integration-
role"
            },
            "Action": [
                "elasticfilesystem:ClientMount",
                "elasticfilesystem:ClientWrite",
                "elasticfilesystem:ClientRootAccess"
            ],
            "Resource": "arn:aws:elasticfilesystem:us-
east-1:123456789012:file-system/fs-1234567890abcdef0"
        }
    ]
}
```

Step 3: Associate your IAM role with your RDS for Oracle DB instance

In this step, you associate your IAM role with your DB instance. Be aware of the following requirements:

- You must have access to an IAM role with the required Amazon EFS permissions policy attached to it.
- You can associate only one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be **Available**.

For more information, see Identity and access management for Amazon EFS in the *Amazon Elastic File System User Guide*.

Console

To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases**.
3. If your database instance is unavailable, choose **Actions** and then **Start**. When the instance status shows **Started**, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
6. Choose the role to add in the **Add IAM roles to this instance** section.
7. For **Feature**, choose **EFS_INTEGRATION**.
8. Choose **Add role**.

AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier mydbinstance \
   --feature-name EFS_INTEGRATION \
   --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name EFS_INTEGRATION ^
   --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. `EFS_INTEGRATION` must be specified for the `--feature-name` option.

Adding the EFS_INTEGRATION option

To integrate Amazon RDS for Oracle with Amazon EFS, your DB instance must be associated with an option group that includes the `EFS_INTEGRATION` option.

Multiple Oracle DB instances that belong to the same option group share the same EFS file system. Different DB instances can access the same data, but access can be divided by using different Oracle directories. For more information see Transferring files between RDS for Oracle and an Amazon EFS file system.

Console

To configure an option group for Amazon EFS integration

1. Create a new option group or identify an existing option group to which you can add the `EFS_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.
2. Add the `EFS_INTEGRATION` option to the option group. You need to specify the `EFS_ID` file system ID and set the `USE_IAM_ROLE` flag.

   For more information, see Adding an option to an option group.
3. Associate the option group with your DB instance in either of the following ways:

   - Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance.
   - Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To configure an option group for EFS integration

1. Create a new option group or identify an existing option group to which you can add the `EFS_INTEGRATION` option.

   For information about creating an option group, see Creating an option group.
2. Add the `EFS_INTEGRATION` option to the option group.

For example, the following AWS CLI command adds the `EFS_INTEGRATION` option to an option group named **`myoptiongroup`**.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
   --option-group-name myoptiongroup \
   --options "OptionName=EFS_INTEGRATION,OptionSettings=\
   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

For Windows:

```
aws rds add-option-to-option-group ^
   --option-group-name myoptiongroup ^
   --options "OptionName=EFS_INTEGRATION,OptionSettings=^
   [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

3. Associate the option group with your DB instance in either of the following ways:

- Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see Creating an Amazon RDS DB instance.
- Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance.

Configuring Amazon EFS file system permissions

By default, only the root user (UID `0`) has read, write, and execute permissions for a newly created EFS file system. For other users to modify the file system, the root user must explicitly grant them access. The user for the RDS for Oracle DB instance is in the `others` category. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level in the *Amazon Elastic File System User Guide*.

To allow your RDS for Oracle DB instance to read and write files on an EFS file system, do the following:

- Mount an EFS file system locally on your Amazon EC2 or on-premises instance.
- Configure fine grain permissions.

For example, to grant `other` users permissions to write to the EFS file system root, run `chmod 777` on this directory. For more information, see Example Amazon EFS file system use cases and permissions in the *Amazon Elastic File System User Guide*.

Transferring files between RDS for Oracle and an Amazon EFS file system

To transfer files between an RDS for Oracle instance and an Amazon EFS file system, create at least one Oracle directory and configure EFS file system permissions to control DB instance access.

Topics

- Creating an Oracle directory
- Transferring data to and from an EFS file system: examples

Creating an Oracle directory

To create an Oracle directory, use the procedure `rdsadmin.rdsadmin_util.create_directory_efs`. The procedure has the following parameters.

Parameter name	Data type	Defaul	Requir	Description
`p_directory_name`	VARCHAR2	–	Yes	The name of the Oracle directory.
`p_path_on_efs`	VARCHAR2	–	Yes	The path on the EFS file system. The prefix of the path name uses the pattern `/rdsefs-`*`fsid`*`/`, where *`fsid`* is a placeholder for your EFS file system ID. For example, if your EFS file system is named `fs-1234567890abcdef0` , and you create a subdirectory on this file system named `mydir`, you could specify the following value: `/rdsefs-fs-1234567890abcdef0/mydir`

Assume that you create a subdirectory named `/datapump1` on the EFS file system `fs-1234567890abcdef0`. The following example creates an Oracle directory `DATA_PUMP_DIR_EFS` that points to the `/datapump1` directory on the EFS file system. The file system path value for the `p_path_on_efs` parameter is prefixed with the string `/rdsefs-`.

```
BEGIN
  rdsadmin.rdsadmin_util.create_directory_efs(
    p_directory_name => 'DATA_PUMP_DIR_EFS',
    p_path_on_efs    => '/rdsefs-fs-1234567890abcdef0/datapump1');
END;
/
```

Transferring data to and from an EFS file system: examples

The following example uses Oracle Data Pump to export the table named `MY_TABLE` to file `datapump.dmp`. This file resides on an EFS file system.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(operation => 'EXPORT', job_mode => 'TABLE',
 job_name=>null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump-exp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

The following example uses Oracle Data Pump to import the table named `MY_TABLE` from file `datapump.dmp`. This file resides on an EFS file system.

```
DECLARE
```

```
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'TABLE',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdnl,
    filename  => 'datapump-imp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'NAME_EXPR','IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

For more information, see Importing data into Oracle on Amazon RDS.

Removing the EFS_INTEGRATION option

The steps for removing the `EFS_INTEGRATION` option depend on whether you're removing the option from multiple DB instances or a single instance.

Number of DB instances	Action	Related information
Multiple	Remove the `EFS_INTEGRATION` option from the option group to which the DB instances belong. This change affects all instances that use the option group.	Removing an option from an option group
Single	Modify the DB instance and specify a different option group that doesn't include the `EFS_INTEGRATION` option. You can specify the default (empty) option group or a different custom option group.	Modifying an Amazon RDS DB instance

After you remove the EFS_INTEGRATION option, you can optionally delete the EFS file system that was connected to your DB instances.

Troubleshooting Amazon EFS integration

Your RDS for Oracle DB instance monitors the connectivity to an Amazon EFS file system. When monitoring detects an issue, it might try to correct the issue and publish an event in the RDS console. For more information, see Viewing Amazon RDS events.

Use the information in this section to help you diagnose and fix common issues when you work with Amazon EFS integration.

Notification	Description	Action
`The EFS for RDS Oracle instance` *instance_name* `isn't available on the primary host. NFS port 2049 of your EFS isn't reachable.`	The DB instance can't communicate with the EFS file system.	Make sure of the following: • The EFS file system exists. • The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS).
`The EFS isn't reachable.`	An error occurred during the installation of the `EFS_INTEGRATION` option.	Make sure of the following: • The EFS file system exists. • The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS). • The `enableDnsSupport` attribute is turned on for your VPC.

Notification	Description	Action
		• You are using the Amazon provided DNS server in your VPC. Amazon EFS integrati on doesn't work with a custom DHCP DNS.
`The associated role with your DB instance wasn't found.`	An error occurred during the installation of the `EFS_INTEGRATION` option.	Make sure that you associated an IAM role with your RDS for Oracle DB instance.
`The associated role with your DB instance wasn't found.`	An error occurred during the installation of the `EFS_INTEGRATION` option. RDS for Oracle was restored from a DB snapshot with the `USE_IAM_ROLE` option setting of `TRUE`.	Make sure that you associated an IAM role with your RDS for Oracle DB instance.
`The associated role with your DB instance wasn't found.`	An error occurred during the installation of the `EFS_INTEGRATION` option. RDS for Oracle was created from an all-in-one CloudForm ation template with the `USE_IAM_ROLE` option setting of `TRUE`.	As a workaround, complete the following steps: 1. Create a DB instance with the IAM role and default option group. 2. On a subsequent stack update, add the custom option group with the `EFS_INTEGRATION` option.
`PLS-00302: component 'CREATE_DIRECTORY_ EFS' must be declared`	This error can occur when you're using a version of RDS for Oracle that doesn't support Amazon EFS.	Make sure that you are using RDS for Oracle DB instance version 19.0.0.0.ru-2022-0 7.rur-2022-07.r1 or higher.

Notification	Description	Action
`Read access of your EFS is denied. Check your file system policy.`	Your DB instance can't read the EFS file system.	Make sure that your EFS file system allows read access through the IAM role or on the EFS file system level.
N/A	Your DB instance can't write to the EFS file system.	Take the following steps: 1. Make sure that your EFS file system is mounted on an Amazon EC2 instance. 2. Give the `others` group write access to your RDS user. The simplest technique is to run the `chmod 777` command on the top directory of the EFS file system.

Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the `JVM` option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see Introduction to Java in Oracle database in the Oracle documentation. You can use Oracle JVM with all versions of Oracle Database 21c (21.0.0) and Oracle Database 19c (19.0.0).

Considerations for Oracle JVM

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the `RDS_JAVA_ADMIN` role, which grants a subset of the privileges granted by the `JAVA_ADMIN` role. To list the privileges granted to the `RDS_JAVA_ADMIN` role, run the following query on your DB instance:

```
SELECT * FROM dba_java_policy
   WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
   AND enabled = 'ENABLED'
   ORDER BY type_name, name, grantee;
```

Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.small DB instance classes. For more information, see DB instance classes.
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the `JVM` option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.

- Configure your DB instance to restrict network access. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

  By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see Oracle JRE and JDK Cryptographic Roadmap.

Adding the Oracle JVM option

The following is the general process for adding the `JVM` option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the `JVM` option is added. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

> **Note**
>
> During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the JVM option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

- For **Engine**, choose the DB engine used by the DB instance (**oracle-ee**, **oracle-se**, **oracle-se1**, or **oracle-se2**).
- For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the **JVM** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.
4. Grant the required permissions to users.

   The Amazon RDS master user has the permissions to use the `JVM` option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

   The following example grants the permissions to use the `JVM` option to the `test_proc` user.

```
create user test_proc identified by password;
CALL dbms_java.grant_permission('TEST_PROC',
 'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

After the user is granted the permissions, the following query should return output.

```
select * from dba_java_policy where grantee='TEST_PROC';
```

> **Note**
>
> The Oracle user name is case-sensitive, and it usually has all uppercase characters.

Removing the Oracle JVM option

You can remove the `JVM` option from a DB instance. There is a brief outage while the option is removed. After you remove the `JVM` option, you don't need to restart your DB instance.

> **Warning**
>
> Removing the `JVM` option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see Backing up, restoring, and exporting data.

To remove the `JVM` option from a DB instance, do one of the following:

- Remove the `JVM` option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the `JVM` option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Enterprise Manager

Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM on Oracle Database 19c non-CDBs or CDBs. The following table describes the supported OEM options.

Option	Option ID	Supported OEM releases
OEM Database Express	`OEM`	OEM Database Express 19c
OEM Management Agent	`OEM_AGENT`	OEM Cloud Control for 13c

Note

You can use OEM Database or OEM Management Agent, but not both.

Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager Database Express (EM Express) through the use of the OEM option. Amazon RDS supports EM Express for Oracle Database 19c using the CDB or non-CDB architecture.

EM Express is a web-based database management tool included in your database and is only available when it is open. It supports key performance management and basic database administration functions. For more information, see Introduction to Oracle Enterprise Manager Database Express in the Oracle Database documentation.

> **Note**
>
> EM Express isn't supported on the db.t3.small DB instance class. For more information about DB instance classes, see RDS for Oracle DB instance classes.

OEM option settings

Amazon RDS supports the following settings for the OEM option.

Option setting	Valid values	Description
Port	An integer value	The port on the RDS for Oracle DB instance that listens for EM Express. The default is 5500.
Security Groups	—	A security group that has access to **Port**.

Step 1: Adding the OEM option

The general process for adding the OEM option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with your DB instance.

When you add the OEM option, a brief outage occurs while your DB instance is automatically restarted.

To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the oracle edition for your DB instance.

   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group.

2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see OEM option settings.

   > **Note**
   >
   > If you add the OEM option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the OEM option, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

> **Note**
>
> You can also use the AWS CLI to add the OEM option. For examples, see Adding an option to an option group.

Step 2: (CDB only) Unlocking the DBSNMP user account

If your DB instance uses the CDB architecture, you must log in to EM Express as DBSNMP. in a CDB, DBSNMP is a common user. By default, this account is locked. If your DB instance doesn't use the CDB architecture, skip this step.

To unlock the DBSNMP user account in a CDB instance

1. In SQL*Plus or another Oracle SQL application, log in to your DB instance as your master user.
2. Run the following stored procedure to unlock the DBSNMP account:

   ```
   EXEC rdsadmin.rdsadmin_util.reset_oem_agent_password('new_password');
   ```

   If you receive an error stating that the procedure doesn't exist, reboot your CDB instance to install it automatically. For more information, see Rebooting a DB instance.

Step 3: Accessing EM Express through your browser

When you access EM Express from your web browser, a login window appears that prompts you for a user name and password.

To access EM Express through your browser

1. Identify the endpoint and EM Express port for your Amazon RDS DB instance. For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your RDS for Oracle DB instance.
2. Enter a URL in your browser locator bar using the following format.

   ```
   https://endpoint.rds.amazonaws.com:port/em
   ```

   For example, if the endpoint for your Amazon RDS DB instance is `mydb.a1bcde234fgh.us-east-1.rds.amazonaws.com`, and your EM Express port is 1158, then use the following URL to access EM Express.

   ```
   https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em
   ```

3. When prompted for your login details, do one of the following actions, depending on your database architecture:

Your database is a non-CDB.

Type the master user name and master password for your DB instance.

Your database is a CDB.

Enter `DBSNMP` for the user and the `DBSNMP` password. Leave the `Container` field empty.

Modifying OEM Database settings

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can't modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see OEM option settings.

Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

> **Note**
>
> OEM Database Express tasks run asynchronously.

Tasks

- Switching the website front end for OEM Database Express to Adobe Flash
- Switching the website front end for OEM Database Express to Oracle JET

Switching the website front end for OEM Database Express to Adobe Flash

> **Note**
>
> This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a `Loading` screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Database Express. For more information about switching to Oracle JET, see Switching the website front end for OEM Database Express to Oracle JET.

> **Note**
>
> Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

Switching the website front end for OEM Database Express to Oracle JET

> **Note**
>
> This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet`. This procedure is equivalent to the `execemx omx` SQL command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash` procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. For more information about switching to Adobe Flash, see Switching the website front end for OEM Database Express to Adobe Flash.

> **Note**
>
> Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). Amazon RDS supports Management Agent through the use of the `OEM_AGENT` option.

For more information, see Overview of Oracle Enterprise Manager cloud control 12c and Overview of Oracle Enterprise Manager cloud control 13c in the Oracle documentation.

Topics

- Requirements for Management Agent
- OMS host communication prerequisites
- Limitations for Management Agent
- Option settings for Management Agent
- Enabling the Management Agent option for your DB instance
- Removing the Management Agent option
- Performing database tasks with the Management Agent

Requirements for Management Agent

Following are general requirements for using Management Agent:

- Your DB instance must run Oracle Database 19c (19.0.0.0). You can use either the CDB or non-CDB architecture.
- You must use an Oracle Management Service (OMS) that is configured to connect to your DB instance. Note the following OMS requirements:
  - Management Agent versions 13.5.0.0.v2 and 13.5.0.0.v3 require OMS version 13.5.0.23 or 24.1.
  - Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or 24.1.
  - Management Agent versions 13.4.0.9.v1 and 13.4.0.9.v2 require OMS version 13.4.0.9 or later and patch 32198287.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that you complete the steps in Tutorial: Create a VPC for use with a DB instance (IPv4 only) before continuing.

- You can use Management Agent with Oracle Enterprise Manager Cloud Control for 12c and 13c. Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
  - At least 4.5 GiB for OEM 13c Release 1
  - At least 2.5 GiB for OEM 12c
- If you're using Management Agent versions `OEM_AGENT 13.2.0.0.v3` and `13.3.0.0.v2`, and if you want to use TCPS connectivity, follow the instructions in Configuring third party CA certificates for communication with target databases in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

  > **Note**
  >
  > TCPS connectivity between the Management Agent and the DB instance is supported for Management Agent `OEM_AGENT 13.2.0.0.v3`, `13.3.0.0.v2`, `13.4.0.9.v1`, and higher versions.

OMS host communication prerequisites

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:

- To connect from the Management Agent to your OMS host when your OMS host is behind a firewall, add the IP addresses of your DB instances to the firewall. Make sure the firewall for the OMS allows the following network traffic:

  From the OMS host to your DB instance

  Configure a one-way firewall rule that allows traffic from the OMS host to the database listener port (default 1521) and the OEM Agent port (default 3872).

From your DB instance to the OMS host

Configure a one-way firewall rule that allows traffic from the DB instance to the OMS HTTP port (default 4903).

- To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).
- To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:
  - If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by an EC2 instance in a different VPC.
  - If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by a client application through the internet or VPN connections.
- To connect OEM Management Agent version 13.5.0.0 (v1-v3) to a 24.1 OMS host, set `MINIMUM_TLS_VERSION` to use the TLS 1.2 protocol `TLSv1.2` in your configuration options.

Limitations for Management Agent

Following are some limitations to using Management Agent:

- You can't provide custom Oracle Management Agent images.
- Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.
- Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more information about monitoring the operating system, see Monitoring OS metrics with Enhanced Monitoring.
- Autodiscovery isn't supported. You must manually add database targets.
- OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.

- Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the `OEM_AGENT` option, we recommend that you scale up to a larger DB instance class. For more information, see DB instance classes and Modifying an Amazon RDS DB instance.
- The user running the `OEM_AGENT` on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for `DB Alert Log` and `DB Alert Log Error Status` in OEM.

Option settings for Management Agent

Amazon RDS supports the following settings for the Management Agent option.

Option setting	Require	Valid values	Description

Version (`AGENT_VERSION`)	Yes	`13.5.0.0.v3`
		`13.5.0.0.v2`
		`13.5.0.0.v1`
		`13.4.0.9.v2`
		`13.4.0.9.v1`
		`13.3.0.0.v2`
		`13.3.0.0.v1`
		`13.2.0.0.v3`
			The version of the Management Agent software. The minimum supported version is `13.1.0.0.v1` .
			The AWS CLI option name is `OptionVersion` .
			Note
			In the AWS GovCloud (US) Regions, 13.1 versions aren't available.

Option setting	Require	Valid values	Description

		`13.2.0.0.v2`
		
		`13.2.0.0.v1`
		
		`13.1.0.0.v1`	

Port (`AGENT_PORT`)	Yes	An integer value	The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is `Port`.
Security Groups	Yes	Existing security groups	A security group that has access to **Port**. Your OMS host must belong to this security group. The AWS CLI option name is `VpcSecurityGroupMemberships` or `DBSecurityGroupMemberships`.
OMS_HOST	Yes	A string value, for example *`my.example.oms`*	The publicly accessible host name or IP address of the OMS. The AWS CLI option name is `OMS_HOST`.

Option setting	Require	Valid values	Description
OMS_PORT	Yes	An integer value	The HTTPS upload port on the OMS Host that listens for the Management Agent. To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password): `emctl status oms -details` The AWS CLI option name is `OMS_PORT`.
AGENT_REGISTRATION_PASSWORD	Yes	A string value	The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the `OEM_AGENT` option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases. The AWS CLI option name is `AGENT_REGISTRATION_PASSWORD`.
ALLOW_TLS_ONLY	No	`true`, `false` (default)	A value that configures the OEM Agent to support only the `TLSv1` protocol while the agent listens as a server. This setting is no longer supported. Management Agent versions 13.1.0.0. v1 and higher support Transport Layer Security (TLS) by default.

Option setting	Require	Valid values	Description
MINIMUM_TLS_VERSION	No	`TLSv1` (default), `TLSv1.2`	A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. Desupported agent versions only support the `TLSv1` setting. To connect 13.5.0.0 (v1-v3) to a 24.1 OMS host, set this to `TLSv1.2`.
TLS_CIPHER_SUITE	No	See Option settings for Management Agent.	A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.

The following table lists the TLS cipher suites that the Management Agent option supports.

Cipher suite	Agent version supported	FedRAMP compliant
TLS_RSA_WITH_AES_128_CBC_SHA	All	No
TLS_RSA_WITH_AES_128_CBC_SHA256	13.1.0.0.v1 and higher	No
TLS_RSA_WITH_AES_256_CBC_SHA	13.2.0.0.v3 and higher	No
TLS_RSA_WITH_AES_256_CBC_SHA256	13.2.0.0.v3 and higher	No
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	13.2.0.0.v3 and higher	Yes

Cipher suite	Agent version supported	FedRAMP compliant
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	13.4.0.9.v1 and higher	Yes
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384	13.4.0.9.v1 and higher	Yes

Certificate compatibility with cipher suites

RDS for Oracle supports both RSA and Elliptic Curve Digital Signature Algorithm (ECDSA) certificates. When you configure the OEM Agent option for your DB instance, you must ensure that the cipher suites you specify in the `TLS_CIPHER_SUITE` option setting are compatible with the certificate type used by your DB instance.

The following table shows the compatibility between certificate types and cipher suites:

Certificate type	Compatible cipher suites	Incompatible cipher suites
RSA certificates (rds-ca-2019, rds-ca-rsa2048-g1, rds-ca-rsa4096-g1)	TLS_RSA_WITH_AES_128_CBC_SHA TLS_RSA_WITH_AES_128_CBC_SHA256 TLS_RSA_WITH_AES_256_CBC_SHA TLS_RSA_WITH_AES_256_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384

Certificate type	Compatible cipher suites	Incompatible cipher suites
	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	
ECDSA certificates (rds-ca-ecc384-g1)	TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384	TLS_RSA_WITH_AES_128_CBC_SHA TLS_RSA_WITH_AES_128_CBC_SHA256 TLS_RSA_WITH_AES_256_CBC_SHA TLS_RSA_WITH_AES_256_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384

When you specify a cipher suite in the `TLS_CIPHER_SUITE` option setting, make sure it is compatible with the certificate type used by your DB instance. If you attempt to associate an option group with an OEM Agent option that contains a cipher suite incompatible with the certificate type of a DB instance, the operation will fail with an error message indicating the incompatibility.

Enabling the Management Agent option for your DB instance

To enable the Management Agent option, use the following steps:

Topics

- Step 1: Adding the Management Agent option to your DB instance
- Step 2: Unlocking the DBSNMP user account
- Step 3: Adding your targets to the Management Agent console

Step 1: Adding the Management Agent option to your DB instance

To add the Management Agent option to your DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check My Oracle Support documents for information about resolving specific problems.

After you add the Management Agent option, you don't need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.

If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

```
You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted
 third party certificate.
Configure your OMS host with the trusted certificates from your third party.
```

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document 2202569.1.

Console

To add the Management Agent option to your DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the oracle edition for your DB instance.

   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **OEM_AGENT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group. For more information about each setting, see Option settings for Management Agent.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `OEM_AGENT` option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options
 OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-123456
{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}] \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options
 OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-123456
{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}] ^
    --apply-immediately
```

Step 2: Unlocking the DBSNMP user account

The Management Agent uses the DBSNMP user account to connect to the database and report issues to Oracle Enterprise Manager. In a CDB, DBSNMP is a common user. This user account is necessary for both the Management Agent and OEM Database Express. By default, this account is locked. The procedure for unlocking this account differs depending on whether your database uses the non-CDB or CDB architecture.

To unlock the DBSNMP user account

1. In SQL*Plus or another Oracle SQL application, log in to your DB instance as your master user.
2. Do either of the following actions, depending on the database architecture:

   Your database is a non-CDB.

   Run the following SQL statement:

   ```
   ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
   ```

   Your database is a CDB.

   Run the following stored procedure to unlock the DBSNMP account:

   ```
   EXEC rdsadmin.rdsadmin_util.reset_oem_agent_password('new_password');
   ```

   If you receive an error stating that the procedure doesn't exist, reboot your CDB instance to install it automatically. For more information, see Rebooting a DB instance.

Step 3: Adding your targets to the Management Agent console

To add a DB instance as a target, make sure you know the endpoint and port. For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your

RDS for Oracle DB instance. If your database uses the CDB architecture, then add the CDB$ROOT container separately as a target.

To add targets to the Management Agent console

1. In your OMS console, choose **Setup**, **Add Target**, **Add Targets Manually**.
2. Choose **Add Targets Declaratively by Specifying Target Monitoring Properties**.
3. For **Target Type**, choose **Database Instance**.
4. For **Monitoring Agent**, choose the agent with the identifier that is the same as your RDS DB instance identifier.
5. Choose **Add Manually**.
6. Enter the endpoint for your Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.
7. Specify the following database properties:
   - For **Target name**, enter a name.
   - For **Database system name**, enter a name.
   - For **Monitor username**, enter **dbsnmp**.
   - For **Monitor password**, enter the password from Step 2: Unlocking the DBSNMP user account.
   - For **Role**, enter **normal**.
   - For **Oracle home path**, enter **/oracle**.
   - For **Listener Machine name**, the agent identifier already appears.
   - For **Port**, enter the database port. The RDS default port is 1521.
   - For **Database name**, enter the name of your database. If your database is a CDB, this name is RDSCDB.
8. Choose **Test Connection**.
9. Choose **Next**. The target database appears in your list of monitored resources.

Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don't need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Performing database tasks with the Management Agent

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

> **Note**
>
> Tasks are executed asynchronously.

Tasks

- Securing the Management Agent
- Getting the status of the Management Agent
- Restarting the Management Agent
- Listing the targets monitored by the Management Agent
- Listing the collection threads monitored by the Management Agent
- Clearing the Management Agent state
- Making the Management Agent upload its OMS
- Pinging the OMS
- Viewing the status of an ongoing task

Securing the Management Agent

To secure the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.secure_oem_agent`. This procedure is equivalent to running the `emctl secure agent` command.

The following procedure creates a task to secure the Management Agent and returns the ID of the task:

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.secure_oem_agent as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Getting the status of the Management Agent

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent() as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Restarting the Management Agent

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Listing the targets monitored by the Management Agent

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Listing the collection threads monitored by the Management Agent

To list of all the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent() as TASK_ID from
 DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Clearing the Management Agent state

To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent`. This procedure is equivalent to running the `emctl clearstate agent` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent`. This procedure is equivalent to running the `emclt upload agent` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```

To display the output file for the task and view the result, see Viewing the status of an ongoing task.

Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

When you want to monitor a task, replace *`task-id`* with the ID of the task that you want to monitor.

To view the contents of bdump files, run the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The following query returns the contents of the `dbtask-1546988886389-2444.log` bdump file.

```
SELECT text FROM
 table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1546988886389-2444.log'));
```

For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory.

Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see Introduction to Oracle Label Security in the Oracle documentation.

Topics

- Requirements for Oracle Label Security
- Considerations when using Oracle Label Security
- Adding the Oracle Label Security option
- Troubleshooting

Requirements for Oracle Label Security

Familiarize yourself with the following requirements for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see RDS for Oracle licensing options.
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.

Considerations when using Oracle Label Security

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see Creating an Oracle Label Security policy in the Oracle documentation.

Consider the following:

- Oracle Label Security is a permanent and persistent option. Because the option is permanent, you can't remove it from an option group. If you add Oracle Label Security to an option group

and associate it with your DB instance, you can later associate a different option group with your DB instance, but this group must also contain the Oracle Label Security option.

- When you work with Label Security, you perform all actions as the LBAC_DBA role. The master user for your DB instance is granted the LBAC_DBA role. You can grant the LBAC_DBA role to other users so that they can administer Label Security policies.
- Make sure to grant access to the OLS_ENFORCEMENT package to any new users who require access to Oracle Label Security. To grant access to the OLS_ENFORCEMENT package, connect to the DB instance as the master user and run the following SQL statement:

```
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

- You can configure Label Security through Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports OEM Cloud Control through the Management Agent option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.

Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.

> **Important**
>
> Oracle Label Security is a permanent and persistent option.

3. Associate the option group with the DB instance.

After you add the Label Security option, as soon as the option group is active, Label Security is active.

To add the label security option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose **oracle-ee**.

b. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the **OLS** option to the option group. For more information about adding options, see Adding an option to an option group.

> **Important**
>
> If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:

- For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

Troubleshooting

The following are issues you might encounter when you use Oracle Label Security.

Issue	Troubleshooting suggestions
When you try to create a policy, you see an error message similar to the following : `insufficient authorization for the SYSDBA package`.	A known issue with Oracle's Label Security feature prevents users with usernames of 16 or 24 characters from running Label Security commands. You can create a new user with a different number of characters, grant LBAC_DBA to the new user, log in as the new user, and run the OLS commands as the new user. For additional information, contact Oracle Support.

Oracle Locator

Amazon RDS supports Oracle Locator through the use of the LOCATOR option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see Oracle Locator in the Oracle documentation.

> **Important**
>
> If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Supported database releases for Oracle Locator

RDS for Oracle supports Oracle Locator for Oracle Database 19c. Oracle Locator isn't supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn't require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition 2 licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing. For more information, see Machine Learning, Spatial and Graph - No License Required! in the Oracle Database Insider blog.

Prerequisites for Oracle Locator

The following are prerequisites for using Oracle Locator:

- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.small DB instance classes. For more information, see RDS for Oracle DB instance classes.
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle Locator

The following are best practices for using Oracle Locator:

- For maximum security, use the LOCATOR option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle Locator option

The following is the general process for adding the LOCATOR option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

> **Note**
>
> During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the LOCATOR option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

For more information, see Creating an option group.

2. Add the **LOCATOR** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle Locator

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see Features Included with Locator in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see Features Not Included with Locator in the Oracle documentation.

Removing the Oracle Locator option

After you drop all objects that use data types provided by the `LOCATOR` option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the `LOCATOR` option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the `LOCATOR` option, you don't need to restart your DB instance.

To drop the `LOCATOR` option

1. Back up your data.

> **Warning**
>
> If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the LOCATOR option.

   If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

```
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the LOCATOR option.
4. Do one of the following:

   - Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   - Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With the `NATIVE_NETWORK_ENCRYPTION` option, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see Configuring network data encryption in the Oracle documentation. For more information about AWS security, see the AWS security center.

> **Note**
>
> You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see Oracle Secure Sockets Layer.

Topics

- NATIVE_NETWORK_ENCRYPTION option settings
- Adding the NATIVE_NETWORK_ENCRYPTION option
- Setting NNE values in the sqlnet.ora
- Modifying NATIVE_NETWORK_ENCRYPTION option settings
- Removing the NATIVE_NETWORK_ENCRYPTION option

NATIVE_NETWORK_ENCRYPTION option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the `SQLNET.*CLIENT` options.

Amazon RDS supports the following settings for the `NATIVE_NETWORK_ENCRYPTION` option.

Note

When you use commas to separate values for an option setting, don't put a space after the comma.

Option setting	Valid values	Default values	Description
SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS	TRUE, FALSE	TRUE	The behavior of the server when a client using a non-secure cipher attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU. If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS to FALSE, make sure that the following conditions are met: • SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths). • SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5. • The client is patched with the July 2021 PSU. If the client isn't patched,

Option setting	Valid values	Default values	Description
			the client loses the connection and receives the ORA-12269 error.

Option setting	Valid values	Default values	Description
SQLNET.ALLOW_WEAK_CRYPTO	TRUE, FALSE	TRUE	The behavior of the server when a client using a non-secure cipher attempts to connect to the database. The following ciphers are considered not secure: • DES encryption method (all key lengths) • 3DES encryption method (all key lengths) • RC4 encryption method (all key lengths) • MD5 checksumming method If the setting is TRUE, clients can connect when they use the preceding non-secure ciphers. If the setting is FALSE, the database prevents clients from connecting when they use the preceding non-secure ciphers. Before you set SQLNET.ALLOW_WEAK_CRYPTO to FALSE, make sure that the following conditions are met: • SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).

Option setting	Valid values	Default values	Description
			• SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5. • The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.
SQLNET.CRYPTO_CHECKSUM_CLIENT	Accepted Rejected Requested Required	Requested	The data integrity behavior when a DB instance connects to the client, or a server acting as a client. When a DB instance uses a database link, it acts as a client. Requested indicates that the client doesn't require the DB instance to perform a checksum.
SQLNET.CRYPTO_CHECKSUM_SERVER	Accepted Rejected Requested Required	Requested	The data integrity behavior when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client. Requested indicates that the DB instance doesn't require the client to perform a checksum.

Option setting	Valid values	Default values	Description
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	SHA256, SHA384, SHA512, SHA1, MD5	SHA256, SHA384, SHA512	A list of checksum algorithms. You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error. This parameter and SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER must have a common cipher.
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	SHA256, SHA384, SHA512, SHA1, MD5	SHA256, SHA384, SHA512, SHA1, MD5	A list of checksum algorithms. You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error. This parameter and SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT must have a common cipher.
SQLNET.ENCRYPTION_CLIENT	Accepted, Rejected, Requested, Required	Requested	The encryption behavior of the client when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client. Requested indicates that the client does not require traffic from the server to be encrypted.

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_SERVER	Accepted Rejected Requested , Required	Requested	The encryption behavior of the server when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client. Requested indicates that the DB instance does not require traffic from the client to be encrypted.

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_TYPES_CLIENT	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	A list of encryption algorithms used by the client. The client attempts to decrypt the server input by trying each algorithm in order, proceeding until an algorithm succeeds or the end of the list is reached. Amazon RDS uses the following default list from Oracle. RDS starts with RC4_256 and proceeds down the list in order. You can change the order or limit the algorithms that the DB instance will accept. 1. RC4_256: RSA RC4 (256-bit key size) 2. AES256: AES (256-bit key size) 3. AES192: AES (192-bit key size) 4. 3DES168: 3-key Triple-DES (112-bit effective key size) 5. RC4_128: RSA RC4 (128-bit key size) 6. AES128: AES (128-bit key size) 7. 3DES112: 2-key Triple-DES (80-bit effective key size) 8. RC4_56: RSA RC4 (56-bit key size) 9. DES: Standard DES (56-bit key size) 10. RC4_40: RSA RC4 (40-bit key size) 11. DES40: DES40 (40-bit key size) You can specify either one value or a comma-separated list of values. If you a comma, don't insert a space after

Option setting	Valid values	Default values	Description
			the comma; otherwise, you receive an `InvalidParameterValue` error. This parameter and `SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER` must have a common cipher.

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_TYPES_SERVER	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	A list of encryption algorithms used by the DB instance. The DB instance uses each algorithm, in order, to attempt to decrypt the client input until an algorithm succeeds or until the end of the list is reached. Amazon RDS uses the following default list from Oracle. You can change the order or limit the algorithms that the client will accept. 1. RC4_256: RSA RC4 (256-bit key size) 2. AES256: AES (256-bit key size) 3. AES192: AES (192-bit key size) 4. 3DES168: 3-key Triple-DES (112-bit effective key size) 5. RC4_128: RSA RC4 (128-bit key size) 6. AES128: AES (128-bit key size) 7. 3DES112: 2-key Triple-DES (80-bit effective key size) 8. RC4_56: RSA RC4 (56-bit key size) 9. DES: Standard DES (56-bit key size) 10RC4_40: RSA RC4 (40-bit key size) 11DES40: DES40 (40-bit key size) You can specify either one value or a comma-separated list of values. If you a comma, don't insert a space after the comma; otherwise, you receive an InvalidParameterValue error.

Option setting	Valid values	Default values	Description
			This parameter and SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER must have a common cipher.

Adding the NATIVE_NETWORK_ENCRYPTION option

The general process for adding the NATIVE_NETWORK_ENCRYPTION option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

To add the NATIVE_NETWORK_ENCRYPTION option to a DB instance using the AWS Management Console

1. For **Engine**, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
3. Add the **NATIVE_NETWORK_ENCRYPTION** option to the option group. For more information about adding options, see Adding an option to an option group.

   > **Note**
   >
   > After you add the **NATIVE_NETWORK_ENCRYPTION** option, you don't need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:

- For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the **NATIVE_NETWORK_ENCRYPTION** option, you don't need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see Modifying an Amazon RDS DB instance.

Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

- `SQLNET.ALLOW_WEAK_CRYPTO`
- `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS`
- `SQLNET.CRYPTO_CHECKSUM_CLIENT`
- `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT`
- `SQLNET.ENCRYPTION_CLIENT`
- `SQLNET.ENCRYPTION_TYPES_CLIENT`

For information, see Configuring network data encryption and integrity for Oracle servers and clients in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called `/tmp/nettrace*`. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see About negotiating encryption and integrity in the Oracle Database documentation.

Modifying NATIVE_NETWORK_ENCRYPTION option settings

After you enable the NATIVE_NETWORK_ENCRYPTION option, you can modify its settings. Currently, you can modify NATIVE_NETWORK_ENCRYPTION option settings only with the AWS CLI or RDS API. You can't use the console. The following example modifies two settings in the option.

```
aws rds add-option-to-option-group \
    --option-group-name my-option-group \
    --options
 "OptionName=NATIVE_NETWORK_ENCRYPTION,OptionSettings=[{Name=SQLNET.CRYPTO_CHECKSUM_TYPES_SERVE
{Name=SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER,Value=SHA256}]" \
    --apply-immediately
```

To learn how to modify option settings using the CLI, see AWS CLI. For more information about each setting, see NATIVE_NETWORK_ENCRYPTION option settings.

Topics

- Modifying CRYPTO_CHECKSUM_* values
- Modifying ALLOW_WEAK_CRYPTO* settings

Modifying CRYPTO_CHECKSUM_* values

If you modify **NATIVE_NETWORK_ENCRYPTION** option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER. The configuration is valid because the CRYPTO_CHECKSUM_TYPES_CLIENT and CRYPTO_CHECKSUM_TYPES_SERVER both use SHA256.

Option setting	Values before modification	Values after modification
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	**SHA256**, SHA384, SHA512	No change

Option setting	Values before modification	Values after modification
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	**SHA256**, SHA384, SHA512, SHA1, MD5	SHA1,MD5, **SHA256**

For another example, assume that you want to modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER from its default setting to SHA1,MD5. In this case, make sure you set SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT.

Modifying ALLOW_WEAK_CRYPTO* settings

To set the SQLNET.ALLOW_WEAK_CRYPTO* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRYPTION_TYPES_CLIENT and SQLNET.ENCRYPTION_TYPES_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET.ALLOW_WEAK_CRYPTO* options to FALSE, first set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to a secure encryption method such as AES256.

Option setting	Values
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	SHA256, SHA384, SHA512
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	SHA1,MD5,SHA256
SQLNET.ENCRYPTION_TYPES_CLIENT	RC4_256, 3DES168, DES40
SQLNET.ENCRYPTION_TYPES_SERVER	RC4_256, 3DES168, DES40

Removing the NATIVE_NETWORK_ENCRYPTION option

You can remove NNE from a DB instance.

To remove the NATIVE_NETWORK_ENCRYPTION option from a DB instance, do one of the following:

- To remove the option from multiple DB instances, remove the NATIVE_NETWORK_ENCRYPTION option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NATIVE_NETWORK_ENCRYPTION option, you don't need to restart your DB instances. For more information, see Removing an option from an option group.
- To remove the option from a single DB instance, modify the DB instance and specify a different option group that doesn't include the NATIVE_NETWORK_ENCRYPTION option. You can specify the default (empty) option group, or a different custom option group. After you remove the NATIVE_NETWORK_ENCRYPTION option, you don't need to restart your DB instance. For more information, see Modifying an Amazon RDS DB instance.

Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides On-line Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see the Oracle documentation.

> **Important**
>
> If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the Enterprise Edition of Oracle Database 19c and higher.

Prerequisites for Oracle OLAP

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see Licensing Information in the Oracle documentation.
- Your DB instance must be of a sufficient instance class. Oracle OLAP isn't supported for the db.t3.small DB instance classes. For more information, see RDS for Oracle DB instance classes.
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.
- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.

Best practices for Oracle OLAP

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.

- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle OLAP option

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the OLAP option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

To add the OLAP option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   - For **Engine**, choose the Oracle edition for your DB instance.
   - For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **OLAP** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle OLAP

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see the Oracle documentation.

Removing the Oracle OLAP option

After you drop all objects that use data types provided by the OLAP option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the OLAP option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the OLAP option, you don't need to restart your DB instance.

To drop the OLAP option

1. Back up your data.

   > **Warning**
   >
   > If the instance uses data types that were enabled as part of the option, and if you remove the OLAP option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the OLAP option.
3. Drop any objects that reference data types or features of the OLAP option.
4. Do one of the following:

   - Remove the OLAP option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   - Modify the DB instance and specify a different option group that doesn't include the OLAP option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Secure Sockets Layer

To enable SSL encryption for an RDS for Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and SQL*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

> **Note**
>
> You can use either SSL or Native Network Encryption (NNE) on the same RDS for Oracle DB instance, but not both. If you use SSL encryption, make sure to turn off any other connection encryption. For more information, see Oracle native network encryption.

SSL/TLS and NNE are no longer part of Oracle Advanced Security. In RDS for Oracle, you can use SSL encryption with all licensed editions of the following database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

Topics

- TLS versions for the Oracle SSL option
- Cipher suites for the Oracle SSL option
- FIPS support
- Certificate compatibility with cipher suites
- Adding the SSL option
- Configuring SQL*Plus to use SSL with an RDS for Oracle DB instance
- Connecting to an RDS for Oracle DB instance using SSL
- Setting up an SSL connection over JDBC
- Enforcing a DN match with an SSL connection
- Troubleshooting SSL connections

TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. When you add a new Oracle SSL option, set `SQLNET.SSL_VERSION` explicitly to a valid value. The following values are allowed for this option setting:

- `"1.0"` – Clients can connect to the DB instance using TLS version 1.0 only. For existing Oracle SSL options, `SQLNET.SSL_VERSION` is set to `"1.0"` automatically. You can change the setting if necessary.
- `"1.2"` – Clients can connect to the DB instance using TLS 1.2 only.
- `"1.2 or 1.0"` – Clients can connect to the DB instance using either TLS 1.2 or 1.0.

Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the `SSL_RSA_WITH_AES_256_CBC_SHA` cipher suite. To specify a different cipher suite to use over SSL connections, use the `SQLNET.CIPHER_SUITE` option setting.

You can specify multiple values for `SQLNET.CIPHER_SUITE`. This technique is useful if you have database links between your DB instances and decide to update your cipher suites.

The following table summarizes SSL support for RDS for Oracle in all editions of Oracle Database 19c and 21c.

Cipher suite (SQLNET.CIPHER_SUITE)	TLS version support (SQLNET.SSL_VERSION)	FIPS support	FedRAMP compliant
SSL_RSA_WITH_AES_256_CBC_SHA (default)	1.0 and 1.2	Yes	No
SSL_RSA_WITH_AES_256_CBC_SHA256	1.2	Yes	No
SSL_RSA_WITH_AES_256_GCM_SHA384	1.2	Yes	No
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	1.2	Yes	Yes

Cipher suite (SQLNET.CIPHER_SUITE)	TLS version support (SQLNET.SSL_VERSION)	FIPS support	FedRAMP compliant
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	1.2	Yes	Yes
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	1.2	Yes	Yes
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384	1.2	Yes	Yes

FIPS support

RDS for Oracle allows you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You turn on the FIPS standard by setting `FIPS.SSLFIPS_140` to `TRUE` for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries encrypt data between the client and the RDS for Oracle DB instance.

Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and RDS for Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The table in Cipher suites for the Oracle SSL option shows the FIPS-compliant SSL cipher suites for each TLS version. For more information, see Oracle database FIPS 140-2 settings in the Oracle Database documentation.

Certificate compatibility with cipher suites

RDS for Oracle supports both RSA and Elliptic Curve Digital Signature Algorithm (ECDSA) certificates. When you configure SSL for your DB instance, you must ensure that the cipher suites you specify in the `SQLNET.CIPHER_SUITE` option setting are compatible with the certificate type used by your DB instance.

The following table shows the compatibility between certificate types and cipher suites:

Certificate type	Compatible cipher suites	Incompatible cipher suites
RSA certificates (rds-ca-2019, rds-ca-rsa2048-g1, rds-ca-rsa4096-g1)	SSL_RSA_WITH_AES_256_CBC_SHA SSL_RSA_WITH_AES_256_CBC_SHA256 SSL_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
ECDSA certificates (rds-ca-ecc384-g1)	TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	SSL_RSA_WITH_AES_256_CBC_SHA

Certificate type	Compatible cipher suites	Incompatible cipher suites
	TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384	SSL_RSA_WITH_AES_256_CBC_SHA256 SSL_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA

When you specify multiple cipher suites in the `SQLNET.CIPHER_SUITE` option setting, make sure to include at least one cipher suite that is compatible with the certificate type used by your DB instance. If you're using an option group with multiple DB instances that have different certificate types, include at least one cipher suite for each certificate type.

If you attempt to associate an option group with an SSL option that contains only cipher suites incompatible with the certificate type of a DB instance, the operation will fail with an error message indicating the incompatibility.

Adding the SSL option

To use SSL, your RDS for Oracle DB instance must be associated with an option group that includes the `SSL` option.

Console

To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.

   For information about creating an option group, see Creating an option group.

2. Add the SSL option to the option group.

   If you want to use only FIPS-verified cipher suites for SSL connections, set the option `FIPS.SSLFIPS_140` to `TRUE`. For information about the FIPS standard, see FIPS support.

   For information about adding an option to an option group, see Adding an option to an option group.

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating an DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying an DB instance, see Modifying an Amazon RDS DB instance.

AWS CLI

To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.

   For information about creating an option group, see Creating an option group.

2. Add the SSL option to the option group.

   Specify the following option settings:

   - `Port` – The SSL port number
   - `VpcSecurityGroupMemberships` – The VPC security group for which the option is enabled
   - `SQLNET.SSL_VERSION` – The TLS version that client can use to connect to the DB instance

For example, the following AWS CLI command adds the SSL option to an option group named `ora-option-group`.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group --option-group-name ora-option-group \
  --options
 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=
```

For Windows:

```
aws rds add-option-to-option-group --option-group-name ora-option-group ^
  --options
 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

   For information about creating an DB instance, see Creating an Amazon RDS DB instance.

   For information about modifying an DB instance, see Modifying an Amazon RDS DB instance.

Configuring SQL*Plus to use SSL with an RDS for Oracle DB instance

Before you can connect to an RDS for Oracle DB instance that uses the Oracle SSL option, you must configure SQL*Plus before connecting.

> **Note**
>
> To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see Controlling access with security groups. Also, these instructions are for SQL*Plus and other clients that directly use an Oracle home. For JDBC connections, see Setting up an SSL connection over JDBC.

To configure SQL*Plus to use SSL to connect to an RDS for Oracle DB instance

1. Set the ORACLE_HOME environment variable to the location of your Oracle home directory.

   The path to your Oracle home directory depends on your installation. The following example sets the ORACLE_HOME environment variable.

   ```
   prompt>export ORACLE_HOME=/home/user/app/user/product/19.0.0/dbhome_1
   ```

   For information about setting Oracle environment variables, see SQL*Plus environment variables in the Oracle documentation, and also see the Oracle installation guide for your operating system.

2. Append $ORACLE_HOME/lib to the LD_LIBRARY_PATH environment variable.

   The following is an example that sets the LD_LIBRARY_PATH environment variable.

   ```
   prompt>export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib
   ```

3. Create a directory for the Oracle wallet at $ORACLE_HOME/ssl_wallet.

   The following is an example that creates the Oracle wallet directory.

   ```
   prompt>mkdir $ORACLE_HOME/ssl_wallet
   ```

4. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the ssl_wallet directory. For information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

5. In the $ORACLE_HOME/network/admin directory, modify or create the tnsnames.ora file and include the following entry.

   ```
   net_service_name =
     (DESCRIPTION =
       (ADDRESS_LIST =
         (ADDRESS =
           (PROTOCOL = TCPS)
           (HOST = endpoint)
           (PORT = ssl_port_number)
         )
       )
       (CONNECT_DATA =
   ```

```
      (SID = database_name)
    )
    (SECURITY =
      (SSL_SERVER_CERT_DN =
"C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=endpoint")
    )
  )
```

6. In the same directory, modify or create the sqlnet.ora file and include the following parameters.

> **Note**
>
> To communicate with entities over a TLS secured connection, Oracle requires a wallet with the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create and maintain Oracle wallets, as shown in step 7. For more information, see Setting up Oracle wallet using ORAPKI in the Oracle documentation.

```
WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY =
 $ORACLE_HOME/ssl_wallet)))
SSL_CLIENT_AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
SSL_SERVER_DN_MATCH = ON
```

> **Note**
>
> You can set SSL_VERSION to a higher value if your DB instance supports it.

7. Run the following command to create the Oracle wallet.

```
prompt>orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
```

8. Extract each certificate in the .pem bundle file into a separate .pem file using an OS utility.
9. Add each certificate to your wallet using separate `orapki` commands, replacing *`certificate-pem-file`* with the absolute file name of the .pem file.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert
```

```
        certificate-pem-file -auto_login_only
```

For more information, see Rotating your SSL/TLS certificate.

Connecting to an RDS for Oracle DB instance using SSL

After you configure SQL*Plus to use SSL as described previously, you can connect to the RDS for Oracle DB instance with the SSL option. Optionally, you can first export the TNS_ADMIN value that points to the directory that contains the tnsnames.ora and sqlnet.ora files. Doing so ensures that SQL*Plus can find these files consistently. The following example exports the TNS_ADMIN value.

```
export TNS_ADMIN=${ORACLE_HOME}/network/admin
```

Connect to the DB instance. For example, you can connect using SQL*Plus and a *<net_service_name>* in a tnsnames.ora file.

```
sqlplus mydbuser@net_service_name
```

You can also connect to the DB instance using SQL*Plus without using a tnsnames.ora file by using the following command.

```
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCPS)(HOST = endpoint) (PORT
 = ssl_port_number))(CONNECT_DATA = (SID = database_name)))'
```

You can also connect to the RDS for Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = endpoint) (PORT
 = port_number))(CONNECT_DATA = (SID = database_name)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

Setting up an SSL connection over JDBC

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, you can use the following command. For more information about creating the keystore, see the Creating a keystore in the Oracle documentation. For reference information, see keytool in the *Java Platform, Standard Edition Tools Reference*.

```
keytool -genkey -alias client -validity 365 -keyalg RSA -keystore clientkeystore
```

Take the following steps to trust the Amazon RDS root CA certificate.

To trust the Amazon RDS root CA certificate

1. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the ssl_wallet directory.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .
2. Extract each certificate in the .pem file into a separate file using an OS utility.
3. Convert each certificate to .der format using a separate `openssl` command, replacing *`certificate-pem-file`* with the name of the certificate .pem file (without the .pem extension).

   ```
   openssl x509 -outform der -in certificate-pem-file.pem -out certificate-pem-file.der
   ```
4. Import each certificate into the keystore using the following command.

   ```
   keytool -import -alias rds-root -keystore clientkeystore.jks -file certificate-pem-file.der
   ```

   For more information, see Rotating your SSL/TLS certificate.
5. Confirm that the key store was created successfully.

   ```
   keytool -list -v -keystore clientkeystore.jks
   ```

Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "dns-name-provided-by-amazon-rds";
    private static final Integer SSL_PORT = "ssl-option-port-configured-in-option-
group";
    private static final String DB_SID = "oracle-sid";
    private static final String DB_USER = "user-name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
                "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=
%d))(CONNECT_DATA=(SID=%s)))",
                DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.J2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString,
 properties);
        // If no exception, that means handshake has passed, and an SSL connection can
 be opened
    }
}
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Enforcing a DN match with an SSL connection

You can use the Oracle parameter SSL_SERVER_DN_MATCH to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don't enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identity.

To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

```
properties.put("oracle.net.ssl_server_dn_match", "TRUE");
```

Use the following connection string to enforce DN matching when using SSL.

```
final String connectionString = String.format(
    "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))" +
    "(CONNECT_DATA=(SID=%s))" +
    "(SECURITY = (SSL_SERVER_CERT_DN =
\"C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s\")))",
    DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);
```

Troubleshooting SSL connections

You might query your database and receive the ORA-28860 error.

```
ORA-28860: Fatal SSL error
28860. 00000 - "Fatal SSL error"
*Cause: An error occurred during the SSL connection to the peer. It is likely that this
 side sent data which the peer rejected.
*Action: Enable tracing to determine the exact cause of this error.
```

This error occurs when the client attempts to connect using a version of TLS that the server doesn't support. To avoid this error, edit the sqlnet.ora and set `SSL_VERSION` to the correct TLS version. For more information, see Oracle Support Document 2748438.1 in My Oracle Support.

Oracle Spatial

Amazon RDS supports Oracle Spatial through the use of the `SPATIAL` option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see Spatial Concepts in the Oracle documentation. Amazon RDS supports Oracle Spatial in all editions of all supported releases.

How Spatial Patch Bundles (SPBs) work

Every quarter, RDS for Oracle releases new minor engine versions for every supported major engine. A Release Update (RU) engine version incorporates bug fixes from Oracle by including the RU patches for the specified quarter. A Spatial Patch Bundle (SPB) engine version contains RU patches plus patches specific to Oracle Spatial. For example, 19.0.0.0.ru-2025-01.spb-1.r1 is a minor engine version that contains the RU patches in engine version 19.0.0.0.ru-2025-01.rur-2025-01.r1 plus Spatial patches. SPBs are supported only for Oracle Database 19c.

SPBs function in the same way as RUs, although they are named differently. An RU uses the naming format 19.0.0.0.ru-2025-01.rur-2025-01.r1. An SPB name includes the text "spb," as in 19.0.0.0.ru-2025-01.spb-1.r1. Typically, an SPB is released 2–3 weeks after its corresponding quarterly RU. For example, 19.0.0.0.ru-2025-01.spb-1.r1 is released after 19.0.0.0.ru-2025-01.rur-2025-01.r1.

RDS for Oracle has separate paths for automatic minor version upgrades of RUs and SPBs. If your DB instance uses an RU, then RDS automatically upgrades your instance to an RU. If your DB instance uses an SPB, then RDS upgrades your instance to an SPB.

For more information about RUs and SPBs, see Oracle minor version upgrades. For a list of supported RUs and SPBs for Oracle Database 19c, see Amazon RDS for Oracle Database 19c (19.0.0.0) in *Amazon RDS for Oracle Release Notes*.

Prerequisites for Oracle Spatial

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn't supported for the db.t3.small DB instance classes. For more information, see RDS for Oracle DB instance classes.

- Make sure that your DB instance has **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance.

Best practices for Oracle Spatial

The following are best practices for using Oracle Spatial:

- For maximum security, use the `SPATIAL` option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer.
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC and Working with a DB instance in a VPC.

Adding the Oracle Spatial option

The following is the general process for adding the `SPATIAL` option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the `SPATIAL` option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.

> **Note**
>
> During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the SPATIAL option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the Oracle edition for your DB instance.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **SPATIAL** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Removing the Oracle Spatial option

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don't need to restart your DB instance.

To drop the SPATIAL option

1. Back up your data.

   Warning

   If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see Backing up, restoring, and exporting data.

2. Check whether any existing objects reference data types or features of the SPATIAL option.

   If SPATIAL options exist, the instance can get stuck when applying the new option group that doesn't have the SPATIAL option. You can identify the objects by using the following queries:

```
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the SPATIAL option.
4. Do one of the following:

   - Remove the SPATIAL option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
   - Modify the DB instance and specify a different option group that doesn't include the SPATIAL option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle SQLT

Amazon RDS supports Oracle SQLTXPLAIN (SQLT) through the use of the SQLT option. You can use SQLT with any edition of Oracle Database 19c and higher.

The Oracle `EXPLAIN PLAN` statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So `EXPLAIN PLAN` helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

SQLT version	Oracle Database 21c	Oracle Database 19c
2018-07-25.v1	Supported	Supported
2018-03-31.v1	Not supported	Not supported
2016-04-29.v1	Not supported	Not supported

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
- To download SQLT: Document 215187.1
- For SQLT usage instructions: Document 1614107.1
- For frequently asked questions about SQLT: Document 1454160.1
- For information about reading SQLT output: Document 1456176.1
- For interpreting the Main report: Document 1922234.1

Amazon RDS doesn't support the following SQLT methods:

- XPLORE
- XHUME

Prerequisites for SQLT

The following are prerequisites for using SQLT:

- You must remove users and roles that are required by SQLT, if they exist.

  The SQLT option creates the following users and roles on a DB instance:

  - SQLTXPLAIN user
  - SQLTXADMIN user
  - SQLT_USER_ROLE role

  If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;
DROP USER SQLTXADMIN CASCADE;
DROP ROLE SQLT_USER_ROLE CASCADE;
```

- You must remove tablespaces that are required by SQLT, if they exist.

  The SQLT option creates the following tablespaces on a DB instance:

  - RDS_SQLT_TS
  - RDS_TEMP_SQLT_TS

  If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

SQLT option settings

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle

Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

Option setting	Valid values	Default value	Description
LICENSE_PACK	T, D, N	N	The Oracle Management Packs that you want to access with SQLT. Enter one of the following values: • T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT. • D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT. • N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them. **Note** Amazon RDS does not provide licenses for these Oracle Management Packs. If you indicate that you want to use a pack that is not included in

Option setting	Valid values	Default value	Description
			your DB instance, you can use SQLT with the DB instance. However, SQLT can't access the pack, and the SQLT report doesn't include the data for the pack. For example, if you specify T, but the DB instance doesn't include the Oracle Tuning Pack, SQLT works on the DB instance, but the report it generates doesn't contain data related to the Oracle Tuning Pack.
VERSION	2016-04-29.v1 2018-03-31.v1 2018-07-25.v1	2016-04-29.v1	The version of SQLT that you want to install. **Note** For Oracle Database 19c and 21c, the only supported version is 2018-07-25.v1 . This version is the default for these releases.

Adding the SQLT option

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

To add the SQLT option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **SQLT** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.
4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.

   a. Use a SQL client to connect to the DB instance as the master user.

   For information about connecting to an Oracle DB instance using a SQL client, see Connecting to your Oracle DB instance.

   b. Run the following query:

```
SELECT sqltxplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
```

   The query returns the current version of the SQLT option on Amazon RDS. `12.1.160429` is an example of a version of SQLT that is available on Amazon RDS.

5. Change the passwords of the users that are created by the SQLT option.

   a. Use a SQL client to connect to the DB instance as the master user.

   b. Run the following SQL statement to change the password for the SQLTXADMIN user:

```
ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

   c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

```
ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

> **Note**
>
> Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 19c to Oracle Database 21c.

Using SQLT

SQLT works with the Oracle SQL*Plus utility.

To use SQLT

1. Download the SQLT .zip file from Document 215187.1 on the My Oracle Support site.

   > **Note**
   >
   > You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.

2. Unzip the SQLT .zip file.
3. From a command prompt, change to the `sqlt/run` directory on your file system.
4. From the command prompt, open SQL*Plus, and connect to the DB instance as the master user.

   For information about connecting to a DB instance using SQL*Plus, see Connecting to your Oracle DB instance.
5. Get the SQL ID of a SQL statement:

   ```
   SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT='sql_statement';
   ```

   Your output is similar to the following:

   ```
   SQL_ID
   -------------
   chvsmttqjzjkn
   ```
6. Analyze a SQL statement with SQLT:

   ```
   START sqltxtract.sql sql_id sqltxplain_user_password
   ```

   For example, for the SQL ID `chvsmttqjzjkn`, enter the following:

```
START sqltxtract.sql chvsmttqjzjkn sqltxplain_user_password
```

SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT_USER_ROLE to each application user with the following statement:

```
GRANT SQLT_USER_ROLE TO application_user_name;
```

> **Note**
>
> Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user's account, by granting SQLT_USER_ROLE to the application user.

Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in Using SQLT for the new version of SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.

Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see Document 1614201.1 on the My Oracle Support site.

> **Note**
>
> Version downgrades are not supported.

Modifying SQLT settings

After you enable SQLT, you can modify the `LICENSE_PACK` and `VERSION` settings for the option.

For more information about how to modify option settings, see Modifying an option setting. For more information about each setting, see SQLT option settings.

Removing the SQLT option

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

- To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see Oracle Statspack in the Oracle documentation.

> **Note**
>
> Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

To set up Oracle Statspack

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
   - If Statspack is installed, and the PERFSTAT account is associated with Statspack, skip to Step 4.
   - If Statspack is not installed, and the PERFSTAT account exists, drop the account as follows:

     ```
     DROP USER PERFSTAT CASCADE;
     ```

     Otherwise, attempting to add the Statspack option generates an error and RDS-Event-0058.
3. Add the Statspack option to an option group. See Adding an option to an option group.

   Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the PERFSTAT account.

4. Reset the password using the following SQL statement, replacing *pwd* with your new password:

```
ALTER USER PERFSTAT IDENTIFIED BY pwd ACCOUNT UNLOCK;
```

   You can log in using the PERFSTAT user account and run the Statspack scripts.

5. Grant the CREATE JOB privilege to the PERFSTAT account using the following statement:

```
GRANT CREATE JOB TO PERFSTAT;
```

6. Ensure that idle wait events in the PERFSTAT.STATS$IDLE_EVENT table are populated.

   Because of Oracle Bug 28523746, the idle wait events in PERFSTAT.STATS$IDLE_EVENT may not be populated. To ensure all idle events are available, run the following statement:

```
INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
MINUS
SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
COMMIT;
```

Generating Statspack reports

A Statspack report compares two snapshots.

To generate Statspack reports

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:

   - Create a Statspack snapshot manually.
   - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:

```
VARIABLE jn NUMBER;
exec dbms_job.submit(:jn, 'statspack.snap;',SYSDATE,'TRUNC(SYSDATE
+1/24,''HH24'')');
COMMIT;
```

3. View the snapshots using the following query:

```
SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
```

4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing *begin_snap* and *end_snap* with the snapshot IDs:

```
exec rdsadmin.rds_run_spreport(begin_snap,end_snap);
```

For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

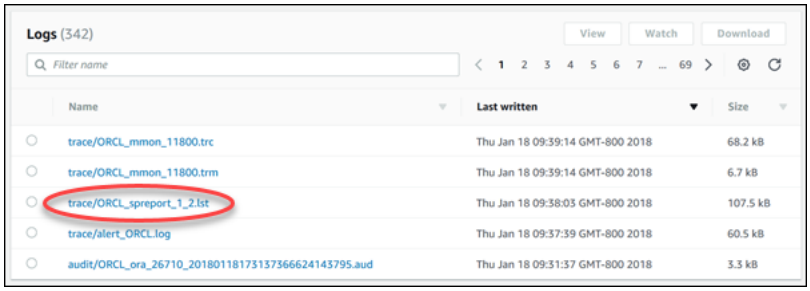
```
exec rdsadmin.rds_run_spreport(1,2);
```

The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.

5. Monitor the output for errors.

Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

```
exec rdsadmin.rds_run_spreport(2,1);
*
ERROR at line 1:
ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
```



If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn't exist, the output shows an error.

```
exec rdsadmin.rds_run_spreport(1,50);
*
ERROR at line 1:
ORA-20000: Could not find both snapshot IDs
```

6. (Optional)

   To retrieve the report, call the trace file procedures, as explained in Working with Oracle trace files.

   Alternatively, download the Statspack report from the RDS console. Go to the **Log** section of the DB instance details and choose **Download**. The following example shows `trace/ORCL_spreport_1_2.lst`

   If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of `.err`. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named `ORCL_spreport_1_7.err`. You can download the error report using the same techniques as for a standard Snapshot report.

Removing Statspack snapshots

To remove a range of Oracle Statspack snapshots, use the following command:

```
exec statspack.purge(begin snap, end snap);
```

Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including `SYSDATE` and `SYSTIMESTAMP`.

The time zone option differs from the `rdsadmin_util.alter_db_time_zone` command. The `alter_db_time_zone` command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about `alter_db_time_zone`, see Setting the database time zone. For more information about upgrade considerations, see Time zone considerations.

Restrictions for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

- Remove the option from an option group after you add the time zone option.
- Remove the option group from a DB instance after you add the group.
- Modify the time zone setting of the option to a different time zone.

Recommendations for setting the time zone

Before you add the time zone option to your production database, we strongly recommend that you do the following:

- Take a snapshot of your DB instance. If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.
- Add the time zone option to a test DB instance. Adding the time zone option can cause problems with tables that use the system date to add dates or times. We recommend that you analyze your data and applications on the test instance. This way you can assess the impact of changing the time zone on your production instance.

If your DB instance uses the default option group, then follow these steps:

1. Take a snapshot of your DB instance.

2. Add the time zone option to your DB instance.

If your DB instance currently uses a nondefault option group, then follow these steps:

1. Take a snapshot of your DB instance.
2. Create a new option group.
3. Add the time zone option to it, along with all other options that are currently associated with the existing option group.

   This prevents the existing options from being uninstalled while enabling the time zone option.
4. Add the option group to your DB instance.

Time zone option settings

Amazon RDS supports the following settings for the time zone option.

Option setting	Valid values	Description
`TIME_ZONE`	One of the available time zones. For the full list, see Available time zones.	The new time zone for your DB instance.

Adding the time zone option

Complete the following steps to add the time zone option to your DB instance:

1. (Recommended) Take a snapshot of your DB instance.
2. Do one of the following tasks:
   - Create a new option group from scratch. For more information, see Creating an option group.
   - Copy an existing option group using the AWS CLI or API. For more information, see Copying an option group.
   - Reuse an existing non-default option group. A best practice is to use an option group that isn't currently associated with any DB instances or snapshots.
3. Add the new option to the option group from the preceding step.

4. If the option group that is currently associated with your DB instance has options enabled, add these options to your new option group. This strategy prevents the existing options from being uninstalled while enabling the new option.
5. Add the new option group to your DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

Console

To add the time zone option to an option group and associate it with a DB instance

1. In the RDS console, choose **Option groups.**
2. Choose the name of the option group to which you want to add the option.
3. Choose **Add option**.
4. For **Option name**, choose **Timezone**, and then configure the option settings.
5. Associate the option group with a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the new option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `Timezone` option and the `TIME_ZONE` option setting to an option group called `myoptiongroup`. The time zone is set to `Africa/Cairo`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/
Cairo}]" \
```

```
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/
Cairo}]" ^
    --apply-immediately
```

Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

Removing the time zone option

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

Available time zones

You can use the following values for the time zone option.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/M

Zone	Time zone
	exico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

Oracle time zone file autoupgrade

With the `TIMEZONE_FILE_AUTOUPGRADE` option, you can upgrade the current time zone file to the latest version on your RDS for Oracle DB instance.

Topics

- Overview of Oracle time zone files
- Strategies for updating your time zone file
- Downtime during the time zone file update
- Preparing to update the time zone file
- Adding the time zone file autoupgrade option
- Checking your data after the update of the time zone file

Overview of Oracle time zone files

An Oracle Database *time zone file* stores the following information:

- Offset from Coordinated Universal Time (UTC)
- Transition times for Daylight Saving Time (DST)
- Abbreviations for standard time and DST

Oracle Database supplies multiple versions of time zone files. When you create an Oracle database in an on-premises environment, you choose the time zone file version. For more information , see Choosing a Time Zone File in the *Oracle Database Globalization Support Guide*.

If the rules change for DST, Oracle publishes new time zone files. Oracle releases these new time zone files independently of the schedule for quarterly Release Updates (RUs) and Release Update Revisions (RURs). The time zone files reside on the database host in the directory `$ORACLE_HOME/oracore/zoneinfo/`. The time zone file names use the format DSTv*`version`*, as in DSTv35.

How the time zone file affects data transfer

In Oracle Database, the `TIMESTAMP WITH TIME ZONE` data type stores time stamp and time zone data. Data with the `TIMESTAMP WITH TIME ZONE` data type uses the rules in the associated time zone file version. Thus, existing `TIMESTAMP WITH TIME ZONE` data is affected when you update the time zone file.

Problems can occur when you transfer data between databases that use different versions of the time zone file. For example, if you import data from a source database with a higher time zone file version than the target database, the database issues the `ORA-39405` error. Previously, you had to work around this error by using either of the following techniques:

- Create an RDS for Oracle DB instance with the desired time zone file, export data from your source database, and then import it into the new database.
- Use AWS DMS or logical replication to migrate your data.

Automatic updates using the TIMEZONE_FILE_AUTOUPGRADE option

When the option group attached to your RDS for Oracle DB instance includes the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS updates your time zone files automatically. By ensuring that your Oracle databases use the same time zone file version, you avoid time-consuming manual techniques when you move data between different environments. The `TIMEZONE_FILE_AUTOUPGRADE` option is supported for both container databases (CDBs) and non-CDBs.

When you add the `TIMEZONE_FILE_AUTOUPGRADE` option to your option group, you can choose whether to add the option immediately or during the maintenance window. After your DB instance applies the new option, RDS checks whether it can install a newer DSTv*`version`* file. The target DSTv*`version`* depends on the following:

- The minor engine version that your DB instance is currently running
- The minor engine version to which you want to upgrade your DB instance

For example, your current time zone file version might be DSTv33. When RDS applies the update to your option group, it might determine that DSTv34 is currently available on your DB instance file system. RDS will then update your time zone file to DSTv34 automatically.

To find the available DST versions in the supported RDS release updates, look at the patches in Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle. For example, version 19.0.0.0.ru-2022-10.rur-2022-10.r1 lists patch 34533061: RDBMS - DSTV39 UPDATE - TZDATA2022C.

Strategies for updating your time zone file

Upgrading your DB engine and adding the TIMEZONE_FILE_AUTOUPGRADE option to an option group are separate operations. Adding the TIMEZONE_FILE_AUTOUPGRADE option initiates the update of your time zone file if a more current one is available. You run the following commands (only relevant options are shown) either immediately or at the next maintenance window:

- Upgrade your DB engine only using the following RDS CLI command:

```
modify-db-instance --engine-version name ...
```

- Add the TIMEZONE_FILE_AUTOUPGRADE option only using the following CLI command:

```
add-option-to-option-group --option-group-name name --options
 OptionName=TIMEZONE_FILE_AUTOUPGRADE ...
```

- Upgrade your DB engine and add a new option group to your instance using the following CLI command:

```
modify-db-instance --engine-version name --option-group-name name ...
```

Your update strategy depends on whether you want to upgrade your database and time zone file together or perform just one of these operations. Keep in mind that if you update your option group and then upgrade your DB engine in separate API operations, it's possible for a time zone file update to be currently in progress when you upgrade your DB engine.

The examples in this section assume the following:

- You have not yet added TIMEZONE_FILE_AUTOUPGRADE to the option group currently associated with your DB instance.
- Your DB instance uses database version 19.0.0.0.ru-2019-07.rur-2019-07.r1 and time zone file DSTv33.
- Your DB instance file system includes file DSTv34.
- Release update 19.0.0.0.ru-2022-10.rur-2022-10.r1 includes DSTv35.

To update your time zone file, you can use the following strategies.

Topics

- Update the time zone file without upgrading the engine
- Upgrade the time zone file and DB engine version
- Upgrade your DB engine version without updating the time zone file

Update the time zone file without upgrading the engine

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to update the time zone file used by your DB instance from DSTv33 to DSTv34, but you don't want to upgrade your engine to a new minor version, which includes DSTv35.

In an `add-option-to-option-group` command, add `TIMEZONE_FILE_AUTOUPGRADE` to the option group used by your DB instance. Specify whether to add the option immediately or defer it to the maintenance window. After applying the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS does the following:

1. Checks for a new DST version.
2. Determines that DSTv34 is available on the file system.
3. Updates the time zone file immediately.

Upgrade the time zone file and DB engine version

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to minor version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, and update your time zone file to DSTv35 during the engine upgrade. Thus, your goal is to skip DSTv34 and update your time zone files directly to DSTv35.

To upgrade the engine and time zone file together, run `modify-db-instance` with the `--option-group-name` and `--engine-version` options. You can run the command immediately or defer it to maintenance window. `In --option-group-name`, specify an option group that includes the `TIMEZONE_FILE_AUTOUPGRADE` option. For example:

```
aws rds modify-db-instance
    --db-instance-identifier my-instance \
    --engine-version new-version \
    ----option-group-name og-with-timezone-file-autoupgrade \
    --apply-immediately
```

RDS begins upgrading your engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1. After applying the TIMEZONE_FILE_AUTOUPGRADE option, RDS checks for a new DST version, sees that DSTv35 is available in 19.0.0.0.ru-2022-10.rur-2022-10.r1, and immediately starts the update to DSTv35.

To upgrade your engine immediately and then upgrade your a timezone file, perform the operations in sequence:

1. Upgrade your DB engine only using the following CLI command:

```
aws rds modify-db-instance \
    --db-instance-identifier my-instance \
    --engine-version new-version \
    --apply-immediately
```

2. Add the TIMEZONE_FILE_AUTOUPGRADE option to the option group attached to your instance using the following CLI command:

```
aws rds add-option-to-option-group \
    --option-group-name og-in-use-by-your-instance \
    --options OptionName=TIMEZONE_FILE_AUTOUPGRADE \
    --apply-immediately
```

Upgrade your DB engine version without updating the time zone file

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, but retain time zone file DSTv33. You might choose this strategy for the following reasons:

- Your data doesn't use the TIMESTAMP WITH TIME ZONE data type.
- Your data uses the TIMESTAMP WITH TIME ZONE data type, but your data is not affected by the time zone changes.
- You want to postpone updating the time zone file because you can't tolerate the extra downtime.

Your strategy depends on which of the following possibilities are true:

- Your DB instance isn't associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. In your `modify-db-instance` command, don't specify a new option group so that RDS doesn't update your time zone file.
- Your DB instance is currently associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. Within a single `modify-db-instance` command, associate your DB instance with an option group that doesn't include `TIMEZONE_FILE_AUTOUPGRADE` and upgrade your DB engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1.

Downtime during the time zone file update

When RDS updates your time zone file, existing data that uses `TIMESTAMP WITH TIME ZONE` might change. In this case, your primary consideration is downtime.

> **Warning**
>
> If you add the `TIMEZONE_FILE_AUTOUPGRADE` option, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the time zone file update depends on factors such as the following:

- The amount of `TIMESTAMP WITH TIME ZONE` data in your database
- The DB instance configuration
- The DB instance class
- The storage configuration
- The database configuration
- The database parameter settings

Additional downtime can occur when you do the following:

- Add the option to the option group when the DB instance uses an outdated time zone file
- Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file

> **Note**
>
> During the time zone file update, RDS for Oracle calls `PURGE DBA_RECYCLEBIN`.

Preparing to update the time zone file

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure `DBMS_DST.FIND_AFFECTED_TABLES`. For more information about the prepare window, see Upgrading the Time Zone File and Timestamp with Time Zone Data in the Oracle Database documentation.

To prepare to update the time zone file

1. Connect to your Oracle database using a SQL client.
2. Determine the current timezone file version used.

```
SELECT * FROM V$TIMEZONE_FILE;
```

3. Determine the latest timezone file version available on your DB instance.

```
SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
```

4. Determine the total size of tables that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```
SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE 'TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
         (SELECT OWNER, TABLE_NAME
          FROM   DBA_TAB_COLUMNS
          WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE');
```

5. Determine the names and sizes of segments that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```
SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024
 "SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
```

```
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE 'TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
         (SELECT OWNER, TABLE_NAME
          FROM   DBA_TAB_COLUMNS
          WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
GROUP BY OWNER, SEGMENT_NAME;
```

6. Run the prepare step.

   - The procedure DBMS_DST.CREATE_AFFECTED_TABLE creates a table to store any affected data. You pass the name of this table to the DBMS_DST.FIND_AFFECTED_TABLES procedure. For more information, see CREATE_AFFECTED_TABLE Procedure in the Oracle Database documentation.
   - This procedure CREATE_ERROR_TABLE creates a table to log errors. For more information, see CREATE_ERROR_TABLE Procedure in the Oracle Database documentation.

   The following example creates the affected data and error tables, and finds all affected tables.

```
EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')

EXEC DBMS_DST.BEGIN_PREPARE(new_version);
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
EXEC DBMS_DST.END_PREPARE;

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;
```

7. Query the affected and error tables.

```
SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;
```

Adding the time zone file autoupgrade option

When you add the option to an option group, the option group is in one of the following states:

- An existing option group is currently attached to at least one DB instance. When you add the option, all DB instances that use this option group automatically restart. This causes a brief outage.
- An existing option group is not attached to any DB instance. You plan to add the option and then associate the existing option group with existing DB instances or with a new DB instance.
- You create a new option group and add the option. You plan to associate the new option group with existing DB instances or with a new DB instance.

Console

To add the time zone file autoupgrade option to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine** choose the Oracle Database edition for your DB instance.

   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group.
4. Choose the option group that you want to modify, and then choose **Add option**.
5. In the **Add option** window, do the following:

   a. Choose **TIMEZONE_FILE_AUTOUPGRADE**.

   b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Add option**.

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the `TIMEZONE_FILE_AUTOUPGRADE` option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" ^
    --apply-immediately
```

Checking your data after the update of the time zone file

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- `rdsadmin.rds_dst_affected_tables` – Lists the tables that contain data affected by the update
- `rdsadmin.rds_dst_error_table` – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see FIND_AFFECTED_TABLES Procedure in the Oracle documentation.

Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage. This option is only supported for the Bring Your Own License (BYOL) model.

TDE is useful in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party. TDE is also useful when you need to comply with security-related regulations.

A detailed explanation about TDE in Oracle Database is beyond the scope of this guide. For information, see the following Oracle Database resources:

- Introduction to Transparent Data Encryption in the Oracle Database documentation
- Oracle advanced security in the Oracle Database documentation
- Oracle advanced security Transparent Data Encryption best practices, which is an Oracle whitepaper

For more information about using TDE with RDS for Oracle, see the following blogs:

- Oracle Database Encryption Options on Amazon RDS
- Migrate a cross-account TDE-enabled Amazon RDS for Oracle DB instance with reduced downtime using AWS DMS

TDE encryption modes

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

> **Note**
>
> Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command `ALTER SYSTEM set encryption key`.

After you enable the TDE option, you can check the status of the Oracle Wallet by using the following command:

```
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

The previous statements for encrypting a tablespace are the same as you would use on an on-premises Oracle database.

Restrictions for the TDE option

The TDE option is permanent and persistent. After you associate your DB instance with an option group that has the TDE option enabled, you can't do the following actions:

- Disable the TDE option in the currently associated option group.
- Associate your DB instance with a different option group that doesn't include the TDE option.
- Share a DB snapshot that uses the TDE option. For more information about sharing DB snapshots, see Sharing a DB snapshot for Amazon RDS.

For more information about persistent and permanent options, see Persistent and permanent options.

Determining whether your DB instance is using TDE

You might want to determine whether your DB instance is associated with an option group that has the TDE option enabled. To view the option group that a DB instance is associated with, use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.

Adding the TDE option

To add the TDE option to your DB instance, complete the following steps:

1. (Recommended) Take a snapshot of your DB instance.
2. Do one of the following tasks:
   - Create a new option group from scratch. For more information, see Creating an option group.
   - Copy an existing option group using the AWS CLI or API. For more information, see Copying an option group.
   - Reuse an existing non-default option group. A best practice is to use an option group that isn't currently associated with any DB instances or snapshots.
3. Add the new option to the option group from the preceding step.
4. If the option group that is currently associated with your DB instance has options enabled, add these options to your new option group. This strategy prevents the existing options from being uninstalled while enabling the new option.
5. Add the new option group to your DB instance.

Console

To add the TDE option to an option group and associate it with your DB instance

1. In the RDS console, choose **Option groups.**
2. Choose the name of the option group to which you want to add the option.
3. Choose **Add option**.
4. For **Option name**, choose **TDE**, and then configure the option settings.
5. Choose **Add option**.

> **Important**
>
> If you add the **TDE** option to an option group that is currently attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group.
6. Associate the option group with a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.

- For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. The DB instance doesn't restart as part of this operation. For more information, see Modifying an Amazon RDS DB instance.

AWS CLI

In the following example, you use the AWS CLI add-option-to-option-group command to add the TDE option to an option group called `myoptiongroup`. For more information, see Getting started: Flink 1.13.2 .

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --option-group-name "myoptiongroup" \
    --options "OptionName=TDE" \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --option-group-name "myoptiongroup" ^
    --options "OptionName=TDE" ^
    --apply-immediately
```

Copying your data to a DB instance that doesn't include the TDE option

You can't remove the TDE option from a DB instance or associate it with an option group that doesn't include the TDE option. To migrate your data to an instance that doesn't include the TDE option, do the following:

1. Decrypt the data on your DB instance.
2. Copy the data to a new DB instance that is not associated with an option group that has TDE enabled.
3. Delete your original DB instance.

You can use the same name for the new instance as the previous DB instance.

Considerations when using TDE with Oracle Data Pump

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (`ENCRYPTION_MODE=PASSWORD`) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (`ENCRYPTION_MODE=TRANSPARENT`) for Oracle Data Pump. For more information, see Importing using Oracle Data Pump.

Oracle UTL_MAIL

Amazon RDS supports Oracle UTL_MAIL through the use of the UTL_MAIL option and SMTP servers. You can send email directly from your database by using the UTL_MAIL package. Amazon RDS supports UTL_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions

The following are some limitations to using UTL_MAIL:

- UTL_MAIL does not support Transport Layer Security (TLS) and therefore emails are not encrypted.

  To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle wallets, follow the instructions in Configuring UTL_HTTP access using certificates and an Oracle wallet.

  The specific certificates that are required for your wallet vary by service. For AWS services, these can typically be found in the Amazon trust services repository.
- UTL_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL_MAIL, only the master user for your DB instance is granted the execute privilege. If necessary, the master user can grant the execute privilege to other users so that they can use UTL_MAIL.

Important

We recommend that you enable Oracle's built-in auditing feature to track the use of UTL_MAIL procedures.

Prerequisites for Oracle UTL_MAIL

The following are prerequisites for using Oracle UTL_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see Setting up a custom DNS server.

Adding the Oracle UTL_MAIL option

The general process for adding the Oracle UTL_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL_MAIL option, as soon as the option group is active, UTL_MAIL is active.

To add the UTL_MAIL option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

   a. For **Engine**, choose the edition of Oracle you want to use.

   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group.
2. Add the **UTL_MAIL** option to the option group. For more information about adding options, see Adding an option to an option group.
3. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance.
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance.

Using Oracle UTL_MAIL

After you enable the UTL_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP_OUT_SERVER parameter to a valid IP address or public DNS name. For the SMTP_OUT_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL_MAIL tries the next server, and so on.

You can set the default SMTP_OUT_SERVER for a DB instance by using a DB parameter group. You can set the SMTP_OUT_SERVER parameter for a session by running the following code on your database on your DB instance.

```
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL_MAIL option is enabled, and your SMTP_OUT_SERVER is configured, you can send mail by using the SEND procedure. For more information, see UTL_MAIL in the Oracle documentation.

Removing the Oracle UTL_MAIL option

You can remove Oracle UTL_MAIL from a DB instance.

To remove UTL_MAIL from a DB instance, do one of the following:

- To remove UTL_MAIL from multiple DB instances, remove the UTL_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group.
- To remove UTL_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL_MAIL option. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance.

Troubleshooting

The following are issues you might encounter when you use UTL_MAIL with Amazon RDS.

- Throttling. SMTP port (25) is throttled based on the elastic network interface owner's policies. If you can successfully send email by using UTL_MAIL, and you see the error `ORA-29278: SMTP transient error: 421 Service not available`, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see Error retries and exponential backoff in AWS and How to handle a "throttling – Maximum sending rate exceeded" error.

  You can request that this throttle be removed. For more information, see How do I remove the throttle on port 25 from my EC2 instance?.

Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML and relational data. The XML DB protocol server isn't supported on RDS for Oracle.

XML DB is preinstalled on Oracle Database 12c and higher. Thus, you don't need to use an option group to explicitly install XML DB as an additional feature.

To learn how to configure and use XML DB, see Oracle XML DB Developer's Guide in the Oracle Database documentation.

Upgrading the RDS for Oracle DB engine

When Amazon RDS supports a new version of Oracle Database, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see *Amazon RDS for Oracle Release Notes*.

> **Important**
>
> RDS for Oracle Databases 11g, 12c, and 18c are no longer supported. If you maintain Oracle Database 11g, 12c, or 18c snapshots, you can upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.

Topics

- Overview of RDS for Oracle engine upgrades
- Oracle major version upgrades
- Oracle minor version upgrades
- Considerations for Oracle database upgrades
- Testing an Oracle DB upgrade
- Upgrading the version of an RDS for Oracle DB instance
- Upgrading an Oracle DB snapshot

Overview of RDS for Oracle engine upgrades

Before upgrading your RDS for Oracle DB instance, familiarize yourself with the following concepts.

Topics

- Major and minor version upgrades
- Support dates and mandatory upgrades for RDS for Oracle
- Oracle engine version management
- Automatic snapshots during engine upgrades
- Oracle upgrades in a Multi-AZ deployment
- Oracle upgrades of read replicas

Major and minor version upgrades

Major versions are major releases of Oracle Database that occur every 1-2 years. Oracle Database 19c and Oracle Database 21c are major releases.

Every quarter, RDS for Oracle releases new minor engine versions for every supported major engine. A Release Update (RU) engine version incorporates bug fixes from Oracle by including the RU patches for the specified quarter. For example, 21.0.0.0.ru-2024-10.rur-2024-10.r1 is a minor version of Oracle Database 21c that incorporates the October 2024 RU.

A Spatial Patch Bundle (SPB) engine version contains RU patches and patches specific to Oracle Spatial. For example, 19.0.0.0.ru-2025-01.spb-1.r1 is a minor engine version that contains the RU patches in engine version 19.0.0.0.ru-2025-01.rur-2025-01.r1 plus Spatial patches. Typically, RDS for Oracle releases SPBs 2–3 weeks after the corresponding RU. For an explanation of the differences between RUs and SPBs, see Release Updates (RUs) and Spatial Patch Bundles (SPBs). For information about supported RUs and SPBs, see Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle.

RDS for Oracle supports the following upgrades to a DB instance.

Upgrade type	Application compatibility	Upgrade methods	Sample upgrade path
Major version	A major version upgrade can introduce changes that aren't compatible with existing applications.	Manual only	From Oracle Database 19c to Oracle Database 21c
Minor version	A minor version upgrade includes only changes that are backward-compatible with existing applications.	Automatic or manual	From 21.0.0.0.ru-2023-07.rur-2022-07.r1 to 21.0.0.0.ru-2023-10.rur-2022-10.r1

Important

When you upgrade your DB engine, an outage occurs. The duration of the outage depends on your engine version and DB instance size.

Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

Support dates and mandatory upgrades for RDS for Oracle

Database versions of RDS for Oracle have expected support dates. When a major or minor version of an RDS for Oracle DB engine nears its end-of-support date, RDS begins mandatory upgrades, also known as *forced upgrades*. RDS publishes the following information:

- A recommendation for you to begin manually upgrading instances on deprecated versions to supported versions
- A date after which you can no longer create instances on the unsupported versions
- A date on which RDS begins to upgrade your instances to supported versions automatically during maintenance windows
- A date on which RDS begins to upgrade your instances to supported versions automatically outside of maintenance windows

Important

Forced upgrades can have unexpected consequences for CloudFormation stacks. If you rely on RDS to upgrade your DB instances automatically, you might encounter issues with CloudFormation.

This section contains the following topics:

Topics

- Support dates for major releases of RDS for Oracle
- Support dates for minor versions of RDS for Oracle

Support dates for major releases of RDS for Oracle

RDS for Oracle major versions remain available at least until the end of support date for the corresponding Oracle Database release version. You can use the following dates to plan your

testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an RDS for Oracle version for longer than originally stated, we plan to update this table to reflect the later date.

> **Note**
>
> You can view the major versions of your Oracle databases by running the describe-db-major-engine-versions AWS CLI command or by using the DescribeDBMajorEngineVersions RDS API operation.

Oracle Database major release version	Expected date for upgrading to a newer version
Oracle Database 19c	December 31, 2029 with BYOL Premier Support (fees waived for Extended Support) December 31, 2032 with BYOL Extended Support (extra cost) or an Unlimited License Agreement December 31, 2029 with License Included (LI)
Oracle Database 21c	July 31, 2027 (not available for Extended Support)

RDS notifies you at least 12 months before you need to upgrade to a newer major version. The notification describes the upgrade process, including the timing of important milestones, the effect on your DB instances, and recommended actions. We recommend that you thoroughly test your applications with new RDS for Oracle versions before you upgrade your database to a major version.

After this advance notification period, an automatic upgrade to the subsequent major version might be applied to any RDS for Oracle DB instance still running the older version. If so, the upgrade is started during scheduled maintenance windows.

For more information, see Release Schedule of Current Database Releases in My Oracle Support.

Support dates for minor versions of RDS for Oracle

In some cases, we end support for minor versions of major releases in RDS for Oracle. RDS notifies you at least 6 months before you need to upgrade to a newer minor version. The notification describes the upgrade process, including the timing of important milestones, the effect on the DB instances running the deprecated minor version, and recommended actions. We recommend that you thoroughly test your applications with new RDS for Oracle versions before you upgrade your database to a new minor version.

For more information about deprecated and desupported minor versions, see Release notes for Amazon Relational Database Service (Amazon RDS) for Oracle.

Oracle engine version management

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions of RDS for Oracle to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.

> **Note**
>
> Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to *Amazon RDS for Oracle Release Notes*.

Automatic snapshots during engine upgrades

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

> **Note**
>
> To change your backup retention period, see Modifying an Amazon RDS DB instance.

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.

Oracle upgrades in a Multi-AZ deployment

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the database upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the current standby DB instance.
2. Fails over the primary DB instance to the standby DB instance.
3. Upgrades the database version on the new primary DB instance, which was formerly the standby instance. The primary database is unavailable during the upgrade.
4. Updates the operating system on the new standby DB instance, which was formerly the primary DB instance.
5. Upgrades the database version on the new standby DB instance.
6. Fails over the new primary DB instance back to the original primary DB instance, and the new standby DB instance back to the original standby DB instance. Thus, Amazon RDS returns the replication configuration to its original state.

Oracle upgrades of read replicas

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.
2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

Oracle major version upgrades

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.

> **Important**
>
> Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

Topics

- Supported versions for major upgrades
- Supported instance classes for major upgrades
- Gathering statistics before major upgrades
- Allowing major upgrades

Supported versions for major upgrades

Amazon RDS supports the following major version upgrades.

Current version	Upgrade supported
19.0.0.0 using the CDB architecture	21.0.0.0

A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

Supported instance classes for major upgrades

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see DB instance classes.

Gathering statistics before major upgrades

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.

To gather optimizer statistics, connect to the DB instance as the master user, and run the `DBMS_STATS.GATHER_DICTIONARY_STATS` procedure, as in the following example.

```
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see GATHER_DICTIONARY_STATS Procedure in the Oracle documentation.

Allowing major upgrades

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the EngineVersion parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command modify-db-instance, specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see Upgrading a DB instance engine version.

If you upgrade a major version using the console, you don't need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

Oracle minor version upgrades

In RDS for Oracle, a minor version upgrade is an update to a major DB engine version. In RDS, a minor engine version is either a Release Update (RU) or Spatial Patch Bundle (SPB). For example, if your DB instance runs major version Oracle Database 19c and minor version

19.0.0.0.ru-2025-10.rur-2025-10.r1, you can upgrade your DB engine to minor version 19.0.0.0.ru-2026-01.rur-2026-01.r1. RDS for Oracle doesn't support minor version downgrades.

You can upgrade your DB engine to a minor version manually or automatically. To learn how to upgrade manually, see Manually upgrading the engine version. To learn how to configure automatic upgrades, see Automatically upgrading the minor engine version. Whether you upgrade manually or automatically, a minor version upgrade entails downtime. Consider this downtime when you plan your upgrades.

Amazon RDS also supports upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

> **Important**
>
> Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see Testing an Oracle DB upgrade.

- How Amazon RDS schedules automatic minor version upgrades
- Managing an automatic minor version upgrade in RDS for Oracle

Release Updates (RUs) and Spatial Patch Bundles (SPBs)

In RDS, a release update (RU) is a quarterly minor engine version that includes security fixes, bug fixes, and new features for Oracle Database. A Spatial Patch Bundle (SPB) is an RU engine version that includes patches designed for the Oracle Spatial option. For example, the SPB named 19.0.0.0.ru-2025-01.spb-1.r1 includes all patches in the corresponding RU 19.0.0.0.ru-2025-01.rur-2025-01.r1 plus patches specific to Spatial. SPBs are supported only for Oracle Database 19c.

When your instance is configured for automatic minor version upgrades, RUs and SPBs are on separate upgrade paths. Typically, an SPB is released 2–3 weeks after its corresponding RU. The following table shows sample minor versions for Oracle Database 19c.

Standard RU upgrade path	SPB upgrade path
19.0.0.0.ru-2025-01.rur-2025-01.r1	19.0.0.0.ru-2025-01.spb-1.r1
19.0.0.0.ru-2025-04.rur-2025-04.r1	19.0.0.0.ru-2025-04.spb-1.r1
19.0.0.0.ru-2025-07.rur-2025-07.r1	19.0.0.0.ru-2025-07.spb-1.r1
19.0.0.0.ru-2025-10.rur-2025-10.r1	19.0.0.0.ru-2025-10.spb-1.r1

If your DB instance is configured for automatic upgrades, your instance is on the upgrade path corresponding to your current version. For example, if your DB instance runs version 19.0.0.0.ru-2025-01.rur-2025-01.r1, then when 19.0.0.0.ru-2025-04.rur-2025-04.r1 is released, your instance automatically upgrades to this RU. Similarly, if your DB instance runs 19.0.0.0.ru-2025-01.spb-1.r1, then when 19.0.0.0.ru-2025-04.spb-1.r1 is released, your instance automatically upgrades to this SPB. An instance running 19.0.0.0.ru-2025-01.rur-2025-01.r1, which is an RU, won't automatically upgrade to 19.0.0.0.ru-2025-04.spb-1.r1, which is an SPB on a separate upgrade path.

You can upgrade your DB instance to SPBs even if your instance doesn't use Spatial, but the Spatial patches apply only to Oracle Spatial. You can upgrade manually from an RU to an SPB at the same engine version or higher. For example, you can upgrade your instance from 19.0.0.0.ru-2025-01.rur-2025-01.r1 to either of the following engine versions:

- 19.0.0.0.ru-2025-01.spb-1.r1
- 19.0.0.0.ru-2025-04.spb-1.r1

You can upgrade your instance from an SPB to an RU only if the RU is a higher engine version. For example, you can upgrade from SPB version 19.0.0.0.ru-2025-04.spb-1.r1 to a higher RU version 19.0.0.0.ru-2025-07.rur-2025-07.r1 but not to the same RU version 19.0.0.0.ru-2025-04.rur-2025-04.r1.

If your DB instance is configured for automatic minor version upgrades, and you manually upgrade from an RU to an SPB or from an SPB to an RU, your automatic upgrade path changes. Suppose

that you manually upgrade from RU version 19.0.0.0.ru-2025-01.rur-2025-01.r1 to SPB version 19.0.0.0.ru-2025-01.spb-1.r1. Your next automatic minor version upgrade will be to SPB version 19.0.0.0.ru-2025-04.spb-1.r1.

Because SPBs function as RUs, the RDS APIs for upgrading your instance to RUs and SPBs are identical. The following commands demonstrate upgrading to an RU and to an SPB.

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --engine-version 19.0.0.0.ru-2025-01.rur-2025-01.r1

aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --engine-version 19.0.0.0.ru-2025-01.spb-1.r1
```

For more information about the Oracle Spatial option, see How Spatial Patch Bundles (SPBs) work. For supported RUs and SPBs for Oracle Database 19c, see Amazon RDS for Oracle Database 19c (19.0.0.0).

Turning on automatic minor version upgrades for Oracle

In an automatic minor version upgrade, RDS applies the latest available minor version to your Oracle database without manual intervention. An Amazon RDS for Oracle DB instance schedules your upgrade during the next maintenance window in the following circumstances:

- Your DB instance has the **Auto minor version upgrade** option turned on.
- Your DB instance isn't already running the latest minor DB engine version.

To learn how to turn on automatic upgrades, see Automatically upgrading the minor engine version.

Using AWS Organizations upgrade rollout policy for automatic minor version upgrades

Amazon RDS for Oracle supports AWS Organizations upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. This policy eliminates the operational overhead of coordinating automatic minor version upgrades either manually or through custom tools, while ensuring upgrades are first applied in non-production environments before being rolled out to production. When a new minor engine version becomes

available, Amazon RDS upgrades your DB instances based on their configured upgrade rollout order:

Upgrade Rollout Order	Typical Use Case	When Upgrade Begins
First	Development and Test Environments	Earliest - ideal for validating new versions
Second	Staging and Non-critical Production Environments	After "First" phase completes
Last	Critical Production Environments	After "Second" phase completes

> **Important**
>
> If you do not configure an upgrade rollout order for your DB instance, it defaults to second.

For detailed information about phase timing and duration, see How Amazon RDS schedules automatic minor version upgrades. For information about configuring upgrade rollout policies in AWS Organizations, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

Notification of automatic minor version upgrades in RDS for Oracle

If automatic minor version upgrade is enabled on your DB instance, RDS for Oracle creates pending maintenance actions to notify you before applying upgrades. You can view these pending maintenance actions on the **Maintenance & backups** tab of your database details page in the Amazon RDS console.

When a new minor version becomes available, RDS for Oracle publishes an early notification (pending maintenance action). The early notification has the following format:

```
An automatic minor version upgrade to engine-version will be applied during your
 maintenance window on apply-date based on the upgrade rollout order rollout-order. You
```

```
can change the upgrade rollout order or apply this upgrade manually at any time before
the scheduled date through the AWS console or AWS CLI.
```

`apply-date` in the early notification is the date when Amazon RDS will upgrade your DB instance. `rollout-order` is your upgrade rollout order (first, second, or last). If you have not configured an upgrade rollout policy, this value is second by default. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

When the upgrade rollout phase begins, the pending maintenance action message changes to the following format:

```
Automatic minor version upgrade to engine-version
```

This message indicates that the upgrade has been scheduled and will be applied during your maintenance window on the scheduled apply date. You can check the scheduled apply date on the **Maintenance & backups** tab of your database details page in the Amazon RDS console or in the `CurrentApplyDate` field of the `describe-pending-maintenance-actions` API response.

The following example shows you can get the details about pending maintenance actions by using the `describe-pending-maintenance-actions` command in the AWS CLI:

```
aws rds describe-pending-maintenance-actions

    "PendingMaintenanceActions": [
        {
            "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:orclinst1",
            "PendingMaintenanceActionDetails": [
                {
                    "Action": "db-upgrade",
                    "Description": "Automatic minor version upgrade to
 21.0.0.0.ru-2024-07.rur-2024-07.r1",
                    "CurrentApplyDate": "2024-12-02T08:10:00Z"
                }
            ]
        }, ...
```

For more information about describe-pending-maintenance-actions, see the *AWS CLI Command Reference*.

How Amazon RDS schedules automatic minor version upgrades

When you use AWS Organizations upgrade rollout policy, Amazon RDS upgrades DB instances in phases based on their configured rollout order. This section describes the timing and duration of each phase.

Phase 0: Early Notification

When RDS for Oracle releases a new minor version (typically 3 to 4 weeks after Oracle's quarterly RU release), all DB instances with auto minor version upgrade enabled receive an early notification. This notification appears on the **Maintenance & backups** tab of the database details page in the Amazon RDS console and in the `describe-pending-maintenance-actions` API response. The early notification phase lasts 2 weeks. During this phase, no automatic upgrades occur.

Phase 1: Upgrade Rollout Order First

At the end of the early notification phase, RDS for Oracle begins upgrading DB instances with the upgrade rollout order first. This phase lasts 2 to 3 weeks for the January, April, July quarterly minor versions, and 7 to 8 weeks for the October quarterly minor version. The extended period for the October minor version provides sufficient time to test the new minor version during the year-end holiday season. New DB instances created during this phase with the upgrade rollout order first will be upgraded automatically.

Phase 2: Upgrade Rollout Order Second

At the end of phase 1, RDS for Oracle begins upgrading DB instances with upgrade rollout order second. This phase lasts 2 weeks for all quarterly minor versions. New DB instances created with upgrade rollout order first or second during this phase will be upgraded automatically.

Phase 3: Upgrade Rollout Order Last

At the end of Phase 2, RDS for Oracle begins upgrading DB instances with upgrade rollout order last. This phase lasts until the next quarterly minor version release. New DB instances created with upgrade rollout order first, second, or last during this phase will be upgraded automatically.

Phase	When it starts	Duration	Pending maintenance action message
Phase 0: Early Notification	When RDS for Oracle releases a new minor version	2 weeks	An automatic minor version upgrade to *engine-version* will be applied during your maintenance window on *apply-date* based on the upgrade rollout order *rollout-order*. You can change the upgrade rollout order or apply this upgrade manually at any time before the scheduled date through the AWS console or AWS CLI.
Phase 1: Upgrade Rollout Order First	End of early notification phase	2 to 4 weeks for January/April/July minor versions, 7 to	Automatic minor version upgrade to

Phase	When it starts	Duration	Pending maintenance action message
		9 weeks for October minor version	*engine-version*
Phase 2: Upgrade Rollout Order Second	End of Phase 1	2 weeks	Automatic minor version upgrade to *engine-version*
Phase 3: Upgrade Rollout Order Last	End of Phase 2	Until the next quarterly minor version release	Automatic minor version upgrade to *engine-version*

Managing an automatic minor version upgrade in RDS for Oracle

When auto minor version upgrade is enabled on your DB instance, Amazon RDS automatically upgrades your DB instance to the latest minor version during your maintenance window. However, you can choose to apply the upgrade manually before the scheduled date using the AWS CLI or on the **Maintenance & backups** tab of the database details page.

To upgrade your DB instance immediately instead of waiting for the scheduled maintenance window:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
    --apply-action db-upgrade \
    --opt-in-type immediate
```

To apply the upgrade during your next maintenance window instead of the scheduled apply date:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
```

```
    --apply-action db-upgrade \
    --opt-in-type next-maintenance
```

To opt out of an automatic minor version upgrade, modify your DB instance and turn off the automatic minor version upgrade option. This unschedules any pending automatic upgrade.

To learn more about how to turn off automatic minor version upgrade, see Automatically upgrading the minor engine version. If you need assistance with turning off automatic minor version upgrade, please reach out to the AWS Support.

Sometimes a new minor version becomes available before RDS applies a previous minor version. For example, your instance is running on `21.0.0.0.ru-2025-07.rur-2025-07.r1` when both `21.0.0.0.ru-2025-10.rur-2025-10.r1` and `21.0.0.0.ru-2026-01.rur-2026-01.r1` are available as upgrade targets. In this situation, to avoid unnecessary downtime for your DB instances, RDS schedules the automatic minor version upgrade to the most recent version, skipping the upgrade to the previous version. In this example, RDS upgrades your instance from `21.0.0.0.ru-2025-07.rur-2025-07.r1` directly to `21.0.0.0.ru-2026-01.rur-2026-01.r1`.

Considerations for Oracle database upgrades

Before you upgrade your Oracle instance, review the following information.

Topics

- Oracle Multitenant considerations
- Option group considerations
- Parameter group considerations
- Time zone considerations
- Spatial Patch Bundle (SPB) considerations

Oracle Multitenant considerations

The following table describes the Oracle Database architectures supported in different releases.

Oracle Database release	RDS support status	Architecture
Oracle Database 21c	Supported	CDB only

Oracle Database release	RDS support status	Architecture
Oracle Database 19c	Supported	CDB or non-CDB

The following table describes supported and unsupported upgrade paths.

Upgrade path	Supported?
CDB to CDB	Yes
Non-CDB to CDB	No, but you can convert a non-CDB to a CDB and then upgrade it
CDB to non-CDB	No

For more information about Oracle Multitenant in RDS for Oracle, see Single-tenant configuration of the CDB architecture.

Option group considerations

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see Creating an option group or Copying an option group.

If your DB instance uses a custom option group that contains the `APEX` and `APEX-DEV` options, you can sometimes reduce the upgrade time. To do this, upgrade your version of Oracle APEX at the same time as your DB instance. For more information, see Upgrading the Oracle APEX version.

Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group in Amazon RDS or Copying a DB parameter group in Amazon RDS.

Time zone considerations

You can use the time zone option to change the *system time zone* used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see Oracle time zone.

When you create an Oracle DB instance, the database automatically sets the *database time zone*. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the `TIMESTAMP WITH TIME ZONE` data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the time zone file automatically, you can include the `TIMEZONE_FILE_AUTOUPGRADE` option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see Oracle time zone file autoupgrade.

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the `TIMEZONE_FILE_AUTOUPGRADE` option.

After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
- Original Export/Import (desupported for general use)

> **Note**
>
> When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see TIMESTAMP WITH TIMEZONE restrictions in the Oracle documentation.

Spatial Patch Bundle (SPB) considerations

In RDS for Oracle, release update (RU) is a minor engine version that includes security fixes, bug fixes, and new features for Oracle Database. A Spatial Patch Bundle (SPB) is minor engine version that also includes patches designed for the Oracle Spatial option. For example, 19.0.0.0.ru-2025-01.spb-1.r1 is a minor engine version that contains the RU patches in engine version 19.0.0.0.ru-2025-01.rur-2025-01.r1 plus Spatial patches.

When you upgrade your database to SPBs, consider the following:

- SPBs are supported only for Oracle Database 19c.
- Typically, an SPB is released 2–3 weeks after its corresponding quarterly RU.
- You can upgrade your DB instance to an SPB even if the instance doesn't use the Oracle Spatial option, but the Spatial patches in the engine version apply only to Oracle Spatial. You can create a new instance on an SPB and install the Oracle Spatial option later.
- If you enable automatic minor version upgrade for your DB instance, your upgrade path depends on whether your instance currently uses an SPB or RU. If your instance uses an SPB, RDS automatically upgrades your instance to the latest SPB. If your instance uses an RU, RDS automatically upgrades your instance to the latest RU.
- You can manually upgrade your DB instance from an RU to an SPB only if the SPB is the same engine version or higher as your current RU.
- You can manually upgrade your DB instance from an SPB to an RU only if the RU is a higher version.

Testing an Oracle DB upgrade

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see Database Upgrade Guide in the Oracle documentation.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations.
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations.
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring to a DB instance.
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console
   - AWS CLI
   - RDS API
7. Perform testing:
   - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
   - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
   - Test all stored procedures, functions, and triggers.
   - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.
   - Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see DB instance classes.
8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

Upgrading the version of an RDS for Oracle DB instance

To manually upgrade the DB engine version of an RDS for Oracle DB instance,use the AWS Management Console, the AWS CLI, or the RDS API. For general information about database upgrades in RDS, see Upgrading the version of an RDS for Oracle DB instance. To get valid upgrade targets, use the AWS CLI describe-db-engine-versions command.

Console

To upgrade the engine version of an RDS for Oracle DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.
3. Choose **Modify**.
4. For **DB engine version**, choose a higher database version.
5. Choose **Continue** and check the summary of modifications. Make sure that you understand the implications of a database version upgrade. You can't convert an upgraded DB instance back to the previous version. Make sure you have tested both your database and your application with the new version before continuing.
6. Decide when to schedule your DB instance upgrade. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see Using the schedule modifications setting.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of an RDS for Oracle DB instance, you can use the CLI modify-db-instance command. Specify the following parameters:

- `--db-instance-identifier` – the name of the RDS for Oracle DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.

- `--allow-major-version-upgrade` – to upgrade the DB engine version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

The following example upgrades a CDB instance named `myorainst` from its current version of `19.0.0.0.ru-2024-01.rur-2024-01.r1` to version `21.0.0.0.ru-2024-04.rur-2024-04.r1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myorainst \
    --engine-version 21.0.0.0.ru-2024-04.rur-2024-04.r1 \
    --allow-major-version-upgrade \
    --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myorainst ^
    --engine-version 21.0.0.0.ru-2024-04.rur-2024-04.r1 ^
    --allow-major-version-upgrade ^
    --no-apply-immediately
```

RDS API

To upgrade an RDS for Oracle DB instance, use the ModifyDBInstance action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example *`myorainst`*.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the DescribeDBEngineVersions operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.

- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Upgrading an Oracle DB snapshot

Upgrading your Oracle DB snapshots in Amazon RDS ensures that your database remains secure, compatible, and fully supported. As older Oracle versions reach the end of patch support, you can upgrade any manual DB snapshots tied to these versions to avoid potential vulnerabilities or service limitations. For more information, see Oracle engine version management.

Amazon RDS supports upgrading snapshots in all AWS Regions.

Console

To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**, and then select the DB snapshot that you want to upgrade.
3. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
4. Choose the **New engine version** to upgrade the snapshot to.
5. (Optional) For **Option group**, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.
6. Choose **Save changes** to save your changes.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

   > **Note**
   >
   > If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade an Oracle DB snapshot by using the AWS CLI, call the modify-db-snapshot command with the following parameters:

- `--db-snapshot-identifier` – The name of the DB snapshot.
- `--engine-version` – The version to upgrade the snapshot to.

You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.

- `--option-group-name` – The option group for the upgraded DB snapshot.

Example

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier mydbsnapshot \
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \
    --option-group-name default:oracle-se2-19
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier mydbsnapshot ^
    --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
    --option-group-name default:oracle-se2-19
```

RDS API

To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the ModifyDBSnapshot operation with the following parameters:

- `DBSnapshotIdentifier` – The name of the DB snapshot.
- `EngineVersion` – The version to upgrade the snapshot to.

You might also need to include the `OptionGroupName` parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations.

Using third-party software with your RDS for Oracle DB instance

You can host an RDS for Oracle DB instance that supports tools and third-party software.

Topics

- Using Oracle GoldenGate with Amazon RDS for Oracle
- Using the Oracle Repository Creation Utility on RDS for Oracle
- Configuring Oracle Connection Manager on an Amazon EC2 instance
- Installing a Siebel database on Oracle on Amazon RDS

Using Oracle GoldenGate with Amazon RDS for Oracle

Oracle GoldenGate collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with databases for online transaction processing (OLTP) systems. Oracle GoldenGate creates trail files that contain the most recent changed data from the source database. It then pushes these files to the server, where a process converts the trail file into standard SQL to be applied to the target database.

Oracle GoldenGate with RDS for Oracle supports the following features:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades
- Data replication between an RDS for Oracle DB instance and a non-Oracle database

> **Note**
>
> For a list of supported databases, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

You can use Oracle GoldenGate with RDS for Oracle to upgrade to major versions of Oracle Database. For example, you can use Oracle GoldenGate to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

Topics

- Supported versions and licensing options for Oracle GoldenGate
- Requirements and limitations for Oracle GoldenGate
- Oracle GoldenGate architecture
- Setting up Oracle GoldenGate
- Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate
- Monitoring Oracle GoldenGate
- Troubleshooting Oracle GoldenGate

Supported versions and licensing options for Oracle GoldenGate

You can use Standard Edition 2 (SE2) or Enterprise Edition (EE) of RDS for Oracle with Oracle GoldenGate version 12c and higher. You can use the following Oracle GoldenGate features:

- Oracle GoldenGate Remote Capture (extract) is supported.
- Capture (extract) is supported on RDS for Oracle DB instances that use the traditional non-CDB database architecture. Oracle GoldenGate Remote PDB capture is supported on CDBs running Oracle Database 21c or Oracle Database 19c version 19.0.0.0.ru-2024-04.rur-2024-04.r1 or higher.
- Oracle GoldenGate Remote Delivery (replicat) is supported on RDS for Oracle DB instances that use either the non-CDB or CDB architectures. Remote Delivery supports Integrated Replicat, Parallel Replicat, Coordinated Replicat, and classic Replicat.
- RDS for Oracle supports the Classic and Microservices architectures of Oracle GoldenGate.
- Oracle GoldenGate DDL and Sequence value replication is supported when using Integrated capture mode.

You are responsible for managing Oracle GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see RDS for Oracle licensing options.

Requirements and limitations for Oracle GoldenGate

When you're working with Oracle GoldenGate and RDS for Oracle, consider the following requirements and limitations:

- You're responsible for setting up and managing Oracle GoldenGate for use with RDS for Oracle.
- You're responsible for setting up an Oracle GoldenGate version that is certified with the source and the target databases. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.
- You can use Oracle GoldenGate on many different AWS environments for many different use cases. If you have a support-related issue relating to Oracle GoldenGate, contact Oracle Support Services.
- You can use Oracle GoldenGate on RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure encryption for data sent between the Oracle GoldenGate hub and the source and

target database instances. RDS for Oracle DB instances support encryption with Oracle Secure Sockets Layer or Oracle native network encryption.

Oracle GoldenGate architecture

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

Source database

Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

Oracle GoldenGate hub

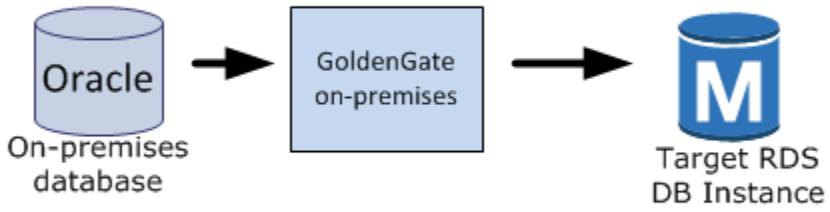
An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

- An Amazon EC2 instance with Oracle Database and Oracle GoldenGate installed
- An on-premises Oracle installation

You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use Oracle GoldenGate for cross-Region replication.

Target database

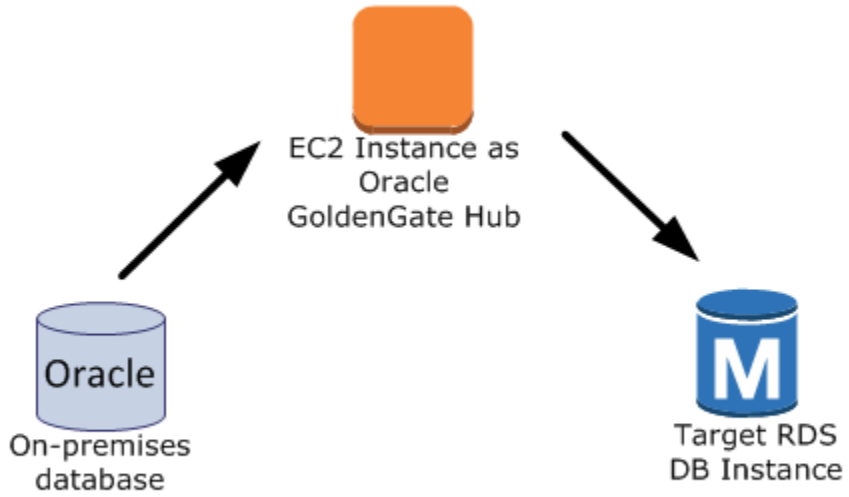
Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.



The following sections describe common scenarios for Oracle GoldenGate on Amazon RDS.

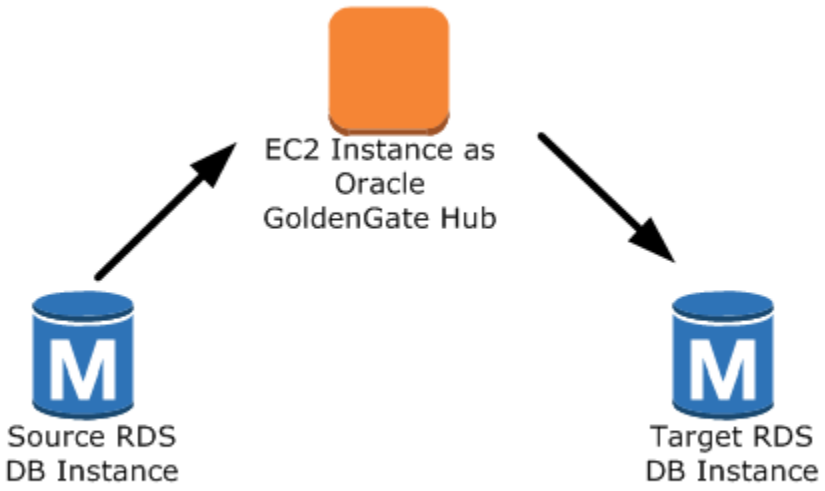
Topics

- On-premises source database and Oracle GoldenGate hub
- On-premises source database and Amazon EC2 hub
- Amazon RDS source database and Amazon EC2 hub
- Amazon EC2 source database and Amazon EC2 hub
- Amazon EC2 hubs in different AWS Regions



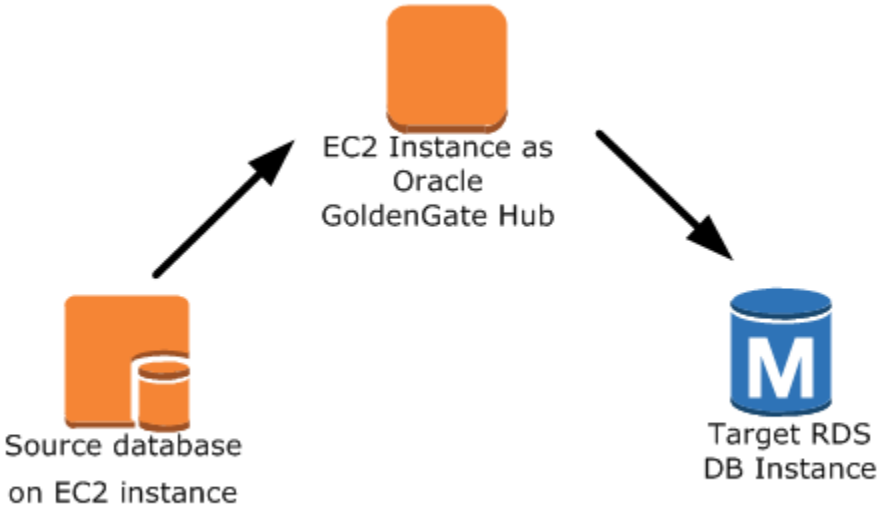
On-premises source database and Oracle GoldenGate hub

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.



On-premises source database and Amazon EC2 hub

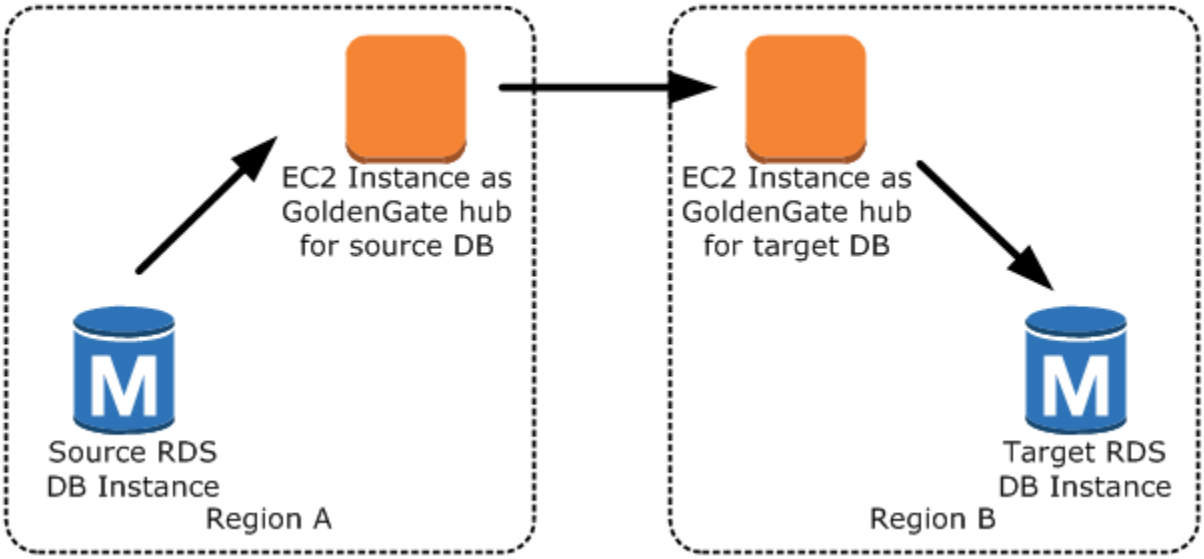
In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.



Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon EC2 source database and Amazon EC2 hub



In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon EC2 hubs in different AWS Regions

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a

different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.

> **Note**
>
> Any issues that affect running Oracle GoldenGate on an on-premises environment also affect running Oracle GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that `EXTRACT` and `REPLICAT` are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.

Setting up Oracle GoldenGate

To set up Oracle GoldenGate using Amazon RDS, configure the hub on an Amazon EC2 instance, and then configure the source and target databases. The following sections give an example of how to set up Oracle GoldenGate for use with Amazon RDS for Oracle.

Topics

- Setting up an Oracle GoldenGate hub on Amazon EC2
- Setting up a source database for use with Oracle GoldenGate on Amazon RDS
- Setting up a target database for use with Oracle GoldenGate on Amazon RDS

Setting up an Oracle GoldenGate hub on Amazon EC2

To create an Oracle GoldenGate hub on an Amazon EC2 instance, you first create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The Oracle GoldenGate software versions depend on the source and target database versions. For more information about installing Oracle GoldenGate, see the Oracle GoldenGate documentation.

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following requirements:

- You have allocated enough storage for the trail files.
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.

To set up an Oracle GoldenGate classic architecture hub on an Amazon EC2 instance

1. Create subdirectories in the Oracle GoldenGate directory.

   In the Amazon EC2 command line shell, start `ggsci`, the Oracle GoldenGate command interpreter. The `CREATE SUBDIRS` command creates subdirectories under the `/gg` directory for parameter, report, and checkpoint files.

   ```
   prompt$ cd /gg
   prompt$ ./ggsci

   GGSCI> CREATE SUBDIRS
   ```

2. Configure the `mgr.prm` file.

   The following example adds lines to the `$GGHOME/dirprm/mgr.prm` file.

   ```
   PORT 8199
   PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5
   ```

3. Start the manager.

   The following example starts `ggsci` and runs the `start mgr` command.

```
GGSCI> start mgr
```

The Oracle GoldenGate hub is now ready for use.

Setting up a source database for use with Oracle GoldenGate on Amazon RDS

Complete the following tasks to set up a source database for use with Oracle GoldenGate.

Setup steps

- Step 1: Turn on supplemental logging on the source database
- Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true
- Step 3: Set the log retention period on the source database
- Step 4: Create an Oracle GoldenGate user account on the source database
- Step 5: Grant user account privileges on the source database
- Step 6: Add a TNS alias for the source database

Step 1: Turn on supplemental logging on the source database

To turn on the minimum database-level supplemental logging, run the following PL/SQL procedure:

```
EXEC rdsadmin.rdsadmin_util.alter_supplemental_logging(p_action => 'ADD')
```

Step 2: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter, see the Oracle Database documentation.

Step 3: Set the log retention period on the source database

Make sure that you configure the source database to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

For example, set the retention period for archived redo logs to 24 hours.

```
EXEC rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24)
```

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence
 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Because your DB instance retains your archived redo logs, make sure that you have sufficient space for the files. To see how much space you have used in the last *num_hours* hours, run the following query, replacing *num_hours* with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) BYTES FROM V$ARCHIVED_LOG
   WHERE NEXT_TIME>=SYSDATE-num_hours/24 AND DEST_ID=1;
```

Step 4: Create an Oracle GoldenGate user account on the source database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archived redo logs for the source database. To provide these, create a user account on the source database. For more information about the permissions for an Oracle GoldenGate user account, see the Oracle documentation.

The following statements create a user account named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1  IDENTIFIED BY "password"
   DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
```

```
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 5: Grant user account privileges on the source database

In this task, you grant necessary account privileges for database users on your source database.

To grant account privileges on the source database

1. Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command `grant` and the `rdsadmin.rdsadmin_util` procedure `grant_sys_object`. The following statements grant privileges to a user named oggadm1.

   ```
   GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
   GRANT RESOURCE TO oggadm1;
   GRANT SELECT ANY DICTIONARY TO oggadm1;
   GRANT FLASHBACK ANY TABLE TO oggadm1;
   GRANT SELECT ANY TABLE TO oggadm1;
   GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
   EXEC rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
   GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
   GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
   GRANT ALTER ANY TABLE TO oggadm1;
   ```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. Run the following PL/SQL program.

   ```
   EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
       grantee                 => 'OGGADM1',
       privilege_type          => 'capture',
       grant_select_privileges => true,
       do_grants               => TRUE);
   ```

   To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

Step 6: Add a TNS alias for the source database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the EXTRACT process. For more information on the `tnsnames.ora` file, see the Oracle documentation.

```
OGGSOURCE=
   (DESCRIPTION=
        (ENABLE=BROKEN)
        (ADDRESS_LIST=
            (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-
west-2.rds.amazonaws.com)(PORT=8200)))
        (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
```

Setting up a target database for use with Oracle GoldenGate on Amazon RDS

In this task, you set up a target DB instance for use with Oracle GoldenGate.

Setup steps

- Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true
- Step 2: Create an Oracle GoldenGate user account on the target database
- Step 3: Grant account privileges on the target database
- Step 4: Add a TNS alias for the target database

Step 1: Set the ENABLE_GOLDENGATE_REPLICATION initialization parameter to true

When you set the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter is to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter, see the Oracle Database documentation.

Step 2: Create an Oracle GoldenGate user account on the target database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these privileges, create a user account on the target database.

The following statement creates a user named `oggadm1`.

```
CREATE TABLESPSACE administrator;
CREATE USER oggadm1  IDENTIFIED BY "password"
   DEFAULT TABLESPACE administrator
   TEMPORARY TABLESPACE temp;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 3: Grant account privileges on the target database

In this task, you grant necessary account privileges for database users on your target database.

To grant account privileges on the target database

1. Grant necessary privileges to the Oracle GoldenGate user account on the target database. In the following example, you grant privileges to `oggadm1`.

```
GRANT CREATE SESSION        TO oggadm1;
GRANT ALTER SESSION         TO oggadm1;
GRANT CREATE CLUSTER        TO oggadm1;
GRANT CREATE INDEXTYPE      TO oggadm1;
GRANT CREATE OPERATOR       TO oggadm1;
GRANT CREATE PROCEDURE      TO oggadm1;
GRANT CREATE SEQUENCE       TO oggadm1;
GRANT CREATE TABLE          TO oggadm1;
GRANT CREATE TRIGGER        TO oggadm1;
GRANT CREATE TYPE           TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT CREATE ANY TABLE      TO oggadm1;
GRANT ALTER ANY TABLE       TO oggadm1;
GRANT LOCK ANY TABLE        TO oggadm1;
GRANT SELECT ANY TABLE      TO oggadm1;
GRANT INSERT ANY TABLE      TO oggadm1;
GRANT UPDATE ANY TABLE      TO oggadm1;
GRANT DELETE ANY TABLE      TO oggadm1;
```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. Run the following PL/SQL program.

```
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
    grantee                 => 'OGGADM1',
    privilege_type          => 'apply',
    grant_select_privileges => true,
    do_grants               => TRUE);
```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

Step 4: Add a TNS alias for the target database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the `REPLICAT` process. For Oracle Multitenant databases, make sure that the TNS alias points to the service name of the PDB. For more information on the `tnsnames.ora` file, see the Oracle documentation.

```
OGGTARGET=
    (DESCRIPTION=
        (ENABLE=BROKEN)
        (ADDRESS_LIST=
            (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abcdef12345.us-
west-2.rds.amazonaws.com)(PORT=8200)))
        (CONNECT_DATA=(SERVICE_NAME=ORCL))
    )
```

Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate

The Oracle GoldenGate utilities `EXTRACT` and `REPLICAT` work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by `EXTRACT`, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or Amazon EC2 instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the `REPLICAT` utility.

Running the Oracle GoldenGate EXTRACT utility

The `EXTRACT` utility retrieves, converts, and outputs data from the source database to trail files. The basic process is as follows:

1. `EXTRACT` queues transaction details to memory or to temporary disk storage.

2. The source database commits the transaction.
3. EXTRACT writes the transaction details to a trail file.
4. The trail file routes these details to the Oracle GoldenGate on-premises or the Amazon EC2 instance hub and then to the target database.

The following steps start the EXTRACT utility, capture the data from EXAMPLE.TABLE in source database OGGSOURCE, and create the trail files.

To run the EXTRACT utility

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or Amazon EC2 instance). The following listing shows an example EXTRACT parameter file named $GGHOME/dirprm/eabc.prm.

```
EXTRACT EABC

USERID oggadm1@OGGSOURCE, PASSWORD "my-password"
EXTTRAIL /path/to/goldengate/dirdat/ab

IGNOREREPLICATES
GETAPPLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1

TABLE EXAMPLE.TABLE;
```

2. On the Oracle GoldenGate hub, log in to the source database and launch the Oracle GoldenGate command line interface ggsci. The following example shows the format for logging in.

```
dblogin oggadm1@OGGSOURCE
```

3. Add transaction data to turn on supplemental logging for the database table.

```
add trandata EXAMPLE.TABLE
```

4. Using the ggsci command line, enable the EXTRACT utility using the following commands.

```
add extract EABC tranlog, INTEGRATED tranlog, begin now
add exttrail /path/to/goldengate/dirdat/ab
   extract EABC,
```

```
   MEGABYTES 100
```

5. Register the EXTRACT utility with the database so that the archive logs are not deleted. This task allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command.

```
register EXTRACT EABC, DATABASE
```

6. Start the EXTRACT utility with the following command.

```
start EABC
```

Running the Oracle GoldenGate REPLICAT utility

The REPLICAT utility "pushes" transaction information in the trail files to the target database.

The following steps enable and start the REPLICAT utility so that it can replicate the captured data to the table EXAMPLE.TABLE in target database OGGTARGET.

To run the REPLICATE utility

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example REPLICAT parameter file named $GGHOME/dirprm/rabc.prm.

```
REPLICAT RABC

USERID oggadm1@OGGTARGET, password "my-password"

ASSUMETARGETDEFS
MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

2. Log in to the target database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGTARGET
```

3. Using the `ggsci` command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named `gg_checkpoint`.

```
add checkpointtable oggadm1.oggchkpt
```

4. To enable the `REPLICAT` utility, use the following command.

```
add replicat RABC EXTTRAIL /path/to/goldengate/dirdat/ab CHECKPOINTTABLE
 oggadm1.oggchkpt
```

5. Start the `REPLICAT` utility by using the following command.

```
start RABC
```

Monitoring Oracle GoldenGate

When you use Oracle GoldenGate for replication, make sure that the Oracle GoldenGate process is up and running and the source and target databases are synchronized. You can use the following monitoring tools:

- Amazon CloudWatch is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- Amazon SNS is a message notification service that is used in this pattern to send email notifications.

For detailed instructions, see Monitor Oracle GoldenGate logs by using Amazon CloudWatch.

Troubleshooting Oracle GoldenGate

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS for Oracle.

Topics

- Error opening an online redo log

- Oracle GoldenGate appears to be properly configured but replication is not working
- Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"

Error opening an online redo log

Make sure that you configure your databases to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source DB instance. Such a duration lets Oracle GoldenGate recover logs from the source DB instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence
 1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Oracle GoldenGate appears to be properly configured but replication is not working

For pre-existing tables, you must specify the SCN that Oracle GoldenGate works from.

To fix this issue

1. Log in to the source database and launch the Oracle GoldenGate command line interface (`ggsci`). The following example shows the format for logging in.

   ```
   dblogin userid oggadm1@OGGSOURCE
   ```

2. Using the `ggsci` command line, set up the start SCN for the EXTRACT process. The following example sets the SCN to 223274 for the EXTRACT.

   ```
   ALTER EXTRACT EABC SCN 223274
   ```

```
start EABC
```

3. Log in to the target database. The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGTARGET
```

4. Using the ggsci command line, set up the start SCN for the REPLICAT process. The following example sets the SCN to 223274 for the REPLICAT.

```
start RABC atcsn 223274
```

Integrated REPLICAT slow due to query on SYS."_DBA_APPLY_CDR_INFO"

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an INSERT statement.

When CDR resolves a collision, it can insert records into the exception table _DBA_APPLY_CDR_INFO temporarily. Integrated REPLICAT deletes these records later. In a rare scenario, the integrated REPLICAT can process a large number of collisions, but a new integrated REPLICAT does not replace it. Instead of being removed, the existing rows in _DBA_APPLY_CDR_INFO are orphaned. Any new integrated REPLICAT processes slow down because they are querying orphaned rows in _DBA_APPLY_CDR_INFO.

To remove all rows from _DBA_APPLY_CDR_INFO, use the Amazon RDS procedure rdsadmin.rdsadmin_util.truncate_apply$_cdr_info. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- Version 21.0.0.0.ru-2022-01.rur-2022-01.r1 and higher
- Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher

The following example truncates the table _DBA_APPLY_CDR_INFO.

```
SET SERVEROUTPUT ON SIZE 2000
EXEC rdsadmin.rdsadmin_util.truncate_apply$_cdr_info;
```

Using the Oracle Repository Creation Utility on RDS for Oracle

You can use Amazon RDS to host an RDS for Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle Database 21c
- RCU 12c with Oracle Database 19c

Before you can use RCU, make sure that you do the following:

- Obtain a license for Oracle Fusion Middleware.
- Follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see Oracle Fusion Middleware Licensing Information User Manual in the Oracle documentation.

Fusion MiddleWare supports repositories on Oracle Database Enterprise Edition and Standard Edition 2. Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your RDS for Oracle instance, confirm the Oracle database version that you need to support the components that you want to deploy. To find the requirements for the Fusion Middleware components and versions you want to deploy, use the Certification Matrix. For more information, see Oracle Fusion Middleware Supported System Configurations in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see Upgrading a DB instance engine version.

Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS

DB instance in a private subnet, which provides greater security. You also need an RDS for Oracle DB instance. For more information, see Creating and connecting to an Oracle DB instance.

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
- Audit Services Append (IAU_APPEND)
- Audit Services Viewer (IAU_VIEWER)
- Discussions (DISCUSSIONS)
- Metadata Services (MDS)
- Oracle Business Intelligence (BIPLATFORM)
- Oracle Platform Security Services (OPSS)
- Portal and Services (WEBCENTER)
- Portlet Producers (PORTLET)
- Service Table (STB)
- SOA Infrastructure (SOAINFRA)
- User Messaging Service (UCSUMS)
- WebLogic Services (WLS)

Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

- We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones.
- For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see Oracle Transparent Data Encryption.

  Amazon RDS also provides an encryption at rest option for all database editions. For more information, see Encrypting Amazon RDS resources.

- Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

Topics

- Running RCU using the command line in one step
- Running RCU using the command line in multiple steps
- Running RCU in interactive mode

Running RCU using the command line in one step

If you don't need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid entering passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-createRepository \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
```

```
-dbRole Normal \
-honorOMF \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-f < /tmp/passwordfile.txt
```

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in **Prepare Scripts for System Load** mode by using the `-generateScript` command-line parameter to create the scripts for your schemas.
2. Manually edit and run the generated script `script_systemLoad.sql`.
3. Run RCU again in **Perform Product Load** mode by using the `-dataLoad` command-line parameter to populate the schemas.
4. Run the generated cleanup script `script_postDataLoad.sql`.

To run RCU in silent mode, specify the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for `dbUser` on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-generateScript \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal \
-honorOMF \
[-encryptTablespace true] \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-scriptLocation /tmp/rcuscripts \
-f < /tmp/passwordfile.txt
```

Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see Step 3: Connect your SQL client to an Oracle DB instance.

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-dataLoad \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal \
-honorOMF \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
```

```
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU in interactive mode

To use the RCU graphical user interface, run RCU in interactive mode. Include the `-interactive` parameter and omit the `-silent` parameter. For more information, see Understanding Repository Creation Utility screens in the Oracle documentation.

Example

The following example starts RCU in interactive mode and pre-populates the connection information.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-interactive \
-createRepository \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal
```

Troubleshooting RCU

Be mindful of the following issues.

Topics

- Oracle Managed Files (OMF)
- Object privileges
- Enterprise Scheduler Service

Oracle Managed Files (OMF)

Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, if you specify a data file name when you run RCU, the tablespace code fails with `ORA-20900`. You can use RCU with OMF in the following ways:

- In RCU 12.2.1.0 and later, use the `-honorOMF` command-line parameter.
- In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see Running RCU using the command line in multiple steps.

Object privileges

Because Amazon RDS is a managed service, you don't have full `SYSDBA` access to your RDS for Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories.

The master account can directly grant privileges that it has already been granted `WITH GRANT OPTION`. In some cases, when you attempt to grant SYS object privileges, the RCU might fail with `ORA-01031`. You can retry and run the `rdsadmin_util.grant_sys_object` stored procedure, as shown in the following example:

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('GV_$SESSION','MY_DBA','SELECT');
END;
/
```

If you attempt to grant SYS privileges on the object `SCHEMA_VERSION_REGISTRY`, the operation might fail with `ORA-20199: Error in rdsadmin_util.grant_sys_object`. You can qualify the table `SCHEMA_VERSION_REGISTRY$` and the view `SCHEMA_VERSION_REGISTRY` with the schema owner name, which is `SYSTEM`, and retry the operation. Or, you can create a synonym. Log in as the master user and run the following statements:

```
CREATE OR REPLACE VIEW SYSTEM.SCHEMA_VERSION_REGISTRY
  AS SELECT * FROM SYSTEM.SCHEMA_VERSION_REGISTRY$;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY FOR
 SYSTEM.SCHEMA_VERSION_REGISTRY;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY$ FOR SCHEMA_VERSION_REGISTRY;
```

Enterprise Scheduler Service

When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with `Error: Component drop check failed`.

Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

Access control

You can create rules that filter out user-specified client requests and accept others.

Session multiplexing

You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see Configuring Oracle Connection Manager in the Oracle Database documentation.

Topics

- Supported versions and licensing options for CMAN
- Requirements and limitations for CMAN
- Configuring CMAN

Supported versions and licensing options for CMAN

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see RDS for Oracle releases.

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

Requirements and limitations for CMAN

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

Configuring CMAN

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.

Topics

- Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance
- Step 2: Configure database parameters for CMAN
- Step 3: Associate your DB instance with the parameter group

Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance

To learn how to set up CMAN, follow the detailed instructions in the blog post Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle.

Step 2: Configure database parameters for CMAN

For CMAN features such as Traffic Director Mode and session multiplexing, set `REMOTE_LISTENER` parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address `10.0.159.100` and uses port `1521`.
- The databases `orcla`, `orclb`, and `orclc` reside on separate RDS for Oracle DB instances.

The following table shows how to set the `REMOTE_LISTENER` value. The `LOCAL_LISTENER` value is set automatically by Amazon RDS.

DB instance name	DB instance IP	Local listener value (set automatically)	Remote listener value (set by user)
`orcla`	`10.0.159.200`	`( address= (protocol=tcp) (host=10.0.159.200) (port=1521) )`	`10.0.159.100:1521`
`orclb`	`10.0.159.300`	`( address= (protocol=tcp) (host=10.0.159.300)`	`10.0.159.100:1521`

DB instance name	DB instance IP	Local listener value (set automatically)	Remote listener value (set by user)
		(port=1521))	
orclc	10.0.159.400	(address= (protocol=tcp) (host=10.0.159.400) (port=1521))	10.0.159.100:1521

Step 3: Associate your DB instance with the parameter group

Create or modify your DB instance to use the parameter group that you configured in Step 2: Configure database parameters for CMAN. For more information, see Associating a DB parameter group with a DB instance in Amazon RDS.

Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see Generic architecture of Siebel business application.

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

> **Note**
>
> To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges.

Licensing and versions

To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see RDS for Oracle licensing options.

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0.

Amazon RDS supports database version upgrades. For more information, see Upgrading a DB instance engine version.

Before you begin

Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about how to create an Amazon VPC for use with Siebel CRM, see Creating and connecting to an Oracle DB instance.

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see Creating an Amazon RDS DB instance.

Installing and configuring a Siebel database

After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see Installing the Siebel database on the RDBMS.

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges.

Using other Amazon RDS features with a Siebel database

After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.

Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see Oracle Statspack.

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see Working with option groups. After you create a customized option group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance.

Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see Parameter groups for Amazon RDS. After you create a customized parameter group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance.

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see Siebel CRM Performance Tuning Guide.

Parameter name	Default value	Guidance for optimal Siebel CRM performance
_always_semi_join	CHOOSE	OFF
_b_tree_bitmap_plans	TRUE	FALSE
_like_with_bind_as_equality	FALSE	TRUE
_no_or_expansion	FALSE	FALSE
_optimizer_join_sel_sanity_check	TRUE	TRUE
_optimizer_max_permutations	2000	100
_optimizer_sortmerge_join_enabled	TRUE	FALSE
_partition_view_enabled	TRUE	FALSE

Parameter name	Default value	Guidance for optimal Siebel CRM performance
`open_cursors`	`300`	At least **`2000`**.

Creating snapshots

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS and Restoring to a DB instance.

Support for other Siebel CRM components

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

Siebel CRM component	Amazon AWS Support
Siebel Enterprise (with one or more Siebel Servers)	You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see What is Amazon EC2? You can put your servers in the same VPC with your DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC.
Web Servers (with Siebel Web Server Extensions)	You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see What is Elastic Load Balancing?

Siebel CRM component	Amazon AWS Support
Siebel Gateway Name Server	You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see Working with a DB instance in a VPC.

Oracle Database engine release notes

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual RDS for Oracle DB instances.

You can specify any currently supported Oracle Database version when you create a new DB instance. You can specify the major version, such as Oracle Database 19c, and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For details about the Oracle Database versions that Amazon RDS supports, see the *Amazon RDS for Oracle Release Notes*.

Amazon RDS for PostgreSQL

Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see Available PostgreSQL database versions.

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in Setting up your Amazon RDS environment.

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn't provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

To import PostgreSQL data into a DB instance, follow the information in the Importing data into PostgreSQL on Amazon RDS section.

Important

If you encounter an issue with your RDS for PostgreSQL DB instance, your AWS support agent might need more information about the health of your databases. The goal is to ensure that AWS Support gets the required information as soon as possible.

You can use PG Collector to help gather valuable database information in a consolidated HTML file. For more information on PG Collector, how to run it, and how to download the HTML report, see PG Collector.
Upon successful completion, and unless otherwise noted, the script returns output in a readable HTML format. The script is designed to exclude any data or security details from the HTML that might compromise your business. It also makes no modifications to your database or its environment. However, if you find any information in the HTML that you are uncomfortable sharing, feel free to remove the problematic information before uploading the HTML. When the HTML is acceptable, upload it using the attachments section in the case details of your support case.

Common management tasks for Amazon RDS for PostgreSQL

The following are the common management tasks you perform with an Amazon RDS for PostgreSQL DB instance, with links to relevant documentation for each task.

Task area	Relevant documentation
Setting up Amazon RDS for first-time use Before you can create your DB instance, make sure to complete a few prerequisites. For example, DB instances are created by default with a firewall that prevents access to it. So you need to create a security group with the correct IP addresses and network configuration to access the DB instance.	Setting up your Amazon RDS environment
Understanding Amazon RDS DB instances If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance classes Amazon RDS storage types Provisioned IOPS SSD storage
Finding available PostgreSQL versions Amazon RDS supports several versions of PostgreSQL.	Available PostgreSQL database versions
Setting up high availability and failover support A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	Configuring and managing a Multi-AZ deployment for Amazon RDS
Understanding the Amazon Virtual Private Cloud (VPC) network	Working with a DB instance in a VPC

Task area	Relevant documentation
If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. In some cases, your account might not have a default VPC, and you might want the DB instance in a VPC. In these cases, create the VPC and subnet groups before you create the DB instance.	
Importing data into Amazon RDS PostgreSQL You can use several different tools to import data into your PostgreSQL DB instance on Amazon RDS.	Importing data into PostgreSQL on Amazon RDS
Setting up read-only read replicas (primary and standbys) RDS for PostgreSQL supports read replicas in both the same AWS Region and in a different AWS Region from the primary instance.	Working with DB instance read replicas Working with read replicas for Amazon RDS for PostgreSQL Creating a read replica in a different AWS Region
Understanding security groups By default, DB instances are created with a firewall that prevents access to them. To provide access through that firewall, you edit the inbound rules for the VPC security group associated with the VPC hosting the DB instance.	Controlling access with security groups
Setting up parameter groups and features To change the default parameters for your DB instance, create a custom DB parameter group and change settings to that. If you do this before creating your DB instance, you can choose your custom DB parameter group when you create the instance.	Parameter groups for Amazon RDS

Task area	Relevant documentation
Connecting to your PostgreSQL DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as `psql` or `pgAdmin`.	Connecting to a DB instance running the PostgreSQL database engine Using SSL with a PostgreSQL DB instance
Backing up and restoring your DB instance You can configure your DB instance to take automated backups, or take manual snapshots, and then restore instances from the backups or snapshots.	Backing up, restoring, and exporting data
Monitoring the activity and performance of your DB instance You can monitor a PostgreSQL DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing metrics in the Amazon RDS console Viewing Amazon RDS events
Upgrading the PostgreSQL database version You can do both major and minor version upgrades for your PostgreSQL DB instance.	Upgrades of the RDS for PostgreSQL DB engine Choosing a major version for an RDS for PostgreSQL upgrade
Working with log files You can access the log files for your PostgreSQL DB instance.	RDS for PostgreSQL database log files
Understanding the best practices for PostgreSQL DB instances Find some of the best practices for working with PostgreSQL on Amazon RDS.	Best practices for working with PostgreSQL

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- Understanding PostgreSQL roles and permissions
- Controlling user access to the PostgreSQL database
- Working with parameters on your RDS for PostgreSQL DB instance
- Understanding logging mechanisms supported by RDS for PostgreSQL
- Working with PostgreSQL autovacuum on Amazon RDS for PostgreSQL
- Using a custom DNS server for outbound network access

Working with the Database Preview environment

The PostgreSQL community continuously releases new PostgreSQL version and extensions, including beta versions. This gives PostgreSQL users the opportunity to try out a new PostgreSQL version early. To learn more about the PostgreSQL community beta release process, see Beta Information in the PostgreSQL documentation. Similarly, Amazon RDS makes certain PostgreSQL beta versions available as Preview releases. This allows you to create DB instances using the Preview version and test out its features in the Database Preview Environment.

RDS for PostgreSQL DB instances in the Database Preview Environment are functionally similar to other RDS for PostgreSQL instances. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, AWS re:Post.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using M6i, R6i, M6g, M5, T3, R6g, and R5 instance types only. For more information about RDS instance classes, see DB instance classes.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Topics

- Features not supported in the Database Preview environment
- PostgreSQL version 17 in the Database Preview environment
- Creating a new DB instance in the Database Preview environment

Features not supported in the Database Preview environment

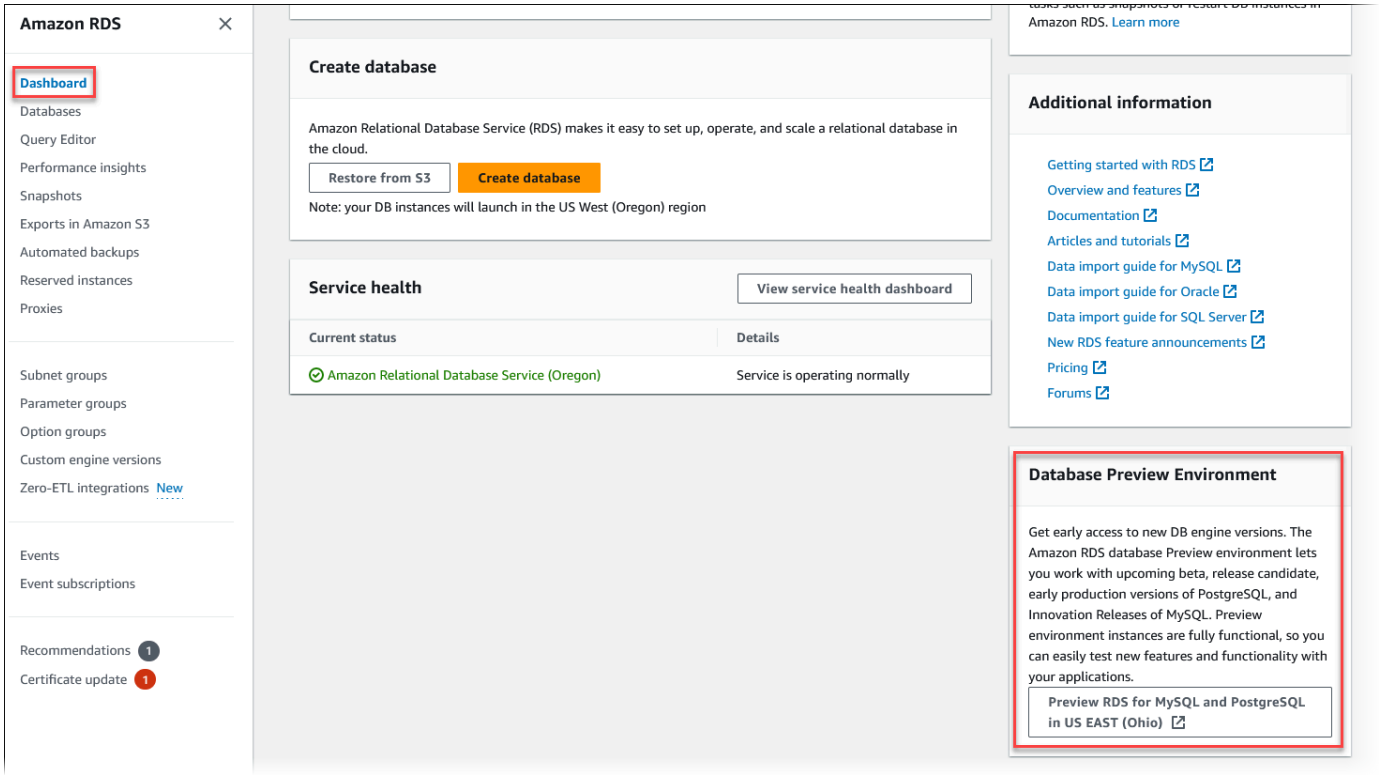
The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas

PostgreSQL version 17 in the Database Preview environment

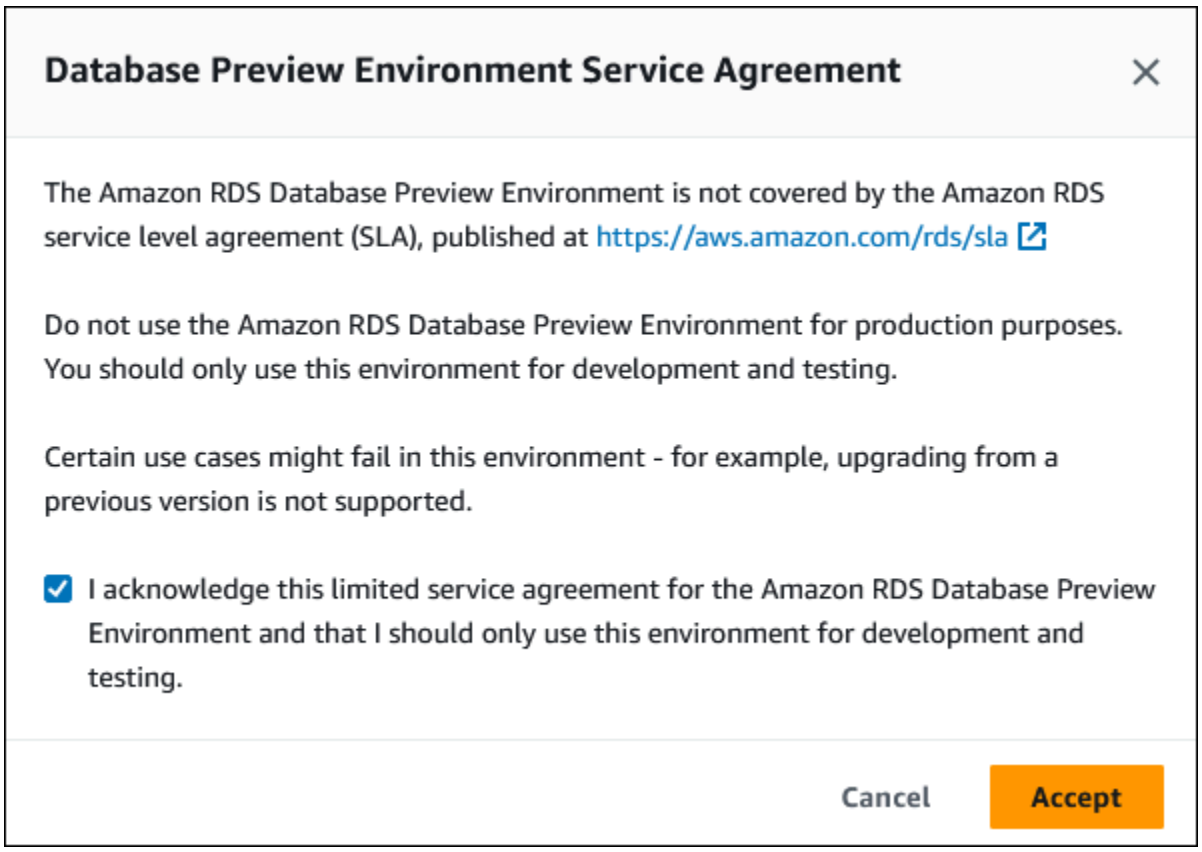
> **Note**
>
> This is preview documentation for Amazon RDS PostgreSQL version 17. It is subject to change.

PostgreSQL version 17.0 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 17.0 contains several improvements that are described in the following PostgreSQL documentation, PostgreSQL 17 Released!



For information on the Database Preview Environment, see the section called “Working with the Database Preview environment”. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

Creating a new DB instance in the Database Preview environment



Use the following procedure to create a DB instance in the preview environment.

To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Dashboard** from the navigation pane.
3. In the Dashboard page, locate the **Database Preview Environment** section on the Dashboard page, as shown in the following image.

You can navigate directly to the Database Preview environment. Before you can proceed, you must acknowledge and accept the limitations.

4. To create the RDS for PostgreSQL DB instance, follow the same process as that for creating any Amazon RDS DB instance. For more information, see the Console procedure in Creating a DB instance.

To create an instance in the Database Preview Environment using the RDS API or the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 14), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the *Amazon RDS for PostgreSQL Release Notes*. You can also view information about support dates for major engine versions by running the describe-db-major-engine-versions AWS CLI command or by using the DescribeDBMajorEngineVersions RDS API operation.

If you aren't ready to manually upgrade to a new major engine version before the RDS end of standard support date, Amazon RDS will automatically enroll your databases in Amazon RDS Extended Support after the RDS end of standard support date. Then, you can continue to run RDS for PostgreSQL version 11 and higher. For more information, see Amazon RDS Extended Support with Amazon RDS and Amazon RDS pricing.

Deprecated versions for Amazon RDS for PostgreSQL

Note the following deprecated versions:

- RDS for PostgreSQL 10 was deprecated in February 2023.
- RDS for PostgreSQL 9.6 was deprecated in March 2022.
- RDS for PostgreSQL 9.5 was deprecated in March 2021.

To learn more about deprecation policy for RDS for PostgreSQL, see Amazon RDS FAQs. For more information about PostgreSQL versions, see Versioning Policy in the PostgreSQL documentation.

Understanding the RDS for PostgreSQL incremental release process

RDS for PostgreSQL delivers security fixes, performance improvements, and new features through incremental releases while maintaining minor version compatibility. These releases are labeled as R1, R2, R3, and so on.

Release version naming convention

- R1 is the initial release of a minor version. It occasionally includes new features, extensions, or upgrades to existing extensions.
- Subsequent release versions (R2, R3, and later) include:
  - Security updates
  - Performance improvements
  - Bug fixes
  - Extension updates

Advantages of RDS for PostgreSQL incremental release process

The incremental release process provides the following advantages:

- Quick adoption of new PostgreSQL community releases while separately managing RDS-specific enhancements through subsequent releases. This streamlines the release process and ensures faster delivery of critical updates.
- Access to bug fixes, new features, security updates, and extension updates while maintaining compatibility with the PostgreSQL minor version.

Managing release updates

Amazon RDS notifies you about new incremental releases through pending maintenance actions in the AWS Management Console. You can update your database using one of these methods:

- Enable automatic updates during scheduled maintenance windows.
- Apply updates manually through pending maintenance actions.

- Use Blue/Green deployments with physical replication to minimize downtime. For more information, see Blue/Green Deployments support minor version upgrade for RDS for PostgreSQL.

Before updating your database, consider the following key points:

- Database reboots are required for updates unless you use Blue/Green deployments with physical replication.
- Some incremental releases are mandatory, particularly those that include security fixes.

For more information about updating your Amazon RDS DB instance instance, see PostgreSQL trusted extensions and apply-pending-maintenance-action.

Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using `psql` by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

> **Note**
>
> Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in `psql`.

As of RDS for PostgreSQL 13, certain extensions can be installed by database users other than the `rds_superuser`. These are known as *trusted extensions*. To learn more, see PostgreSQL trusted extensions.

Certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. This parameter lets an `rds_superuser` limit the extensions that can be installed in the RDS for PostgreSQL DB instance. For more information, see Restricting installation of PostgreSQL extensions.

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in *Amazon RDS for PostgreSQL Release Notes*.

Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. By default, this parameter isn't set, so any supported extension can be added if the user has permissions to do so. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that your RDS for PostgreSQL DB instance can use. Only these extensions can then be installed in the PostgreSQL DB instance.

The default string for the `rds.allowed_extensions` parameter is '*', which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:

- All PostgreSQL 16 versions
- PostgreSQL 15 and all higher versions
- PostgreSQL 14 and all higher versions
- PostgreSQL 13.3 and higher minor versions
- PostgreSQL 12.7 and higher minor versions

To see which extension installations are allowed, use the following psql command.

```
postgres=> SHOW rds.allowed_extensions;
 rds.allowed_extensions
------------------------
 *
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and `DROP EXTENSION` will continue to work. However, after an extension is restricted, `CREATE EXTENSION` commands for the restricted extension will fail.

Installation of extension dependencies with `CREATE EXTENSION CASCADE` are also restricted. The extension and its dependencies must be specified in `rds.allowed_extensions`. If an extension dependency installation fails, the entire `CREATE EXTENSION CASCADE` statement will fail.

If an extension is not included with the `rds.allowed_extensions` parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```

PostgreSQL trusted extensions

To install most PostgreSQL extensions requires `rds_superuser` privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant `rds_superuser` privileges to regular users. With this feature, users can install many extensions if they have the CREATE privilege on the current database instead of requiring the `rds_superuser` role. For more information, see the SQL CREATE EXTENSION command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the CREATE privilege on the current database and do not require the `rds_superuser` role:

- bool_plperl
- btree_gin
- btree_gist
- citext
- cube
- dict_int
- fuzzystrmatch
- hstore
- intarray
- isn
- jsonb_plperl
- ltree
- pg_trgm
- pgcrypto
- plperl
- plpgsql
- pltcl
- tablefunc
- tsm_system_rows
- tsm_system_time
- unaccent
- uuid-ossp

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see PostgreSQL extensions supported on Amazon RDS in *Amazon RDS for PostgreSQL Release Notes*.

Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. The autovacuum feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see Working with PostgreSQL autovacuum on Amazon RDS for PostgreSQL. To learn more about other common DBA tasks, Common DBA tasks for Amazon RDS for PostgreSQL.

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL.

Following, you can find information about some other features supported by RDS for PostgreSQL.

Topics

- Custom data types and enumerations with RDS for PostgreSQL
- Event triggers for RDS for PostgreSQL
- Huge pages for RDS for PostgreSQL
- Performing logical replication for Amazon RDS for PostgreSQL
- Configuring IAM authentication for logical replication connections
- RAM disk for the stats_temp_directory
- Tablespaces for RDS for PostgreSQL
- RDS for PostgreSQL collations for EBCDIC and other mainframe migrations
- Managing logical slot synchronization for RDS for PostgreSQL

Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see Enumerated types in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TYPE
CREATE TABLE t1 (colors rainbow);
CREATE TABLE
INSERT INTO t1 VALUES ('red'), ( 'orange');
INSERT 0 2
SELECT * from t1;
colors
--------
red
orange
(2 rows)
postgres=> ALTER TYPE rainbow RENAME VALUE 'red' TO 'crimson';
ALTER TYPE
postgres=> SELECT * from t1;
colors
---------
crimson
orange
(2 rows)
```

Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, `postgres`) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```
CREATE OR REPLACE FUNCTION raise_notice_func()
```

```
    RETURNS event_trigger
    LANGUAGE plpgsql AS
$$
BEGIN
    RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;

CREATE EVENT TRIGGER event_trigger_1
    ON ddl_command_end
EXECUTE PROCEDURE raise_notice_func();
```

For more information about PostgreSQL event triggers, see Event triggers in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can't create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don't fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

Huge pages for RDS for PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to `mmap` or SYSV shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.

You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all the DB instance classes other than micro, small, and medium DB instance classes.

RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible

parameters state. If this occurs, you can set the `huge_pages` parameter to `off` to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro. This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see Resource Consumption in the PostgreSQL documentation.

Performing logical replication for Amazon RDS for PostgreSQL

Starting with version 10.4, RDS for PostgreSQL supports the publication and subscription SQL syntax that was introduced in PostgreSQL 10. To learn more, see Logical replication in the PostgreSQL documentation.

> **Note**
>
> In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, RDS for PostgreSQL also supports the `pglogical` extension. For more information, see Using pglogical to synchronize data across instances.

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

Topics

- Understanding logical replication and logical decoding
- Working with logical replication slots
- Replicating table level data using logical replication

Understanding logical replication and logical decoding

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication

slots on your instance and stream database changes through these slots to a client such as `pg_recvlogical`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

To turn on logical decoding for an RDS for PostgreSQL DB instance

1. Make sure that the user account that you're using has these roles:
   - The `rds_superuser` role so you can turn on logical replication
   - The `rds_replication` role to grant permissions to manage logical slots and to stream data using logical slots
2. Set the `rds.logical_replication` static parameter to 1. As part of applying this parameter, also set the parameters `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections`. These parameter changes can increase WAL generation, so set the `rds.logical_replication` parameter only when you are using logical slots.
3. Reboot the DB instance for the static `rds.logical_replication` parameter to take effect.
4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the test_decoding and wal2json output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the PostgreSQL documentation.

Working with logical replication slots

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named `test_slot` using the default PostgreSQL output plugin `test_decoding`.

```
SELECT * FROM pg_create_logical_replication_slot('test_slot', 'test_decoding');
slot_name    | xlog_position
-----------------+---------------
regression_slot | 0/16B1970
(1 row)
```

To list logical slots, use the following command.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```
SELECT pg_drop_replication_slot('test_slot');
pg_drop_replication_slot
-----------------------
(1 row)
```

For more examples on working with logical replication slots, see Logical decoding examples in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program pg_recvlogical, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```
pg_recvlogical -d postgres --slot test_slot -U postgres
    --host -instance-name.111122223333.aws-region.rds.amazonaws.com
    -f -  --start
```

To see the contents of the `pg_replication_origin_status` view, query the `pg_show_replication_origin_status` function.

```
SELECT * FROM pg_show_replication_origin_status();
local_id | external_id | remote_lsn | local_lsn
----------+-------------+------------+-----------
(0 rows)
```

Replicating table level data using logical replication

You can use logical replication to replicate data from source tables to target tables in RDS for PostgreSQL. Logical replication first performs an initial load of existing data from the source tables and then continues to replicate ongoing changes.

1. **Create the source tables**

   Connect to the source database in your RDS for PostgreSQL DB instance:

```
source=> CREATE TABLE testtab (slno int primary key);
CREATE TABLE
```

2. **Insert data into the source tables**

```
source=> INSERT INTO testtab VALUES (generate_series(1,1000));
INSERT 0 1000
```

3. **Create a publication for source tables**

   - Create a publication for the source tables:

```
source=> CREATE PUBLICATION testpub FOR TABLE testtab;
CREATE PUBLICATION
```

   - Use a SELECT query to verify the details of the publication that was created:

```
source=> SELECT * FROM pg_publication;
  oid   | pubname | pubowner | puballtables | pubinsert | pubupdate | pubdelete |
 pubtruncate | pubviaroot
--------+---------+----------+--------------+-----------+-----------+-----------
+-------------+------------
 115069 | testpub |    16395 | f            | t         | t         | t         |
 t           | f
(1 row)
```

- Verify that the source tables are added to the publication:

```
source=> SELECT * FROM pg_publication_tables;
pubname | schemaname | tablename
---------+------------+-----------
 testpub | public     | testtab
(1 rows)
```

- To replicate all tables in a database, use:

```
CREATE PUBLICATION testpub FOR ALL TABLES;
```

- If the publication is already created for individual table and you need to add new table, you can run below query to add any new tables into the existing publication:

```
ALTER PUBLICATION <publication_name> add table <new_table_name>;
```

4. **Connect to target database and create target tables**

- Connect to the target database in the target DB instance. Create the target tables with the same names as the source tables:

```
target=> CREATE TABLE testtab (slno int primary key);
CREATE TABLE
```

- Make sure that there's no data present in the target tables by running a SELECT query on the target tables:

```
target=> SELECT count(*) FROM testtab;
 count
-------
     0
```

```
(1 row)
```

5. **Create and verify subscription in target database**

   - Create the subscription in the target database:

```
target=> CREATE SUBSCRIPTION testsub
CONNECTION 'host=<source RDS/host endpoint> port=5432 dbname=<source_db_name>
 user=<user> password=<password>'
PUBLICATION testpub;
NOTICE:  Created replication slot "testsub" on publisher
CREATE SUBSCRIPTION
```

   - Use a SELECT query to verify that the subscription is enabled:

```
target=> SELECT oid, subname, subenabled, subslotname, subpublications FROM
 pg_subscription;
  oid  | subname | subenabled | subslotname | subpublications
-------+---------+------------+-------------+-----------------
 16434 | testsub | t          | testsub     | {testpub}
(1 row)
```

   - When the subscription is created, it loads all data from the source tables to the target tables. Run a SELECT query on the target tables to verify that the initial data loads:

```
target=> SELECT count(*) FROM testtab;
 count
-------
  1000
(1 row)
```

6. **Verify replication slot in source database**

   The creation of a subscription in the target database creates a replication slot in the source database. Verify the replication slot details by running the following SELECT query on the source database:

```
source=> SELECT * FROM pg_replication_slots;

slot_name |  plugin  | slot_type | datoid | database | temporary | active |
 active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn | wal_status
 | safe_wal_size
----------+----------+-----------+--------+----------+-----------+--------
+------------+------+--------------+-------------+---------------------
+------------+---------------
testsub   | pgoutput | logical   | 115048 | source   | f         | t      |
 846 |      |         6945 | 58/B4000568 | 58/B40005A0         | reserved   |
(1 row)
```

7. **Testing replication**

   - Test whether data changes in the source tables are being replicated to the target tables by inserting rows into the source tables:

     ```
     source=> INSERT INTO testtab VALUES(generate_series(1001,2000));
     INSERT 0 1000

     source=> SELECT count(*) FROM testtab;
      count
     -------
       2000
     (1 row)
     ```

   - Verify the number of rows in the target tables to confirm that new inserts are being replicated:

     ```
     target=> SELECT count(*) FROM testtab;
      count
     -------
       2000
     (1 row)
     ```

8. **Refreshing the subscription after adding tables**

   - When you add new tables to an existing publication, it is mandatory to refresh the subscription for the changes to take effect:

     ```
     ALTER SUBSCRIPTION <subscription_name> REFRESH PUBLICATION;
     ```

   - This command fetches missing table information from the publisher and starts replication for tables that were added to the subscribed-to publications since the subscription was created or last refreshed.

Configuring IAM authentication for logical replication connections

Starting with RDS for PostgreSQL versions 11 and higher, you can use AWS Identity and Access Management (IAM) authentication for replication connections. This feature enhances security by allowing you to manage database access using IAM roles instead of passwords. It works both at the cluster and instance granularity and follows the same security model as standard IAM authentication.

IAM authentication for replication connections is an opt-in feature. To enable it, set the `rds.iam_auth_for_replication` parameter to 1 in your DB cluster or DB parameter group. As this is a dynamic parameter, your DB cluster or instance doesn't need to restart, enabling you to leverage IAM authentication with existing workloads without downtime. Before enabling this feature, you must meet the Prerequisites listed below.

Topics

- Prerequisites
- Enabling IAM authentication for replication connections
- Disabling IAM authentication for replication connections
- Limitations and considerations

Prerequisites

To use IAM authentication for replication connections, you need to meet all of the following requirements:

- Your RDS for PostgreSQL DB instance must be version 11 or later.
- On your publisher RDS for PostgreSQL DB instance:
  - Enable IAM database authentication. For more information, see Enabling and disabling IAM database authentication.
  - Enable logical replication by setting the `rds.logical_replication` parameter to 1.

In logical replication, the publisher is the source RDS for PostgreSQL database that sends data to subscriber database. For more information, see Performing logical replication for Amazon RDS for PostgreSQL.

> **Note**
>
> Both IAM authentication and logical replication must be enabled on your publisher RDS for PostgreSQL DB instance. If either one isn't enabled, you can't use IAM authentication for replication connections.

Enabling IAM authentication for replication connections

Complete the following steps to enable IAM authentication for replication connection.

To enable IAM authentication for replication connections

1. Verify that your RDS for PostgreSQL DB cluster or instance meets all prerequisites for IAM authentication with replication connections. For details, see Prerequisites.
2. Configure the `rds.iam_auth_for_replication` parameter based on your RDS for PostgreSQL setup:
   - For RDS for PostgreSQL DB instances: Modify your DB parameter group.
   - For Multi-AZ clusters: Modify your DB cluster parameter group.

   Set `rds.iam_auth_for_replication` to 1. This is a dynamic parameter that takes effect immediately without requiring a reboot.

> **Note**
>
> Multi-AZ clusters use only DB cluster parameter groups. Individual instance parameter groups cannot be modified in Multi-AZ clusters.

3. Connect to your database and grant the necessary roles to your replication user:

   The following SQL commands grant the necessary roles to enable IAM authentication for replication connections:

```
-- Grant IAM authentication role
GRANT rds_iam TO replication_user_name;

-- Grant replication privileges
ALTER USER replication_user_name WITH REPLICATION;
```

   After you complete these steps, the specified user must use IAM authentication for replication connections.

> **Important**
>
> When you enable the feature, users with both `rds_iam` and `rds_replication` roles must use IAM authentication for replication connections. This applies whether the roles are assigned directly to the user or inherited through other roles.

Disabling IAM authentication for replication connections

You can disable IAM authentication for replication connections by using any of the following methods:

- Set the `rds.iam_auth_for_replication` parameter to 0 in your DB parameter group for DB instances or DB cluster parameter group for Multi-AZ clusters.
- Alternatively, you can disable either of these features on your RDS for PostgreSQL DB cluster or instance:
  - Disable logical replication by setting the `rds.logical_replication` parameter to 0

- Disable IAM authentication

When you disable the feature, replication connections can use database passwords for authentication.

> **Note**
>
> Replication connections for users without the `rds_iam` role can use password authentication even when the feature is enabled.

Limitations and considerations

Consider the following limitations and considerations when using IAM authentication for logical replication connections:

- This feature is available only for RDS for PostgreSQL versions 11 and higher.
- The publisher must support IAM authentication for replication connections.
- The IAM authentication token expires after 15 minutes by default. You might need to refresh long-running replication connections before the token expires.

RAM disk for the stats_temp_directory

You can use the RDS for PostgreSQL parameter `rds.pg_stat_ramdisk_size` to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is only available in RDS for PostgreSQL version 14 and lower versions.

Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the `stats_temp_directory`, see the PostgreSQL documentation..

To set up a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to an integer literal value in the parameter group used by your DB instance. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the `rds.pg_stat_ramdisk_size` parameter. Be sure to reboot the DB instance so that the change takes effect. For information about setting parameters, see Parameter groups for Amazon RDS.

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name pg-95-ramdisk-testing \
    --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256,
 ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the `stats_temp_directory`.

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory
--------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

Tablespaces for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can't use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.

To create and use tablespaces with your RDS for PostgreSQL DB instance requires the `rds_superuser` role. Your RDS for PostgreSQL DB instance's main user account (default name, `postgres`) is a member of this role. For more information, see Understanding PostgreSQL roles and permissions.

If you specify a file name when you create a tablespace, the path prefix is `/rdsdbdata/db/base/tablespace`. The following example places tablespace files in `/rdsdbdata/db/base/tablespace/data`. This example assumes that a `dbadmin` user (role) exists and that it's been granted the `rds_superuser` role needed to work with tablespaces.

```
postgres=> CREATE TABLESPACE act_data
  OWNER dbadmin
  LOCATION '/data';
CREATE TABLESPACE
```

To learn more about PostgreSQL tablespaces, see Tablespaces in the PostgreSQL documentation.

RDS for PostgreSQL collations for EBCDIC and other mainframe migrations

RDS for PostgreSQL versions 10 and higher include ICU version 60.2, which is based on Unicode 10.0 and includes collations from the Unicode Common Locale Data Repository, CLDR 32. These software internationalization libraries ensure that character encodings are presented in a consistent way, regardless of operating system or platform. For more information about Unicode CLDR-32, see the CLDR 32 Release Note on the Unicode CLDR website. You can learn more about the internationalization components for Unicode (ICU) at the ICU Technical Committee (ICU-TC) website. For information about ICU-60, see Download ICU 60.

Starting with version 14.3, RDS for PostgreSQL also includes collations that help with data integration and conversion from EBCDIC-based systems. The extended binary coded decimal interchange code or *EBCDIC* encoding is commonly used by mainframe operating systems. These Amazon RDS-provided collations are narrowly defined to sort only those Unicode characters that directly map to EBCDIC code pages. The characters are sorted in EBCDIC code-point order to allow for data validation after conversion. These collations don't include denormalized forms, nor do they include Unicode characters that don't directly map to a character on the source EBCDIC code page.

The character mappings between EBCDIC code pages and Unicode code points are based on tables published by IBM. The complete set is available from IBM as a compressed file for download. RDS for PostgreSQL used these mappings with tools provided by the ICU to create the collations listed in the tables in this section. The collation names include a language and country as required by the ICU. However, EBCDIC code pages don't specify languages, and some EBCDIC code pages cover multiple countries. That means that the language and country portion of the collation names in the table are arbitrary, and they don't need to match the current locale. In other words, the code page number is the most important part of the collation name in this table. You can use any of the collations listed in the following tables in any RDS for PostgreSQL database.

- Unicode to EBCDIC collations table – Some mainframe data migration tools internally use LATIN1 or LATIN9 to encode and process data. Such tools use round-trip schemes to preserve data integrity and support reverse conversion. The collations in this table can be used by tools that process data using LATIN1 encoding, which doesn't require special handling.
- Unicode to LATIN9 collations table – You can use these collations in any RDS for PostgreSQL database.

In the following table, you find collations available in RDS for PostgreSQL that map EBCDIC code pages to Unicode code points. We recommend that you use the collations in this table for application development that requires sorting based on the ordering of IBM code pages.

PostgreSQL collation name	Description of code-page mapping and sort order
da-DK-cp277-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 277 (per conversion tables) are sorted in IBM CP 277 code point order
de-DE-cp273-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 273 (per conversion tables) are sorted in IBM CP 273 code point order
en-GB-cp285-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 285 (per conversion tables) are sorted in IBM CP 285 code point order
en-US-cp037-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 037 (per conversion tables) are sorted in IBM CP 37 code point order
es-ES-cp284-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 284 (per conversion tables) are sorted in IBM CP 284 code point order
fi-FI-cp278-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 278 (per conversion tables) are sorted in IBM CP 278 code point order
fr-FR-cp297-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 297 (per conversion tables) are sorted in IBM CP 297 code point order
it-IT-cp280-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 280 (per conversion tables) are sorted in IBM CP 280 code point order

PostgreSQL collation name	Description of code-page mapping and sort order
nl-BE-cp500-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 500 (per conversion tables) are sorted in IBM CP 500 code point order

Amazon RDS provides a set of additional collations that sort Unicode code points that map to LATIN9 characters using the tables published by IBM, in the order of the original code points according to the EBCDIC code page of the source data.

PostgreSQL collation name	Description of code-page mapping and sort order
da-DK-cp1142m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1142 (per conversion tables) are sorted in IBM CP 1142 code point order
de-DE-cp1141m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1141 (per conversion tables) are sorted in IBM CP 1141 code point order
en-GB-cp1146m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1146 (per conversion tables) are sorted in IBM CP 1146 code point order
en-US-cp1140m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1140 (per conversion

PostgreSQL collation name	Description of code-page mapping and sort order
	tables) are sorted in IBM CP 1140 code point order
es-ES-cp1145m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1145 (per conversion tables) are sorted in IBM CP 1145 code point order
fi-FI-cp1143m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1143 (per conversion tables) are sorted in IBM CP 1143 code point order
fr-FR-cp1147m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1147 (per conversion tables) are sorted in IBM CP 1147 code point order
it-IT-cp1144m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1144 (per conversion tables) are sorted in IBM CP 1144 code point order
nl-BE-cp1148m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1148 (per conversion tables) are sorted in IBM CP 1148 code point order

In the following, you can find an example of using an RDS for PostgreSQL collation.

```
db1=> SELECT pg_import_system_collations('pg_catalog');
 pg_import_system_collations
-----------------------------
                          36
db1=> SELECT '¤' < 'a' col1;
 col1
------
 t
db1=> SELECT '¤' < 'a' COLLATE "da-DK-cp277-x-icu" col1;
 col1
------
 f
```

We recommend that you use the collations in the Unicode to EBCDIC collations table and in the Unicode to LATIN9 collations table for application development that requires sorting based on the ordering of IBM code pages. The following collations (suffixed with the letter “b”) are also visible in `pg_collation`, but are intended for use by mainframe data integration and migration tools at AWS that map code pages with specific code point shifts and require special handling in collation. In other words, the following collations aren't recommended for use.

- da-DK-277b-x-icu
- da-DK-1142b-x-icu
- de-DE-cp273b-x-icu
- de-DE-cp1141b-x-icu
- en-GB-cp1146b-x-icu
- en-GB-cp285b-x-icu
- en-US-cp037b-x-icu
- en-US-cp1140b-x-icu
- es-ES-cp1145b-x-icu
- es-ES-cp284b-x-icu
- fi-FI-cp1143b-x-icu
- fr-FR-cp1147b-x-icu
- fr-FR-cp297b-x-icu
- it-IT-cp1144b-x-icu
- it-IT-cp280b-x-icu

- nl-BE-cp1148b-x-icu
- nl-BE-cp500b-x-icu

To learn more about migrating applications from mainframe environments to AWS, see What is AWS Mainframe Modernization?.

For more information about managing collations in PostgreSQL, see Collation Support in the PostgreSQL documentation.

Managing logical slot synchronization for RDS for PostgreSQL

Starting in community PostgreSQL 17, a new feature to automatically synchronize logical replication slots from primary to standby servers has been introduced through the parameter `sync_replication_slots` or the related function `pg_sync_replication_slots()`, which manually synchronizes slots on execution.

These features are available starting with RDS for PostgreSQL 17. A typical setup will have a primary instance and its read replica, as well as a logical replication subscriber to the primary.

Ensure the subscription is created with the failover option set to true:

```
CREATE SUBSCRIPTION subname CONNECTION 'host=...' PUBLICATION pubname WITH (failover =
 true);
```

This creates a logical slot on the publisher with failover enabled.

```
postgres=> SELECT slot_name, slot_type, failover FROM pg_catalog.pg_replication_slots;
 slot_name | slot_type | failover
-----------+-----------+----------
 subname   | logical   | t
(1 row)
```

By enabling slot synchronization, all of the failover logical replication slots on the primary are automatically created on the physical standbys and are synced periodically. Ensure the following values have been set through parameter groups:

- `rds.logical_replication` must be 1 to enable logical replication
- `hot_standby_feedback` must be 1 on the standby
- `rds.logical_slot_sync_dbname` on the standby must be set to a valid database name

The parameter's default value is `postgres`. If the logical publishing instance has the `postgres` database, the default parameter does not need to be changed.

- `synchronized_standby_slots` on the primary must be set to the physical replication slot of the standby intended to be in-sync
- `sync_replication_slots` must be 1 to enable automatic synchronization

With a failover-enabled subscription slot and the above parameter values, when a standby is promoted, the subscriber can alter its subscription to this newly promoted instance and continue logical replication seamlessly.

Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as *public*, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as *private*, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To check whether your DB instance is public or private, use the AWS Management Console to view the **Connectivity & security** tab for your instance. Under **Security**, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see Scenarios for accessing a DB instance in a VPC.

Contents

- Installing the psql client
- Finding the connection information for an RDS for PostgreSQL DB instance
- Using pgAdmin to connect to a RDS for PostgreSQL DB instance
- Using psql to connect to your RDS for PostgreSQL DB instance
- Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) JDBC Driver
- Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) Python Driver
- Troubleshooting connections to your RDS for PostgreSQL instance
  - Error – FATAL: database name does not exist
  - Error – Could not connect to server: Connection timed out
  - Errors with security group access rules

Installing the psql client

To connect to your DB instance from an EC2 instance, you can install a PostgreSQL client on the EC2 instance. To install the latest version of the psql client on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql<version number>
```

To install the latest version of the psql client on Amazon Linux 2, run the following command:

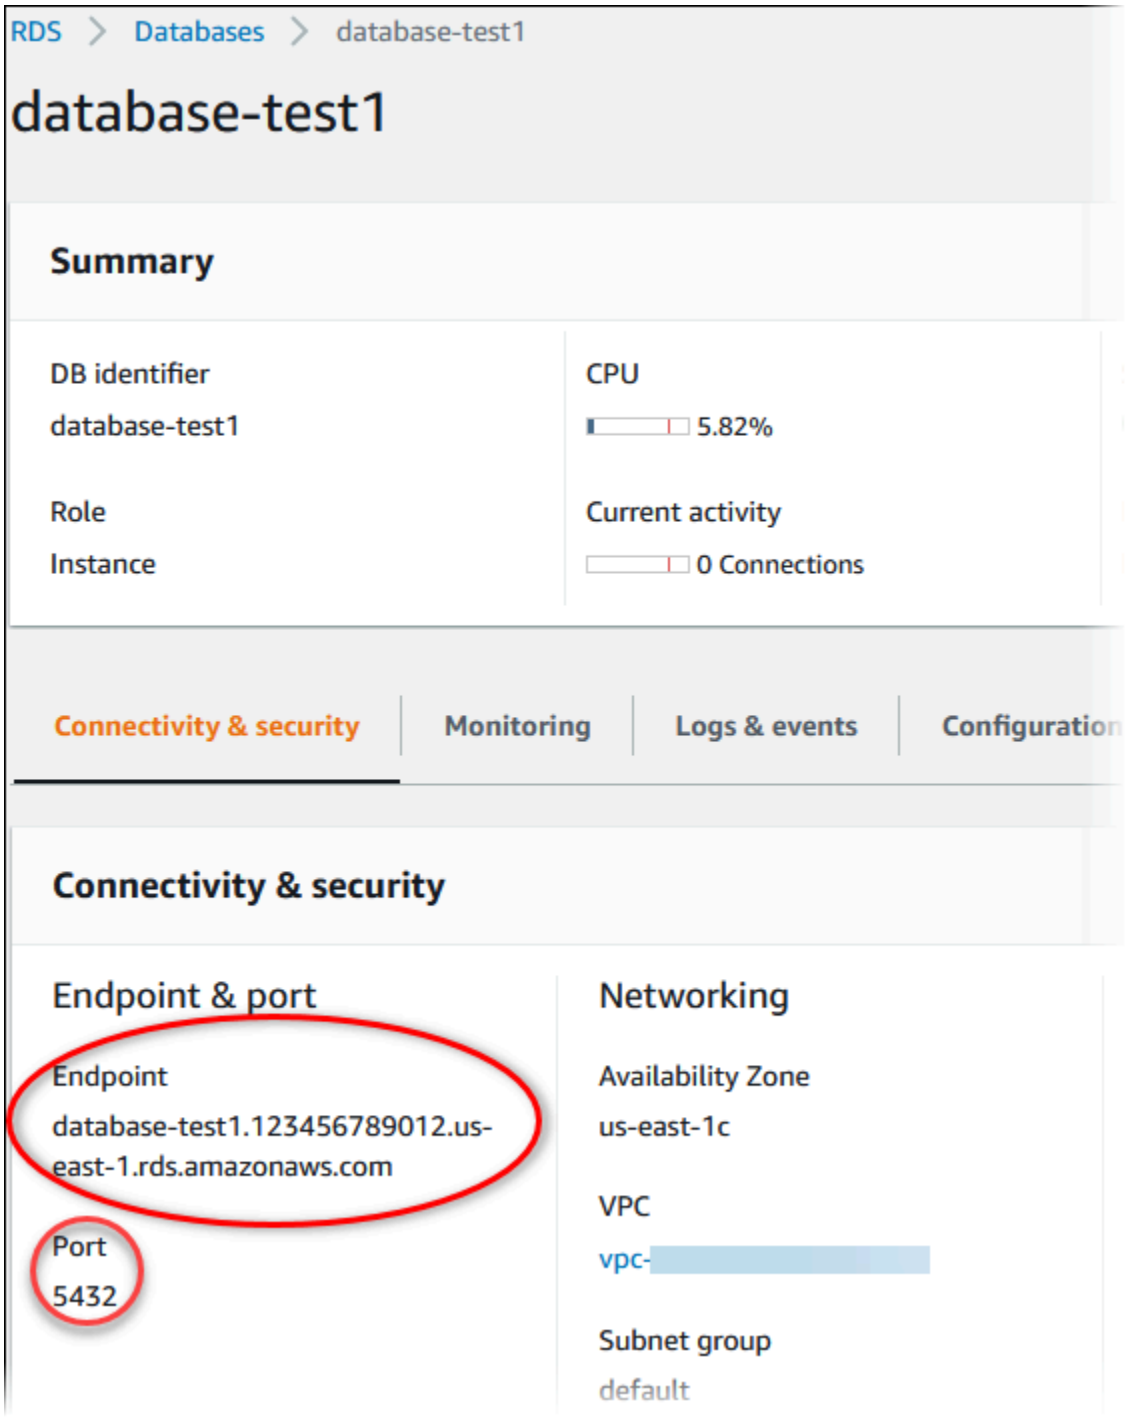
```
sudo yum install -y postgresql
```

To install the latest version of the psql client on Ubuntu, run the following command:

```
sudo apt install -y postgresql-client
```

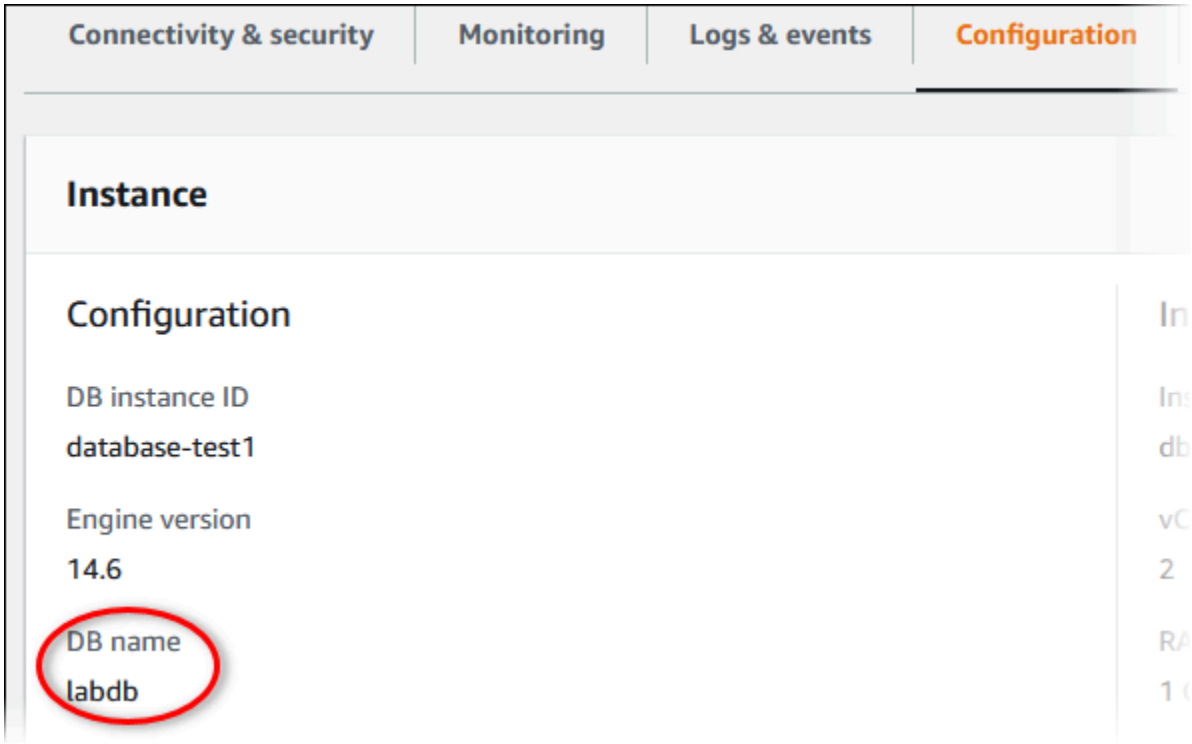
Finding the connection information for an RDS for PostgreSQL DB instance

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:



- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
- The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
- The user name and password for the DB instance. The default 'master username' for PostgreSQL is `postgres`.
- The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation.



To find the endpoint, port number, and DB name using the AWS Management Console

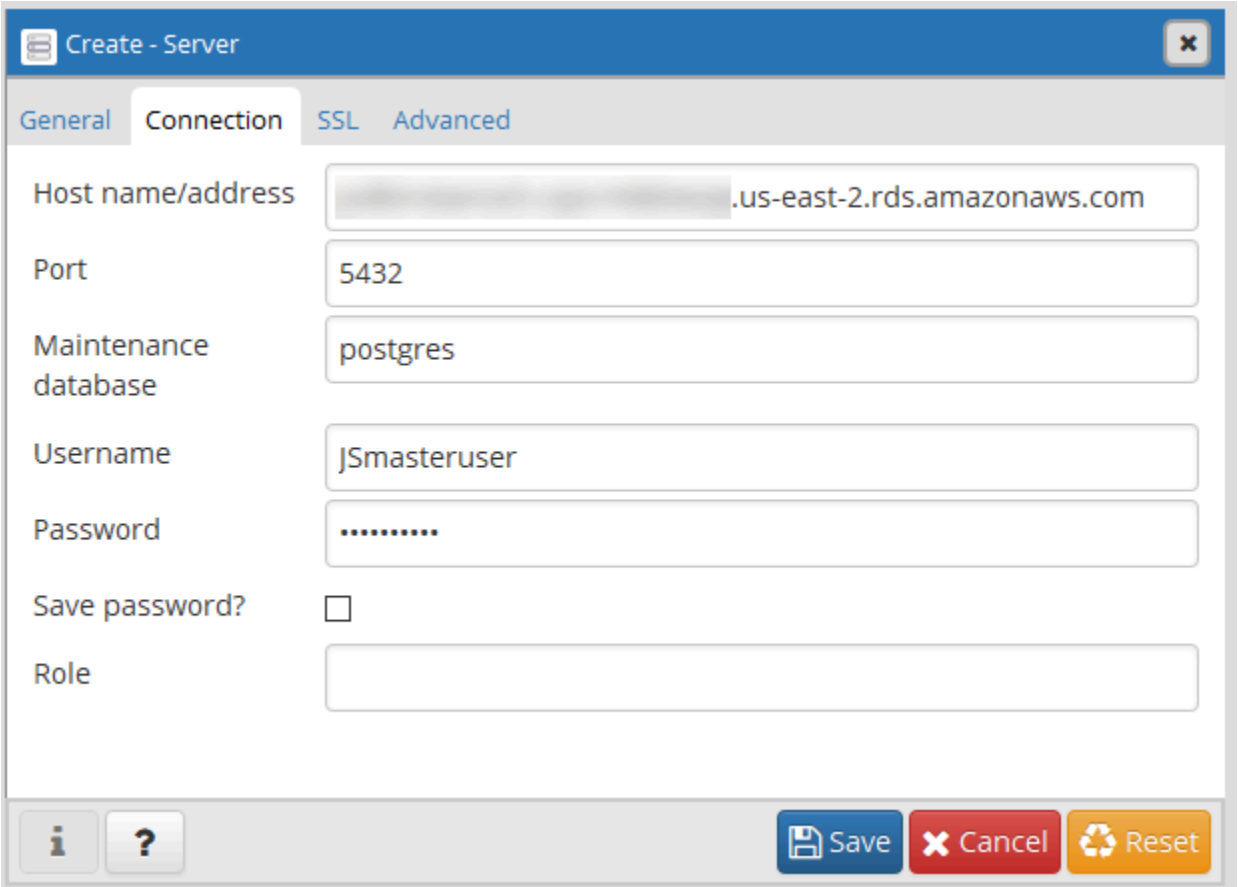
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Open the RDS console and then choose **Databases** to display a list of your DB instances.

3. Choose the PostgreSQL DB instance name to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn't create a database, the DB name displays a dash (-).

Following are two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. The second example uses psql, a command line utility that is part of a PostgreSQL installation.

Using pgAdmin to connect to a RDS for PostgreSQL DB instance

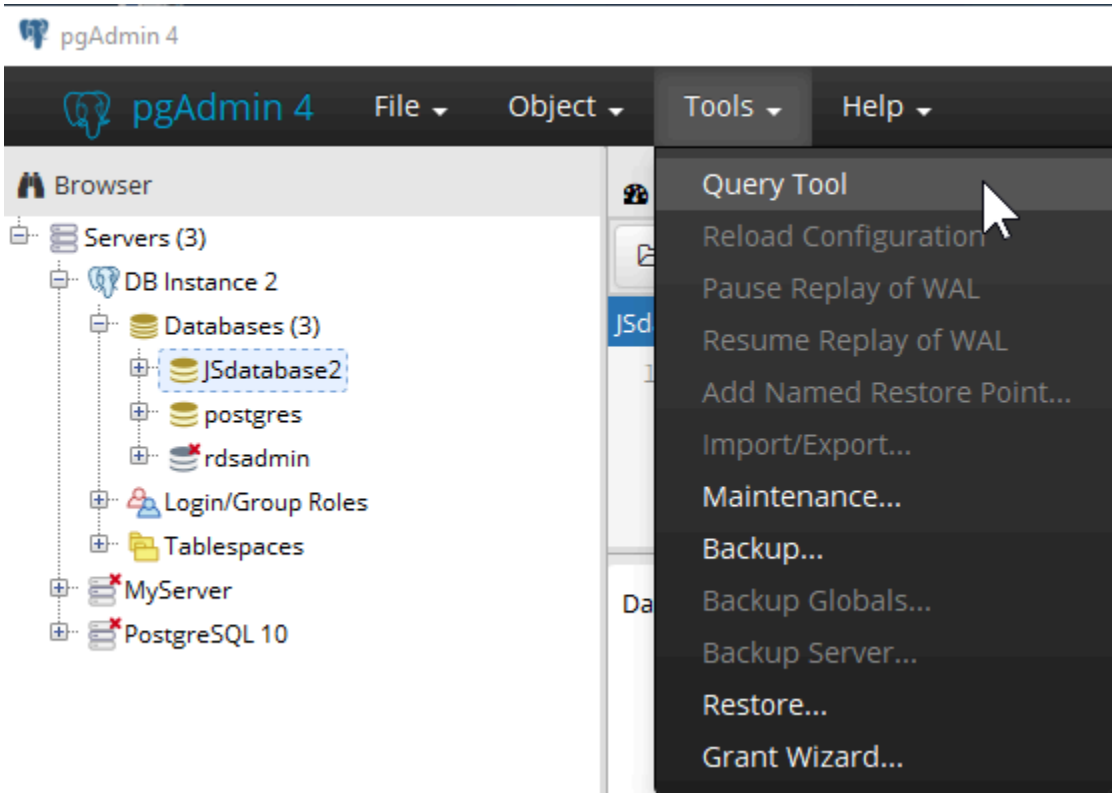


You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from http://www.pgadmin.org/ without having a local instance of PostgreSQL on your client computer.

To connect to your RDS for PostgreSQL DB instance using pgAdmin

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, type a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, type the following information from your DB instance:

   - For **Host**, type the endpoint, for example `mypostgresql.c6c8dntfzzhgv0.us-east-2.rds.amazonaws.com`.



- For **Port**, type the assigned port.
- For **Username**, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, `postgres`).
- For **Password**, type the password that you entered when you created the DB instance.

5. Choose **Save**.

   If you have any problems connecting, see [Troubleshooting connections to your RDS for PostgreSQL instance].

6. To access a database in the pgAdmin browser, expand **Servers**, the DB instance, and **Databases**. Choose the DB instance's database name.

7. To open a panel where you can enter SQL commands, choose **Tools**, **Query Tool**.

Using psql to connect to your RDS for PostgreSQL DB instance

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

You can download the PostgreSQL client from the PostgreSQL website. Follow the instructions specific to your operating system version to install psql.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the `--no-password` option. This option is set for the entire session.

> **Note**
>
> A connection attempt with `--no-password` fails when the server requires password authentication and a password is not available from other sources. For more information, see the psql documentation.

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the **postgres** database using the 'master username' and password.

For Unix, use the following format.

```
psql \
   --host=<DB instance endpoint> \
   --port=<port> \
   --username=<master username> \
   --password \
   --dbname=<database name>
```

For Windows, use the following format.

```
psql ^
   --host=<DB instance endpoint> ^
   --port=<port> ^
   --username=<master username> ^
   --password ^
   --dbname=<database name>
```

For example, the following command connects to a database called `mypgdb` on a PostgreSQL DB instance called `mypostgresql` using fictitious credentials.

```
psql --host=mypostgresql.c6c8mwvfdgv0.us-west-2.rds.amazonaws.com --port=5432 --
username=awsuser --password --dbname=mypgdb
```

Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community pgJDBC driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:postgresql://` to `jdbc:aws-wrapper:postgresql://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the Amazon Web Services (AWS) Python Driver GitHub repository.

Troubleshooting connections to your RDS for PostgreSQL instance

Topics

- Error – FATAL: database name does not exist
- Error – Could not connect to server: Connection timed out
- Errors with security group access rules

Error – FATAL: database *name* does not exist

If when trying to connect you receive an error like `FATAL: database name does not exist`, try using the default database name **postgres** for the `--dbname` option.

Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is `Could not connect to server: Connection timed out.` If you receive this error, check the following:

- Check that the host name used is the DB instance endpoint and that the port number used is correct.
- Make sure that the DB instance's public accessibility is set to **Yes** to allow external connections. To modify the **Public access** setting, see Modifying an Amazon RDS DB instance.
- Make sure that the user connecting to the database has CONNECT access to it. You can use the following query to provide connect access to the database.

```
GRANT CONNECT ON DATABASE database name TO username;
```

- Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

  To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the **Database port** setting, see Modifying an Amazon RDS DB instance.
- Check whether the port you're attempting to use is already occupied by a local instance of PostgreSQL or another service running on your computer. For example, if you have a local PostgreSQL database running on the same port (default is 5432), it might prevent a successful connection to the RDS for PostgreSQL DB instance. Make sure that the port is free, or try connecting with a different port number if possible.
- See also Errors with security group access rules.

Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC security group that authorizes connections. Check if the DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For **Source**, choosing **My IP** allows access to the DB instance from the IP address detected in your browser. For more information, see Provide access to your DB instance in your VPC by creating a security group.

Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see Controlling access with security groups.

Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see Data protection in Amazon RDS.

Topics

- Using SSL with a PostgreSQL DB instance
- Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. By default, RDS for PostgreSQL uses and expects all clients to connect using SSL/TLS, but you can also require it. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1, 1.2, and 1.3.

For general information about SSL support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see Configuring the client in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

Topics

- Connecting to a PostgreSQL DB instance over SSL
- Requiring an SSL connection to a PostgreSQL DB instance
- Determining the SSL connection status
- SSL cipher suites in RDS for PostgreSQL

Connecting to a PostgreSQL DB instance over SSL

To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .
2. Connect to your PostgreSQL DB instance over SSL.

   When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

   When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based and JDBC clients default to `prefer`.

   Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using `psql` to connect to a PostgreSQL DB instance using SSL with certificate verification.

```
$ psql "host=db-name.555555555555.ap-southeast-1.rds.amazonaws.com
    port=5432 dbname=testDB user=testuser sslrootcert=rds-ca-rsa2048-g1.pem
 sslmode=verify-full"
```

Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. The `rds.force_ssl` parameter default value is 1 (on) for RDS for PostgreSQL version 15 and later. For all other RDS for PostgreSQL major versions 14 and older, the default value of this parameter is 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance.

To change the value of this parameter, you need to create a custom DB parameter group. You then change the value for `rds.force_ssl` in your custom DB parameter group to 1 to turn on this feature. If you prepare the custom DB parameter group before creating your RDS for PostgreSQL DB instance you can choose it (instead of a default parameter group) during the creation process. If you do this after your RDS for PostgreSQL DB instance is already running, you need to reboot the instance so that your instance uses the custom parameter group. For more information, see Parameter groups for Amazon RDS.

When the `rds.force_ssl` feature is active on your DB instance, connection attempts that aren't using SSL are rejected with the following message:

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com port=5432 dbname=testDB
 user=testuser
psql: error: FATAL: no pg_hba.conf entry for host "w.x.y.z", user "testuser", database
 "testDB", SSL off
```

Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`.

```
postgres=> CREATE EXTENSION sslinfo;
CREATE EXTENSION
postgres=> SELECT ssl_is_used();
ssl_is_used
---------
t
(1 row)
```

For more detailed information, you can use the following query to get information from `pg_settings`:

```
SELECT name as "Parameter name", setting as value, short_desc FROM pg_settings WHERE
 name LIKE '%ssl%';
             Parameter name             |                  value                  |
                  short_desc
----------------------------------------+-----------------------------------------
+-------------------------------------------------
 ssl                                    | on                                      |
 Enables SSL connections.
 ssl_ca_file                            | /rdsdbdata/rds-metadata/ca-cert.pem     |
 Location of the SSL certificate authority file.
 ssl_cert_file                          | /rdsdbdata/rds-metadata/server-cert.pem |
 Location of the SSL server certificate file.
 ssl_ciphers                            | HIGH:!aNULL:!3DES                       |
 Sets the list of allowed SSL ciphers.
 ssl_crl_file                           |                                         |
 Location of the SSL certificate revocation list file.
 ssl_dh_params_file                     |                                         |
 Location of the SSL DH parameters file.
 ssl_ecdh_curve                         | prime256v1                              |
 Sets the curve to use for ECDH.
 ssl_key_file                           | /rdsdbdata/rds-metadata/server-key.pem  |
 Location of the SSL server private key file.
 ssl_library                            | OpenSSL                                 |
 Name of the SSL library.
 ssl_max_protocol_version               |                                         |
 Sets the maximum SSL/TLS protocol version to use.
 ssl_min_protocol_version               | TLSv1.2                                 |
 Sets the minimum SSL/TLS protocol version to use.
 ssl_passphrase_command                 |                                         |
 Command to obtain passphrases for SSL.
 ssl_passphrase_command_supports_reload | off                                     |
 Also use ssl_passphrase_command during server reload.
 ssl_prefer_server_ciphers              | on                                      |
 Give priority to server ciphersuite order.
(14 rows)
```

You can also collect all the information about your RDS for PostgreSQL DB instance's SSL usage by process, client, and application by using the following query:

```
SELECT datname as "Database name", usename as "User name", ssl, client_addr,
 application_name, backend_type
   FROM pg_stat_ssl
   JOIN pg_stat_activity
```

```
   ON pg_stat_ssl.pid = pg_stat_activity.pid
   ORDER BY ssl;
 Database name | User name | ssl |  client_addr   |    application_name    |
 backend_type
---------------+-----------+-----+----------------+------------------------
+-----------------------------
               |           | f   |                |                        | autovacuum
 launcher
               | rdsadmin  | f   |                |                        | logical
 replication launcher
               |           | f   |                |                        | background
 writer
               |           | f   |                |                        |
 checkpointer
               |           | f   |                |                        | walwriter
 rdsadmin      | rdsadmin  | t   | 127.0.0.1      |                        | client
 backend
 rdsadmin      | rdsadmin  | t   | 127.0.0.1      | PostgreSQL JDBC Driver | client
 backend
 postgres      | postgres  | t   | 204.246.162.36 | psql                   | client
 backend
(8 rows)
```

To identify the cipher used for your SSL connection, you can query as follows:

```
postgres=> SELECT ssl_cipher();
ssl_cipher
--------------------
DHE-RSA-AES256-SHA
(1 row)
```

To learn more about the `sslmode` option, see Database connection control functions in the *PostgreSQL documentation*.

SSL cipher suites in RDS for PostgreSQL

The PostgreSQL configuration parameter ssl_ciphers specifies the categories of cipher suites that are allowed for SSL connections to the database when using TLS 1.2 and lower.

In RDS for PostgreSQL 16 and later, you can modify the `ssl_ciphers` parameter to use specific values from the allowlisted cipher suites. This is a dynamic parameter that doesn't require a

database instance reboot. To view the allowlisted cipher suites, use either the Amazon RDS console or the following AWS CLI command:

```
aws rds describe-db-parameters --db-parameter-group-name <your-parameter-group> --
region <region> --endpoint-url <endpoint-url> --output json | jq '.Parameters[] |
 select(.ParameterName == "ssl_ciphers")'
```

The following table lists both the default cipher suites and the allowed cipher suites for versions that support custom configurations.

PostgreSQL engine version	Default ssl_cipher suite values	Allowlisted custom ssl_cipher suite values
18	HIGH:!aNULL:!3DES	TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
17	HIGH:!aNULL:!3DES	TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256

PostgreSQL engine version	Default ssl_cipher suite values	Allowlisted custom ssl_cipher suite values
		TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
16	HIGH:!aNULL:!3DES	TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
15	HIGH:!aNULL:!3DES	Custom ssl_ciphers isn't supported
14	HIGH:!aNULL:!3DES	Custom ssl_ciphers isn't supported
13	HIGH:!aNULL:!3DES	Custom ssl_ciphers isn't supported
12	HIGH:!aNULL:!3DES	Custom ssl_ciphers isn't supported

PostgreSQL engine version	Default ssl_cipher suite values	Allowlisted custom ssl_cipher suite values
11.4 and higher minor versions	`HIGH:MEDIUM:+3DES:!aNULL:!RC4`	Custom ssl_ciphers isn't supported
11.1, 11.2	`HIGH:MEDIUM:+3DES:!aNULL`	Custom ssl_ciphers isn't supported
10.9 and higher minor versions	`HIGH:MEDIUM:+3DES:!aNULL:!RC4`	Custom ssl_ciphers isn't supported
10.7 and lower minor versions	`HIGH:MEDIUM:+3DES:!aNULL`	Custom ssl_ciphers isn't supported

To configure all instance connections to use the `TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384` cipher suite, modify your parameter group as shown in the following example:

```
aws rds modify-db-parameter-group --db-parameter-group-name <your-parameter-group> --
parameters
 "ParameterName='ssl_ciphers',ParameterValue='TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384',ApplyMet
```

This example uses an ECDSA cipher, which requires your instance to use a certificate authority with elliptic curve cryptography (ECC) to establish a connection. For information about certificate authorities provided by Amazon RDS, see Certificate authorities.

You can verify the ciphers in use through the methods described in Determining the SSL connection status.

Ciphers may have different names depending on the context:

- The allowlisted ciphers that you can configure in your parameter group are referred to with their IANA names.
- The `sslinfo` and `psql` logon banner refer to ciphers using their OpenSSL names.

By default, the value of `ssl_max_protocol_version` in RDS for PostgreSQL 16 and later is TLS v1.3. You must set the value of this parameter to TLS v1.2 as TLS v1.3 doesn't use the cipher

configurations specified in the `ssl_ciphers` parameter. When you set the value as TLS v1.2, connections use only the ciphers that you define in `ssl_ciphers`.

```
aws rds modify-db-parameter-group --db-parameter-group-name <your-parameter-group> --
parameters
 "ParameterName='ssl_max_protocol_version',ParameterValue='TLSv1.2',ApplyMethod=immediate"
```

To ensure database connections use SSL, set the `rds.force_ssl parameter` to 1 in your parameter group. For more information about parameters and parameter groups, see Parameter groups for Amazon RDS.

Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB instance. You also find information about how to check if those applications verify the server certificate when they connect.

> **Note**
>
> A client application that's configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client's trust store. Update the client trust store when necessary for new certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . For information about using SSL/TLS with PostgreSQL DB instances, see Using SSL with a PostgreSQL DB instance.

Topics

- Determining whether applications are connecting to PostgreSQL DB instances using SSL
- Determining whether a client requires certificate verification in order to connect
- Updating your application trust store
- Using SSL/TLS connections for different types of applications

Determining whether applications are connecting to PostgreSQL DB instances using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to `0` (off) for DB instances using PostgreSQL versions before version 15. By default, `rds.force_ssl` is set to 1 (on) for DB instances using PostgreSQL version 15 and later major versions. If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Parameter groups for Amazon RDS.

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
SELECT datname, usename, ssl, client_addr
  FROM pg_stat_ssl INNER JOIN pg_stat_activity ON pg_stat_ssl.pid =
 pg_stat_activity.pid
  WHERE ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
 datname  | usename | ssl | client_addr
----------+---------+-----+-------------
 benchdb  | pgadmin | t   | 53.95.6.13
 postgres | pgadmin | t   | 53.95.6.13
(2 rows)
```

This query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used for both libpq-based clients (such as psql) and JDBC is set to `prefer`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `verify-ca` or `verify-full`. An error is thrown if the certificate is invalid.

Use PGSSLROOTCERT to verify the certificate with the PGSSLMODE environment variable, with PGSSLMODE set to `verify-ca` or `verify-full`.

```
PGSSLMODE=verify-full PGSSLROOTCERT=/fullpath/ssl-cert.pem psql -h
 pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U masteruser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `verify-ca` or `verify-full` to verify the certificate.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full
 sslrootcert=/full/path/ssl-cert.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see Secure TCP/IP connections with SSL in the PostgreSQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

> **Note**
>
> When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**

  JDBC enables database connections with Java applications.

  For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL JDBC driver documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL JDBC driver documentation.

- **Python**

  A popular Python library for connecting to PostgreSQL databases is `psycopg2`.

For information about using psycopg2, see the psycopg2 documentation. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the connect command accepts in The psycopg2 module content.

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance or cluster.

Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. To do so, configure your DB instance to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with Directory Service. To learn more, see What is Directory Service? in the *AWS Directory Service Administration Guide*.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB instance the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use password authentication or password authentication with either Kerberos or AWS Identity and Access Management (IAM) authentication. For more information about IAM authentication, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.

> **Note**
>
> RDS for PostgreSQL doesn't support Kerberos authentication for Active Directory groups.

Topics

- Region and version availability
- Overview of Kerberos authentication for PostgreSQL DB instances
- Setting up Kerberos authentication for PostgreSQL DB instances

- Managing an RDS for PostgreSQL DB instance in an Active Directory domain
- Connecting to PostgreSQL with Kerberos authentication

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for PostgreSQL with Kerberos authentication, see Supported Regions and DB engines for Kerberos authentication in Amazon RDS.

Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.
2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the *IAM User Guide*.
3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the *Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the *Amazon VPC Peering Guide*.
5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:

- Creating an Amazon RDS DB instance
- Modifying an Amazon RDS DB instance
- Restoring to a DB instance
- Restoring a DB instance to a specified time for Amazon RDS

You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:

- Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for PostgreSQL DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

Topics

- Step 1: Create a directory using AWS Managed Microsoft AD
- Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and Directory Service
- Step 3: Create an IAM role for Amazon RDS to access the Directory Service
- Step 4: Create and configure users
- Step 5: Enable cross-VPC traffic between the directory and the DB instance
- Step 6: Create or modify a PostgreSQL DB instance
- Step 7: Create PostgreSQL users for your Kerberos principals
- Step 8: Configure a PostgreSQL client

Step 1: Create a directory using AWS Managed Microsoft AD

Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name `Admin` and the specified password. You use this account to manage your directory.

  > **Important**
  >
  > Make sure to save this password. Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `Admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin

- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The `Admin` account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. In the Directory Service console navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

   Edition

   Choose the edition that meets your requirements.

   Directory DNS name

   The fully qualified name for the directory, such as **`corp.example.com`**.

   Directory NetBIOS name

   An optional short name for the directory, such as `CORP`.

   Directory description

   An optional description for the directory.

   Admin password

   The password for the directory administrator. The directory creation process creates an administrator account with the user name `Admin` and this password.

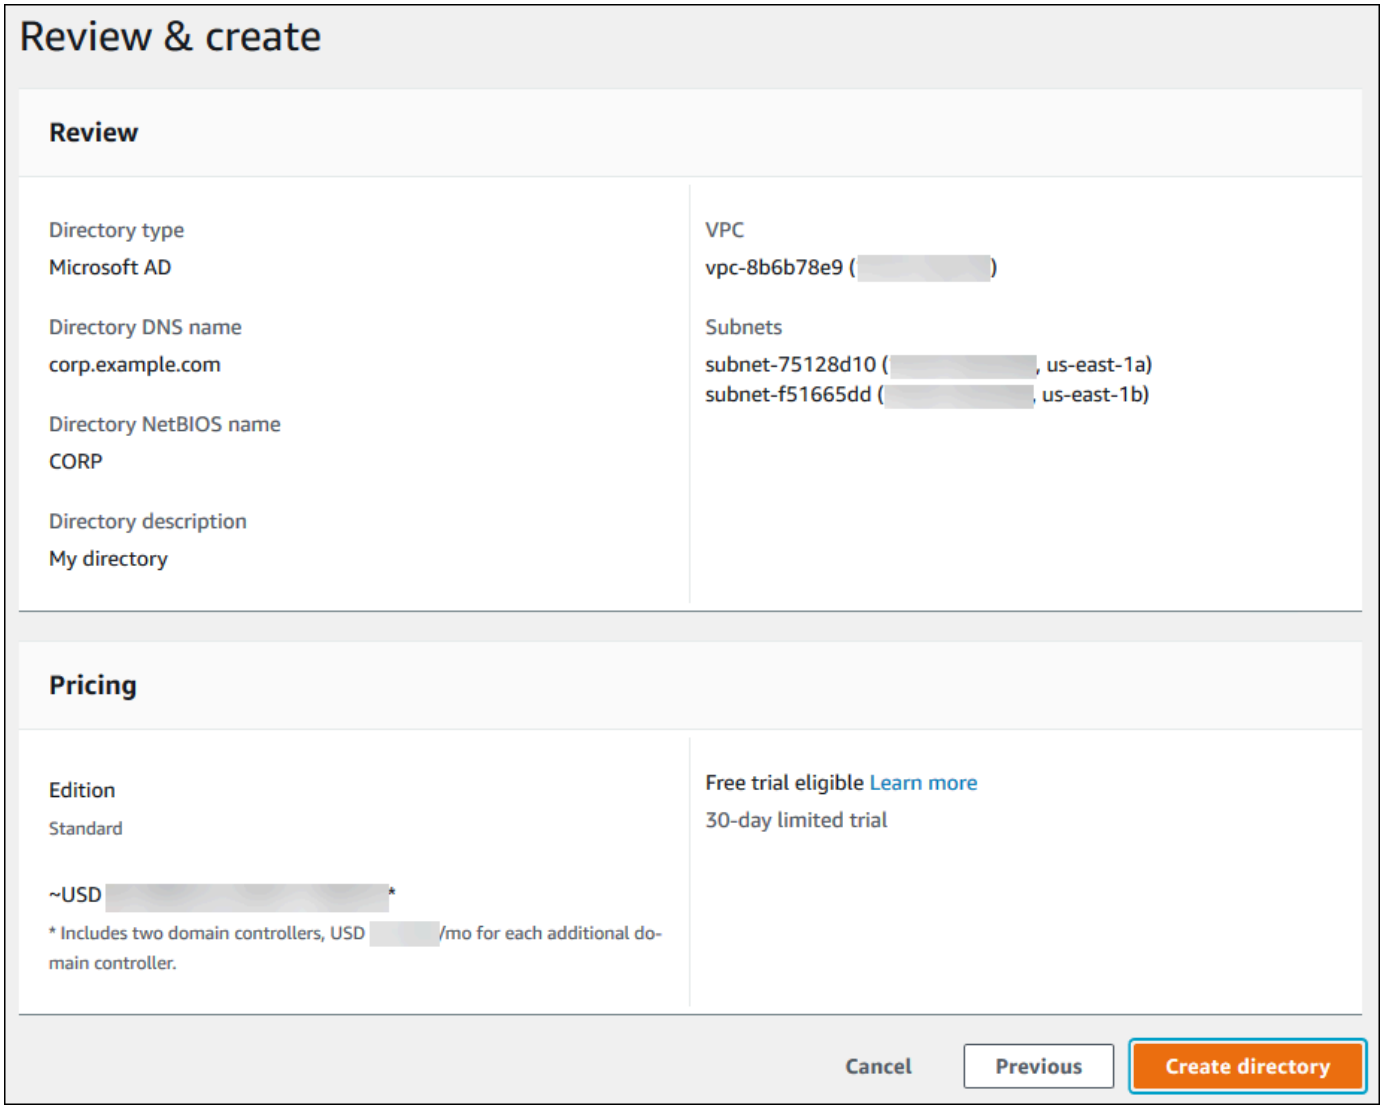
The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!@#$%^&*_-+=`|\(){}[]:;"'<>,.?/)

Confirm password

Retype the administrator password.

> **Important**
>
> Make sure that you save this password. Directory Service doesn't store this password, and it can't be retrieved or reset.



5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

   VPC

   Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

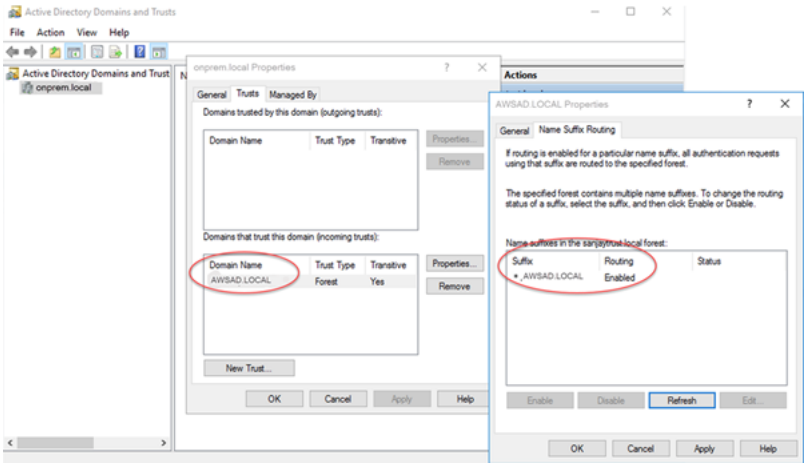
   Subnets

   Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.
7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.

Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and Directory Service



If you don't plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon RDS to access the Directory Service.

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD). The trust can be one-way, where the AWS Managed Microsoft

AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using Directory Service, see When to create a trust relationship in the *AWS Directory Service Administration Guide*.

> **Note**
>
> If you use an on-premises Microsoft Active Directory, Windows clients connect using the domain name of the Directory Service in the endpoint rather than rds.amazonaws.com. To learn more, see Connecting to PostgreSQL with Kerberos authentication.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for Amazon RDS to access the Directory Service

For Amazon RDS to call Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Note**
>
> The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

As an alternative to using the `AmazonRDSDirectoryServiceAccess` managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
```

```
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
    "Effect": "Allow",
    "Resource": "*"
    }
  ]
}
```

For opt-in AWS Regions, use Region-specific service principals in IAM role trust policies. When you create a trust policy for services in these Regions, specify the Region code in the service principal.

The following example shows a trust policy that includes Region-specific service principals:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.REGION-CODE.amazonaws.com",
          "rds.REGION-CODE.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Replace REGION-CODE with the code for your specific Region. For example, use the following service principals for the Asia Pacific (Melbourne) Region:

```
"Service": [
  "directoryservice.rds.ap-southeast-4.amazonaws.com",
  "rds.ap-southeast-4.amazonaws.com"
]
```

Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see Add Users and Computers to the Active Directory domain in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the *AWS Directory Service Administration Guide*.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB instance.

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

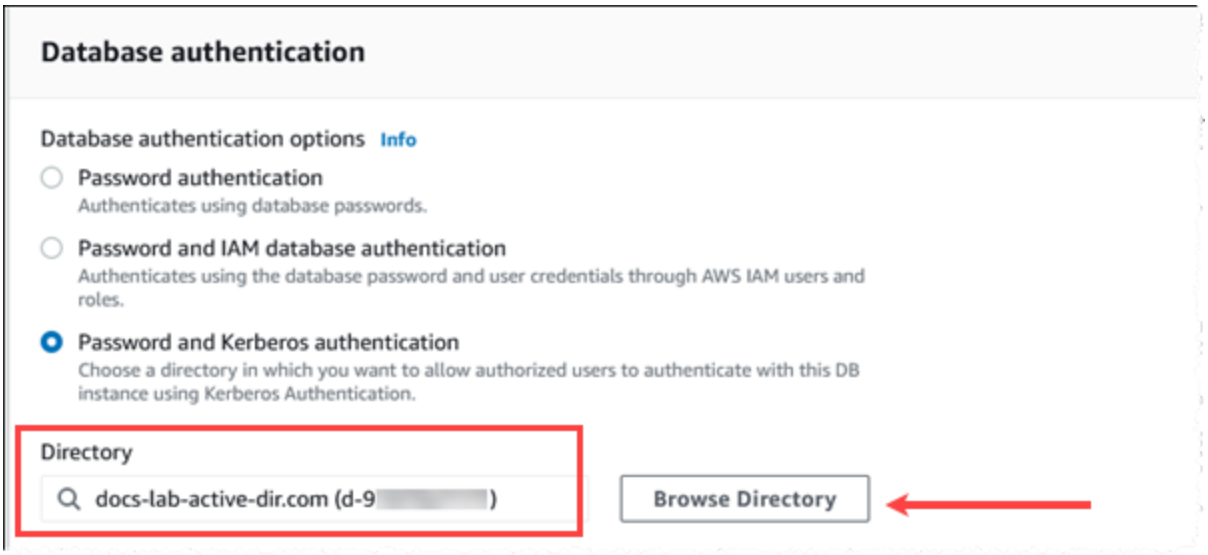
1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the *Directory Service Administration Guide*.
2. Sign in to the Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify a PostgreSQL DB instance



Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation. For instructions, see Creating an Amazon RDS DB instance.
- Modify an existing PostgreSQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation. For instructions, see Modifying an Amazon RDS DB instance.
- Restore a PostgreSQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation. For instructions, see Restoring to a DB instance.
- Restore a PostgreSQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation. For instructions, see Restoring a DB instance to a specified time for Amazon RDS.

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.

AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

> **Important**
>
> If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your RDS for PostgreSQL DB instance is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in Step 4: Create and configure users need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your RDS for PostgreSQL DB instance, you use `postgres`, as shown in the following steps.

To create PostgreSQL database users for Kerberos principals

1. Use `psql` to connect to your RDS for PostgreSQL DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --
port=5432 --username=postgres --password
```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case `alias` (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

```
postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
CREATE ROLE
```

3. Grant the `rds_ad` role to the database user.

```
postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
GRANT ROLE
```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the RDS for PostgreSQL DB instance by using their Kerberos credentials.

It's required that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.

Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.

Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```
[libdefaults]
 default_realm = EXAMPLE.COM
[realms]
 EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
 }
[domain_realm]
 .example.com = EXAMPLE.COM
 example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
 default_realm = EXAMPLE.COM
[realms]
 EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
 }
 ONPREM.COM = {
```

```
  kdc = onprem.com
  admin_server = onprem.com
 }
[domain_realm]
 .example.com = EXAMPLE.COM
 example.com = EXAMPLE.COM
 .onprem.com = ONPREM.COM
 onprem.com = ONPREM.COM
 .rds.amazonaws.com = EXAMPLE.COM
 .amazonaws.com.cn = EXAMPLE.COM
 .amazon.com = EXAMPLE.COM
```

Managing an RDS for PostgreSQL DB instance in an Active Directory domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the modify-db-instance CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the modify-db-instance CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the modify-db-instance CLI command. Specify the domain identifier of the new domain for the `--domain` option.

Understanding Domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.

- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

> **Note**
>
> Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see Using a custom DNS server for outbound network access.

Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see Connecting to a DB instance running the PostgreSQL database engine . For information about obtaining the endpoint, port number, and other details needed for connection, see Connect to a PostgreSQL DB instance.

> **Note**
>
> GSSAPI authentication and encryption in PostgreSQL are implemented by the Kerberos library `libkrb5.so`. Features such as `postgres_fdw` and `dblink` also rely on this same library for outbound connections with Kerberos authentication or encryption.

pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your RDS for PostgreSQL database.
   - For **Host**, enter the endpoint for the RDS for PostgreSQL DB instance. An endpoint looks similar to the following:

     ```
     RDS-DB-instance.111122223333.aws-region.rds.amazonaws.com
     ```

     To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of `rds.amazonaws.com` in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, the endpoint would be specified as follows:

     ```
     RDS-DB-instance.111122223333.aws-region.corp.example.com
     ```

   - For **Port**, enter the assigned port.
   - For **Maintenance database**, enter the name of the initial database to which the client will connect.
   - For **Username**, enter the user name that you entered for Kerberos authentication in Step 7: Create PostgreSQL users for your Kerberos principals.
5. Choose **Save**.

Psql

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   ```
   kinit username
   ```

   Replace *username* with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put IP address for your DB instance endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the IP address and then put it in the `/etc/hosts` file.

   ```
   % dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
   ;; Truncated, retrying in TCP mode.
   ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
   34.210.197.118

   % echo " 34.210.197.118  PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/
   hosts
   ```

   If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

   For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format *PostgreSQL-endpoint.AWS-Region.corp.example.com* for the endpoint and put it in the `/etc/hosts` file.

   ```
   % echo " 34.210.197.118  PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/
   hosts
   ```

3. Use the following psql command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

   ```
   psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-
   Region.rds.amazonaws.com postgres
   ```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following psql command with the domain name from the previous step (`corp.example.com`):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-
Region.corp.example.com postgres
```

Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

Topics

- Turning on custom DNS resolution
- Turning off custom DNS resolution
- Setting up a custom DNS server

Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the `rds.custom_dns_resolution` parameter by setting it to 1, and then restart the DB instance for the changes to take place.

Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the `rds.custom_dns_resolution` parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

> **Note**
>
> If you don't set up a custom DNS server and `rds.custom_dns_resolution` is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see Working with private hosted zones.

To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.

   > **Note**
   >
   > The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.
5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53.

   For more information, see Security groups for your VPC and Adding and removing rules.
6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

   For more information, see Security groups for your VPC and Adding and removing rules in the *Amazon VPC User Guide*.
7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.

Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see What is VPC peering? in *Amazon VPC Peering Guide*.

Upgrades of the RDS for PostgreSQL DB engine

There are two types of upgrades that you can manage for your PostgreSQL database:

- Operating system updates – Occasionally, Amazon RDS might need to update the underlying operating system of your database to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see Applying updates to a DB instance .
- Database engine upgrades – When Amazon RDS supports a new version of a database engine, you can upgrade your databases to the new version.

A *database* in this context is an RDS for PostgreSQL DB instance or Multi-AZ DB cluster.

There are two kinds of engine upgrades for PostgreSQL databases: major version upgrades and minor version upgrades.

Major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your databases. You can initiate a major version upgrade by modifying your DB instance or Multi-AZ DB cluster. Before you perform a major version upgrade, we recommend that you follow the steps described in Choosing a major version for an RDS for PostgreSQL upgrade.

Amazon RDS handles Multi-AZ major version upgrades in the following ways:

- **Multi-AZ DB instance deployment** – Amazon RDS simultaneously upgrades the primary and any standby instances. Your database might not be available for several minutes while the upgrade completes.
- **Multi-AZ DB cluster deployment** – Amazon RDS simultaneously upgrades the reader and writer instances. Your database might not be available for several minutes while the upgrade completes.

If you upgrade a DB instance that has in-Region read replicas, Amazon RDS upgrades the replicas along with the primary DB instance.

Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas. If you perform a major version upgrade of a Multi-AZ DB cluster, then the replication state of its read replicas changes to

terminated. You must manually delete and recreate the read replicas after the upgrade completes.

> **Tip**
>
> You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see *Using Blue/Green Deployments for database updates*.

Minor version upgrades

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your database. Or, you can enable the **Auto minor version upgrade** option when you create or modify a database. Doing so means that Amazon RDS automatically upgrades your database after testing and approving the new version.

Amazon RDS handles Multi-AZ minor version upgrades in the following ways:

- **Multi-AZ DB instance deployment** – Amazon RDS simultaneously upgrades the primary and any standby instances. Your database might not be available for several minutes while the upgrade completes.
- **Multi-AZ DB cluster deployment** – Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance). Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, they can further reduce downtime to one second or less. For more information, see *Amazon RDS Proxy*. Alternately, you can use an open source database proxy such as ProxySQL, PgBouncer, or the AWS Advanced JDBC Wrapper Driver.

If your database has read replicas, you must first upgrade all of the read replicas before you upgrade the source instance or cluster.

For more information, see Automatic minor version upgrades for RDS for PostgreSQL. For information about manually performing a minor version upgrade, see Manually upgrading the engine version.

For more information about database engine versions and the policy for deprecating database engine versions, see Database Engine Versions in the Amazon RDS FAQs.

Topics

- Considerations for PostgreSQL upgrades
- Finding valid upgrade targets
- PostgreSQL version numbers
- RDS version numbers in RDS for PostgreSQL
- Choosing a major version for an RDS for PostgreSQL upgrade
- How to perform a major version upgrade for RDS for PostgreSQL
- Automatic minor version upgrades for RDS for PostgreSQL
- Upgrading PostgreSQL extensions in RDS for PostgreSQL databases
- Monitoring RDS for PostgreSQL engine upgrades with events

Considerations for PostgreSQL upgrades

To safely upgrade your databases, Amazon RDS uses the `pg_upgrade` utility described in the PostgreSQL documentation

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the database before any upgrade changes have been made. If the upgrade fails for your databases, you can restore this snapshot to create a database running the old version. The second DB snapshot is taken after the upgrade completes. These DB snapshots are deleted automatically once the backup retention period expires.

> **Note**
>
> Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your database to a number greater than 0. To change the backup retention period for a DB instance, see the section called “Modifying a DB instance”. You can't configure a custom backup retention period for a Multi-AZ DB cluster.

When you perform a major version upgrade of a DB instance, any in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the `pg_upgrade` to complete successfully on the primary DB instance. Then the primary DB instance

upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete. When you perform a major version upgrade of a Multi-AZ DB cluster, the replication state of its read replicas changes to **terminated**.

After an upgrade is complete, you can't revert to the previous version of the DB engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new database.

Finding valid upgrade targets

When you use the AWS Management Console to upgrade a database, it shows the valid upgrade targets for the database. You can also use the following AWS CLI command to identify the valid upgrade targets for a database:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version version-number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 16.1 database, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version 16.1 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version 16.1 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

PostgreSQL version numbers

The version numbering sequence for the PostgreSQL database engine is as follows:

- For PostgreSQL versions 10 and higher, the engine version number is in the form *major.minor*. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

  A major version upgrade increases the integer part of the version number, such as upgrading from 10.*minor* to 11.*minor*.
- For PostgreSQL versions lower than 10, the engine version number is in the form *major.major.minor*. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

  A major version upgrade increases the major part of the version number. For example, an upgrade from *9.6*.12 to 11.14 is a major version upgrade, where *9.6* and *11* are the major version numbers.

For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

RDS version numbers in RDS for PostgreSQL

RDS version numbers use the *major*.*minor*.*patch* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. For information about RDS Extended Support version numbering, see Amazon RDS Extended Support version naming.

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

Starting with the release of PostgreSQL version 15.2-R2, you can find out the RDS version number of your RDS for PostgreSQL database with the following SQL query:

```
postgres=> SELECT rds_tools.rds_version();
```

For example, querying an RDS for PostgreSQL 15.2 database returns the following:

```
rds_version
----------------
 15.2.R2
(1 row)
```

Choosing a major version for an RDS for PostgreSQL upgrade

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your database manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in How to perform a major version upgrade for RDS for PostgreSQL.

When you upgrade a PostgreSQL Single-AZ DB instance or Multi-AZ DB instance deployment to its next major version, any read replicas associated with the database are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in How to perform a major version upgrade for RDS for PostgreSQL.

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see Upgrading PostgreSQL extensions in RDS for PostgreSQL databases.

You can find out which major versions are available for your RDS for PostgreSQL database by running the following AWS CLI query:

```
aws rds describe-db-engine-versions --engine postgres  --engine-version your-version
 --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

The following table summarizes the results of this query for all available versions. An asterisk (*) on the version number means that version is no longer supported. If your current version is unsupported, we recommend that you upgrade to the newest minor version upgrade target or to one of the other available upgrade targets for that version.

Current source version	Upgrade targets
17.6	None
17.5	17.6
17.4	17.6, 17.5
17.3*, 17.2	17.6, 17.5, 17.4
17.1*	17.6, 17.5, 17.4, 17.2
16.10	17.6
16.9	17.6, 17.5 16.10

* This version is no longer supported.

How to perform a major version upgrade for RDS for PostgreSQL

We recommend the following process when performing a major version upgrade on an Amazon RDS for PostgreSQL database:

1. **Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see the section called "Parameter groups" and the section called "DB cluster parameter groups".
2. **Check for unsupported database classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see Supported DB engines for DB instance classes.
3. **Check for unsupported usage:**
   - **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.

     You can use the following query to verify that there are no open prepared transactions on your database.

     ```
     SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
     ```

   - **Reg* data types** – Remove all uses of the *reg** data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the *reg** data types. The `pg_upgrade` utility can't persist this data type, which is used by Amazon RDS to do the upgrade.

     To verify that there are no uses of unsupported *reg** data types, use the following query for each database.

     ```
     SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
      pg_catalog.pg_attribute a
       WHERE c.oid = a.attrelid
           AND NOT a.attisdropped
           AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
                              'pg_catalog.regprocedure'::pg_catalog.regtype,
                              'pg_catalog.regoper'::pg_catalog.regtype,
                              'pg_catalog.regoperator'::pg_catalog.regtype,
                              'pg_catalog.regconfig'::pg_catalog.regtype,
                              'pg_catalog.regdictionary'::pg_catalog.regtype)
           AND c.relnamespace = n.oid
           AND n.nspname NOT IN ('pg_catalog', 'information_schema');
     ```

4. **Check for invalid databases:**

- Ensure there are no invalid databases. The `datconnlimit` column in the `pg_database` catalog includes a value of `-2` to mark databases as invalid that were interrupted during a `DROP DATABASE` operation.

  Use the following query to check for invalid databases:

  ```
  SELECT datname FROM pg_database WHERE datconnlimit = - 2;
  ```

- The previous query returns invalid database names. You can use `DROP DATABASE` *`invalid_db_name`*`;` to drop invalid databases. You can also use the following command to drop invalid databases:

  ```
  SELECT 'DROP DATABASE ' || quote_ident(datname) || ';' FROM pg_database WHERE
   datconnlimit = -2 \gexec
  ```

  For more information about invalid databases, see Understanding the behavior of autovacuum with invalid databases.

5. **Handle logical replication slots** – An upgrade can't occur if the database has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.

   If the logical replication slots aren't needed, you can delete them using the following SQL:

   ```
   SELECT * FROM pg_replication_slots WHERE slot_type NOT LIKE 'physical';
   SELECT pg_drop_replication_slot(slot_name);
   ```

   Logical replication setups that use the `pglogical` extension also need to have slots dropped for a successful major version upgrade. For information about how to identify and drop slots created using the `pglogical` extension, see Managing logical replication slots for RDS for PostgreSQL.

   On source version 17 and later, logical replication slots on non-read-replicas can be retained through upgrades. Logical replication slots created on read replicas are not retained through upgrades.

Ensure that all transactions and logical decoding messages have been consumed from the slot before initiating the upgrade. If there are unconsumed write-ahead log files (WAL) held by logical replication slots, the upgrade will fail with a message identifying the problem slots. See the PostgreSQL documentation for further details.

On Multi-AZ clusters with source versions earlier than 17.8 or 18.2, ensure that `flow_control` is disabled. For more information, see Turning on and turning off flow control for Multi-AZ DB clusters. You can turn off flow control by removing the extension from the `shared_preload_libraries` and rebooting your DB instance.

6. **Handle read replicas** – An upgrade of a Single-AZ DB instance or Multi-AZ DB instance deployment also upgrades the in-Region read replicas along with the primary DB instance. Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas.

   You can't upgrade read replicas separately. If you could, it could lead to situations where the primary and replica databases have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

   The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica. For more information about read replicas, see Working with read replicas for Amazon RDS for PostgreSQL.

7. **Handle large objects** – In PostgreSQL, large objects (also known as BLOBs) are used to store and manage large binary objects (like files, images, videos, etc.) that are larger than the maximum size allowed for regular column data types. For more information see PostgreSQL Large Objects documentation.

   An upgrade can run out of memory and fail if there are millions of large objects and the instance cannot handle them during an upgrade. The PostgreSQL major version upgrade process comprises of two broad phases: dumping the schema via pg_dump and restoring it through pg_restore. If your database has millions of large objects you need to ensure your instance has sufficient memory to handle the pg_dump and pg_restore during an upgrade and scale it to a larger instance type.

   Before you begin an upgrade, check if your database is having any large objects. The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large

object data is stored in `pg_largeobject`. Use the following query to check for the number of large objects:

```
SELECT count(*) FROM pg_largeobject_metadata;
```

To cleanup existing large objects or orphaned large objects, see Managing large objects with the lo module.

When planning a major version upgrade, we recommend using an instance type with at least 32 GB of memory if your database contains 25 to 30 million large objects. This recommendation is based on our tests and can vary depending on your specific workload and database configuration. If your database includes additional objects (such as tables, indexes, or materialized views), we recommend selecting a larger instance type to ensure optimal performance during the upgrade process.

8. **Handle zero-ETL integrations** – If you have an existing zero-ETL integration, delete it before performing a major version upgrade. Then, after completing the upgrade, recreate the integration.

   On source versions majors 17 and up, the zero-ETL integration can be retained through the upgrade.

9. **Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your database before and after upgrading. To change your backup retention period, see Modifying an Amazon RDS DB instance and the section called "Modifying a Multi-AZ DB cluster".

   To perform a backup manually, see the section called "Creating a DB snapshot for a Single-AZ DB instance" and the section called "Creating a Multi-AZ DB cluster snapshot".

10. **Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions *before* performing the major version upgrade. For example, upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include PostGIS and related extensions for processing spatial data.

    - `address_standardizer`
    - `address_standardizer_data_us`
    - `postgis_raster`

- `postgis_tiger_geocoder`
- `postgis_topology`

You cannot directly upgrade to PostgreSQL version 17 if you are using `rdkit` version 4.6.0 and lower, and PostgreSQL version 16 and lower, due to `rdkit` incompatibility. Below are the upgrade options:

- If you are on PostgreSQL version 13 and lower, you need to perform a major version upgrade to version 14.14 and higher 14 versions, 15.9 and higher 15 versions, or 16.5 and higher 16 versions first, and then perform the version upgrade to PostgreSQL 17.
- If you are on PostgreSQL version 14, 15, or 16, you need to perform a minor version upgrade to 14.14 and higher 14 versions, 15.9 and higher 15 versions, or 16.5 and higher 16 versions, and then upgrade to PostgreSQL version 17.

Run the following command for each extension that you're using:

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
```

For more information, see Upgrading PostgreSQL extensions in RDS for PostgreSQL databases. To learn more about upgrading PostGIS, see Step 6: Upgrade the PostGIS extension.

11 **Drop certain extensions before the major version upgrade** – Extensions that are not supported on the target version must be dropped, or else the upgrade will fail.

The `plrust` extension is removed starting in RDS PostgreSQL 18. The `postgis_topology` extension is unavailable on RDS PostgreSQL versions 18.1 and 18.2 due to known issues [1], [2]. These extensions must be removed prior to upgrading.

An upgrade that skips a major version to version 11.x doesn't support updating the `pgRouting` extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skips a major version. It's safe to drop the `pgRouting` extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see Supported PostgreSQL extension versions.

The `tsearch2` and `chkpass` extensions are no longer supported for PostgreSQL versions 11 or later.

You can check if an extension is installed with the following query:

```
SELECT * FROM pg_extension WHERE extname in ('extension_name');
```

12 **Drop unknown data types** – Drop unknown data types depending on the target version.

PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following:

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:
The instance could not be upgraded because the 'unknown' data type is used in user
 tables.
Please remove all usages of the 'unknown' data type and try again."
```

To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:

```
SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE
 'unknown';
```

13 **Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. You can monitor the execution plans on the duplicate test database for any possible execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time.

For more information, see the section called “Restoring from a snapshot” or the section called “Point-in-time recovery”. For Multi-AZ DB clusters, see the section called “Restoring from a snapshot to a Multi-AZ DB cluster” or the section called “Restoring a Multi-AZ DB cluster to a specified time”.

For details on performing the upgrade, see the section called “Manually upgrading the engine version”.

In upgrading a version 9.6 database to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism *before* the upgrade by changing the `max_parallel_workers_per_gather` parameter on your test database to 2.

> **Note**
>
> The default value for `max_parallel_workers_per_gather` parameter in the `default.postgresql10` DB parameter group is 2.

For more information, see Parallel Query in the PostgreSQL documentation. To disable parallelism on version 10, set the `max_parallel_workers_per_gather` parameter to 0.

During the major version upgrade, the `public` and `template1` databases and the `public` schema in every database are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as `locale` and `owner` are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.

> **Note**
>
> During the major version upgrade process, you can't do a point-in-time restore of your DB instance or Multi-AZ DB cluster. After Amazon RDS performs the upgrade, it takes an automatic backup of the database. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your database has completed.

14 **If an upgrade fails with precheck procedure errors, resolve the issues** – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named `pg_upgrade_precheck.log` for all the databases of a database. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see Monitoring Amazon RDS log files.

If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
-------------------------------------------------------------------------
Upgrade could not be run on Wed Apr 4 18:30:52 2018
-------------------------------------------------------------------------
The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the
 requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared
 transactions.* One or more role names start with 'pg_'. Rename all role names that
 start with 'pg_'.

* The following issues in the database 'my"million$"db' need to be corrected before
 upgrading:** The ["line","reg*"] data types are used in user tables. Remove all
 usage of these data types.
** The database name contains characters that are not supported by RDS for
 PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target
 database version. Drop the following extensions from your database: ["tsearch2"].

* The following issues in the database 'mydb' need to be corrected before
 upgrading:** The database has views or materialized views that depend on
 'pg_stat_activity'. Drop the views.
```

15 **If a read replica upgrade fails while upgrading the database, resolve the issue** – A failed read replica is placed in the `incompatible-restore` state and replication is terminated on the database. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

> **Note**
>
> Amazon RDS doesn't upgrade read replicas for Multi-AZ DB clusters. If you perform a major version upgrade on a Multi-AZ DB cluster, then the replication state of its read replicas changes to **terminated**.

A read replica upgrade might fail for the following reasons:

- It was unable to catch up with the primary DB instance even after a wait time.

- It was in a terminal or incompatible lifecycle state such as storage-full, incompatible-restore, and so on.
- When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.
- The read replica used incompatible parameters.
- The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

16. **Upgrade your production database** – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Manually upgrading the engine version.

17. Run the ANALYZE operation to refresh the `pg_statistic` table. You should do this for every database on all your PostgreSQL databases. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

```
ANALYZE VERBOSE;
```

The VERBOSE flag is optional, but using it shows you the progress. For more information, see ANALYZE in the PostgreSQL documentation.

When analyzing specific tables instead of using ANALYZE VERBOSE, run the ANALYZE command for each table as follows:

```
ANALYZE table_name;
```

For partitioned tables, always analyze the parent table. This process:

- Automatically samples rows across all partitions
- Updates statistics for each partition recursively
- Maintains essential planning statistics at the parent level

While parent tables store no actual data, analyzing them is vital for query optimization. Running ANALYZE only on individual partitions can lead to poor query performance since the optimizer won't have the comprehensive statistics needed for efficient cross-partition planning.

> **Note**
>
> Run ANALYZE on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see Upgrading PostgreSQL extensions in RDS for PostgreSQL databases.
- Optionally, use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Monitoring Amazon RDS log files.

  You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs.
- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

Automatic minor version upgrades for RDS for PostgreSQL

If you enable the **Auto minor version upgrade** option when creating or modifying a DB instance or Multi-AZ DB cluster, you can have your database automatically upgraded.

Amazon RDS also supports upgrade rollout policy to manage automatic minor version upgrades across multiple database resources and AWS accounts. For more information, see Using AWS Organizations upgrade rollout policy for automatic minor version upgrades.

For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version

- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine postgres \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine postgres ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 16.1 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine postgres \
--engine-version 16.1 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
```

```
--engine postgres ^
--engine-version 16.1 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
---------------------------------
|    DescribeDBEngineVersions    |
+--------------+-----------------+
|  AutoUpgrade |  EngineVersion  |
+--------------+-----------------+
|  False       |  16.2           |
|  True        |  16.3           |
|  False       |  16.4           |
|  False       |  16.5           |
|  False       |  16.6           |
|  False       |  17.1           |
|  False       |  17.2           |
+--------------+-----------------+
```

In this example, the `AutoUpgrade` value is `True` for PostgreSQL version 16.3. So, the automatic minor upgrade target is PostgreSQL version 16.3, which is highlighted in the output.

A PostgreSQL database is automatically upgraded during your maintenance window if the following criteria are met:

- The database has the **Auto minor version upgrade** option enabled.
- The database is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see Automatically upgrading the minor engine version.

> **Note**
>
> A PostgreSQL upgrade doesn't upgrade PostgreSQL extensions. To upgrade extensions, see Upgrading PostgreSQL extensions in RDS for PostgreSQL databases.

Upgrading PostgreSQL extensions in RDS for PostgreSQL databases

A PostgreSQL engine upgrade doesn't upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

> **Note**
>
> For information about updating the PostGIS extension, see Managing spatial data with the PostGIS extension (Step 6: Upgrade the PostGIS extension).
> To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded database. For more information, see pg_repack installation in the `pg_repack` documentation.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

For the list of supported versions of PostgreSQL extensions, see Supported PostgreSQL extension versions.

To list your currently installed extensions, use the PostgreSQL pg_extension catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL pg_available_extension_versions view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

Monitoring RDS for PostgreSQL engine upgrades with events

When you upgrade the engine version of a RDS for PostgreSQL database, Amazon RDS emits a specific event during each phase of the process. To track the progress of an upgrade, you can view or subscribe to these events.

For more information about RDS events, see Monitoring Amazon RDS events.

For detailed information about a specific Amazon RDS event that occurs during your engine upgrade, see Amazon RDS event categories and event messages.

Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. You can upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see Upgrades of the RDS for PostgreSQL DB engine. To learn how to restore a DB snapshot, see Restoring to a DB instance.

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

To view the available engine versions for your RDS for PostgreSQL DB snapshot, use the following AWS CLI example.

```
aws rds describe-db-engine-versions --engine postgres  --engine-version example-
engine-version --query "DBEngineVersions[*].ValidUpgradeTarget[*].
{EngineVersion:EngineVersion}" --output text --include-all
```

For more information about available engine versions for RDS for PostgreSQL DB snapshots, see Choosing a major version for an RDS for PostgreSQL upgrade.

> **Note**
>
> You can't upgrade automated DB snapshots that are created during the automated backup process.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.
4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.

5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

   During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

   > **Note**
   >
   > If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Parameters

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `--engine-version` – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
    --db-snapshot-identifier my_db_snapshot \
    --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
    --db-snapshot-identifier my_db_snapshot ^
```

```
    --engine-version new_version
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API ModifyDBSnapshot operation.

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Amazon Resource Names (ARNs) in Amazon RDS.
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

Working with read replicas for Amazon RDS for PostgreSQL

You can scale reads for your Amazon RDS for PostgreSQL DB instances by adding read replicas to the instances. As with other Amazon RDS database engines, RDS for PostgreSQL uses native replication mechanisms of PostgreSQL to keep read replicas up to date with changes on the source DB. For general information about read replicas and Amazon RDS, see Working with DB instance read replicas.

Following, you can find information specific to working with read replicas with RDS for PostgreSQL.

Read replica limitations with PostgreSQL

The following are limitations for PostgreSQL read replicas:

- PostgreSQL read replicas are read-only. Although a read replica isn't a writeable DB instance, you can promote it to become a standalone RDS for PostgreSQL DB instance. However, the process isn't reversible.
- You can't create a read replica from another read replica if your RDS for PostgreSQL DB instance is running a PostgreSQL version earlier than 14.1. RDS for PostgreSQL supports cascading read replicas on RDS for PostgreSQL version 14.1 and higher releases only. For more information, see Using cascading read replicas with RDS for PostgreSQL.
- If you promote a PostgreSQL read replica, it becomes a writable DB instance. It stops receiving write-ahead log (WAL) files from a source DB instance, and it's no longer a read-only instance. You can create new read replicas from the promoted DB instance as you do for any RDS for PostgreSQL DB instance. For more information, see Promoting a read replica to be a standalone DB instance.
- If you promote a PostgreSQL read replica from within a replication chain (a series of cascading read replicas), any existing downstream read replicas continue receiving WAL files from the promoted instance automatically. For more information, see Using cascading read replicas with RDS for PostgreSQL.
- If no user transactions are running on the source DB instance, the associated PostgreSQL read replica reports a replication lag of up to five minutes. The replica lag is calculated as `currentTime - lastCommitedTransactionTimestamp`, which means that when no transactions are being processed, the value of replica lag increases for a period of time until the write-ahead log (WAL) segment switches. By default RDS for PostgreSQL switches the WAL

segment every 5 minutes, which results in a transaction record and a decrease in the reported lag.

- You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and higher versions only. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.
- Point-in-time recovery (PITR) isn't supported for read replicas. You can use PITR with a primary (writer) instance only, not a read replica. To learn more, see Restoring a DB instance to a specified time for Amazon RDS.
- Read replicas for PostgreSQL versions 12 and lower automatically reboot during the 60-90 day maintenance window to apply password rotation. If the replica loses connection to the source before the scheduled reboot, it still reboots to resume replication. For PostgreSQL versions 13 and higher, read replicas might experience brief replication disconnections and reconnections during the password rotation process.

Read replica configuration with PostgreSQL

RDS for PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica DB instance is an asynchronously created physical replica of the source DB instance. It's created by a special connection that transmits write ahead log (WAL) data from the source DB instance to the read replica. For more information, see Streaming Replication in the PostgreSQL documentation.

PostgreSQL asynchronously streams database changes to this secure connection as they're made on the source DB instance. You can encrypt communications from your client applications to the source DB instance or any read replicas by setting the `ssl` parameter to `1`. For more information, see Using SSL with a PostgreSQL DB instance .

PostgreSQL uses a *replication* role to perform streaming replication. The role is privileged, but you can't use it to modify any data. PostgreSQL uses a single process for handling replication.

You can create a PostgreSQL read replica without affecting operations or users of the source DB instance. Amazon RDS sets the necessary parameters and permissions for you, on the source DB instance and the read replica, without affecting the service. A snapshot is taken of the source DB instance, and this snapshot is used to create the read replica. If you delete the read replica at some point in the future, no outage occurs.

You can create up to 15 read replicas from one source DB instance within the same Region. As of RDS for PostgreSQL 14.1, you can also create up to three levels of read replica in a chain (cascade) from a source DB instance. For more information, see Using cascading read replicas with RDS for PostgreSQL. In all cases, the source DB instance needs to have automated backups configured. You do this by setting the backup retention period on your DB instance to any value other than 0. For more information, see Creating a read replica.

You can create read replicas for your RDS for PostgreSQL DB instance in the same AWS Region as your source DB instance. This is known as *in-Region* replication. You can also create read replicas in different AWS Regions than the source DB instance. This is known as *cross-Region* replication. For more information about setting up cross-Region read replicas, see Creating a read replica in a different AWS Region. The various mechanisms supporting the replication process for in-Region and cross-Region differ slightly depending on the RDS for PostgreSQL version as explained in How streaming replication works for different RDS for PostgreSQL versions.

For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, be sure to also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if they prevent the read replica from starting. For example, suppose that the `max_connections` parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

RDS for PostgreSQL read replicas have access to external databases that are available through foreign data wrappers (FDWs) on the source DB instance. For example, suppose that your RDS for PostgreSQL DB instance is using the `mysql_fdw` wrapper to access data from RDS for MySQL. If so, your read replicas can also access that data. Other supported FDWs include `oracle_fdw`, `postgres_fdw`, and `tds_fdw`. For more information, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL.

Using RDS for PostgreSQL read replicas with Multi-AZ configurations

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, with a standby replica. A *standby replica* is a dedicated read replica that can assume the workload if the source DB fails over. You can't use your standby replica to serve read traffic. However, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. To learn more about Multi-AZ deployments, see Multi-AZ DB instance deployments for Amazon RDS.

If the source DB instance of a Multi-AZ deployment fails over to a standby, the associated read replicas switch to using the standby (now primary) as their replication source. The read replicas might need to restart, depending on the RDS for PostgreSQL version, as follows:

- **PostgreSQL 13 and higher versions** – Restarting isn't required. The read replicas are automatically synchronized with the new primary. However, in some cases your client application might cache Domain Name Service (DNS) details for your read replicas. If so, set the time-to-live (TTL) value to less than 30 seconds. Doing this prevents the read replica from holding on to a stale IP address (and thus, prevents it from synchronizing with the new primary). To learn more about this and other best practices, see Amazon RDS basic operational guidelines.
- **PostgreSQL 12 and all earlier versions** – The read replicas restart automatically after a fail over to the standby replica because the standby (now primary) has a different IP address and a different instance name. Restarting synchronizes the read replica with the new primary.

To learn more about failover, see Failing over a Multi-AZ DB instance for Amazon RDS. To learn more about how read replicas work in a Multi-AZ deployment, see Working with DB instance read replicas.

To provide failover support for a read replica, you can create the read replica as a Multi-AZ DB instance so that Amazon RDS creates a standby of your replica in another Availability Zone (AZ). Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Logical decoding on a read replica

RDS for PostgreSQL supports logical replication from standbys with PostgreSQL 16.1. This allows you to create logical decoding from a read-only standby that reduces the load on the primary DB instance. You can achieve higher-availability for your applications that need to synchronize data across multiple systems. This feature boosts the performance of your data warehouse and data analytics.

Also, replication slots on a given standby persist the promotion of that standby to a primary. This means that in the event of a primary DB instance failover or the promotion of a standby to be the new primary, the replication slots will persist and the former standby subscribers will not be affected.

To create logical decoding on a read replica

1. **Turn on logical replication** – To create logical decoding on a standby, you must turn on logical replication on your source DB instance and its physical replica. For more information, see Read replica configuration with PostgreSQL.

   - **To turn on logical replication for a newly created RDS for PostgreSQL DB instance** – Create a new DB custom parameter group and set the static parameter `rds.logical_replication` to 1. Then, associate this DB parameter group with the Source DB instance and its physical read replica. For more information, see Associating a DB parameter group with a DB instance in Amazon RDS.
   - **To turn on logical replication for an existing RDS for PostgreSQL DB instance** – Modify the DB custom parameter group of the source DB instance and its physical read replica to set the static parameter `rds.logical_replication` to 1. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

   > **Note**
   >
   > You must reboot the DB instance to apply these parameter changes.

   You can use the following query to verify the values for `wal_level` and `rds.logical_replication` on the source DB instance and its physical read replica.

```
Postgres=>SELECT name,setting FROM pg_settings WHERE name IN
 ('wal_level','rds.logical_replication');

 name                    | setting
-------------------------+---------
 rds.logical_replication | on
 wal_level               | logical
(2 rows)
```

2. **Create a table in the source database** – Connect to the database in your source DB instance. For more information, see Connecting to a DB instance running the PostgreSQL database engine.

   Use the following queries to create table in your source database and to insert values:

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE
```

```
Postgres=>INSERT INTO LR_test VALUES (generate_series(1,10000));
INSERT 0 10000
```

3. **Create a publication for the source table** – Use the following query to create a publication for the table on the source DB instance.

```
Postgres=>CREATE PUBLICATION testpub FOR TABLE LR_test;
CREATE PUBLICATION
```

Use a SELECT query to verify the details of the publication that was created on both the source DB instance and the physical read replica instance.

```
Postgres=>SELECT * from pg_publication;

oid    | pubname | pubowner | puballtables | pubinsert | pubupdate | pubdelete |
 pubtruncate | pubviaroot
-------+---------+----------+--------------+-----------+-----------+-----------
+-------------+------------
 16429 | testpub |    16413 | f            | t         | t         | t         | t
          | f
(1 row)
```

4. **Create a subscription from logical replica instance** – Create another RDS for PostgreSQL DB instance as the logical replica instance. Make sure that VPC is setup correctly to ensure that this logical replica instance can access the physical read replica instance. For more information, see Amazon VPC and Amazon RDS. If your source DB instance is idle, connectivity issues might occur and the primary doesn't send the data to standby.

```
Postgres=>CREATE SUBSCRIPTION testsub CONNECTION 'host=Physical replica host name
 port=port
                dbname=source_db_name user=user password=password'
 PUBLICATION testpub;
NOTICE:  created replication slot "testsub" on publisher
CREATE SUBSCRIPTION
```

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
```

```
CREATE TABLE
```

Use a SELECT query to verify the details of the subscription on the logical replica instance.

```
Postgres=>SELECT oid,subname,subenabled,subslotname,subpublications FROM
 pg_subscription;

oid    | subname | subenabled | subslotname | subpublications
-------+---------+------------+-------------+-----------------
 16429 | testsub | t          | testsub     | {testpub}
(1 row)
postgres=> select count(*) from LR_test;
 count
-------
 10000
(1 row)
```

5. **Inspect logical replication slot state** – You can only see the physical replication slot on your source DB instance.

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;

slot_name                                    | slot_type | confirmed_flush_lsn
---------------------------------------------+-----------+---------------------
 rds_us_west_2_db_dhqfsmo5wbbjqrn3m6b6ivdhu4 | physical  |
(1 row)
```

However, on your read replica instance, you can see the logical replication slot and the `confirmed_flush_lsn` value changes as the application actively consumes logical changes.

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;

slot_name | slot_type | confirmed_flush_lsn
----------+-----------+---------------------
 testsub   | logical   | 0/500002F0
(1 row)
```

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
 pg_replication_slots;

slot_name | slot_type | confirmed_flush_lsn
-----------+-----------+---------------------
 testsub   | logical   | 0/5413F5C0
(1 row)
```

Using cascading read replicas with RDS for PostgreSQL

As of version 14.1, RDS for PostgreSQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for PostgreSQL DB instance. Updates to the WAL log aren't sent by the source DB instance to each read replica. Instead, each read replica in a cascading series sends WAL log updates to the next read replica in the series. This reduces the burden on the source DB instance.

With cascading read replicas, your RDS for PostgreSQL DB instance sends WAL data to the first read replica in the chain. That read replica then sends WAL data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for PostgreSQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for PostgreSQL DB instance. For example, suppose that you have an RDS for PostgreSQL 14.1 DB instance, `rpg-db-main`. You can do the following:

- Starting with `rpg-db-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `rpg-db-main`. A complete series of instances from an RDS for PostgreSQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, turn on automatic backups on your RDS for PostgreSQL. Create the read replica first and then turn on automatic backups on the RDS for PostgreSQL DB instance. The process is the same as for other Amazon RDS DB engines. For more information, see Creating a read replica.

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload off of your `rpg-db-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `rpg-db-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see Promoting a read replica to be a standalone DB instance.

Note

- RDS for PostgreSQL doesn't support major version upgrades for cascading replicas. Before performing a major version upgrade, you need to remove cascading replicas. You can recreate them after completing the upgrade on your source DB instance and first-level replicas.
- For cascading read replicas, RDS for PostgreSQL supports 15 read replicas for each source DB instance at first level of replication, and 5 read replicas for each source DB instance at the second and third level of replication.

Creating cross-Region cascading read replicas with RDS for PostgreSQL

RDS for PostgreSQL supports cross-Region cascading read replicas. You can create a cross-Region replica from the source DB instance, and then create same-Region replicas from it. You can also create a same-Region replica from the source DB instance, and then create cross-Region replicas from it.

Create a cross-Region replica and then create same-Region replicas

You can use an RDS for PostgreSQL DB instance with version 14.1 or higher, `rpg-db-main`, to do the following:

1. Start with `rpg-db-main` (US-EAST-1), create the first cross-Region read replica in the chain, `read-replica-1` (US-WEST-2).
2. Using the first cross-Region `read-replica-1` (US-WEST-2), create the second read replica in the chain, `read-replica-2` (US-WEST-2).
3. Using `read-replica-2`, create the third read replica in the chain, `read-replica-3` (US-WEST-2).

Create a same-Region replica and then create cross-Region replicas

You can use an RDS for PostgreSQL DB instance with version 14.1 or higher, `rpg-db-main`, to do the following:

1. Starting with `rpg-db-main` (US-EAST-1), create the first read replica in the chain, `read-replica-1` (US-EAST-1).
2. Using `read-replica-1` (US-EAST-1), create the first cross-Region read replica in the chain, `read-replica-2` (US-WEST-2).
3. Using `read-replica-2` (US-WEST-2), create the third read replica in the chain, `read-replica-3` (US-WEST-2).

Limitations in creating cross-Region read replicas

- A cross-Region cascading chain of database replicas can span a maximum of two Regions, with a maximum of four levels. The four levels include the database source and three read replicas.

Advantages of using cascading read replicas

- Improved read scalability – By distributing read queries across multiple replicas, cascading replication helps balance the load. This improves performance, especially in read-heavy applications, by reducing the strain on the writer database.
- Geographical distribution – Cascading replicas can be located in different geographic locations. This reduces latency for users located far from the primary database and provides a local read replica, enhancing performance and user experience.
- High availability and disaster recovery – In the event of a primary server failure, replicas can be promoted to primary, ensuring continuity. cascading replication further enhances this by providing multiple layers of failover options, improving the overall resilience of the system.

- Flexibility and modular growth – As the system grows, new replicas can be added at different levels without major reconfiguration of the primary database. This modular approach allows for scalable and manageable growth of the replication setup.

Best practice for using cross-Region read replicas

- Before promoting a replica, create additional replicas. This will save time, and provide efficient handling of the workload.

How streaming replication works for different RDS for PostgreSQL versions

As discussed in Read replica configuration with PostgreSQL, RDS for PostgreSQL uses PostgreSQL's native streaming replication protocol to send WAL data from the source DB instance. It sends source WAL data to read replicas for both in-Region and cross-Region read replicas. With version 9.4, PostgreSQL introduced physical replication slots as a supporting mechanism for the replication process.

A *physical replication slot* prevents a source DB instance from removing WAL data before it's consumed by all read replicas. Each read replica has its own physical slot on the source DB instance. The slot keeps track of the oldest WAL (by logical sequence number, LSN) that might be needed by the replica. After all slots and DB connections have progressed beyond a given WAL (LSN), that LSN becomes a candidate for removal at the next checkpoint.

Amazon RDS uses Amazon S3 to archive WAL data. For in-Region read replicas, you can use this archived data to recover the read replica when necessary. An example of when you might do so is if the connection between source DB and read replica is interrupted for any reason.

In the following table, you can find a summary of differences between PostgreSQL versions and the supporting mechanisms for in-Region and cross-Region used by RDS for PostgreSQL.

Version	In-Region	Cross-Region
PostgreSQL 14.1 and higher versions	• Replication slots • Amazon S3 archive	• Replication slots

Version	In-Region	Cross-Region
PostgreSQL 13 and lower versions	• Amazon S3 archive	• Replication slots

For more information, see Monitoring and tuning the replication process.

Understanding the parameters that control PostgreSQL replication

The following parameters affect the replication process and determine how well read replicas stay up to date with the source DB instance:

max_wal_senders

The `max_wal_senders` parameter specifies the maximum number of connections that the source DB instance can support at the same time over the streaming replication protocol.

The default value varies for RDS for PostgreSQL versions:

- For versions 13, 14, and 15, the default value is 20.
- For versions 16 and above, the default value is 35.

This parameter should be set to slightly higher than the actual number of read replicas. If this parameter is set too low for the number of read replicas, replication stops.

For more information, see max_wal_senders in the PostgreSQL documentation.

> **Note**
>
> `max_wal_senders` is a static parameter that requires a DB instance reboot for changes to take effect.

wal_keep_segments

The `wal_keep_segments` parameter specifies the number of write-ahead log (WAL) files that the source DB instance keeps in the `pg_wal` directory. The default setting is 32.

If `wal_keep_segments` isn't set to a large enough value for your deployment, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS generates a replication error and begins recovery on the read replica. It does so by replaying the source

DB instance's archived WAL data from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. You can see this process in action as captured by the PostgreSQL log in Example: How a read replica recovers from replication interruptions.

> **Note**
>
> In PostgreSQL version 13, the `wal_keep_segments` parameter is named `wal_keep_size`. It serves the same purpose as `wal_keep_segments`, but its default value is in megabytes (MB) (2048 MB) rather than the number of files. For more information, see wal_keep_segments and wal_keep_size in the PostgreSQL documentation.

max_slot_wal_keep_size

The `max_slot_wal_keep_size` parameter controls the quantity of WAL data that the RDS for PostgreSQL DB instance retains in the `pg_wal` directory to serve slots. This parameter is used for configurations that use replication slots. The default value for this parameter is `-1`, meaning that there's no limit to how much WAL data is kept on the source DB instance. For information about monitoring your replication slots, see Monitoring replication slots for your RDS for PostgreSQL DB instance.

For more information about this parameter, see max_slot_wal_keep_size in the PostgreSQL documentation.

Whenever the stream that provides WAL data to a read replica is interrupted, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL data from Amazon S3 or by using the WAL data associated with the replication slot. When this process is complete, PostgreSQL re-establishes streaming replication.

Example: How a read replica recovers from replication interruptions

In the following example, you find the log details that demonstrate the recovery process for a read replica. The example is from an RDS for PostgreSQL DB instance running PostgreSQL version 12.9 in the same AWS Region as the source DB, so replication slots aren't used. The recovery process is the same for other RDS for PostgreSQL DB instances running PostgreSQL earlier than version 14.1 with in-Region read replicas.

When the read replica lost contact with the source DB instance, Amazon RDS records the issue in the log as `FATAL: could not receive data from WAL stream` message, along with the `ERROR: requested WAL segment ... has already been removed`. As shown in the bold line, Amazon RDS recovers the replica by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG:  switched WAL source from archive to stream
 after failure
2014-11-07 19:01:10 UTC::@:[11575]:LOG: started streaming WAL from primary at 1A/
D3000000 on timeline 1
2014-11-07 19:01:10 UTC::@:[11575]:FATAL: could not receive data from WAL stream:
ERROR:  requested WAL segment 00000001000000001A000000D3 has already been removed
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: could not restore file "00000002.history"
 from archive: return code 0
2014-11-07 19:01:15 UTC::@:[23180]:DEBUG: switched WAL source from stream to archive
 after failure recovering 00000001000000001A000000D3
2014-11-07 19:01:16 UTC::@:[23180]:LOG:  restored log file "00000001000000001A000000D3"
 from archive
```

When Amazon RDS replays enough archived WAL data on the replica to catch up, streaming to the read replica begins again. When streaming resumes, Amazon RDS writes an entry to the log file similar to the following.

```
2014-11-07 19:41:36 UTC::@:[24714]:LOG:started streaming WAL from primary at 1B/
B6000000 on timeline 1
```

Setting the parameters that control shared memory

The parameters you set determine the size of shared memory for tracking transaction IDs, locks, and prepared transactions. **The shared memory structure of a standby instance must be equal or greater than that of a primary instance.** This ensures that the former doesn't run out of shared memory during recovery. If the parameter values on the replica are less than the parameter values on the primary, Amazon RDS will automatically adjust the replica parameters and restart the engine.

The parameters affected are:

- max_connections
- max_worker_processes
- max_wal_senders

- max_prepared_transactions
- max_locks_per_transaction

To avoid RDS reboots of replicas due to insufficient memory, we recommend applying the parameter changes as a rolling reboot to each replica. You must apply the following rules, when you set the parameters:

- **Increasing the parameter values:**
  - You should always increase the parameter values of all the read replicas first, and perform a rolling reboot of all replicas. Then, apply the parameter changes on the primary instance and reboot.
- **Decreasing the parameter values:**
  - You should first decrease the parameter values of the primary instance and perform a reboot. Then, apply the parameter changes to all the associated read replicas and perform a rolling reboot.

Monitoring and tuning the replication process

We strongly recommend that you routinely monitor your RDS for PostgreSQL DB instance and read replicas. You need to ensure that your read replicas are keeping up with changes on the source DB instance. Amazon RDS transparently recovers your read replicas when interruptions to the replication process occur. However, it's best to avoid needing to recover at all. Recovering using replication slots is faster than using the Amazon S3 archive, but any recovery process can affect read performance.

To determine how well your read replicas are keeping up with the source DB instance, you can do the following:

- **Check the amount of `ReplicaLag` between source DB instance and replicas.** *Replica lag* is the amount of time, in seconds, that a read replica lags behind its source DB instance. This metric reports the result of the following query.

  ```
  SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS "ReplicaLag";
  ```

  Replica lag is an indication of how well a read replica is keeping up with the source DB instance. It's the amount of latency between the source DB instance and a specific read instance. A high

value for replica lag can indicate a mismatch between the DB instance classes or storage types (or both) used by the source DB instance and its read replicas. The DB instance class and storage types for DB source instance and all read replicas should be the same.

Replica lag can also be the result of intermittent connection issues. You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. To learn more about `ReplicaLag` and other metrics for Amazon RDS, see Amazon CloudWatch metrics for Amazon RDS.

- **Check the PostgreSQL log for information you can use to adjust your settings.** At every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@:[26820]:LOG:  checkpoint complete: wrote 376 buffers
 (0.2%);
0 transaction log file(s) added, 0 removed, 1 recycled; write=35.681 s, sync=0.013 s,
 total=35.703 s;
sync files=10, longest=0.013 s, average=0.001 s
```

  You can use this information to figure out how many transaction files are being recycled in a given time period. You can then change the setting for `wal_keep_segments` if necessary. For example, suppose that the PostgreSQL log at `checkpoint complete` shows `35 recycled` for a 5-minute interval. In this case, the `wal_keep_segments` default value of 32 isn't sufficient to keep pace with the streaming activity, so you should increase the value of this parameter.

- **Use Amazon CloudWatch to monitor metrics that can predict replication issues.** Rather than analyzing the PostgreSQL log directly, you can use Amazon CloudWatch to check metrics that have been collected. For example, you can check the value of the `TransactionLogsGeneration` metric to see how much WAL data is being generated by the source DB instance. In some cases, the workload on your DB instance might generate a large amount of WAL data. If so, you might need to change the DB instance class for your source DB instance and read replicas. Using an instance class with high (10 Gbps) network performance can reduce replica lag.

Monitoring replication slots for your RDS for PostgreSQL DB instance

All versions of RDS for PostgreSQL use replication slots for cross-Region read replicas. RDS for PostgreSQL 14.1 and higher versions use replication slots for in-Region read replicas. In-region read replicas also use Amazon S3 to archive WAL data. In other words, if your DB instance and read

replicas are running PostgreSQL 14.1 or higher, replication slots and Amazon S3 archives are both available for recovering the read replica. Recovering a read replica using its replication slot is faster than recovering from Amazon S3 archive. So, we recommend that you monitor the replication slots and related metrics.

You can view the replication slots on your RDS for PostgreSQL DB instances by querying the `pg_replication_slots` view, as follows.

```
postgres=> SELECT * FROM pg_replication_slots;
slot_name                  | plugin | slot_type | datoid | database | temporary |
 active | active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn |
 wal_status | safe_wal_size | two_phase
---------------------------+--------+-----------+--------+----------+-----------
+--------+------------+------+--------------+-------------+---------------------
+------------+---------------+-----------
rds_us_west_1_db_555555555 |        | physical  |        |          | f         | t
  |      13194 |      |              | 23/D8000060 |                     | reserved   |
               | f
(1 row)
```

The `wal_status` of `reserved` value means that the amount of WAL data held by the slot is within the bounds of the `max_wal_size` parameter. In other words, the replication slot is properly sized. Other possible status values are as follows:

- `extended` – The slot exceeds the `max_wal_size` setting, but the WAL data is retained.
- `unreserved` – The slot no longer has the all required WAL data. Some of it will be removed at the next checkpoint.
- `lost` – Some required WAL data has been removed. The slot is no longer usable.

The `unreserved` and `lost` states of the `wal_status` are seen only when `max_slot_wal_keep_size` is non-negative.

The `pg_replication_slots` view shows you the current state of your replication slots. To assess the performance of your replication slots, you can use Amazon CloudWatch and monitor the following metrics:

- **`OldestReplicationSlotLag`** – Shows the amount of Write-Ahead Log (WAL) data on the source that hasn't been consumed by the most lagging replica.

- **`TransactionLogsDiskUsage`** – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see Monitoring Amazon RDS metrics with Amazon CloudWatch. For more information about monitoring streaming replication on your RDS for PostgreSQL DB instances, see Best practices for Amazon RDS PostgreSQL replication on the *AWS Database Blog*.

Configuring delayed replication with RDS for PostgreSQL

Overview and Benefits

The delayed replication feature in RDS for PostgreSQL allows you to intentionally delay the replication of data changes from your primary database to one or more standby (read replica) servers. This provides valuable protection against data corruption, accidental data loss, or erroneous transactions that could otherwise be immediately propagated to all replicas.

Delayed replication is supported in the following RDS for PostgreSQL versions:

- 14.19 and higher 14 versions
- 15.14 and higher 15 versions
- 16.10 and higher 16 versions
- 17.6 and higher 17 versions

By introducing a time lag in the replication process, you gain a window of opportunity to detect and respond to data-related incidents before they affect your entire DB cluster. Key benefits of delayed replication include the following:

- Allows you to recover from accidental deletions, updates, or other logical mistakes.
- Provides a buffer against the spread of corrupted data across your DB cluster.
- Offers an additional recovery point option to complement your traditional backup strategies.
- Allows you to configure the delay period based on your organization's specific needs and risk tolerance.

Enabling and Configuring Delayed Replication

To enable delayed replication on an RDS for PostgreSQL read replica, follow these steps:

> **Note**
>
> For cascaded read replicas, use the same `recovery_min_apply_delay` parameter and steps described below.

To enable delayed replication

1. Create a new custom parameter group or modify an existing one. For more information, see DB parameter groups for Amazon RDS DB instances.
2. In the parameter group, configure the `recovery_min_apply_delay` parameter:
   - Set the value to the desired delay in milliseconds. For example, 3600000 for a 1-hour delay.
   - Allowed range: 0 to 86400000 ms (0 to 24 hours)
   - Default: 0
3. Apply the parameter group to the read replica instance you want to configure for delayed replication.
4. Reboot the read replica instance for the changes to take effect.

> **Note**
>
> The `recovery_min_apply_delay` parameter is dynamic. If you modify an existing parameter group that's already attached to the instance, the changes take effect immediately without requiring a reboot. However, when applying a new parameter group to the instance, you must reboot for the changes to take effect.

Managing Delayed Replication Recovery

Delayed replication is particularly useful in scenarios where traditional point-in-time recovery methods may be insufficient or too time-consuming.

During the delayed replication period, you can use the following PostgreSQL functions to manage the recovery process:

- `pg_wal_replay_pause()`: Request to pause the recovery process on the delayed replica.
- `pg_wal_replay_resume()`: Restart the recovery process if it was previously paused.

- `pg_is_wal_replay_paused()`: Check if the recovery process is currently paused.
- `pg_get_wal_replay_pause_state()`: Get the current state of the recovery process (not paused, pause requested, or paused).

Users with the `rds_superuser` role have EXECUTE privileges on `pg_wal_replay_pause()` and `pg_wal_replay_resume()`. If other database users need access to these functions, you must grant them the `rds_superuser` role. For more information about the `rds_superuser` role, see Understanding the rds_superuser role.

Access to other functions like `pg_is_wal_replay_paused()` and `pg_get_wal_replay_pause_state()` doesn't require the `rds_superuser` role.

You can use the following recovery target parameters to precisely control the point in time to which the delayed replica is recovered. These parameters are static and require a database reboot to apply changes:

- recovery_target
- recovery_target_lsn
- recovery_target_name
- recovery_target_time
- recovery_target_xid
- recovery_target_inclusive

> **Important**
>
> You can specify only one recovery target parameter at a time. Configuring multiple recovery target parameters in the configuration file results in an error.

Planning considerations

Consider the following when planning delayed replication with RDS for PostgreSQL:

- During the automatic rotation of `rdsrepladmin` credentials (which occurs every 90 days), delayed read replicas may temporarily enter a `REPLICATION_ERROR` state. If the delayed replica has sufficient WAL logs to maintain the configured delay, it may pause WAL receiver process,

causing WAL accumulation on the source. You should monitor the replication status on the replica and the storage consumption on the source to avoid hitting storage-full.

- When delayed read replicas encounter system events (such as reboot or restart), they enter a `REPLICATION_ERROR` state where the WAL receiver process remains inactive until the configured delay period expires. This behavior can cause WAL accumulation on the source instance, potentially leading to storage exhaustion. Consider the following preventive measures:
  - Configure CloudWatch alarms to monitor storage utilization on source instances.
  - Enable storage auto-scaling to handle unexpected WAL growth.
  - Set the `max_slot_wal_keep_size` parameter on the source instance to limit WAL retention per replication slot.
  - Monitor replication lag and slot status regularly.
- Longer delays increase WAL logs on replicas, consuming more storage. Monitor storage space using CloudWatch alarms, enable auto-scaling, or catch up replicas when needed.
- When promoting a delayed read replica, the `recovery_min_apply_delay` parameter is not honored, and all pending WAL records are immediately applied.
- The `recovery_min_apply_delay` parameter is independent on each level of a cascading replication setup. Setting a delay on a replica does not add to the delay of any cascaded replicas.

For more information, see the RDS for PostgreSQL Read Replicas documentation and the RDS for PostgreSQL Disaster Recovery documentation.

Understanding limitations

The delayed replication feature for Amazon RDS for PostgreSQL has the following limitations:

- Blue/Green deployments have the following limitations when configuring delayed replication:
  - **Green source instance** — The `recovery_min_apply_delay parameter` is disregarded, even if configured in the parameter group. Any delay settings on the green source instance do not take effect.
  - **Green replica instance** — The `recovery_min_apply_delay parameter` is fully supported and applied to the PostgreSQL configuration file. Delay settings function as expected during the switchover workflow.
  - RDS Blue/Green deployments for major version upgrades
- During major version upgrades, any delayed read replicas will be automatically terminated to allow the source instance to proceed with the upgrade process in order to ensure minimal

downtime. After the source instance completed the upgrade, you must manually recreate the delayed replicas.

- Delayed replication is not compatible with the following features.
  - RDS for PostgreSQL Logical Replication
  - RDS for PostgreSQL Multi-AZ Clusters (including both inbound and outbound replication)
  - Aurora PostgreSQL

Troubleshooting for RDS for PostgreSQL read replica

Following, you can find troubleshooting ideas for some common RDS for PostgreSQL read replica issues.

Terminate the query that causes the read replica lag

Transactions either in active or idle in transaction state that are running for a long time in the database might interfere with the WAL replication process, thereby increasing the replication lag. Therefore, be sure to monitor the runtime of these transactions with the PostgreSQL `pg_stat_activity` view.

Run a query on the primary instance similar to the following to find the process ID (PID) of the query that's running for a long time:

```
SELECT datname, pid,usename, client_addr, backend_start,
xact_start, current_timestamp - xact_start AS xact_runtime, state,
backend_xmin FROM pg_stat_activity WHERE state='active';
```

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
 xact_duration,*
FROM  pg_stat_activity
WHERE state  = 'idle in transaction'
AND   xact_start is not null
ORDER BY 1 DESC;
```

After identifying the PID of the query, you can choose to end the query.

Run a query on the primary instance similar to the following to terminate the query that's running for a long time:

```
SELECT pg_terminate_backend(PID);
```

Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for PostgreSQL with Amazon RDS Optimized Reads. An RDS for PostgreSQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 50% faster query processing compared to one that doesn't use it.

Topics

- Overview of RDS Optimized Reads in PostgreSQL
- Use cases for RDS Optimized Reads
- Best practices for RDS Optimized Reads
- Using RDS Optimized Reads
- Monitoring DB instances that use RDS Optimized Reads
- Limitations for RDS Optimized Reads in PostgreSQL

Overview of RDS Optimized Reads in PostgreSQL

Optimized Reads is available by default on RDS for PostgreSQL versions 15.2 and higher, 14.7 and higher, and 13.10 and higher when using NVMe-based DB instance classes. For hardware specifications that indicate which instances use NVMe, see Hardware specifications for DB instance classes.

When you use an RDS for PostgreSQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves up to 50% faster query performance using the local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage. You can achieve faster query processing by placing the temporary tables that are generated by PostgreSQL on the local storage, which reduces the traffic to Elastic Block Storage (EBS) over the network.

In PostgreSQL, temporary objects are assigned to a temporary namespace that drops automatically at the end of the session. The temporary namespace while dropping removes any objects that are session-dependent, including schema-qualified objects, such as tables, functions, operators, or even extensions.

In RDS for PostgreSQL, the `temp_tablespaces` parameter is configured for this temporary work area where the temporary objects are stored.

The following queries return the name of the tablespace and its location.

```
postgres=> show temp_tablespaces;
temp_tablespaces
---------------------
rds_temp_tablespace
(1 row)
```

The `rds_temp_tablespace` is a tablespace configured by RDS that points to the NVMe local storage. You can always switch back to Amazon EBS storage by modifying this parameter in the `Parameter group` using the AWS Management Console to point to any tablespace other than `rds_temp_tablespace`. For more information, see Modifying parameters in a DB parameter group in Amazon RDS. You can also use the SET command to modify the value of the `temp_tablespaces` parameter to `pg_default` at the session level using SET command. Modifying the parameter redirects the temporary work area to Amazon EBS. Switching back to Amazon EBS helps when the local storage for your RDS instance or cluster isn't sufficient to perform a specific SQL operation.

```
postgres=> SET temp_tablespaces TO 'pg_default';
SET
```

```
postgres=> show temp_tablespaces;

 temp_tablespaces
------------------
 pg_default
```

Use cases for RDS Optimized Reads

The following are some use cases that can benefit from Optimized Reads:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
- Other workloads that use internal temporary tables.
- `CREATE INDEX` or `REINDEX` operations for sorting.

Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of the workload on the DB instance or Multi-AZ DB cluster, modify it to use a larger DB instance class.

Using RDS Optimized Reads

When you provision an RDS for PostgreSQL DB instance with one of the NVMe based DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

For more information about Multi-AZ deployment, see Configuring and managing a Multi-AZ deployment for Amazon RDS.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for PostgreSQL DB instance or Multi-AZ DB cluster using one of the NVMe based DB instance classes. For more information, see Creating an Amazon RDS DB instance.
- Modify an existing RDS for PostgreSQL DB instance or Multi-AZ DB cluster to use one of the NVMe based DB instance classes. For more information, see Modifying an Amazon RDS DB instance.

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see DB instance classes.

To switch back to a non-optimized reads RDS instance, modify the DB instance class of your RDS instance or cluster to the similar instance class that only supports EBS storage for your database workloads. For example, if the current DB instance class is db.r6gd.4xlarge, choose db.r6g.4xlarge to switch back. For more information, see Modifying an Amazon RDS DB instance.

Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads using the following CloudWatch metrics:

- `FreeLocalStorage`
- `ReadIOPSLocalStorage`
- `ReadLatencyLocalStorage`
- `ReadThroughputLocalStorage`
- `WriteIOPSLocalStorage`
- `WriteLatencyLocalStorage`
- `WriteThroughputLocalStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS.

To monitor current usage of your local storage, lo in to your database and run the following query:

```
SELECT
    spcname AS "Name",
    pg_catalog.pg_size_pretty(pg_catalog.pg_tablespace_size(oid)) AS "size"
FROM
    pg_catalog.pg_tablespace
WHERE
    spcname IN ('rds_temp_tablespace');
```

For more information about the temporary files and their usage, see Managing temporary files with PostgreSQL.

Limitations for RDS Optimized Reads in PostgreSQL

The following limitation apply to RDS Optimized Reads in PostgreSQL:

- Transactions can fail when the instance store is full.

Importing data into PostgreSQL on Amazon RDS

Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you're transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see What is AWS Database Migration Service?

Modify your DB parameter group to include the following settings *for your import only*. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient

settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Parameter	Recommended value when importing	Description
maintenance_work_mem	524288, 1048576, 2097152, or 4194304 (in KB). These settings are comparable to 512 MB, 1 GB, 2 GB, and 4 GB.	The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.
max_wal_size	256 (for version 9.6), 4096 (for versions 10 and higher)	Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces checkpoint_segments for PostgreSQL 9.6 and later. For PostgreSQL version 9.6, this value is in 16 MB units. For later versions, the value is in 1 MB units. For example, in version 9.6, 128 means 128 chunks that are each 16 MB in size. In version 12.4, 2048 means 2048 chunks that are each 1 MB in size.
checkpoint_timeout	1800	The value for this setting allows for less frequent WAL rotation.
synchronous_commit	Off	Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off FSYNC).
wal_buffers	8192	This is value is in 8 KB units. This again helps your WAL generation speed

Parameter	Recommended value when importing	Description
`autovacuum`	0	Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

> **Note**
>
> The PostgreSQL command `pg_dumpall` requires super_user permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

Topics

- Importing a PostgreSQL database from an Amazon EC2 instance
- Using the \copy command to import data to a table on a PostgreSQL DB instance
- Importing data from Amazon S3 into an RDS for PostgreSQL DB instance
- Transporting PostgreSQL databases between DB instances

Importing a PostgreSQL database from an Amazon EC2 instance

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can follow this process to migrate the data.

1. Create a file using pg_dump that contains the data to be loaded
2. Create the target DB instance
3. Use *psql* to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance

The following sections provide more details on each step listed above.

Step 1: Create a file using pg_dump that contains the data to load

The pg_dump utility uses the COPY command to create a schema and data dump of a PostgreSQL database. The dump script generated by pg_dump loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the pg_restore command and the -d parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called mydb2dump.sql for a database called mydb2.

```
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that is contained the dumped data. Alternatively, you can create a database with a different name. In this case, you use the pg_restore command and the -d parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database]
 > [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database
 name] [database].dump
```

Step 3: Use psql to create the database on the DB instance and load data

You can use the same connection you used to run the pg_dump command to connect to the target DB instance and recreate the database. Using *psql*, you can use the master user name and master password to create the database on the DB instance

The following example uses *psql* and a dump file named mydb2dump.sql to create a database called mydb2 on a PostgreSQL DB instance called mypginstance:

For Linux, macOS, or Unix:

```
psql \
   -f mydb2dump.sql \
   --host mypginstance.555555555555.aws-region.rds.amazonaws.com \
   --port 8199 \
   --username myawsuser \
   --password password \
   --dbname mydb2
```

For Windows:

```
psql ^
   -f mydb2dump.sql ^
   --host mypginstance.555555555555.aws-region.rds.amazonaws.com ^
   --port 8199 ^
   --username myawsuser ^
   --password password ^
   --dbname mydb2
```

> **Note**
>
> Specify a password other than the prompt shown here as a security best practice.

Step 4: Create a DB snapshot of the DB instance

Once you have verified that the data was loaded into your DB instance, we recommend that you create a DB snapshot of the target PostgreSQL DB instance. DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use such a snapshot to seed new DB instances. For information about creating a DB snapshot, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

Using the \copy command to import data to a table on a PostgreSQL DB instance

The PostgreSQL `\copy` command is a meta-command available from the `psql` interactive client tool. You can use `\copy` to import data into a table on your RDS for PostgreSQL DB instance. To

use the \copy command, you need to first create the table structure on the target DB instance so that \copy has a destination for the data being copied.

You can use \copy to load data from a comma-separated values (CSV) file, such as one that's been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using psql.

```
psql --host=db-instance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=target-db
```

You then run \copy command with the following parameters to identify the target for the data and its format.

- target_table – The name of the table that should receive the data being copied from the CSV file.
- column_list – Column specifications for the table.
- 'filename' – The complete path to the CSV file on your local workstation.

```
 \copy target_table from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```
\copy target_table (column-1, column-2, column-3, ...)
    from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV HEADER;
```

If the \copy command fails, PostgreSQL outputs error messages.

Creating a new DB instance in the Database Preview environment using psql command with the \copy meta-command as shown in the following examples. This example uses *source-table* as the source table name, *source-table.csv* as the .csv file, and *target-db* as the target database:

For Linux, macOS, or Unix:

```
$psql target-db \
    -U <admin user> \
```

```
    -p <port> \
    -h <DB instance name> \
    -c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For Windows:

```
$psql target-db ^
    -U <admin user> ^
    -p <port> ^
    -h <DB instance name> ^
    -c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For complete details about the `\copy` command, see the psql page in the PostgreSQL documentation, in the *Meta-Commands* section.

Importing data from Amazon S3 into an RDS for PostgreSQL DB instance

You can import data that's been stored using Amazon Simple Storage Service into a table on an RDS for PostgreSQL DB instance. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A *bucket* is an Amazon S3 container for objects and files. The data can be in a comma-separate value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the *Amazon Simple Storage Service User Guide*.

- Create a bucket
- Add an object to a bucket

Cross-account import from Amazon S3 is supported. For more information, see Granting cross-account permissions in the *Amazon Simple Storage Service User Guide*.

You can use the customer managed key for encryption while importing data from S3. For more information, see KMS keys stored in AWS KMS in the *Amazon Simple Storage Service User Guide*.

Topics

- Installing the aws_s3 extension
- Overview of importing data from Amazon S3 data
- Setting up access to an Amazon S3 bucket
- Importing data from Amazon S3 to your RDS for PostgreSQL DB instance
- Function reference

Installing the aws_s3 extension

Before you can use Amazon S3 with your RDS for PostgreSQL DB instance, you need to install the `aws_s3` extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3. The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

To install the `aws_s3` extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the psql `\dx` metacommand.

```
postgres=> \dx
       List of installed extensions
    Name     | Version |   Schema   |                 Description
-------------+---------+------------+---------------------------------------------
 aws_commons | 1.2     | public     | Common data types across AWS services
```

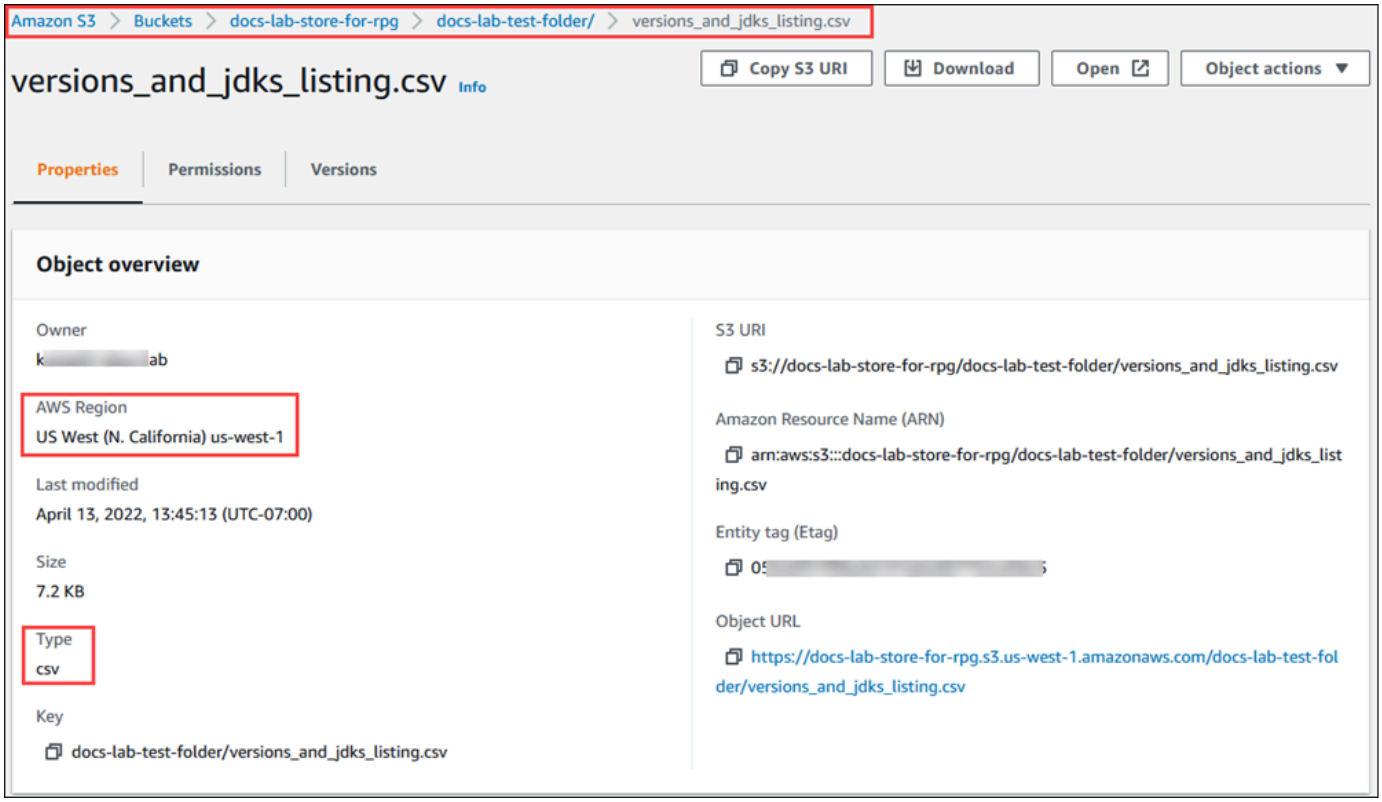
```
 aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
 plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Overview of importing data from Amazon S3 data

To import S3 data into Amazon RDS

First, gather the details that you need to supply to the function. These include the name of the table on your RDS for PostgreSQL DB instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see View an object in the *Amazon Simple Storage Service User Guide*.



> **Note**
>
> Multi part data import from Amazon S3 isn't currently supported.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

   ```
   postgres=> CREATE TABLE t1
       (col1 varchar(80),
       col2 varchar(80),
       col3 varchar(80));
   ```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at https://console.aws.amazon.com/s3/, and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

   Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more more information, see Setting up access to an Amazon S3 bucket. The image following shows an example.

3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://amzn-s3-demo-bucket/sample_file_path ./
```

4. Set up permissions on your RDS for PostgreSQL DB instance to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket.

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see aws_commons.create_s3_uri. The following is an example of constructing this object during a psql session.

```
postgres=> SELECT aws_commons.create_s3_uri(
   'docs-lab-store-for-rpg',
   'versions_and_jdks_listing.csv',
   'us-west-1'
) AS s3_uri \gset
```

In the next step, you pass this object (`aws_commons._s3_uri_1`) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see aws_s3.table_import_from_s3. For examples, see Importing data from Amazon S3 to your RDS for PostgreSQL DB instance.

Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

Topics

- Using an IAM role to access an Amazon S3 bucket
- Using security credentials to access an Amazon S3 bucket
- Troubleshooting access to Amazon S3

Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the aws_s3.table_import_from_s3 function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:

   - `s3:GetObject`

- `s3:ListBucket`

Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- arn:aws:s3:::*amzn-s3-demo-bucket*
- arn:aws:s3:::*amzn-s3-demo-bucket*/*

For more information on creating an IAM policy for RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

> **Note**
>
> Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
   --policy-name rds-s3-import-policy \
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3import",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket"
         ],
         "Effect": "Allow",
         "Resource": [
```

```
            "arn:aws:s3:::amzn-s3-demo-bucket",
            "arn:aws:s3:::amzn-s3-demo-bucket/*"
          ]
        }
      ]
    }'
```

For Windows:

```
aws iam create-policy ^
   --policy-name rds-s3-import-policy ^
   --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3import",
         "Action": [
           "s3:GetObject",
           "s3:ListBucket"
         ],
         "Effect": "Allow",
         "Resource": [
           "arn:aws:s3:::amzn-s3-demo-bucket",
           "arn:aws:s3:::amzn-s3-demo-bucket/*"
         ]
       }
     ]
   }'
```

2. Create an IAM role.

   You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

   We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

   If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

Example

For Linux, macOS, or Unix:

```
aws iam create-role \
   --role-name rds-s3-import-role \
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
             }
       }
     ]
   }'
```

For Windows:

```
aws iam create-role ^
   --role-name rds-s3-import-role ^
   --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
```

```
      {
        "Effect": "Allow",
        "Principal": {
           "Service": "rds.amazonaws.com"
         },
        "Action": "sts:AssumeRole",
        "Condition": {
            "StringEquals": {
               "aws:SourceAccount": "111122223333",
               "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
               }
            }
      }
    ]
  }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role` Replace *your-policy-arn* with the policy ARN that you noted in an earlier step.

   Example

   For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
   --policy-arn your-policy-arn \
   --role-name rds-s3-import-role
```

   For Windows:

```
aws iam attach-role-policy ^
   --policy-arn your-policy-arn ^
   --role-name rds-s3-import-role
```

4. Add the IAM role to the DB instance.

   You do so by using the AWS Management Console or AWS CLI, as described following.

Console

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance** .
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

AWS CLI

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace *`your-role-arn`* with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier my-db-instance \
   --feature-name s3Import \
   --role-arn your-role-arn   \
   --region your-region
```

  For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier my-db-instance ^
   --feature-name s3Import ^
   --role-arn your-role-arn ^
   --region your-region
```

RDS API

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the AddRoleToDBInstance operation.

Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the aws_s3.table_import_from_s3 function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the aws_commons.create_aws_credentials function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create_aws_credentials(
   'sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the aws_s3.table_import_from_s3 function with the `credentials` parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   't', '', '(format csv)',
   :'s3_uri',
   :'creds'
);
```

Or you can include the aws_commons.create_aws_credentials function call inline within the `aws_s3.table_import_from_s3` function call.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   't', '', '(format csv)',
   :'s3_uri',
   aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- Troubleshooting Amazon RDS identity and access
- Troubleshooting Amazon S3 in the *Amazon Simple Storage Service User Guide*
- Troubleshooting Amazon S3 and IAM in the *IAM User Guide*

Importing data from Amazon S3 to your RDS for PostgreSQL DB instance

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the aws_s3 extension. For reference information, see aws_s3.table_import_from_s3.

> **Note**
>
> The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   't1',
   '',
   '(format csv)',
   :'s3_uri'
);
```

The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB instance to copy the data into.
- `''` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter.

- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the aws_commons.create_s3_uri function to create an `s3_uri` structure, see Overview of importing data from Amazon S3 data.

For more information about this function, see aws_s3.table_import_from_s3.

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

> **Note**
>
> Importing 0 bytes file will cause an error.

Topics

- Importing an Amazon S3 file that uses a custom delimiter
- Importing an Amazon S3 compressed (gzip) file
- Importing an encoded Amazon S3 file

Importing an Amazon S3 file that uses a custom delimiter

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the aws_s3.table_import_from_s3 function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...
```

To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

```
postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
```

2. Use the following form of the aws_s3.table_import_from_s3 function to import data from the Amazon S3 file.

   You can include the aws_commons.create_s3_uri function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

```
postgres=> SELECT aws_s3.table_import_from_s3(
   'test',
   'a,b,d,e',
   'DELIMITER ''|''',
   aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'pipeDelimitedSampleFile', 'us-
east-2')
);
```

The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;
a | b | c | d | e
---+------+---+---+------+-----------
1 | foo1 | | bar1 | elephant1
2 | foo2 | | bar2 | elephant2
3 | foo3 | | bar3 | elephant3
4 | foo4 | | bar4 | elephant4
```

Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: `Content-Encoding`
- Value: `gzip`

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see Uploading objects in the *Amazon Simple Storage Service User Guide*.

For more information about Amazon S3 metadata and details about system-provided metadata, see Editing object metadata in the Amazon S3 console in the *Amazon Simple Storage Service User Guide*.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(
 'test_gzip', '', '(format csv)',
 'amzn-s3-demo-bucket', 'test-data.gz', 'us-east-2'
);
```

Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3(
 'test_table', '', 'encoding ''WIN1252''',
 aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'SampleFile', 'us-east-2')
);
```

Function reference

Functions

- aws_s3.table_import_from_s3
- aws_commons.create_s3_uri
- aws_commons.create_aws_credentials

aws_s3.table_import_from_s3

Imports Amazon S3 data into an Amazon RDS table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   s3_info aws_commons._s3_uri_1
)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   s3_info aws_commons._s3_uri_1,
   credentials aws_commons._aws_credentials_1
)
```

Parameters

table_name

A required text string containing the name of the PostgreSQL database table to import the data into.

column_list

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter.

options

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL COPY documentation.

s3_info

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
- `file_path` – The Amazon S3 file name including the path of the file.
- `region` – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

credentials

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see aws_commons.create_aws_credentials.

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (
   table_name text,
```

```
   column_list text,
   options text,
   bucket text,
   file_path text,
   region text
)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```
aws_s3.table_import_from_s3 (
   table_name text,
   column_list text,
   options text,
   bucket text,
   file_path text,
   region text,
   access_key text,
   secret_key text,
   session_token text
)
```

Alternate parameters

bucket

A text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A text string containing the Amazon S3 file name including the path of the file.

region

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

access_key

A text string containing the access key to use for the import operation. The default is NULL.

secret_key

A text string containing the secret key to use for the import operation. The default is NULL.

session_token

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

aws_commons.create_s3_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the aws_s3.table_import_from_s3 function.

Syntax

```
aws_commons.create_s3_uri(
   bucket text,
   file_path text,
   region text
)
```

Parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

aws_commons.create_aws_credentials

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the aws_s3.table_import_from_s3 function.

Syntax

```
aws_commons.create_aws_credentials(
```

```
    access_key text,
    secret_key text,
    session_token text
)
```

Parameters

access_key

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

secret_key

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

session_token

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the `pg_transport` extension on both the source and the destination DB instance. The `pg_transport` extension provides a physical transport mechanism that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

> **Note**
>
> PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in Setting up a DB instance for transport. You can then transport the database by using the function described in Transporting a PostgreSQL database.

Topics

- What happens during database transport
- Limitations for using PostgreSQL transportable databases
- Setting up to transport a PostgreSQL database
- Transporting a PostgreSQL database to the destination from the source
- Transportable databases function reference
- Transportable databases parameter reference

What happens during database transport

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The `transport.import_from_server` function creates the in-transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times *after* the backup finishes.

If the transport fails, the `pg_transport` extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination's partially transported database.

Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```
ALTER DATABASE db-name SET default_transaction_read_only = false;
```

Limitations for using PostgreSQL transportable databases

Transportable databases have the following limitations:

- **Read replicas** – You can't use transportable databases on read replicas or parent instances of read replicas.
- **Unsupported column types** – You can't use the `reg` data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.
- **Tablespaces** – All source database objects must be in the default `pg_default` tablespace.
- **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.
- **Extensions** – The source DB instance can have only the `pg_transport` installed.
- **Roles and ACLs** – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.
- **Concurrent transports** – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.
- **RDS for PostgreSQL DB instances only** – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

Setting up to transport a PostgreSQL database

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

- The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.
- The destination DB can't have a database of the same name as the source DB that you want to transport.

- The account you use to run the transport needs `rds_superuser` privileges on both the source DB and the destination DB.
- The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see Controlling access with security groups.

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

> **Note**
>
> If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.

To configure the custom DB group parameters for transporting databases

For the following steps, use an account that has `rds_superuser` privileges.

1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter group using the appropriate version for your instances. You do this so you can change values for several parameters. For more information, see Parameter groups for Amazon RDS.
2. In the custom DB parameter group, change values for the following parameters:
   - `shared_preload_libraries` – Add `pg_transport` to the list of libraries.
   - `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.
   - `pg_transport.work_mem` – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.
   - `max_worker_processes` – The value of this parameter needs to be set using the following calculation:

```
(3 * pg_transport.num_workers) + 9
```

This value is required on the destination to handle various background worker processes involved in the transport. To learn more about `max_worker_processes`, see Resource Consumption in the PostgreSQL documentation.

For more information about `pg_transport` parameters, see Transportable databases parameter reference.

3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.
4. Connect to your RDS for PostgreSQL source DB instance.

```
psql --host=source-instance.111122223333.aws-region.rds.amazonaws.com --port=5432
 --username=postgres --password
```

5. Remove extraneous extensions from the public schema of the DB instance. Only the `pg_transport` extension is allowed during the actual transport operation.
6. Install the `pg_transport` extension as follows:

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the `pg_transport` extension.

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

Transporting a PostgreSQL database to the destination from the source

After you complete the process described in Setting up to transport a PostgreSQL database, you can start the transport. To do so, run the `transport.import_from_server` function on the destination DB instance. In the syntax following you can find the function parameters.

```
SELECT transport.import_from_server(
   'source-db-instance-endpoint',
```

```
    source-db-instance-port,
   'source-db-instance-user',
   'source-user-password',
   'source-database-name',
   'destination-user-password',
   false);
```

The `false` value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify `true` for the `dry_run` option when you call the function, as shown following:

```
postgres=> SELECT transport.import_from_server(
    'docs-lab-source-db.666666666666aws-region.rds.amazonaws.com', 5432,
    'postgres', '********', 'labdb', '******', true);
INFO:  Starting dry-run of import of database "labdb".
INFO:  Created connections to remote database        (took 0.03 seconds).
INFO:  Checked remote cluster compatibility          (took 0.05 seconds).
INFO:  Dry-run complete                          (took 0.08 seconds total).
 import_from_server
--------------------

(1 row)
```

The INFO lines are output because the `pg_transport.timing` parameter is set to its default value, `true`. Set the `dry_run` to `false` when you run the command and the source database is imported to the destination, as shown following:

```
INFO:  Starting import of database "labdb".
INFO:  Created connections to remote database        (took 0.02 seconds).
INFO:  Marked remote database as read only           (took 0.13 seconds).
INFO:  Checked remote cluster compatibility          (took 0.03 seconds).
INFO:  Signaled creation of PITR blackout window     (took 2.01 seconds).
INFO:  Applied remote database schema pre-data       (took 0.50 seconds).
INFO:  Created connections to local cluster          (took 0.01 seconds).
INFO:  Locked down destination database              (took 0.00 seconds).
INFO:  Completed transfer of database files          (took 0.24 seconds).
INFO:  Completed clean up                            (took 1.02 seconds).
INFO:  Physical transport complete               (took 3.97 seconds total).
import_from_server
--------------------
(1 row)
```

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

```
pg_transport.num_workers=8 25% of files transported failed to download file data
```

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for `pg_transport.num_workers`. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

```
pg_transport.num_workers=4 75% of files transported failed to download file data
```

Keep in mind that the `max_worker_processes` parameter is also taken into account during the transport process. In other words, you might need to modify both `pg_transport.num_workers` and `max_worker_processes` to successfully transport the database. The example shown finally worked when the `pg_transport.num_workers` was set to 2:

```
pg_transport.num_workers=2 100% of files transported
```

For more information about the `transport.import_from_server` function and its parameters, see Transportable databases function reference.

Transportable databases function reference

The `transport.import_from_server` function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

Syntax

```
transport.import_from_server(
   host text,
   port int,
   username text,
   password text,
   database text,
   local_password text,
   dry_run bool
)
```

Return Value

None.

Parameters

You can find descriptions of the `transport.import_from_server` function parameters in the following table.

Parameter	Description
`host`	The endpoint of the source DB instance.
`port`	An integer representing the port of the source DB instance. PostgreSQL DB instances often use port 5432.
`username`	The user of the source DB instance. This user must be a member of the `rds_superuser` role.
`password`	The user password of the source DB instance.
`database`	The name of the database in the source DB instance to transport.
`local_password`	The local password of the current user for the destination DB instance. This user must be a member of the `rds_superuser` role.
`dry_run`	An optional Boolean value specifying whether to perform a dry run. The default is `false`, which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set `dry_run` to `true`.

Example

For an example, see Transporting a PostgreSQL database to the destination from the source.

Transportable databases parameter reference

Several parameters control the behavior of the `pg_transport` extension. Following, you can find descriptions of these parameters.

`pg_transport.num_workers`

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

`pg_transport.timing`

Specifies whether to report timing information during the transport. The default is `true`, meaning that timing information is reported. We recommend that you leave this parameter set to `true` so you can monitor progress. For example output, see Transporting a PostgreSQL database to the destination from the source.

`pg_transport.work_mem`

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64 megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.

The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.

Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

> **Note**
>
> Cross-account export to Amazon S3 isn't supported.

All currently available versions of RDS for PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see Amazon RDS for PostgreSQL updates in the *Amazon RDS for PostgreSQL Release Notes*.

If you don't have a bucket set up for your export, see the following topics the *Amazon Simple Storage Service User Guide*.

- Setting up Amazon S3
- Creating a bucket

By default, the data exported from RDS for PostgreSQL to Amazon S3 uses server-side encryption with an AWS managed key. If you are using bucket encryption, the Amazon S3 bucket must be encrypted with an AWS Key Management Service (AWS KMS) key (SSE-KMS). Currently, buckets encrypted with Amazon S3 managed keys (SSE-S3) are not supported.

> **Note**
>
> You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3 for Amazon RDS.

Topics

- Installing the aws_s3 extension
- Overview of exporting data to Amazon S3
- Specifying the Amazon S3 file path to export to
- Setting up access to an Amazon S3 bucket
- Exporting query data using the aws_s3.query_export_to_s3 function
- Function reference
- Troubleshooting access to Amazon S3

Installing the aws_s3 extension

Before you can use Amazon Simple Storage Service with your RDS for PostgreSQL DB instance, you need to install the `aws_s3` extension. This extension provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an RDS for PostgreSQL DB instance. The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

To install the `aws_s3` extension

1. Use psql (or pgAdmin) to connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the psql `\dx` metacommand.

```
postgres=> \dx
       List of installed extensions
    Name     | Version |   Schema   |                Description
-------------+---------+------------+-------------------------------------------
```

```
 aws_commons | 1.2     | public     | Common data types across AWS services
 aws_s3      | 1.1     | public     | AWS S3 extension for importing data from S3
 plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

Verify that your RDS for PostgreSQL version supports exports to Amazon S3

You can verify that your RDS for PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example verifies support for version 10.14.

```
aws rds describe-db-engine-versions --region us-east-1
--engine postgres --engine-version 10.14 | grep s3Export
```

If the output includes the string `"s3Export"`, then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

Overview of exporting data to Amazon S3

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

To export RDS for PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see Specifying the Amazon S3 file path to export to.
2. Provide permission to access the Amazon S3 bucket.

   To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

   1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
   2. Create an IAM role.
   3. Attach the policy you created to the role you created.

4. Add this IAM role to your DB instance.

   For details about this process, see Setting up access to an Amazon S3 bucket.

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

   After you complete the preceding preparation tasks, use the aws_s3.query_export_to_s3 function to export query results to Amazon S3. For details about this process, see Exporting query data using the aws_s3.query_export_to_s3 function.

Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- Bucket name – A *bucket* is a container for Amazon S3 objects or files.

  For more information on storing data with Amazon S3, see Creating a bucket and Working with objects in the *Amazon Simple Storage Service User Guide*.

- File path – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_part`*XX* appended. The *XX* represents 2, then 3, and so on.

  For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`.

- AWS Region (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.

> **Note**
>
> Currently, the AWS Region must be the same as the region of the exporting DB instance.

For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

To hold the Amazon S3 file information about where the export is to be stored, you can use the aws_commons.create_s3_uri function to create an `aws_commons._s3_uri_1` composite structure as follows.

```
psql=> SELECT aws_commons.create_s3_uri(
   'amzn-s3-demo-bucket',
   'sample-filepath',
   'us-west-2'
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the aws_s3.query_export_to_s3 function. For examples, see Exporting query data using the aws_s3.query_export_to_s3 function.

Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

To give a PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:

      - `s3:PutObject`
      - `s3:AbortMultipartUpload`

b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

> **Warning**
>
> We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.
> We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives `S3:PutObject` access to all resources using `"Resource":"*"`, then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to *any publicly writable bucket within your AWS Region*.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy  --policy-name rds-s3-export-policy  --policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "s3export",
         "Action": [
           "s3:PutObject*",
           "s3:ListBucket",
           "s3:GetObject*",
           "s3:DeleteObject*",
           "s3:GetBucketLocation",
           "s3:AbortMultipartUpload"
         ],
```

```
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ]
      }
    ]
  }'
```

2. Create an IAM role.

   You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.

   We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

   If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

   - Use `aws:SourceArn` if you want cross-service access for a single resource.
   - Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

   In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

   Example

   For Linux, macOS, or Unix:

```
aws iam create-role  \
    --role-name rds-s3-export-role  \
    --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
```

```
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
             }
       }
     ]
   }'
```

For Windows:

```
aws iam create-role  ^
    --role-name rds-s3-export-role  ^
    --assume-role-policy-document '{
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
          },
         "Action": "sts:AssumeRole",
         "Condition": {
             "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
             }
       }
     ]
   }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

   The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace *your-policy-arn* with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy  --policy-arn your-policy-arn  --role-name rds-s3-
export-role
```

4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

Console

To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.

AWS CLI

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace *`your-role-arn`* with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

  Example

  For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
   --db-instance-identifier my-db-instance \
   --feature-name s3Export \
   --role-arn your-role-arn   \
   --region your-region
```

  For Windows:

```
aws rds add-role-to-db-instance ^
   --db-instance-identifier my-db-instance ^
   --feature-name s3Export ^
   --role-arn your-role-arn ^
   --region your-region
```

Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the aws_s3.query_export_to_s3 function.

Topics

- Prerequisites
- Calling aws_s3.query_export_to_s3
- Exporting to a CSV file that uses a custom delimiter
- Exporting to a binary file with encoding

Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3.
- Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to.
- Make sure that the DB instance has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket.

The examples following use a database table called `sample_table`. These examples export the data into a bucket called *amzn-s3-demo-bucket*. The example table and data are created with the following SQL statements in psql.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,
 'Wednesday');
```

Calling aws_s3.query_export_to_s3

The following shows the basic ways of calling the aws_s3.query_export_to_s3 function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the aws_commons.create_s3_uri function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri(
   'amzn-s3-demo-bucket',
   'sample-filepath',
   'us-west-2'
) AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called *amzn-s3-demo-bucket*.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM
 sample_table', :'s3_uri_1');

psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM
 sample_table', :'s3_uri_1', options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `:'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

  ```
  SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
     aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2')
  );
  ```

- `options :='format text'` – The `options` parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_part`*XX* appended. The *XX* represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part2
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see aws_s3.query_export_to_s3. For more about accessing files in Amazon S3, see View an object in the *Amazon Simple Storage Service User Guide*.

Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the aws_s3.query_export_to_s3 function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
 options :='format csv, delimiter $$:$$');
```

Exporting to a binary file with encoding

The following example shows how to call the aws_s3.query_export_to_s3 function to export data to a binary file that has Windows-1253 encoding.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
 options :='format binary, encoding WIN1253');
```

Function reference

Functions

- aws_s3.query_export_to_s3
- aws_commons.create_s3_uri

aws_s3.query_export_to_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see Exporting query data using the aws_s3.query_export_to_s3 function.

Syntax

```
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text,
    kms_key text
)
```

Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

s3_info

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket to contain the file.
- `file_path` – The Amazon S3 file name and path.
- `region` – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

  Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

To create an `aws_commons._s3_uri_1` composite structure, see the aws_commons.create_s3_uri function.

options

An optional text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

kms_key text

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the `s3_info` parameter. Following are additional syntax variations for the `aws_s3.query_export_to_s3` function.

Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters.

```
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text,
    options text,
    kms_key text
)
```

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

options

An optional text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

kms_key text

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

Output parameters

```
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

rows_uploaded

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

files_uploaded

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has `_part`*XX* appended to the name. The *XX* represents 2, then 3, and so on as needed.

bytes_uploaded

The total number of bytes uploaded to Amazon S3.

Examples

```
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-
demo-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-
demo-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-
demo-bucket', 'sample-filepath','us-west-2','format text');
```

aws_commons.create_s3_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the aws_s3.query_export_to_s3 function. For an example of using the `aws_commons.create_s3_uri` function, see Specifying the Amazon S3 file path to export to.

Syntax

```
aws_commons.create_s3_uri(
   bucket text,
   file_path text,
   region text
)
```

Input parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones.

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see Provide access to your DB instance in your VPC by creating a security group.

See also the following for recommendations:

- Troubleshooting Amazon RDS identity and access

- Troubleshooting Amazon S3 and IAM in the *IAM User Guide*

Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the *AWS Lambda Developer Guide.*

Note

Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:

- All PostgreSQL 18 versions
- All PostgreSQL 17 versions
- All PostgreSQL 16 versions
- All PostgreSQL 15 versions
- PostgreSQL 14.1 and higher minor versions
- PostgreSQL 13.2 and higher minor versions
- PostgreSQL 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the *AWS Lambda Developer Guide*.

Topics

- Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda
- Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda
- Step 3: Install the aws_lambda extension for an RDS for PostgreSQL DB instance
- Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)

- Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance
- Step 6: Grant other users permission to invoke Lambda functions
- Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance
- Lambda function error messages
- AWS Lambda function and parameter reference

Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance sends network traffic to the Lambda service's VPC. How you configure this depends on whether your DB instance is public or private.

- **Public RDS for PostgreSQL DB instance** – A DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is `true`. To find the value of this property, you can use the describe-db-instances AWS CLI command. Or, you can use the AWS Management Console to open the **Connectivity & security** tab and check that **Publicly accessible** is **Yes**. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

  To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).
- **Private RDS for PostgreSQL DB instance** – In this case, the instance's "PubliclyAccessible" property is `false` or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation) NAT gateway. For more information, see NAT gateways. Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see VPC endpoints in the *Amazon VPC User Guide*. The endpoint responds to calls made by your RDS for PostgreSQL DB instance to your Lambda functions. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the `rds.custom_dns_resolution` from its default value of 0 (not enabled) to 1. To do so:
  - Create a custom DB parameter group.
  - Change the value of the `rds.custom_dns_resolution` parameter from its default of `0` to 1.
  - Modify your DB instance to use your custom DB parameter group.

- Reboot the instance to have the modified parameter take effect.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

To configure IAM permissions for using your Amazon RDS instance with Lambda

1. Use the create-policy AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

```
aws iam create-policy  --policy-name rds-lambda-policy --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
        "Sid": "AllowAccessToExampleFunction",
        "Effect": "Allow",
        "Action": "lambda:InvokeFunction",
        "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"
        }
    ]
}'
```

   Alternatively, you can use the predefined `AWSLambdaRole` policy that allows you to invoke any of your Lambda functions. For more information, see Identity-based IAM policies for Lambda

2. Use the create-role AWS CLI command to create an IAM role that the policy can assume at runtime.

```
aws iam create-role  --role-name rds-lambda-role --assume-role-policy-document '{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
        "Effect": "Allow",
        "Principal": {
            "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
        }
    ]
}'
```

3. Apply the policy to the role by using the attach-role-policy AWS CLI command.

```
aws iam attach-role-policy \
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
    --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your RDS for PostgreSQL DB instance by using the add-role-to-db-instance AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

```
aws rds add-role-to-db-instance \
       --db-instance-identifier my-instance-name \
       --feature-name Lambda \
       --role-arn  arn:aws:iam::444455556666:role/rds-lambda-role   \
       --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

Step 3: Install the `aws_lambda` extension for an RDS for PostgreSQL DB instance

To use AWS Lambda with your RDS for PostgreSQL DB instance, add the `aws_lambda` PostgreSQL extension to your RDS for PostgreSQL DB instance. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.

To install the aws_lambda extension in your RDS for PostgreSQL DB instance

Use the PostgreSQL psql command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with rds_superuser privileges. The default postgres user is shown in the example.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Install the aws_lambda extension. The aws_commons extension is also required. It provides helper functions to aws_lambda and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQLDB instance, it's installed with aws_lambda as shown following.

```
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
```

The aws_lambda extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)

You can use the helper functions in the aws_commons extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in Step 2: Configure IAM for your instance and Lambda requires the ARN, so we recommend that you use your function's ARN.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your RDS for PostgreSQL DB instance.

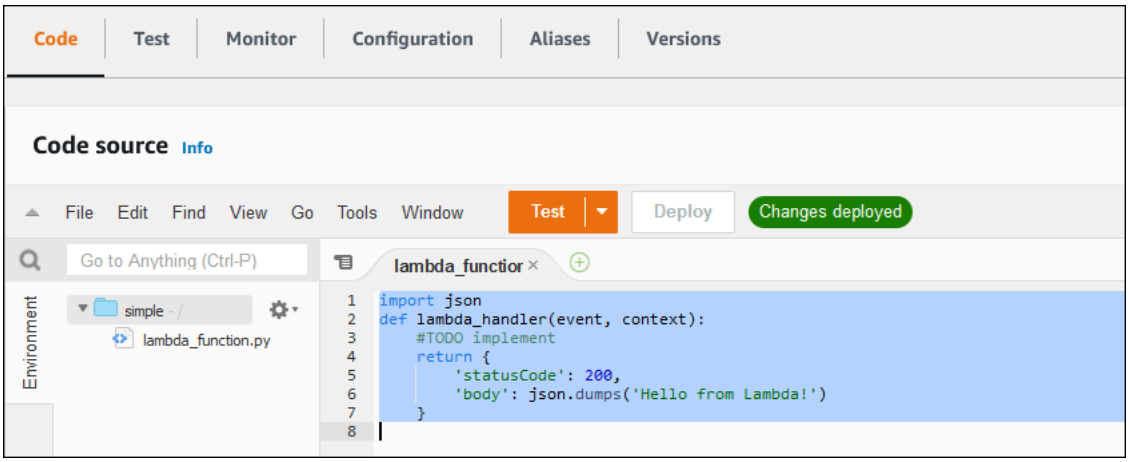
To hold the Lambda function name information, you use the aws_commons.create_lambda_function_arn function. This helper function creates an

`aws_commons._lambda_function_arn_1` composite structure with the details needed by the invoke function. Following, you can find three alternative approaches to setting up this composite structure.

```
SELECT aws_commons.create_lambda_function_arn(
   'my-function',
   'aws-region'
) AS aws_lambda_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(
   '111122223333:function:my-function',
   'aws-region'
) AS lambda_partial_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(
   'arn:aws:lambda:aws-region:111122223333:function:my-function'
) AS lambda_arn_1 \gset
```



Any of these values can be used in calls to the aws_lambda.invoke function. For examples, see Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance.

Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **`RequestResponse`** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.
- **`Event`** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

To invoke an example function

1. Connect to your DB instance using `psql` or pgAdmin.

   ```
   psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```
   SELECT * from
    aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-
   region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from
    Postgres!"}'::json );
   ```

   The response looks as follows.

   ```
   status_code |                         payload                         |
    executed_version | log_result
   -------------+---------------------------------------------------------
   +------------------+------------
            200 | {"statusCode": 200, "body": "\"Hello from Lambda!\""} | $LATEST
        |
   (1 row)
   ```

If your invocation attempt doesn't succeed, see Lambda function error messages.

Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

To grant others permission to invoke Lambda functions

1. Connect to your DB instance using `psql` or pgAdmin.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Run the following SQL commands:

```
postgres=>  GRANT USAGE ON SCHEMA aws_lambda TO db_username;
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
```

Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance

Following, you can find several examples of calling the aws_lambda.invoke function. Most of the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions. All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see Invoking Lambda functions in the *AWS Lambda Developer Guide*. For more information about `aws_lambda_arn_1`, see aws_commons.create_lambda_function_arn.

Examples list

- Example: Synchronous (RequestResponse) invocation of Lambda functions
- Example: Asynchronous (Event) invocation of Lambda functions
- Example: Capturing the Lambda execution log in a function response
- Example: Including client context in a Lambda function
- Example: Invoking a specific version of a Lambda function

Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json);
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json, 'RequestResponse');
```

The parameters are described as follows:

- `:'aws_lambda_arn_1'` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

  ```
  SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function',
   'aws-region'),
  '{"body": "Hello from Postgres!"}'::json
  );
  ```

- `'{"body": "Hello from PostgreSQL!"}'::json` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.

Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The `Event` invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the `Event` invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json, 'Event');
```

Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the `log_type` parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to None, but you can specify `Tail` to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
 aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json,
 'RequestResponse', 'Tail');
```

Set the aws_lambda.invoke function's `log_type` parameter to `Tail` to include the execution log in the response. The default value for the `log_type` parameter is None.

The `log_result` that's returned is a `base64` encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about `log_type`, see aws_lambda.invoke.

Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a `context` parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
 aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json,
 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the aws_lambda.invoke function's `context` parameter.

For more information about the `context` parameter, see the aws_lambda.invoke reference.

Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the `qualifier` parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using '*`custom_version`*' as an alias for the version.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-
function:custom_version', 'us-west-2'),
'{"body": "Hello from Postgres!"}'::json);
```

For more information about `qualifier` and other parameters, see the aws_lambda.invoke reference.

Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

  VPC configuration issues can raise the following error messages when trying to connect:

  ```
  ERROR:  invoke API failed
  DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
  CONTEXT:  SQL function "invoke" statement 1
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

  If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the `rds.custom_dns_resolution` parameter to 1 and setup AWS PrivateLink as outlined in Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda. For more information, see Interface VPC endpoints (AWS PrivateLink).

- **Lack of permissions needed to invoke Lambda functions**

  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

  ```
  ERROR:  permission denied for schema aws_lambda
  ```

  ```
  ERROR:  permission denied for function invoke
  ```

A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions.

- **Improper handling of errors in your Lambda functions**

  If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
 Postgres!"}'::json);
ERROR:  lambda invocation failed
DETAIL:  "arn:aws:lambda:us-west-2:555555555555:function:my-function" returned error
 "Unhandled", details: "<Error details string>".
```

  Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function and parameter reference

Following is the reference for the functions and parameters to use for invoking Lambda with RDS for PostgreSQL.

Functions and parameters

- aws_lambda.invoke
- aws_commons.create_lambda_function_arn
- aws_lambda parameters

aws_lambda.invoke

Runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also Invoke in the *AWS Lambda Developer Guide.*

Syntax

JSON

```
aws_lambda.invoke(
```

```
IN function_name TEXT,
IN payload JSON,
IN region TEXT DEFAULT NULL,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSON DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSON,
OUT executed_version TEXT,
OUT log_result TEXT)
```

```
aws_lambda.invoke(
IN function_name aws_commons._lambda_function_arn_1,
IN payload JSON,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSON DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSON,
OUT executed_version TEXT,
OUT log_result TEXT)
```

JSONB

```
aws_lambda.invoke(
IN function_name TEXT,
IN payload JSONB,
IN region TEXT DEFAULT NULL,
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT)
```

```
aws_lambda.invoke(
IN function_name aws_commons._lambda_function_arn_1,
IN payload JSONB,
```

```
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT
)
```

Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the *AWS Lambda Developer Guide.*

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the `function_name` or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the `function_name` ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- `RequestResponse` – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the `RequestResponse` invocation type when your workflow depends on receiving the Lambda function result immediately.
- `Event` – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the `Event` invocation type when you don't need results of the Lambda function before your workflow moves on.
- `DryRun` – This type of invocation tests access without running the Lambda function.

log_type

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

- Tail – The returned `log_result` output parameter will include the last 4 KB of the execution log.
- None – No Lambda log information is returned.

context

Client context in JSON or JSONB format. Fields to use include than `custom` and `env`.

qualifier

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

Output parameters

status_code

An HTTP status response code. For more information, see Lambda Invoke response elements in the *AWS Lambda Developer Guide.*

payload

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

executed_version

The version of the Lambda function that ran.

log_result

The execution log information returned if the `log_type` value is `Tail` when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

aws_commons.create_lambda_function_arn

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the aws_lambda.invoke aws_lambda.invoke function.

Syntax

```
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
    )
    RETURNS aws_commons._lambda_function_arn_1
```

Input parameters

function_name

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

region

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see Regions, Availability Zones, and Local Zones.

aws_lambda parameters

In this table, you can find parameters associated with the `aws_lambda` function.

Parameter	Description
`aws_lambda.connect_timeout_ms`	This is a dynamic parameter and it sets the maximum wait time while connecting to AWS Lambda. The default values is `1000`. Allowed values for this parameter are 1 - 900000.
`aws_lambda.request_timeout_ms`	This is a dynamic parameter and it sets the maximum wait time while waiting for response from AWS Lambda. The default values is `3000`. Allowed values for this parameter are 1 - 900000.
`aws_lambda.endpoint_override`	Specifies the endpoint that can be used to connect to AWS Lambda. An empty string selects the default AWS Lambda endpoint for the region. You must restart the database for this static parameter change to take effect.

Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. If you're a DBA already familiar with PostgreSQL, you need to be aware of some of the important differences between running PostgreSQL on your hardware and RDS for PostgreSQL. For example, because it's a managed service, Amazon RDS doesn't allow shell access to your DB instances. That means that you don't have direct access to `pg_hba.conf` and other configuration files. For RDS for PostgreSQL, changes that are typically made to the PostgreSQL configuration file of an on-premises instance are made to a custom DB parameter group associated with the RDS for PostgreSQL DB instance. For more information, see Parameter groups for Amazon RDS.

You also can't access log files in the same way that you do with an on-premises PostgreSQL instance. To learn more about logging, see RDS for PostgreSQL database log files.

As another example, you don't have access to the PostgreSQL `superuser` account. On RDS for PostgreSQL, the `rds_superuser` role is the most highly privileged role, and it's granted to `postgres` at set up time. Whether you're familiar with using PostgreSQL on-premises or completely new to RDS for PostgreSQL, we recommend that you understand the `rds_superuser` role, and how to work with roles, users, groups, and permissions. For more information, see Understanding PostgreSQL roles and permissions.

Following are some common DBA tasks for RDS for PostgreSQL.

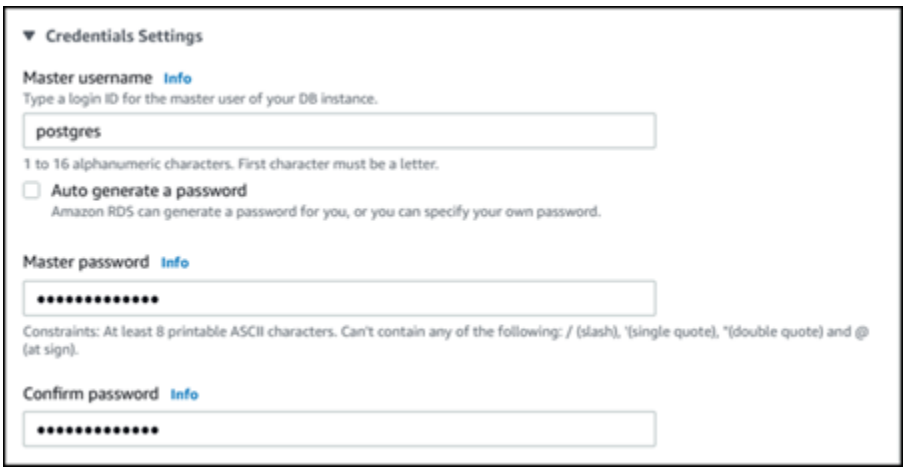
Topics

- Collations supported in RDS for PostgreSQL
- Understanding PostgreSQL roles and permissions
- Dead connection handling in PostgreSQL
- Working with PostgreSQL autovacuum on Amazon RDS for PostgreSQL
- Managing TOAST OID contention in Amazon RDS for PostgreSQL
- Working with logging mechanisms supported by RDS for PostgreSQL
- Managing temporary files with PostgreSQL
- Using pgBadger for log analysis with PostgreSQL
- Using PGSnapper for monitoring PostgreSQL
- Managing custom casts in RDS for PostgreSQL
- Working with parameters on your RDS for PostgreSQL DB instance

Collations supported in RDS for PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, RDS for PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.



When you create a new DB instance in RDS for PostgreSQL , it checks the operating system for the available collation. The PostgreSQL parameters of the `CREATE DATABASE` command `LC_COLLATE` and `LC_CTYPE` are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the `LOCALE` parameter in `CREATE DATABASE` to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.

RDS for PostgreSQL depends on the glibc library in the operating system for collation support. RDS for PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, RDS for PostgreSQL now includes an independent default collation library. This collation library is available in RDS for PostgreSQL 14.6, 13.9, 12.13, 11.18, 10.23 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

Understanding PostgreSQL roles and permissions

When you create an RDS for PostgreSQL DB instance using the AWS Management Console, an administrator account is created at the same time. By default, its name is `postgres`, as shown in the following screenshot:

You can choose another name rather than accept the default (`postgres`). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (`postgres`) throughout this guide.

If you use the `create-db-instance` AWS CLI rather than the AWS Management Console, you create the name by passing it with the `master-username` parameter in the command. For more information, see Creating an Amazon RDS DB instance.

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default `postgres` name or choose a different name, this first database user account is a member of the `rds_superuser` group and has `rds_superuser` privileges.

Topics

- Understanding the rds_superuser role
- Controlling user access to the PostgreSQL database
- Delegating and controlling user password management
- Using SCRAM for PostgreSQL password encryption

Understanding the rds_superuser role

In PostgreSQL, a *role* can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to `CREATE USER` and `CREATE GROUP` have been replaced by the more general, `CREATE ROLE` with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.

> **Note**
>
> The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see Database Roles in the PostgreSQL documentation.

The `postgres` user is the most highly privileged database user on your RDS for PostgreSQL DB instance. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION
 VALID UNTIL 'infinity'
```

The properties `NOSUPERUSER`, `NOREPLICATION`, `INHERIT`, and `VALID UNTIL 'infinity'` are the default options for CREATE ROLE, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role, and permissions to create roles and databases. The `rds_superuser` role allows the `postgres` user to do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see Working with PostgreSQL features supported by Amazon RDS for PostgreSQL
- Create roles for users and grant privileges to users. For more information, see CREATE ROLE and GRANT in the PostgreSQL documentation.
- Create databases. For more information, see CREATE DATABASE in the PostgreSQL documentation.
- Grant `rds_superuser` privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the `rds_replication` role to database users that don't have the `rds_superuser` role.
- Grant (and revoke) the `rds_password` role to database users that don't have the `rds_superuser` role.
- Obtain status information about all database connections by using the `pg_stat_activity` view. When needed, `rds_superuser` can stop any connections by using `pg_terminate_backend` or `pg_cancel_backend`.

In the `CREATE ROLE postgres...` statement, you can see that the `postgres` user role specifically disallows PostgreSQL `superuser` permissions. RDS for PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL `superuser` account. Many of the tasks that require `superuser` access on a stand-alone PostgreSQL are managed automatically by Amazon RDS.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The `rds_superuser` role is one of several *predefined* roles in an RDS for PostgreSQL DB instance.

> **Note**
>
> In PostgreSQL 13 and earlier releases, *predefined* roles are known as *default* roles.

In the following list, you find some of the other predefined roles that are created automatically for a new RDS for PostgreSQL DB instance. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds_password** – A role that can change passwords and set up password constraints for database users. The `rds_superuser` role is granted with this role by default, and can grant the role to database users. For more information, see Controlling user access to the PostgreSQL database.
  - For RDS for PostgreSQL versions older than 14, `rds_password` role can change passwords and set up password constraints for database users and users with `rds_superuser` role. From RDS for PostgreSQL version 14 and later, `rds_password` role can change passwords and set up password constraints only for database users. Only users with `rds_superuser` role can perform these actions on other users with `rds_superuser` role.
- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone PostgreSQL database. This role is used internally by RDS for PostgreSQL for many management tasks.
- **rdstopmgr** – A role that's used internally by Amazon RDS to support Multi-AZ deployments.
- **rds_reserved** – A role that's used internally by Amazon RDS to reserve database connections.

Viewing roles and their privileges

You can view predefined roles and their privileges in your RDS for PostgreSQL DB instance using different commands depending on your PostgreSQL version. To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and run following commands using the `psql`.

For `psql` 15 and earlier versions

Connect to your RDS for PostgreSQL DB instance and use the \du command in psql:

```
postgres=> \du
                                                          List of roles
    Role name    |                         Attributes                          |
                 Member of
-----------------+-----------------------------------------------------------------
+-----------------------------------------------------
 postgres        | Create role, Create DB                                      +|
 {rds_superuser}
                 | Password valid until infinity                               |
 rds_ad          | Cannot login                                                | {}
 rds_iam         | Cannot login                                                | {}
 rds_password    | Cannot login                                                | {}
 rds_replication | Cannot login                                                | {}
 rds_superuser   | Cannot login                                                |
 {pg_monitor,pg_signal_backend,rds_password,rds_replication}
 rdsadmin        | Superuser, Create role, Create DB, Replication, Bypass RLS+| {}
                 | Password valid until infinity                               |
```

For `psql` 16 and later versions

```
postgres=> \drg+
                            List of role grants
   Role name   |          Member of          |       Options       | Grantor
---------------+-----------------------------+---------------------+----------
 postgres      | rds_superuser               | INHERIT, SET        | rdsadmin
 rds_superuser | pg_checkpoint               | ADMIN, INHERIT, SET | rdsadmin
 rds_superuser | pg_monitor                  | ADMIN, INHERIT, SET | rdsadmin
 rds_superuser | pg_signal_backend           | ADMIN, INHERIT, SET | rdsadmin
 rds_superuser | pg_use_reserved_connections | ADMIN, INHERIT, SET | rdsadmin
 rds_superuser | rds_password                | ADMIN, INHERIT, SET | rdsadmin
 rds_superuser | rds_replication             | ADMIN, INHERIT, SET | rdsadmin
```

To check role membership without version dependency, you can use the following SQL query:

```
SELECT m.rolname AS "Role name", r.rolname AS "Member of"
FROM pg_catalog.pg_roles m
JOIN pg_catalog.pg_auth_members pam ON (pam.member = m.oid)
LEFT JOIN pg_catalog.pg_roles r ON (pam.roleid = r.oid)
LEFT JOIN pg_catalog.pg_roles g ON (pam.grantor = g.oid)
WHERE m.rolname !~ '^pg_'
ORDER BY 1, 2;
```

In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's **Create database** page. If you chose another name, that name is shown in the list of roles instead.

Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database's `public` schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your RDS for PostgreSQL DB instance, we recommend that you revoke these default `public` privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

To set up roles and privileges for a new database instance

Suppose you're setting up a database on a newly created RDS for PostgreSQL DB instance for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or pgAdmin) to connect to your RDS for PostgreSQL DB instance:

   ```
   psql --host=your-db-instance.666666666666.aws-region.rds.amazonaws.com --port=5432
    --username=postgres --password
   ```

   When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.
2. To prevent database users from creating objects in the `public` schema, do the following:

```
postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

3. Next, you create a new database instance:

```
postgres=> CREATE DATABASE lab_db;
CREATE DATABASE
```

4. Revoke all privileges from the PUBLIC schema on this new database.

```
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
REVOKE
```

5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;
CREATE ROLE
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
GRANT
```

7. Grant all users with the `lab_tech` role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
GRANT
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
CREATE ROLE
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
CREATE ROLE
```

9. Grant these two users the privileges associated with the lab_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
GRANT ROLE
postgres=> GRANT lab_tech TO lab_user2;
GRANT ROLE
```

At this point, `lab_user1` and `lab_user2` can connect to the `lab_db` database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see Managing PostgreSQL Users and Roles.

For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the `rds_password` role can manage passwords.

> **Note**
>
> To use restricted password management, your RDS for PostgreSQL DB instance must be running PostgreSQL 10.6 or higher.

By default, this feature is `off`, as shown in the following:

```
postgres=> SHOW rds.restrict_password_commands;
  rds.restrict_password_commands
--------------------------------
 off
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your RDS for PostgreSQL DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
```

```
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (`ALTER ROLE myrole RENAME TO newname`) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

Using SCRAM for PostgreSQL password encryption

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see Password Authentication in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your RDS for PostgreSQL DB instance. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see PostgreSQL JDBC Driver in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see List of drivers in the PostgreSQL documentation.

RDS for PostgreSQL version 13.1 and higher support scram-sha-256. These versions also let you configure your DB instance to require SCRAM, as discussed in the following procedures.

Setting up RDS for PostgreSQL DB instance to require SCRAM

you can require the RDS for PostgreSQL DB instance to accept only passwords that use the scram-sha-256 algorithm.

> **Important**
>
> For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:
>
> - Ensure that the database allows both SCRAM and MD5 authentication.
> - To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your RDS for PostgreSQL DB instance for the parameters that control password encryption.
- If your RDS for PostgreSQL DB instance uses a default parameter group, you need to create a custom DB parameter group and apply it to your RDS for PostgreSQL DB instance so that you can modify parameters when needed. If your RDS for PostgreSQL DB instance uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the `password_encryption` parameter to `scram-sha-256`.
- Notify all database users that they need to update their passwords. Do the same for your `postgres` account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
- Verify that all passwords are encrypted using as the type of encryption.
- If all passwords use scram-sha-256, you can change the `rds.accepted_password_auth_method` parameter from `md5+scram` to `scram-sha-256`.

Warning

After you change `rds.accepted_password_auth_method` to scram-sha-256 alone, any users (roles) with md5–encrypted passwords can't connect.

Getting ready to require SCRAM for your RDS for PostgreSQL DB instance

Before making any changes to your RDS for PostgreSQL DB instance, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the `rds_tools` extension. To see which PostgreSQL versions support `rds_tools`, see Extension versions for Amazon RDS for PostgreSQL.

To get a list of database users (roles) and password encryption methods

1. Use `psql` to connect to your RDS for PostgreSQL DB instance, as shown in the following.

```
psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. Install the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools;
CREATE EXTENSION
```

3. Get a listing of roles and encryption.

```
postgres=> SELECT * FROM
      rds_tools.role_password_encryption_type();
```

You see output similar to the following.

```
       rolname        | encryption_type
----------------------+-----------------
 pg_monitor           |
 pg_read_all_settings |
 pg_read_all_stats    |
 pg_stat_scan_tables  |
 pg_signal_backend    |
 lab_tester           | md5
 user_465             | md5
```

```
 postgres             | md5
(8 rows)
```

Creating a custom DB parameter group

> **Note**
>
> If your RDS for PostgreSQL DB instance already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Amazon RDS, see Working with parameters on your RDS for PostgreSQL DB instance.

The password encryption type used for passwords is set in one parameter, `password_encryption`. The encryption that the RDS for PostgreSQL DB instance allows is set in another parameter, `rds.accepted_password_auth_method`. Changing either of these from the default values requires that you create a custom DB parameter group and apply it to your instance.

You can also use the AWS Management Console or the RDS API to create a custom DB parameter group. For more information, see

You can now associate the custom parameter group with your DB instance.

To create a custom DB parameter group

1. Use the `create-db-parameter-group` CLI command to create the custom DB parameter group. This example uses `postgres13` as the source for this custom parameter group.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-parameter-group --db-parameter-group-name 'docs-lab-scram-passwords' \
     --db-parameter-group-family postgres13  --description 'Custom parameter group for SCRAM'
   ```

   For Windows:

   ```
   aws rds create-db-parameter-group --db-parameter-group-name "docs-lab-scram-passwords" ^
   ```

```
  --db-parameter-group-family postgres13  --description "Custom DB parameter group
for SCRAM"
```

2. Use the modify-db-instance CLI command to apply this custom parameter group to your RDS for PostgreSQL DB cluster.

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-instance --db-instance-identifier 'your-instance-name' \
           --db-parameter-group-name "docs-lab-scram-passwords
   ```

   For Windows:

   ```
   aws rds modify-db-instance --db-instance-identifier "your-instance-name" ^
           --db-parameter-group-name "docs-lab-scram-passwords
   ```

   To resynchronize your RDS for PostgreSQL DB instance with your custom DB parameter group, you need to reboot the primary and all other instances of the cluster. To minimize impact to your users, schedule this to occur during your regular maintenance window.

Configuring password encryption to use SCRAM

The password encryption mechanism used by an RDS for PostgreSQL DB instance is set in the DB parameter group in the `password_encryption` parameter. Allowed values are unset, `md5`, or `scram-sha-256`. The default value depends on the RDS for PostgreSQL version, as follows:

- RDS for PostgreSQL 14 and above – Default is `scram-sha-256`
- RDS for PostgreSQL 13 – Default is `md5`

With a custom DB parameter group attached to your RDS for PostgreSQL DB instance, you can modify values for the password encryption parameter.

Name	Values	Allowed values	Modifiable	Source	Apply type
password_encryption	md5	md5, scram-sha-256	true	system	dynamic
rds.accepted_password_auth_method	md5+scram	md5+scram, scram	true	system	dynamic

To change password encryption setting to scram-sha-256

- Change the value of password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

  For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name \
  'docs-lab-scram-passwords' --parameters
 'ParameterName=password_encryption,ParameterValue=scram-
sha-256,ApplyMethod=immediate'
```

  For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name ^
  "docs-lab-scram-passwords" --parameters
 "ParameterName=password_encryption,ParameterValue=scram-
sha-256,ApplyMethod=immediate"
```

Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, `postgres`) as shown following.

```
psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

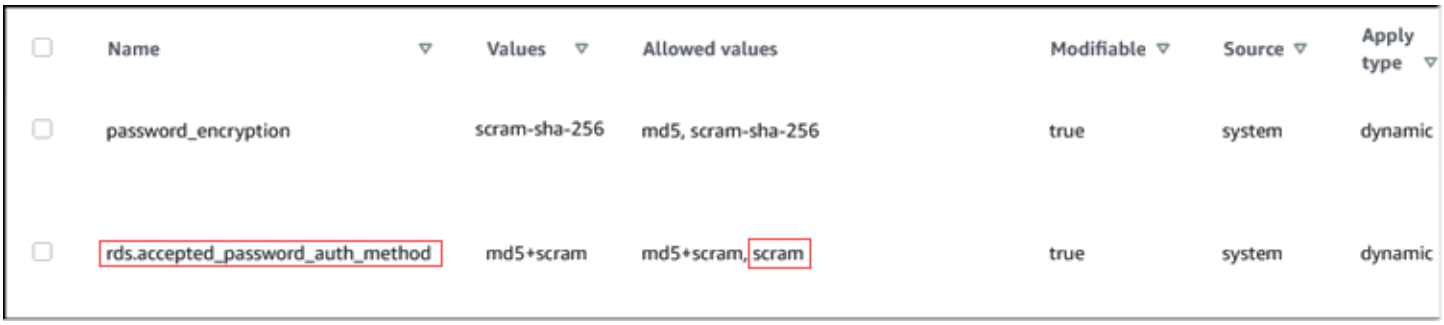
2. Check the setting of the `password_encryption` parameter on your RDS for PostgreSQL DB instance by using the following command.

```
postgres=> SHOW password_encryption;
 password_encryption
---------------------
 md5
 (1 row)
```

3. Change the value of this parameter to scram-sha-256. For more information, see [Configuring password encryption to use SCRAM].
4. Check the value again to make sure that it's now set to `scram-sha-256`, as follows.

```
postgres=> SHOW password_encryption;
 password_encryption
---------------------
 scram-sha-256
 (1 row)
```

5. Notify all database users to change their passwords. Be sure to also change your own password for account `postgres` (the database user with `rds_superuser` privileges).



```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

6. Repeat the process for all databases on your RDS for PostgreSQL DB instance.

Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use `md5` encryption for passwords can't log in to the RDS for PostgreSQL DB instance.

The `rds.accepted_password_auth_method` specifies the encryption method that the RDS for PostgreSQL DB instance accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

Name	Values	Allowed values	Modifiable	Source	Apply type
password_encryption	scram-sha-256	md5, scram-sha-256	true	system	dynamic
rds.accepted_password_auth_method	md5+scram	md5+scram, scram	true	system	dynamic

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your RDS for PostgreSQL DB instance use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
  rolname        | encryption_type
  ---------------------+----------------
  pg_monitor           |
  pg_read_all_settings |
  pg_read_all_stats    |
  pg_stat_scan_tables  |
  pg_signal_backend    |
  lab_tester           | scram-sha-256
  user_465             | scram-sha-256
  postgres             | scram-sha-256
  ( rows)
```

2. Repeat the query across all DB instances in your RDS for PostgreSQL DB instance.

   If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

   For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scram-
passwords' \
  --parameters
 'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

   For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scram-
passwords" ^
  --parameters
 "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

Dead connection handling in PostgreSQL

Dead connections occur when a database session remains active on the server despite the client application having abandoned or terminated abnormally. This situation typically arises when client processes crash or terminate unexpectedly without properly closing their database connections or canceling ongoing requests.

PostgreSQL efficiently identifies and cleans up dead connections when server processes are idle or attempt to send data to clients. However, detection is challenging for sessions that are idle, waiting for client input, or actively running queries. To handle these scenarios, PostgreSQL provides `tcp_keepalives_*`, `tcp_user_timeout`, and `client_connection_check_interval` parameters.

Topics

- Understanding TCP keepalive
- Key TCP keepalive parameters in RDS for PostgreSQL
- Use cases for TCP keepalive settings
- Best practices

Understanding TCP keepalive

TCP Keepalive is a protocol-level mechanism that helps maintain and verify connection integrity. Each TCP connection maintains kernel-level settings that govern keepalive behavior. When the keepalive timer expires, the system does the following:

- Sends a probe packet with no data and the ACK flag set.
- Expects a response from the remote endpoint according to TCP/IP specifications.
- Manages connection state based on the response or lack thereof.

Key TCP keepalive parameters in RDS for PostgreSQL

Parameter	Description	Default values
`tcp_keepalives_idle`	Specifies number of seconds of inactivity before sending keepalive message.	300

Parameter	Description	Default values
tcp_keepalives_interval	Specifies number of seconds between retransmissions of unacknowledged keepalive messages.	30
tcp_keepalives_count	Maximum lost keepalive messages before declaring connection dead	2
tcp_user_timeout	Specifies how long (in Milliseconds) unacknowledged data can remain before forcibly closing the connection.	0
client_connection_check_interval	Sets the interval (in Milliseconds) for checking client connection status during long-running queries. This ensures quicker detection of closed connections.	0

Use cases for TCP keepalive settings

Keeping idle sessions alive

To prevent idle connections from being terminated by firewalls or routers due to inactivity:

- Configure `tcp_keepalives_idle` to send keepalive packets at regular intervals.

Detecting dead connections

To detect dead connections promptly:

- Adjust `tcp_keepalives_idle`, `tcp_keepalives_interval`, and `tcp_keepalives_count`. For example, with Aurora PostgreSQL defaults, it takes about a minute (2 probes × 30 seconds) to detect a dead connection. Lowering these values can speed up detection.
- Use `tcp_user_timeout` to specify the maximum wait time for an acknowledgment.

TCP keepalive settings help the kernel detect dead connections, but PostgreSQL may not act until the socket is used. If a session is running a long query, dead connections might only be detected after query completion. In PostgreSQL 14 and higher versions, `client_connection_check_interval` can expedite dead connection detection by periodically polling the socket during query execution.

Best practices

- **Set reasonable keepalive intervals:** Tune `tcp_user_timeout`, `tcp_keepalives_idle`, `tcp_keepalives_count` and `tcp_keepalives_interval` to balance detection speed and resource use.
- **Optimize for your environment:** Align settings with network behavior, firewall policies, and session needs.
- **Leverage PostgreSQL features:** Use `client_connection_check_interval` in PostgreSQL 14 and higher versions for efficient connection checks.

Working with PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see Best practices for working with PostgreSQL.

Topics

- Allocating memory for autovacuum
- Reducing the likelihood of transaction ID wraparound
- Determining if the tables in your database need vacuuming
- Determining which tables are currently eligible for autovacuum
- Determining if autovacuum is currently running and for how long
- Performing a manual vacuum freeze
- Reindexing a table when autovacuum is running
- Managing autovacuum with large indexes
- Other parameters that affect autovacuum
- Setting table-level autovacuum parameters
- Logging autovacuum and vacuum activities
- Understanding the behavior of autovacuum with invalid databases
- Identify and resolve aggressive vacuum blockers in RDS for PostgreSQL

Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the `autovacuum_work_mem` parameter. In RDS for PostgreSQL versions 14 and prior, the `autovacuum_work_mem` parameter is set to -1, indicating that the setting of `maintenance_work_mem` is used instead. For all other versions, `autovacuum_work_mem` is determined by GREATEST({DBInstanceClassMemory/32768}, 65536).

Manual vacuum operations always use the `maintenance_work_mem` setting, with a default setting of GREATEST({DBInstanceClassMemory/63963136*1024}, 65536), and it can also be adjusted at the session level using the `SET` command for more targeted manual `VACUUM` operations.

The `autovacuum_work_mem` determines memory for autovacuum to hold identifiers of dead tuples (`pg_stat_all_tables.n_dead_tup`) for vacuuming indexes.

When doing calculations to determine the `autovacuum_work_mem` parameter's value, be aware of the following:

- If you set the parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance. For larger instances, setting `maintenance_work_mem` or `autovacuum_work_mem` to at least 1 GB can improve the performance of vacuuming tables with a high number of dead tuples. However, in PostgreSQL versions 16 and prior, vacuum's memory usage is capped at 1 GB, which is sufficient to process approximately 179 million dead tuples in a single pass. If a table has more dead tuples than this, vacuum will need to make multiple passes through the table's indexes, significantly increasing the time required. Starting with PostgreSQL version 17, there isn't a limit of 1 GB, and autovacuum can process more than 179 million tuples by using radix trees.

  A tuple identifier is 6 bytes in size. To estimate the memory needed for vacuuming an index of a table, query `pg_stat_all_tables.n_dead_tup` to find the number of dead tuples, then multiply this number by 6 to determine the memory required for vacuuming the index in a single pass. You may use the following query:

  ```
  SELECT
      relname AS table_name,
      n_dead_tup,
      pg_size_pretty(n_dead_tup * 6) AS estimated_memory
  FROM
      pg_stat_all_tables
  WHERE
      relname = 'name_of_the_table';
  ```

- The `autovacuum_work_mem` parameter works in conjunction with the `autovacuum_max_workers` parameter. Each worker among `autovacuum_max_workers` can use the memory that you allocate. If you have many small tables, allocate more `autovacuum_max_workers` and less `autovacuum_work_mem`. If you have large tables (larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Thus, make sure that the combination of worker processes and memory equals the total memory that you want to allocate.

Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. *Adaptive autovacuum* is a feature

for RDS for PostgreSQL. A detailed explanation of TransactionID wraparound is found in the PostgreSQL documentation.

Adaptive autovacuum is turned on by default for RDS for PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- autovacuum_vacuum_cost_delay
- autovacuum_vacuum_cost_limit
- `autovacuum_work_mem`
- autovacuum_naptime

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL SHOW SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

Determining if the tables in your database need vacuuming

You can use the following query to show the number of unfrozen transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.

```
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc
 limit 20;
```

For example, the results of running the preceding query might be the following.

```
datname    | age
mydb       | 1771757888
template0  | 1721757888
template1  | 1721757888
rdsadmin   | 1694008527
postgres   | 1693881061
(5 rows)
```

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 (`autovacuum_freeze_max_age`).

A sample monitoring strategy might look like this:

- Set the `autovacuum_freeze_max_age` value to 200 million transactions.
- If a table reaches 500 million unfrozen transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to `autovacuum_freeze_max_age` for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using VACUUM manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

- Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

  For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL.
- For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze.

Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose `relfrozenxid` value is greater than the number of transactions in `autovacuum_freeze_max_age` are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The autovacuum threshold is defined as:

```
Vacuum-threshold = vacuum-base-threshold + vacuum-scale-factor * number-of-tuples
```

where the `vacuum base threshold` is `autovacuum_vacuum_threshold`, the `vacuum scale factor` is `autovacuum_vacuum_scale_factor`, and the `number of tuples` is `pg_class.reltuples`.

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM
pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM
pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
```

```
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name =
 'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting, '=', 1) as param,
split_part(setting, '=', 2) as value from (select oid opt_oid, unnest(reloptions)
 setting from pg_class) opt)
SELECT '"'||ns.nspname||'"."'||c.relname||'"' as relation,
pg_size_pretty(pg_table_size(c.oid)) as table_size,
age(relfrozenxid) as xid_age,
coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
 autovacuum_freeze_max_age,
(coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float) * c.reltuples)
AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples FROM
pg_class c join pg_namespace ns on ns.oid = c.relnamespace
join pg_stat_all_tables stat on stat.relid = c.oid join vbt on (1=1) join vsf on (1=1)
 join fma on (1=1)
left join sto cvbt on cvbt.param = 'autovacuum_vacuum_threshold' and c.oid =
 cvbt.opt_oid
left join sto cvsf on cvsf.param = 'autovacuum_vacuum_scale_factor' and c.oid =
 cvsf.opt_oid
left join sto cfma on cfma.param = 'autovacuum_freeze_max_age' and c.oid = cfma.opt_oid
WHERE c.relkind = 'r' and nspname <> 'pg_catalog'
AND (age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
OR coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float) *
c.reltuples <= n_dead_tup)
ORDER BY age(relfrozenxid) DESC LIMIT 50;
```

Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS
 xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%VACUUM%'
ORDER BY xact_start;
```

After running the query, you should see output similar to the following.

```
 datname | usename  |  pid  | state  | wait_event |      xact_runtime       | query
 --------+----------+-------+--------+------------+-------------------------
+-------------------------------------------------------------------------------------------------
 mydb    | rdsadmin | 16473 | active |            | 33 days 16:32:11.600656 |
 autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)
 mydb    | rdsadmin | 22553 | active |            | 14 days 09:15:34.073141 |
 autovacuum: VACUUM ANALYZE public.mytable2 (to prevent wraparound)
 mydb    | rdsadmin | 41909 | active |            | 3 days 02:43:54.203349  |
 autovacuum: VACUUM ANALYZE public.mytable3
 mydb    | rdsadmin |   618 | active |            | 00:00:00                |
 SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS
 xact_runtime, query+
         |          |       |        |            |                         | FROM
 pg_stat_activity
           +
         |          |       |        |            |                         | WHERE
 query like '%VACUUM%'
          +
         |          |       |        |            |                         | ORDER BY
 xact_start;
       +
```

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your `maintenance_work_mem` parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

```
GREATEST({DBInstanceClassMemory/63963136*1024},65536)
```

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose` *`table`* to see the exact cause.

Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the `maintenance_work_mem` parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.

   Run the following query to get the PID of the autovacuum session.

   ```
   SELECT datname, usename, pid, current_timestamp - xact_start
   AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY
   xact_start;
   ```

3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set `maintenance_work_mem` for the current session to 2 GB.

   ```
   SET maintenance_work_mem='2 GB';
   SET
   ```

4. In session two, issue a `vacuum freeze verbose` command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.

```
\timing on
Timing is on.
vacuum freeze verbose pgbench_branches;
```

```
INFO:  vacuuming "public.pgbench_branches"
INFO:  index "pgbench_branches_pkey" now contains 50 row versions in 2 pages
DETAIL:  0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO:  index "pgbench_branches_test_index" now contains 50 row versions in 2 pages
DETAIL:  0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO:  "pgbench_branches": found 0 removable, 50 nonremovable row versions
     in 43 out of 43 pages
DETAIL:  0 dead row versions cannot be removed yet.
There were 9347 unused item pointers.
0 pages are entirely empty.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
VACUUM
Time: 2.765 ms
```

5. In session one, if autovacuum was blocking the vacuum session, `pg_stat_activity` shows that waiting is `T` for your vacuum session. In this case, end the autovacuum process as follows.

```
SELECT pg_terminate_backend('the_pid');
```

> **Note**
>
> Some lower versions of Amazon RDS can't terminate an autovacuum process using the preceding command and fail with the following error: `ERROR: 42501: must be a superuser to terminate superuser process LOCATION: pg_terminate_backend, signalfuncs.c:227`.

At this point, your session begins. Autovacuum restarts immediately because this table is probably the highest on its list of work.

6. Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

Reindexing a table when autovacuum is running

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```
postgres=>  vacuum freeze pgbench_branches;
ERROR: index "pgbench_branches_test_index" contains unexpected
   zero page at block 30521
HINT: Please REINDEX it.
```

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a REINDEX command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

To reindex a table when autovacuum is running on the table

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the PID of the autovacuum session running on the table.

   Run the following query to get the PID of the autovacuum session.

   ```
   SELECT datname, usename, pid, current_timestamp - xact_start
   AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) like '%VACUUM%' ORDER BY
   xact_start;
   ```

3. In session two, issue the reindex command.

   ```
   \timing on
   Timing is on.
   reindex index pgbench_branches_test_index;
   REINDEX
     Time: 9.966 ms
   ```

4. In session one, if autovacuum was blocking the process, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

   ```
   SELECT pg_terminate_backend('the_pid');
   ```

   At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.
5. Initiate your command in session two, and then end the autovacuum process in session 1.

Managing autovacuum with large indexes

As part of its operation, *autovacuum* performs several vacuum phases while running on a table. Before the table is cleaned up, all of its indexes are first vacuumed. When removing multiple large indexes, this phase consumes a significant amount of time and resources. Therefore, as a best practice, be sure to control the number of indexes on a table and eliminate unused indexes.

For this process, first check the overall index size. Then, determine if there are potentially unused indexes that can be removed as shown in the following examples.

To check the size of the table and its indexes

```
postgres=> select pg_size_pretty(pg_relation_size('pgbench_accounts'));
pg_size_pretty
6404 MB
(1 row)
```

```
postgres=> select pg_size_pretty(pg_indexes_size('pgbench_accounts'));
pg_size_pretty
11 GB
(1 row)
```

In this example, the size of indexes is larger than the table. This difference can cause performance issues as the indexes are bloated or unused, which impacts the autovacuum as well as insert operations.

To check for unused indexes

Using the `pg_stat_user_indexes` view, you can check how frequently an index is used with the `idx_scan` column. In the following example, the unused indexes have the `idx_scan` value of `0`.

```
postgres=> select * from pg_stat_user_indexes where relname = 'pgbench_accounts' order
 by idx_scan desc;

relid  | indexrelid | schemaname | relname          | indexrelname          | idx_scan
 | idx_tup_read | idx_tup_fetch
-------+------------+------------+------------------+-----------------------+----------
+--------------+--------------
16433  | 16454      | public     | pgbench_accounts | index_f               | 6
 | 6            | 0
16433  | 16450      | public     | pgbench_accounts | index_b               | 3
 | 199999       | 0
16433  | 16447      | public     | pgbench_accounts | pgbench_accounts_pkey | 0
 | 0            | 0
16433  | 16452      | public     | pgbench_accounts | index_d               | 0
 | 0            | 0
16433  | 16453      | public     | pgbench_accounts | index_e               | 0
 | 0            | 0
16433  | 16451      | public     | pgbench_accounts | index_c               | 0
 | 0            | 0
16433  | 16449      | public     | pgbench_accounts | index_a               | 0
 | 0            | 0
(7 rows)
```

```
postgres=> select schemaname, relname, indexrelname, idx_scan from pg_stat_user_indexes
 where relname = 'pgbench_accounts' order by idx_scan desc;

schemaname  | relname          | indexrelname          | idx_scan
------------+------------------+-----------------------+----------
public      | pgbench_accounts | index_f               | 6
public      | pgbench_accounts | index_b               | 3
public      | pgbench_accounts | pgbench_accounts_pkey | 0
public      | pgbench_accounts | index_d               | 0
public      | pgbench_accounts | index_e               | 0
public      | pgbench_accounts | index_c               | 0
public      | pgbench_accounts | index_a               | 0
(7 rows)
```

> **Note**
>
> These statistics are incremental from the time that the statistics are reset. Suppose you have an index that is only used at the end of a business quarter or just for a specific report. It's possible that this index hasn't been used since the statistics were reset. For more information, see Statistics Functions. Indexes that are used to enforce uniqueness won't have scans performed and shouldn't be identified as unused indexes. To identify the unused indexes, you should have in-depth knowledge of the application and its queries.

To check when the stats were last reset for a database, use `pg_stat_database`

```
postgres=> select datname, stats_reset from pg_stat_database where datname =
 'postgres';

datname   | stats_reset
----------+-------------------------------
postgres  | 2022-11-17 08:58:11.427224+00
(1 row)
```

Vacuuming a table as quickly as possible

RDS for PostgreSQL 12 and higher

If you have too many indexes in a large table, your DB instance could be nearing transaction ID wraparound (XID), which is when the XID counter wraps around to zero. Left unchecked, this situation could result in data loss. However, you can quickly vacuum the table without cleaning up the indexes. In RDS for PostgreSQL 12 and higher, you can use VACUUM with the `INDEX_CLEANUP` clause.

```
postgres=> VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) pgbench_accounts;

INFO: vacuuming "public.pgbench_accounts"
INFO: table "pgbench_accounts": found 0 removable, 8 nonremovable row versions in 1 out
 of 819673 pages
DETAIL: 0 dead row versions cannot be removed yet, oldest xmin: 7517
Skipped 0 pages due to buffer pins, 0 frozen pages.
CPU: user: 0.01 s, system: 0.00 s, elapsed: 0.01 s.
```

If an autovacuum session is already running, you must terminate it to begin the manual VACUUM. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze

> **Note**
>
> Skipping index cleanup regularly causes index bloat, which degrades scan performance. The index retains dead rows, and the table retains dead line pointers. As a result, `pg_stat_all_tables.n_dead_tup` increases until autovacuum or a manual VACUUM with index cleanup runs. As a best practice, use this procedure only to prevent transaction ID wraparound.

RDS for PostgreSQL 11 and older

However, in RDS for PostgreSQL 11 and lower versions, the only way to allow vacuum to complete faster is to reduce the number of indexes on a table. Dropping an index can affect query plans. We recommend that you drop unused indexes first, then drop the indexes when XID wraparound is very near. After the vacuum process completes, you can recreate these indexes.

Other parameters that affect autovacuum

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The autovacuum parameters are described fully in the PostgreSQL documentation.

```
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN (
'autovacuum_max_workers',
'autovacuum_analyze_scale_factor',
'autovacuum_naptime',
'autovacuum_analyze_threshold',
'autovacuum_analyze_scale_factor',
'autovacuum_vacuum_threshold',
'autovacuum_vacuum_scale_factor',
'autovacuum_vacuum_threshold',
'autovacuum_vacuum_cost_delay',
'autovacuum_vacuum_cost_limit',
'vacuum_cost_limit',
'autovacuum_freeze_max_age',
```

```
'maintenance_work_mem',
'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:

- maintenance_work_mem
- autovacuum_freeze_max_age
- autovacuum_max_workers
- autovacuum_vacuum_cost_delay
- autovacuum_vacuum_cost_limit

Setting table-level autovacuum parameters

You can set autovacuum-related storage parameters at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for `autovacuum_vacuum_cost_delay` each time `autovacuum_cost_limit` is reached. For more details, see the PostgreSQL documentation about cost-based vacuuming.

Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- `disabled` (PostgreSQL 10, PostgreSQL 9.6)
- `debug5`, `debug4`, `debug3`, `debug2`, `debug1`
- `info` (PostgreSQL 12, PostgreSQL 11)
- `notice`
- `warning` (PostgreSQL 13 and above)
- `error`, log, `fatal`, `panic`

The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of `-1` logs nothing, while a setting of 0 logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- `10000 ms` – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- `(empty)` – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set `rds.force_autovacuum_logging_level` to `WARNING`. We also recommend that you set `log_autovacuum_min_duration` to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than -1 also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see Automatic Vacuuming in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from `debug1` up to `debug5` for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see When to log in the PostgreSQL documentation.

Note

PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

Understanding the behavior of autovacuum with invalid databases

A new value `-2` is introduced into the `datconnlimit` column in the `pg_database` catalog to indicate databases that have been interrupted in the middle of the DROP DATABASE operation as invalid.

This new value is available from the following RDS for PostgreSQL versions:

- 15.4 and all higher versions
- 14.9 and higher versions
- 13.12 and higher versions
- 12.16 and higher versions
- 11.21 and higher versions

Invalid databases do not affect autovacuum's ability to freeze functionality for valid databases. Autovacuum ignores invalid databases. Consequently, regular vacuum operations will continue to function properly and efficiently for all valid databases in your PostgreSQL environment.

Topics

- Monitoring transaction ID
- Adjusting the monitoring query
- Resolving invalid database issue

Monitoring transaction ID

The `age(datfrozenxid)` function is commonly used to monitor the transaction ID (XID) age of databases to prevent transaction ID wraparound.

Since invalid databases are excluded from autovacuum, their transaction ID (XID) counter can reach the maximum value of `2 billion`, wrap around to `- 2 billion`, and continue this cycle indefinitely. A typical query to monitor Transaction ID wraparound might look like:

```
SELECT max(age(datfrozenxid)) FROM pg_database;
```

However, with the introduction of the -2 value for `datconnlimit`, invalid databases can skew the results of this query. Since these databases are not valid and should not be part of regular maintenance checks, they can cause false positives, leading you to believe that the `age(datfrozenxid)` is higher than it actually is.

Adjusting the monitoring query

To ensure accurate monitoring, you should adjust your monitoring query to exclude invalid databases. Follow this recommended query:

```
SELECT
    max(age(datfrozenxid))
FROM
    pg_database
WHERE
    datconnlimit <> -2;
```

This query ensures that only valid databases are considered in the `age(datfrozenxid)` calculation, providing a true reflection of the transaction ID age across your PostgreSQL environment.

Resolving invalid database issue

When attempting to connect to an invalid database, you may encounter an error message similar to the following:

```
postgres=> \c db1
connection to server at "mydb.xxxxxxxxxx.us-west-2.rds.amazonaws.com" (xx.xx.xx.xxx),
 port xxxx failed: FATAL:  cannot connect to invalid database "db1"
HINT:  Use DROP DATABASE to drop invalid databases.
Previous connection kept
```

Additionally, if the `log_min_messages` parameter is set to `DEBUG2` or higher, you may notice the following log entries indicating that the autovacuum process is skipping the invalid database:

```
2024-07-30 05:59:00 UTC::@:[32000]:DEBUG:  autovacuum: skipping invalid database "db6"
2024-07-30 05:59:00 UTC::@:[32000]:DEBUG:  autovacuum: skipping invalid database "db1"
```

To resolve the issue, follow the `HINT` provided during the connection attempt. Connect to any valid database using your RDS master account or a database account with the `rds_superuser` role, and drop invalid database(s).

```
SELECT
    'DROP DATABASE ' || quote_ident(datname) || ';'
FROM
    pg_database
WHERE
    datconnlimit = -2 \gexec
```

Identify and resolve aggressive vacuum blockers in RDS for PostgreSQL

In PostgreSQL, vacuuming is vital for ensuring database health as it reclaims storage and prevents transaction ID wraparound issues. However, there are times when vacuuming can be prevented from operating as desired, which can result in performance degradation, storage bloat, and even impact availability of your DB instance by transaction ID wraparound. Therefore, identifying and resolving these issues are essential for optimal database performance and availability. Read Understanding autovacuum in Amazon RDS for PostgreSQL environments to learn more about autovacuum.

The `postgres_get_av_diag()` function helps identify issues that either prevent or delay the aggressive vacuum progress. Suggestions are provided, which may include commands to resolve the issue where it is identifiable or guidance for further diagnostics where the issue is not identifiable. Aggressive vacuum blockers are reported when the age exceeds RDS' adaptive autovacuum threshold of 500 million transaction IDs.

What is the age of the transaction ID?

The `age()` function for transaction IDs calculates the number of transactions that have occurred since the oldest unfrozen transaction ID for a database (`pg_database.datfrozenxid`) or table (`pg_class.relfrozenxid`). This value indicates database activity since the last aggressive vacuum operation and highlights the likely workload for upcoming VACUUM processes.

What is an aggressive vacuum?

An aggressive VACUUM operation conducts a comprehensive scan of all pages within a table, including those typically skipped during regular VACUUMs. This thorough scan aims to "freeze" transaction IDs approaching their maximum age, effectively preventing a situation known as transaction ID wraparound.

For `postgres_get_av_diag()` to report blockers, the blocker must be at least 500 million transactions old.

Installing autovacuum monitoring and diagnostic tools in RDS for PostgreSQL

The `postgres_get_av_diag()` function is currently available in the following RDS for PostgreSQL versions:

- 17.2 and higher 17 versions
- 16.7 and higher 16 versions
- 15.11 and higher 15 versions
- 14.16 and higher 14 versions
- 13.19 and higher 13 versions

In order to use `postgres_get_av_diag()`, create the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools ;
CREATE EXTENSION
```

Verify that the extension is installed.

```
postgres=> \dx rds_tools
             List of installed extensions
   Name    | Version |  Schema   |                    Description
 ----------+---------+-----------
+-------------------------------------------------------------
 rds_tools |   1.8   | rds_tools | miscellaneous administrative functions for RDS
 PostgreSQL
 1 row
```

Verify that the function is created.

```
postgres=> SELECT
    proname function_name,
    pronamespace::regnamespace function_schema,
    proowner::regrole function_owner
FROM
    pg_proc
WHERE
    proname = 'postgres_get_av_diag';
    function_name     | function_schema | function_owner
----------------------+-----------------+----------------
 postgres_get_av_diag | rds_tools       | rds_superuser
(1 row)
```

Functions of postgres_get_av_diag() in RDS for PostgreSQL

The `postgres_get_av_diag()` function retrieves diagnostic information about autovacuum processes that are blocking or lagging behind in a RDS for PostgreSQL database. The query needs to be executed in the database with the oldest transaction ID for accurate results. For more information about using the database with the oldest transaction ID, see Not connected to the database with the age of oldest transaction ID

```
SELECT
```

```
    blocker,
    DATABASE,
    blocker_identifier,
    wait_event,
    TO_CHAR(autovacuum_lagging_by, 'FM9,999,999,999') AS autovacuum_lagging_by,
    suggestion,
    suggested_action
FROM (
    SELECT
        *
    FROM
        rds_tools.postgres_get_av_diag ()
    ORDER BY
        autovacuum_lagging_by DESC) q;
```

The `postgres_get_av_diag()` function returns a table with the following information:

blocker

Specifies the category of database activity that is blocking the vacuum.

- Active statement
- Idle in transaction
- Prepared transaction
- Logical replication slot
- Read replica with physical replication slot
- Read replica with streaming replication
- Temporary tables

database

Specifies the name of the database where applicable and supported. This is the database in which the activity is ongoing and blocking or will block the autovacuum. This is the database you are required to connect to and take action.

blocker_identifier

Specifies the identifier of the activity that is blocking or will block the autovacuum. The identifier can be a process ID along with a SQL statement, a prepared transaction, an IP address of a read replica, and the name of the replication slot, either logical or physical.

wait_event

Specifies the wait event of the blocking session and is applicable for the following blockers:

- Active statement
- Idle in transaction

autovacum_lagging_by

Specifies the number of transactions that autovacuum is lagging behind in its backlog work per category.

suggestion

Specifies suggestions to resolve the blocker. These instructions include the name of the database in which the activity exists where applicable, the Process ID (PID) of the session where applicable, and the action to be taken.

suggested_action

Suggests the action that needs to be taken to resolve the blocker.

Resolving identifiable vacuum blockers in RDS for PostgreSQL

Autovacuum performs aggressive vacuums and lowers the age of transaction IDs to below the threshold specified by the `autovacuum_freeze_max_age` parameter of your RDS instance. You can track this age using the Amazon CloudWatch metric `MaximumUsedTransactionIDs`.

To find the setting of `autovacuum_freeze_max_age` (which has a default of 200 million transaction IDs) for your Amazon RDS instance, you can use the following query:

```
SELECT
    TO_CHAR(setting::bigint, 'FM9,999,999,999') autovacuum_freeze_max_age
FROM
    pg_settings
WHERE
    name = 'autovacuum_freeze_max_age';
```

Note that `postgres_get_av_diag()` only checks for aggressive vacuum blockers when the age exceeds Amazon RDS' adaptive autovacuum threshold of 500 million transaction IDs. For `postgres_get_av_diag()` to detect blockers, the blocker must be at least 500 million transactions old.

The `postgres_get_av_diag()` function identifies the following types of blockers:

Topics

- Active statement
- Idle in transaction
- Prepared transaction
- Logical replication slot
- Read replicas
- Temporary tables

Active statement

In PostgreSQL, an active statement is an SQL statement that is currently being executed by the database. This includes queries, transactions, or any operations in progress. When monitoring via `pg_stat_activity`, the state column indicates that the process with the corresponding PID is active.

The `postgres_get_av_diag()` function displays output similar to the following when it identifies a statement that is an active statement.

```
blocker               | Active statement
database              | my_database
blocker_identifier    | SELECT pg_sleep(20000);
wait_event            | Timeout:PgSleep
autovacuum_lagging_by | 568,600,871
suggestion            | Connect to database "my_database", review carefully and you
 may consider terminating the process using suggested_action. For more information, see
 Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action      | {"SELECT pg_terminate_backend (29621);"}
```

Suggested action

Following the guidance in the `suggestion` column, the user can connect to the database where the active statement is present and, as specified in the `suggested_action` column, it's advisable to carefully review the option to terminate the session. If termination is safe, you may use the `pg_terminate_backend()` function to terminate the session. This action can be performed by an administrator (such as the RDS master account) or a user with the required `pg_terminate_backend()` privilege.

> **Warning**
>
> A terminated session will undo (ROLLBACK) changes it made. Depending on your requirements, you may want to rerun the statement. However, it is recommended to do so only after the autovacuum process has finished its aggressive vacuum operation.

Idle in transaction

An idle in transaction statement refers to any session that has opened an explicit transaction (such as by issuing a BEGIN statement), performed some work, and is now waiting for the client to either pass more work or signal the end of the transaction by issuing a COMMIT, ROLLBACK, or END (which would result in an implicit COMMIT).

The `postgres_get_av_diag()` function displays output similar to the following when it identifies an `idle in transaction` statement as a blocker.

```
blocker               | idle in transaction
database              | my_database
blocker_identifier    | INSERT INTO tt SELECT * FROM tt;
wait_event            | Client:ClientRead
autovacuum_lagging_by | 1,237,201,759
suggestion            | Connect to database "my_database", review carefully and you
 may consider terminating the process using suggested_action. For more information, see
 Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action      | {"SELECT pg_terminate_backend (28438);"}
```

Suggested action

As indicated in the `suggestion` column, you can connect to the database where the idle in transaction session is present and terminate the session using the `pg_terminate_backend()` function. The user can be your admin (RDS master account) user or a user with the `pg_terminate_backend()` privilege.

> **Warning**
>
> A terminated session will undo (ROLLBACK) changes it made. Depending on your requirements, you may want to rerun the statement. However, it is recommended to do so only after the autovacuum process has finished its aggressive vacuum operation.

Prepared transaction

PostgreSQL allows transactions that are part of a two-phase commit strategy called prepared transactions. These are enabled by setting the `max_prepared_transactions` parameter to a non-zero value. Prepared transactions are designed to ensure that a transaction is durable and remains available even after database crashes, restarts, or client disconnections. Like regular transactions, they are assigned a transaction ID and can affect the autovacuum. If left in a prepared state, autovacuum cannot perform freeezing and it can lead to transaction ID wraparound.

When transactions are left prepared indefinitely without being resolved by a transaction manager, they become orphaned prepared transactions. The only way to fix this is to either commit or rollback the transaction using the `COMMIT PREPARED` or `ROLLBACK PREPARED` commands, respectively.

> **Note**
>
> Be aware that a backup taken during a prepared transaction will still contain that transaction after restoration. Refer to the following information about how to locate and close such transactions.

The `postgres_get_av_diag()` function displays the following output when it identifies a blocker that is a prepared transaction.

```
blocker               | Prepared transaction
database              | my_database
blocker_identifier    | myptx
wait_event            | Not applicable
autovacuum_lagging_by | 1,805,802,632
suggestion            | Connect to database "my_database" and consider either COMMIT
 or ROLLBACK the prepared transaction using suggested_action. For more information, see
 Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action      | {"COMMIT PREPARED 'myptx';",[OR],"ROLLBACK PREPARED 'myptx';"}
```

Suggested action

As mentioned in the suggestion column, connect to the database where the prepared transaction is located. Based on the `suggested_action` column, carefully review whether to perform either `COMMIT` or `ROLLBACK`, and the the appropiate the action.

To monitor prepared transactions in general, PostgreSQL offers a catalog view called `pg_prepared_xacts`. You can use the following query to find prepared transactions.

```
SELECT
    gid,
    prepared,
    owner,
    database,
    transaction AS oldest_xmin
FROM
    pg_prepared_xacts
ORDER BY
    age(transaction) DESC;
```

Logical replication slot

The purpose of a replication slot is to hold unconsumed changes until they are replicated to a target server. For more information, see PostgreSQL's Logical replication.

There are two types of logical replication slots.

Inactive logical replication slots

When replication is terminated, unconsumed transaction logs can't be removed, and the replication slot becomes inactive. Although an inactive logical replication slot isn't currently used by a subscriber, it remains on the server, leading to the retention of WAL files and preventing the removal of old transaction logs. This can increase disk usage and specifically block autovacuum from cleaning up internal catalog tables, as the system must preserve LSN information from being overwritten. If not addressed, this can result in catalog bloat, performance degradation, and an increased risk of wraparound vacuum, potentially causing transaction downtime.

Active but slow logical replication slots

Sometimes removal of dead tuples of catalog is delayed due to the performance degradation of logical replication. This delay in replication slows down updating the `catalog_xmin` and can lead to catalog bloat and wraparound vacuum.

The `postgres_get_av_diag()` function displays output similar to the following when it finds a logical replication slot as a blocker.

```
blocker              | Logical replication slot
```

```
database              | my_database
blocker_identifier    | slot1
wait_event            | Not applicable
autovacuum_lagging_by | 1,940,103,068
suggestion            | Ensure replication is active and resolve any lag for the slot
 if active. If inactive, consider dropping it using the command in suggested_action.
 For more information, see Working with PostgreSQL autovacuum in the Amazon RDS User
 Guide.
suggested_action      | {"SELECT pg_drop_replication_slot('slot1') FROM
 pg_replication_slots WHERE active = 'f';"}
```

Suggested action

To resolve this problem, check the replication configuration for issues with the target schema or data that might be terminating the apply process. The most common reasons are the following:

- Missing columns
- Incompatible data type
- Data mismatch
- Missing table

If the problem is related to infrastructure issues:

- Network issues - How do I resolve issues with an Amazon RDS DB in an incompatible network state?.
- Database or DB instance is not available due to the following reasons:
  - Replica instance is out of storage - Review Amazon RDS DB instances run out of storage for information about adding storage.
  - Incompatible-parameters - Review How can I fix an Amazon RDS DB instance that is stuck in the incompatible-parameters status? for more information about how you can resolve the issue.

If your instance is outside the AWS network or on AWS EC2, consult your administrator on how to resolve the availability or infrastructure-related issues.

Dropping the inactive slot

> **Warning**
>
> Caution: Before dropping a replication slot, carefully ensure that it has no ongoing replication, is inactive, and is in an unrecoverable state. Dropping a slot prematurely could disrupt replication or cause data loss.

After confirming that the replication slot is no longer needed, drop it to allow autovacuum to continue. The condition `active = 'f'` ensures that only an inactive slot is dropped.

```
SELECT pg_drop_replication_slot('slot1') WHERE active ='f'
```

Read replicas

When the `hot_standby_feedback` setting is enabled for Amazon RDS read replicas, it prevents autovacuum on the primary database from removing dead rows that might still be needed by queries running on the read replica. This affects all types of physical read replicas including those managed with or without replication slots. This behavior is necessary because queries running on the standby replica require those rows to remain available on the primary preventing query conflicts and cancellations.

Read replica with physical replication slot

Read replicas with physical replication slots significantly enhance the reliability and stability of replication in RDS for PostgreSQL. These slots ensure the primary database retains essential Write-Ahead Log files until the replica processes them, maintaining data consistency even during network disruptions.

Beginning with RDS for PostgreSQL version 14, all replicas utilize replication slots. In earlier versions, only cross-Region replicas used replication slots.

The `postgres_get_av_diag()` function displays output similar to the following when it finds a read replica with physical replication slot as the blocker.

```
blocker               | Read replica with physical replication slot
database              |
blocker_identifier    | rds_us_west_2_db_xxxxxxxxxxxxxxxxxxxx
wait_event            | Not applicable
autovacuum_lagging_by | 554,080,689
```

```
suggestion            | Run the following query on the replica
 "rds_us_west_2_db_xxxxxxxxxxxxxxxxxxx" to find the long running query:

                      | SELECT * FROM pg_catalog.pg_stat_activity WHERE
 backend_xmin::text::bigint = 757989377;

                      | Review carefully and you may consdier terminating the query on
 read replica using suggested_action. For more information, see Working with PostgreSQL
 autovacuum in the Amazon RDS User Guide.                                    +
          |
suggested_action      | {"SELECT pg_terminate_backend(pid) FROM
 pg_catalog.pg_stat_activity WHERE backend_xmin::text::bigint = 757989377;","
                                                                             +
                      | [OR]

                                                +
                      | ","Disable hot_standby_feedback","

                                                +
                      | [OR]

                                                +
                      | ","Delete the read replica if not needed"}
```

Read replica with streaming replication

Amazon RDS allows setting up read replicas without a physical replication slot in older versions, up to version 13. This approach reduces overhead by allowing the primary to recycle WAL files more aggressively, which is advantageous in environments with limited disk space and can tolerate occasional ReplicaLag. However, without a slot, the standby must remain in sync to avoid missing WAL files. Amazon RDS uses archived WAL files to help the replica catch up if it falls behind, but this process requires careful monitoring and can be slow.

The `postgres_get_av_diag()` function displays output similar to the following when it finds a streaming read replica as the blocker.

```
blocker               | Read replica with streaming replication slot
database              | Not applicable
blocker_identifier    | xx.x.x.xxx/xx
wait_event            | Not applicable
autovacuum_lagging_by | 610,146,760
```

```
suggestion            | Run the following query on the replica "xx.x.x.xxx" to find the
 long running query:
                                                                                +
                      | SELECT * FROM pg_catalog.pg_stat_activity WHERE
 backend_xmin::text::bigint = 348319343;

               +
                      | Review carefully and you may consdier terminating the query on
 read replica using suggested_action. For more information, see Working with PostgreSQL
 autovacuum in the Amazon RDS User Guide.                                        +
                      |
suggested_action      | {"SELECT pg_terminate_backend(pid) FROM
 pg_catalog.pg_stat_activity WHERE backend_xmin::text::bigint = 348319343;","

                       +
                      | [OR]

                                                                                +
                      | ","Disable hot_standby_feedback","

                                                                                +
                      | [OR]

                                                                                +
                      | ","Delete the read replica if not needed"}
```

Suggested action

As recommended in the `suggested_action` column, carefully review these options to unblock autovacuum.

- **Terminate the query** – Following the guidance in the suggestion column, you can connect to the read replica, as specified in the suggested_action column, it's advisable to carefully review the option to terminate the session. If termination is deemed safe, you may use the `pg_terminate_backend()` function to terminate the session. This action can be performed by an administrator (such as the RDS master account) or a user with the required pg_terminate_backend() privilege.

  You may run the following SQL command on the read replica to terminate the query that is preventing the vacuum on the primary from cleaning up old rows. The value of `backend_xmin` is reported in the function's output:

```
SELECT
    pg_terminate_backend(pid)
FROM
    pg_catalog.pg_stat_activity
WHERE
    backend_xmin::text::bigint = backend_xmin;
```

- **Disable hot standby feedback** – Consider disabling the `hot_standby_feedback` parameter if it's causing significant vacuum delays.

  The `hot_standby_feedback` parameter allows a read replica to inform the primary about its query activity, preventing the primary from vacuuming tables or rows that are in use on the standby. While this ensures query stability on the standby, it can significantly delay vacuuming on the primary. Disabling this feature allows the primary to proceed with vacuuming without waiting for the standby to catch up. However, this can lead to query cancellations or failures on the standby if it attempts to access rows that have been vacuumed by the primary.
- **Delete the read replica if not needed** – If the read replica is no longer necessary, you can delete it. This will remove the associated replication overhead and allow the primary to recycle transaction logs without being held back by the replica.

Temporary tables

Temporary tables, created using the `TEMPORARY` keyword, reside in the temp schema, for example pg_temp_xxx, and are only accessible to the session that created them. Temporary tables are dropped when the session ends. However, these tables are invisible to PostgreSQL's autovacuum process, and must be manually vacuumed by the session that created them. Trying to vacuum the temp table from another session has no effect.

In unusual circumstances, a temporary table exists without an active session owning it. If the owning session ends unexpectedly due to a fatal crash, network issue, or similar event, the temporary table might not be cleaned up, leaving it behind as an "orphaned" table. When the PostgreSQL autovacuum process detects an orphaned temporary table, it logs the following message:

```
LOG: autovacuum: found orphan temp table \"%s\".\"%s\" in database \"%s\"
```

The `postgres_get_av_diag()` function displays output similar to the following when it identifies a temporary table as a blocker. For the function to correctly show the output related to temporary tables, it needs to be executed within the same database where those tables exist.

```
blocker               | Temporary table
database              | my_database
blocker_identifier    | pg_temp_14.ttemp
wait_event            | Not applicable
autovacuum_lagging_by | 1,805,802,632
suggestion            | Connect to database "my_database". Review carefully, you
 may consider dropping temporary table using command in suggested_action. For more
 information, see Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action      | {"DROP TABLE ttemp;"}
```

Suggested action

Follow the instructions provided in the `suggestion` column of the output to identify and remove the temporary table that is preventing autovacuum from running. Use the following command to drop the temporary table reported by `postgres_get_av_diag()`. Replace the table name based on the output provided by the `postgres_get_av_diag()` function.

```
DROP TABLE my_temp_schema.my_temp_table;
```

The following query can be used to identify temporary tables:

```
SELECT
    oid,
    relname,
    relnamespace::regnamespace,
    age(relfrozenxid)
FROM
    pg_class
WHERE
relpersistence = 't'
ORDER BY
    age(relfrozenxid) DESC;
```

Resolving unidentifiable vacuum blockers in RDS for PostgreSQL

This section explores additional reasons that can prevent vacuuming from making progress. These issues are currently not directly identifiable by the `postgres_get_av_diag()` function.

Topics

- Invalid pages
- Index inconsistency
- Exceptionally high transaction rate

Invalid pages

An invalid page error occurs when PostgreSQL detects a mismatch in a page's checksum while accessing that page. The contents are unreadable, preventing autovacuum from freezing tuples. This effectively stops the cleanup process. The following error is written into PostgreSQL's log:

```
WARNING:  page verification failed, calculated checksum YYYYY but expected XXXX
ERROR:  invalid page in block ZZZZZ of relation base/XXXXX/XXXXX
CONTEXT:  automatic vacuum of table myschema.mytable
```

Determine the object type

```
ERROR: invalid page in block 4305910 of relation base/16403/186752608
WARNING: page verification failed, calculated checksum 50065 but expected 60033
```

From the error message, the path `base/16403/186752608` provides the following information:

- "base" is the directory name under the PostgreSQL data directory.
- "16403" is the database OID, which you can look up in the `pg_database` system catalog.
- "186752608" is the `relfilenode`, which you can use to look up the schema and object name in the `pg_class` system catalog.

By checking the output of the following query in the impacted database, you can determine the object type. The following query retrieves object information for oid: 186752608. Replace the OID with the one relevant to the error you encountered.

```
SELECT
    relname AS object_name,
    relkind AS object_type,
    nspname AS schema_name
FROM
    pg_class c
    JOIN pg_namespace n ON c.relnamespace = n.oid
```

```
WHERE
    c.oid = 186752608;
```

For more information, see the PostgreSQL documentation pg_class for all the supported object types, noted by the relkind column in pg_class.

Guidance

The most effective solution for this issue depends on the configuration of your specific Amazon RDS instance and the type of data impacted by the inconsistent page.

If the object type is an index:

Rebuilding the index is recommended.

- **Using the CONCURRENTLY option** – Prior to PostgreSQL version 12, rebuilding an index required an exclusive table lock, restricting access to the table. With PostgreSQL version 12, and later versions, the CONCURRENTLY option allows for row-level locking, significantly improving the table's availability. Following is the command:

  ```
  REINDEX INDEX ix_name CONCURRENTLY;
  ```

  While CONCURRENTLY is less disruptive, it can be slower on busy tables. Consider building the index during low-traffic periods if possible.

  For more information, see the PostgreSQL REINDEX documentation.
- **Using the INDEX_CLEANUP FALSE option** – If the indexes are large and estimated to require a significant amount of time to finish, you can unblock autovacuum by executing a manual VACUUM FREEZE while excluding indexes. This functionality is available in PostgreSQL version 12 and later versions.

  Bypassing indexes will allow you to skip the vacuum process of the inconsistent index and mitigate the wraparound issue. However, this will not resolve the underlying invalid page problem. To fully address and resolve the invalid page issue, you will still need to rebuild the index.

If the object type is a materialized view:

If an invalid page error occurs on a materialized view, login to the impacted database and refresh it to resolve the invalid page:

Refresh the materialized view:

```
REFRESH MATERIALIZED VIEW schema_name.materialized_view_name;
```

If refreshing fails, try recreating:

```
DROP MATERIALIZED VIEW schema_name.materialized_view_name;
CREATE MATERIALIZED VIEW schema_name.materialized_view_name AS query;
```

Refreshing or recreating the materialized view restores it without impacting the underlying table data.

For all other object types:

For all other object types, reach out to AWS support.

Index inconsistency

A logically inconsistent index can prevent autovacuum from making progress. The following errors or similar errors are logged during either the vacuum phase of the index or when the index is accessed by SQL statements.

```
ERROR: right sibling's left-link doesn't match:block 5 links to 10 instead of expected
 2 in index ix_name
```

```
ERROR: failed to re-find parent key in index "XXXXXXXXXX" for deletion target page XXX
CONTEXT:  while vacuuming index index_name of relation schema.table
```

Guidance

Rebuild the index or skip indexes using `INDEX_CLEANUP` on manual `VACUUM FREEZE`. For information about how to rebuild the index, see If the object type is an index.

- **Using the CONCURRENTLY option** – Prior to PostgreSQL version 12, rebuilding an index required an exclusive table lock, restricting access to the table. With PostgreSQL version 12, and later versions, the CONCURRENTLY option allows for row-level locking, significantly improving the table's availability. Following is the command:

  ```
  REINDEX INDEX ix_name CONCURRENTLY;
  ```

While CONCURRENTLY is less disruptive, it can be slower on busy tables. Consider building the index during low-traffic periods if possible. For more information, see REINDEX in *PostgreSQL* documentation.

- **Using the INDEX_CLEANUP FALSE option** – If the indexes are large and estimated to require a significant amount of time to finish, you can unblock autovacuum by executing a manual VACUUM FREEZE while excluding indexes. This functionality is available in PostgreSQL version 12 and later versions.

  Bypassing indexes will allow you to skip the vacuum process of the inconsistent index and mitigate the wraparound issue. However, this will not resolve the underlying invalid page problem. To fully address and resolve the invalid page issue, you will still need to rebuild the index.

Exceptionally high transaction rate

In PostgreSQL, high transaction rates can significantly impact autovacuum's performance, leading to slower cleanup of dead tuples and increased risk of transaction ID wraparound. You can monitor the transaction rate by measuring the difference in `max(age(datfrozenxid))` between two time periods, typically per second. Additionally, you can use the following counter metrics from RDS Performance Insights to measure the transaction rate (the sum of xact_commit and xact_rollback) which is the total number of transactions.

Counter	Type	Unit	Metric
xact_commit	Transactions	Commits per second	db.Transactions.xact_commit
xact_rollback	Transactions	Rollbacks per second	db.Transactions.xact_rollback

A rapid increase indicates a high transaction load, which can overwhelm autovacuum, causing bloat, lock contention, and potential performance issues. This can negatively impact the autovacuum process in a couple of ways:

- **Table Activity:** The specific table being vacuumed could be experiencing a high volume of transactions, causing delays.

- **System Resources** The overall system might be overloaded, making it difficult for autovacuum to access the necessary resources to function efficiently.

Consider the following strategies for allowing autovacuum to operate more effectively and keep up with its tasks:

1. Reduce the transaction rate if possible. Consider to batch or group similar transactions where feasible.
2. Target frequently updated tables with manual `VACUUM FREEZE` operation nightly, weekly, or biweekly during off-peak hours.
3. Consider scaling up your instance class to allocate more system resources to handle the high transaction volume and autovacuum.

Resolving vacuum performance issues in RDS for PostgreSQL

This section discusses factors that often contribute to slower vacuum performance and how to address these issues.

Topics

- Vacuum large indexes
- Too many tables or databases to vacuum
- Aggressive vacuum (to prevent wraparound) is running

Vacuum large indexes

VACUUM operates through sequential phases: initialization, heap scanning, index and heap vacuuming, index cleanup, heap truncation, and final cleanup. During the heap scan, the process prunes pages, defragments and freezes them. After completing the heap scan, VACUUM cleans indexes, returns empty pages to the operating system, and performs final cleanup tasks like vacuuming the free space map and updating statistics.

Index vacuuming may require multiple passes when `maintenance_work_mem` (or `autovacuum_work_mem`) is insufficient to process the index. In PostgreSQL 16 and earlier, a 1 GB memory limit for storing dead tuple IDs often forced multiple passes on large indexes. PostgreSQL 17 introduces `TidStore`, which dynamically allocates memory instead of using a single-allocation

array. This removes the 1 GB constraint, uses memory more efficiently, and reduces the need for multiple index scans per each index.

Large indexes may still require multiple passes in PostgreSQL 17 if available memory can't accommodate the entire index processing at once. Typically, larger indexes contain more dead tuples that require multiple passes.

Detecting slow vacuum operations

The `postgres_get_av_diag()` function can detect when vacuum operations are running slowly due to insufficient memory. For more information on this function, see Installing autovacuum monitoring and diagnostic tools in RDS for PostgreSQL.

The `postgres_get_av_diag()` function issues the following notices when the available memory is not enough to complete the index vacuuming in a single pass.

`rds_tools` 1.8

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound and
 it might be slow.
```

```
NOTICE: The current setting of autovacuum_work_mem is "XXX" and might not be
 sufficient. Consider increasing the setting, and if necessary, scaling up the Amazon
 RDS instance class for more memory.
       Additionally, review the possibility of manual vacuum with exclusion of indexes
 using (VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) table_name;).
```

`rds_tools` 1.9

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound and
 it might be slow.
```

```
NOTICE: The current setting of autovacuum_work_mem is XX might not be sufficient.
 Consider increasing the setting to XXX, and if necessary, scaling up the RDS instance
 class for more
       memory. The suggested value is an estimate based on the current number of dead
 tuples for the table being vacuumed, which might not fully reflect the latest state.
 Additionally, review the possibility of manual
       vacuum with exclusion of indexes using (VACUUM (INDEX_CLEANUP FALSE, VERBOSE
 TRUE) table_name;). For more information, see
```

```
        Working with PostgreSQL autovacuum in the Amazon Amazon RDS User Guide
        .
```

> **Note**
>
> The `postgres_get_av_diag()` function relies on `pg_stat_all_tables.n_dead_tup` for estimating the amount of memory required for index vacuuming.

When the `postgres_get_av_diag()` function identifies a slow vacuum operation that requires multiple index scans due to insufficient `autovacuum_work_mem`, it will generate the following message:

```
NOTICE: Your vacuum is performing multiple index scans due to insufficient
 autovacuum_work_mem:XXX for index vacuuming.
        For more information, see Working with PostgreSQL autovacuum in the Amazon
 Amazon RDS User Guide.
```

Guidance

You can apply the following workarounds using manual `VACUUM FREEZE` to speed up freezing the table.

Increase the memory for vacuuming

As suggested by the `postgres_get_av_diag()` function, it's advisable to increase the `autovacuum_work_mem` parameter to address potential memory constraints at the instance level. While `autovacuum_work_mem` is a dynamic parameter, it's important to note that for the new memory setting to take effect, the autovacuum daemon needs to restart its workers. To accomplish this:

1. Confirm that the new setting is in place.
2. Terminate the processes currently running autovacuum.

This approach ensures that the adjusted memory allocation is applied to new autovacuum operations.

For more immediate results, consider manually performing a `VACUUM FREEZE` operation with an increased `maintenance_work_mem` setting within your session:

```
SET maintenance_work_mem TO '1GB';
VACUUM FREEZE VERBOSE table_name;
```

If you're using Amazon RDS and find that you need additional memory to support higher values for `maintenance_work_mem` or `autovacuum_work_mem`, consider upgrading to an instance class with more memory. This can provide the necessary resources to enhance both manual and automatic vacuum operations, leading to improved overall vacuum and database performance.

Disable INDEX_CLEANUP

Manual `VACUUM` in PostgreSQL version 12 and later allows skipping the index cleanup phase, while emergency autovacuum in PostgreSQL version 14 and later does this automatically based on the `vacuum_failsafe_age` parameter.

> **Warning**
>
> Skipping index cleanup can lead to index bloat and negatively impact query performance. To mitigate this, consider reindexing or vacuuming affected indexes during a maintenance window.

For additional guidance on handling large indexes, refer to the documentation on Managing autovacuum with large indexes.

Parallel index vacuuming

Starting with PostgreSQL 13, indexes can be vacuumed and cleaned in parallel by default using manual `VACUUM`, with one vacuum worker process assigned to each index. However, for PostgreSQL to determine if a vacuum operation qualifies for parallel execution, specific criteria must be met:

- There must be at least two indexes.
- The `max_parallel_maintenance_workers` parameter should be set to at least 2.
- The index size must exceed the `min_parallel_index_scan_size` limit, which defaults to 512KB.

You can adjust the `max_parallel_maintenance_workers` setting based on the number of vCPUs available on your Amazon RDS instance and the number of indexes on the table to optimize vacuuming turnaround time.

For more information, see Parallel vacuuming in Amazon RDS for PostgreSQL and Amazon Aurora PostgreSQL.

Too many tables or databases to vacuum

As mentioned in PostgreSQL's The Autovacuum Daemon documentation, the autovacuum daemon operates through multiple processes. This includes a persistent autovacuum launcher responsible for starting autovacuum worker processes for each database within the system. The launcher schedules these workers to initiate approximately every `autovacuum_naptime` seconds per database.

With 'N' databases, a new worker begins roughly every [`autovacuum_naptime`/N seconds]. However, the total number of concurrent workers is limited by the `autovacuum_max_workers` setting. If the number of databases or tables requiring vacuuming exceeds this limit, the next database or table will be processed as soon as a worker becomes available.

When many large tables or databases require vacuuming concurrently, all available autovacuum workers can become occupied for an extended duration, delaying maintenance on other tables and databases. In environments with high transaction rates, this bottleneck can quickly escalate and potentially lead to wraparound vacuum issues within your Amazon RDS instance.

When `postgres_get_av_diag()` detects a high number of tables or databases, it provides the following recommendation:

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound and
 it might be slow.
```

```
NOTICE: The current setting of autovacuum_max_workers:3 might not be sufficient.
 Consider increasing the setting and, if necessary, consider scaling up the Amazon RDS
 instance class for more workers.
```

Guidance

Increase autovacuum_max_workers

To expedite the vacuuming, we recommend adjusting the `autovacuum_max_workers` parameter to allow more concurrent autovacuum workers. If performance bottlenecks persist, consider scaling up your Amazon RDS instance to a class with more vCPUs, which can further improve the parallel processing capabilities.

Aggressive vacuum (to prevent wraparound) is running

The age of the database (MaximumUsedTransactionIDs) in PostgreSQL only decreases when an aggressive vacuum (to prevent wraparound) is successfully completed. Until this vacuum finishes, the age will continue to increase depending on the transaction rate.

The `postgres_get_av_diag()` function generates the following `NOTICE` when it detects an aggressive vacuum. However, it only triggers this output after the vacuum has been active for at least two minutes.

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound,
 monitor autovacuum performance.
```

For more information about aggressive vacuum, see [When an aggressive vacuum is already running].

You can verify if an aggressive vacuum is in progress with the following query:

```
SELECT
    a.xact_start AS start_time,
    v.datname "database",
    a.query,
    a.wait_event,
    v.pid,
    v.phase,
    v.relid::regclass,
    pg_size_pretty(pg_relation_size(v.relid)) AS heap_size,
    (
        SELECT
            string_agg(pg_size_pretty(pg_relation_size(i.indexrelid)) || ':' ||
 i.indexrelid::regclass || chr(10), ', ')
        FROM
            pg_index i
        WHERE
            i.indrelid = v.relid
    ) AS index_sizes,
    trunc(v.heap_blks_scanned * 100 / NULLIF(v.heap_blks_total, 0)) AS step1_scan_pct,
    v.index_vacuum_count || '/' || (
        SELECT
            count(*)
        FROM
            pg_index i
```

```
        WHERE
            i.indrelid = v.relid
    ) AS step2_vacuum_indexes,
    trunc(v.heap_blks_vacuumed * 100 / NULLIF(v.heap_blks_total, 0)) AS
 step3_vacuum_pct,
    age(CURRENT_TIMESTAMP, a.xact_start) AS total_time_spent_sofar
FROM
    pg_stat_activity a
    INNER JOIN pg_stat_progress_vacuum v ON v.pid = a.pid;
```

You can determine if it's an aggressive vacuum (to prevent wraparound) by checking the query column in the output. The phrase "to prevent wraparound" indicates that it is an aggressive vacuum.

```
query                 | autovacuum: VACUUM public.t3 (to prevent wraparound)
```

For example, suppose you have a blocker at transaction age 1 billion and a table requiring an aggressive vacuum to prevent wraparound at the same transaction age. Additionally, there's another blocker at transaction age 750 million. After clearing the blocker at transaction age 1 billion, the transaction age won't immediately drop to 750 million. It will remain high until the table needing the aggressive vacuum or any transaction with an age over 750 million is completed. During this period, the transaction age of your PostgreSQL cluster will continue to rise. Once the vacuum process is completed, the transaction age will drop to 750 million but will start increasing again until further vacuuming is finished. This cycle will continue as long as these conditions persist, until the transaction age eventually drops to the level configured for your Amazon RDS instance, specified by `autovacuum_freeze_max_age`.

Explanation of the NOTICE messages in RDS for PostgreSQL

The `postgres_get_av_diag()` function provides the following NOTICE messages:

When the age has not reached the monitoring threshold yet

The monitoring threshold for `postgres_get_av_diag()` to identify blockers is 500 million transactions by default. If `postgres_get_av_diag()` generates the following NOTICE, it indicates that the transaction age has not yet reached this threshold.

```
NOTICE: postgres_get_av_diag() checks for blockers that prevent aggressive vacuums
 only, it does so only after exceeding dvb_threshold which is 500,000,000 and age of
 this PostgreSQL cluster is currently at 2.
```

Not connected to the database with the age of oldest transaction ID

The `postgres_get_av_diag()` function provides the most accurate output when connected to the database with the oldest transaction ID age. The database with the oldest transaction ID age reported by `postgres_get_av_diag()` will be different than “my_database” in your case. If you are not connected to the correct database, the following NOTICE is generated:

```
NOTICE: You are not connected to the database with the age of oldest transaction
 ID. Connect to my_database database and run postgres_get_av_diag() for accurate
 reporting.
```

Connecting to the database with the oldest transaction age is important for the following reasons:

- **Identifying temporary table blockers:** Because the metadata for temporary tables is specific to each database, they are typically found in the database where they are created. However, if a temporary table happens to be the top blocker and resides in the database with the oldest transaction, this could be misleading. Connecting to the correct database ensures the accurate identification of the temporary table blocker.
- **Diagnosing slow vacuums:** The index metadata and table count information are database-specific and necessary for diagnosing slow vacuum issues.

Database with oldest transaction by age is on an rdsadmin or template0 database

In certain cases, the `rdsadmin` or `template0` databases may be identified as the database with the oldest transaction ID age. If this happens, `postgres_get_av_diag()` will issue the following NOTICE:

```
NOTICE: The database with the age of oldest transaction ID is rdsadmin or template0,
 reach out to support if the reported blocker is in rdsadmin or template0.
```

Verify that the listed blocker is not originating from either of these two databases. If the blocker is reported to be present in either `rdsadmin` or `template0`, contact support as these databases are not user-accessible and require intervention.

It is highly unlikely for either the `rdsadmin` or `template0` database to contain a top blocker.

When an aggressive vacuum is already running

The `postgres_get_av_diag()` function is designed to report when an aggressive vacuum process is running, but it only triggers this output after the vacuum has been active for at least

1 minute. This intentional delay helps reduce the chances of false positives. By waiting, the function ensures that only effective, significant vacuums are reported, leading to more accurate and reliable monitoring of vacuum activity.

The `postgres_get_av_diag()` function generates the following NOTICE when it detects one or more aggressive vacuums in progress.

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound,
 monitor autovacuum performance.
```

As indicated in the NOTICE, continue to monitor the performance of vacuum. For more information about aggressive vacuum see Aggressive vacuum (to prevent wraparound) is running

When autovacuum is off

The `postgres_get_av_diag()` function generates the following NOTICE if autovacuum is disabled on your database instance:

```
NOTICE: Autovacuum is OFF, we strongly recommend to enable it, no restart is
 necessary.
```

Autovacuum is a critical feature of your RDS for PostgreSQL DB instance that ensures smooth database operation. It automatically removes old row versions, reclaims storage space, and prevents table bloat, helping to keep tables and indexes efficient for optimal performance. Additionally, it protects against transaction ID wraparound, which can halt transactions on your Amazon RDS instance. Disabling autovacuum can lead to long-term declines in database performance and stability. We suggest you to keep it on all the times. For more information, see Understanding autovacuum in RDS for PostgreSQL environments.

> **Note**
>
> Turning off autovacuum doesn't stop aggressive vacuums. These will still occur once your tables hit the `autovacuum_freeze_max_age` threshold.

The number of transactions remaining is critically low

The `postgres_get_av_diag()` function generates the following NOTICE when a wraparound vacuum is imminent. This NOTICE is issued when your Amazon RDS instance is 100 million transactions away from potentially rejecting new transactions.

```
WARNING: Number of transactions remaining is critically low, resolve issues with
 autovacuum or perform manual VACUUM FREEZE before your instance stops accepting
 transactions.
```

Your immediate action is required to avoid database downtime. You should closely monitor your vacuuming operations and consider manually initiating a `VACUUM FREEZE` on the affected database to prevent transaction failures.

Managing TOAST OID contention in Amazon RDS for PostgreSQL

TOAST (The Oversized-Attribute Storage Technique) is a PostgreSQL feature designed to handle large data values that exceed the typical 8KB database block size. PostgreSQL doesn't allow physical rows to span multiple blocks. The block size acts as an upper limit on row size. TOAST overcomes this restriction by splitting large field values into smaller chunks. It stores them separately in a dedicated TOAST table linked to the main table. For more information, see the PostgreSQL TOAST storage mechanism and implementation documentation.

Topics

- Understanding TOAST operations
- Identifying performance challenges
- Recommendations
- Monitoring

Understanding TOAST operations

TOAST performs compression and stores large field values out of line. TOAST assigns a unique OID (Object Identifier) to each chunk of oversized data stored in the TOAST table. The main table stores the TOAST value ID and relation ID on the page to reference the corresponding row in the TOAST table. This allows PostgreSQL to efficiently locate and manage these TOAST chunks. However, as the TOAST table grows, the system risks exhausting available OIDs, leading to both performance degradation and potential downtime due to OID depletion.

Object identifiers in TOAST

An Object Identifier (OID) is a system-wide unique identifier used by PostgreSQL to reference database objects like tables, indexes, and functions. These identifiers play a vital role in PostgreSQL's internal operations, allowing the database to efficiently locate and manage objects.

For tables with eligible data sets for toasting, PostgreSQL assigns OIDs to uniquely identify each chunk of oversized data stored in the associated TOAST table. The system associates each chunk with a `chunk_id`, which helps PostgreSQL organize and locate these chunks efficiently within the TOAST table.

Identifying performance challenges

PostgreSQL's OID management relies on a global 32-bit counter so that it wraps around after generating 4 billion unique values. While the database cluster shares this counter, OID allocation involves two steps during TOAST operations:

- **Global counter for allocation** – The global counter assigns a new OID across the cluster.
- **Local search for conflicts** – The TOAST table ensures the new OID does not conflict with existing OIDs already used in that specific table.

Performance degradation can occur when:

- The TOAST table has high fragmentation or dense OID usage, leading to delays in assigning the OID.
- The system frequently allocates and reuses OIDs in environments with high data churn or wide tables that use TOAST extensively.

For more information, see the PostgreSQL TOAST table size limits and OID allocation documentation:

A global counter generates the OIDs and wraps around every 4 billion values, so that from time to time, the system generates an already-used value again. PostgreSQL detects that and tries again with the next OID. A slow INSERT could occur if there is a very long run of used OID values with no gaps in the TOAST table. These challenges become more pronounced as the OID space fills, leading to slower inserts and updates.

Identifying the problem

- Simple `INSERT` statements take significantly longer than usual in an inconsistent and random manner.
- Delays occur only for `INSERT` and `UPDATE` statements involving TOAST operations.
- The following log entries appear in PostgreSQL logs when the system struggles to find available OIDs in TOAST tables:

```
LOG: still searching for an unused OID in relation "pg_toast_20815"
DETAIL: OID candidates have been checked 1000000 times, but no unused OID has been
 found yet.
```

- Performance Insights indicates a high number of average active sessions (AAS) associated with `LWLock:buffer_io` and `LWLock:OidGenLock` wait events.

  You can run the following SQL query to identify long-running INSERT transactions with wait events:

```
SELECT
    datname AS database_name,
    usename AS database_user,
    pid,
    now() - pg_stat_activity.xact_start AS transaction_duration,
    concat(wait_event_type, ':', wait_event) AS wait_event,
    substr(query, 1, 30) AS TRANSACTION,
    state
FROM
    pg_stat_activity
WHERE (now() - pg_stat_activity.xact_start) > INTERVAL '60 seconds'
    AND state IN ('active', 'idle in transaction', 'idle in transaction (aborted)',
 'fastpath function call', 'disabled')
    AND pid <> pg_backend_pid()
AND lower(query) LIKE '%insert%'
ORDER BY
    transaction_duration DESC;
```

  Example query results displaying INSERT operations with extended wait times:

```
 database_name |  database_user  |  pid  | transaction_duration |     wait_event
 |          transaction           | state
```

```
---------------+-----------------+-------+---------------------
+--------------------+--------------------------------+--------
 postgres       | db_admin_user| 70965 | 00:10:19.484061      | LWLock:buffer_io    |
 INSERT INTO "products" (......... | active
 postgres       | db_admin_user| 69878 | 00:06:14.976037      | LWLock:buffer_io    |
 INSERT INTO "products" (......... | active
 postgres       | db_admin_user| 68937 | 00:05:13.942847      | :                   |
 INSERT INTO "products" (......... | active
```

Isolating the problem

- **Test small insert** – Insert a record smaller than the `toast_tuple_target` threshold. Remember that compression is applied before TOAST storage. If this operates without performance issues, the problem is related to TOAST operations.
- **Test new table** – Create a new table with the same structure and insert a record larger than `toast_tuple_target`. If this works without issues, the problem is localized to the original table's OID allocation.

Recommendations

The following approaches can help resolve TOAST OID contention issues.

- **Data cleanup and archive** – Review and delete any obsolete or unnecessary data to free up OIDs for future use, or archive the data. Consider the following limitations:
  - Limited scalability, as future cleanup might not always be possible.
  - Possible long-running VACUUM operation to remove the resulting dead tuples.
- **Write to a new table** – Create a new table for future inserts and use a `UNION ALL` view to combine old and new data for queries. This view presents the combined data from both old and new tables, allowing queries to access them as a single table. Consider the following limitations:
  - Updates on the old table might still cause OID exhaustion.
- **Partition or Shard** – Partition the table or shard data for better scalability and performance. Consider the following limitations:
  - Increased complexity in query logic and maintenance, potential need for application changes to handle partitioned data correctly.

Monitoring

Using system tables

You can use PostgreSQL's system tables to monitor growth of OID usage.

> **Warning**
>
> Depending on the number of OIDs in the TOAST table, it may take time to complete. We recommend that you schedule monitoring during off-business hours to minimize impact.

The following anonymous block counts the number of distinct OIDs used in each TOAST table and displays the parent table information:

```
DO $$
DECLARE
    r record;
    o bigint;
    parent_table text;
    parent_schema text;
BEGIN
    SET LOCAL client_min_messages TO notice;
    FOR r IN
    SELECT
        c.oid,
        c.oid::regclass AS toast_table
    FROM
        pg_class c
    WHERE
        c.relkind = 't'
        AND c.relowner != 10 LOOP
            -- Fetch the number of distinct used OIDs (chunk IDs) from the TOAST table
            EXECUTE 'SELECT COUNT(DISTINCT chunk_id) FROM ' || r.toast_table INTO o;
            -- If there are used OIDs, find the associated parent table and its schema
            IF o <> 0 THEN
                SELECT
                    n.nspname,
                    c.relname INTO parent_schema,
                    parent_table
                FROM
                    pg_class c
```

```
                    JOIN pg_namespace n ON c.relnamespace = n.oid
                WHERE
                    c.reltoastrelid = r.oid;
                -- Raise a concise NOTICE message
                RAISE NOTICE 'Parent schema: % | Parent table: % | Toast table: %
 | Number of used OIDs: %', parent_schema, parent_table, r.toast_table, TO_CHAR(o,
 'FM9,999,999,999,999');
            END IF;
        END LOOP;
END
$$;
```

Example output displaying OID usage statistics by TOAST table:

```
NOTICE:  Parent schema: public | Parent table: my_table | Toast table:
 pg_toast.pg_toast_16559 | Number of used OIDs: 45,623,317
NOTICE:  Parent schema: public | Parent table: my_table1 | Toast table:
 pg_toast.pg_toast_45639925 | Number of used OIDs: 10,000
NOTICE:  Parent schema: public | Parent table: my_table2 | Toast table:
 pg_toast.pg_toast_45649931 | Number of used OIDs: 1,000,000
DO
```

The following anonymous block retrieves the maximum assigned OID for each non-empty TOAST table:

```
DO $$
DECLARE
    r record;
    o bigint;
    parent_table text;
    parent_schema text;
BEGIN
    SET LOCAL client_min_messages TO notice;
    FOR r IN
    SELECT
        c.oid,
        c.oid::regclass AS toast_table
    FROM
        pg_class c
    WHERE
        c.relkind = 't'
        AND c.relowner != 10 LOOP
            -- Fetch the max(chunk_id) from the TOAST table
```

```
            EXECUTE 'SELECT max(chunk_id) FROM ' || r.toast_table INTO o;
            -- If there's at least one TOASTed chunk, find the associated parent table
 and its schema
            IF o IS NOT NULL THEN
                SELECT
                    n.nspname,
                    c.relname INTO parent_schema,
                    parent_table
                FROM
                    pg_class c
                    JOIN pg_namespace n ON c.relnamespace = n.oid
                WHERE
                    c.reltoastrelid = r.oid;
                -- Raise a concise NOTICE message
                RAISE NOTICE 'Parent schema: % | Parent table: % | Toast table:
 % | Max chunk_id: %', parent_schema, parent_table, r.toast_table, TO_CHAR(o,
 'FM9,999,999,999,999');
            END IF;
        END LOOP;
END
$$;
```

Example output displaying maximum chunk IDs for TOAST tables:

```
NOTICE:  Parent schema: public | Parent table: my_table | Toast table:
 pg_toast.pg_toast_16559 | Max chunk_id: 45,639,907
NOTICE:  Parent schema: public | Parent table: my_table1 | Toast table:
 pg_toast.pg_toast_45639925 | Max chunk_id: 45,649,929
NOTICE:  Parent schema: public | Parent table: my_table2 | Toast table:
 pg_toast.pg_toast_45649931 | Max chunk_id: 46,649,935
DO
```

Using Performance Insights

The wait events `LWLock:buffer_io` and `LWLock:OidGenLock` appear in Performance Insights during operations that require assigning new Object Identifiers (OIDs). High Average Active Sessions (AAS) for these events typically point to contention during OID assignment and resource management. This is particularly common in environments with high data churn, extensive large data usage, or frequent object creation.

LWLock:buffer_io

`LWLock:buffer_io` is a wait event that occurs when a PostgreSQL session is waiting for I/O operations on a shared buffer to complete. This typically happens when the database reads data from disk into memory or writes modified pages from memory to disk. The `BufferIO` wait event ensures consistency by preventing multiple processes from accessing or modifying the same buffer while I/O operations are in progress. High occurrences of this wait event may indicate disk bottlenecks or excessive I/O activity in the database workload.

During TOAST operations:

- PostgreSQL allocates OIDs for large objects and ensures their uniqueness by scanning the TOAST table's index.
- Large TOAST indexes may require accessing multiple pages to verify OID uniqueness. This results in increased disk I/O, especially when the buffer pool cannot cache all required pages.

The size of the index directly affects the number of buffer pages that need to be accessed during these operations. Even if the index is not bloated, its sheer size can increase buffer I/O, particularly in high-concurrency or high-churn environments. For more information, see LWLock:BufferIO wait event troubleshooting guide.

LWLock:OidGenLock

`OidGenLock` is a wait event that occurs when a PostgreSQL session is waiting to allocate a new object identifier (OID). This lock ensures that OIDs are generated sequentially and safely, allowing only one process to generate OIDs at a time.

During TOAST operations:

- **OID allocation for chunks in TOAST table** – PostgreSQL assigns OIDs to chunks in TOAST tables when managing large data records. Each OID must be unique to prevent conflicts in the system catalog.
- **High concurrency** – Since access to OID generator is sequential, when multiple sessions are concurrently creating objects that require OIDs, contention for `OidGenLock` can occur. This increases the likelihood of sessions waiting for OID allocation to complete.
- **Dependency on system catalog access** – Allocating OIDs requires updates to shared system catalog tables like `pg_class` and `pg_type`. If these tables experience heavy activity (due to frequent DDL operations), it can increase lock contention for `OidGenLock`.

- **High OID allocation demand** – TOAST heavy workloads with large data records require constant OID allocation, increasing contention.

Additional factors that increase OID contention:

- **Frequent object creation** – Workloads that frequently create and drop objects, such as temporary tables, amplify contention on the global OID counter.
- **Global counter locking** – The global OID counter is accessed serially to ensure uniqueness, creating a single point of contention in high-concurrency environments.

Working with logging mechanisms supported by RDS for PostgreSQL

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:

- The `log_statement` parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see RDS for PostgreSQL database log files.
- The `rds.force_admin_logging_level` parameter logs actions by the Amazon RDS internal user (rdsadmin) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are `disabled`, `debug5`, `debug4`, `debug3`, `debug2`, `debug1`, `info`, `notice`, `warning`, `error`, log, `fatal`, and `panic`. The default value is `disabled`.
- The `rds.force_autovacuum_logging_level` parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see Logging autovacuum and vacuum activities.
- The PostgreSQL Audit (pgAudit) extension can be installed and configured to capture activities at the session level or at the object level. For more information, see Using pgAudit to log database activity.
- The `log_fdw` extension makes it possible for you to access the database engine log using SQL. For more information, see Using the log_fdw extension to access the DB log using SQL.
- The `pg_stat_statements` library is specified as the default for the `shared_preload_libraries` parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that `pg_stat_statements` is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see SQL statistics for RDS PostgreSQL.

- The `log_hostname` parameter captures to the log the hostname of each client connection. For RDS for PostgreSQL version 12 and higher versions, this parameter is set to `off` by default. If you turn it on, be sure to monitor session connection times. When turned on, the service uses the domain name system (DNS) reverse lookup request to get the hostname of the client that's making the connection and add it to the PostgreSQL log. This has a noticeable impact during session connection. We recommend that you turn on this parameter for troubleshooting purposes only.

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see Monitoring metrics in an Amazon RDS instance.

Managing temporary files with PostgreSQL

In PostgreSQL, a complex query might perform several sort or hash operations at the same time, with each operation using instance memory to store results up to the value specified in the `work_mem` parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In RDS for PostgreSQL, these files are stored in Amazon EBS on the data volume. For more information, see Amazon RDS DB instance storage. You can monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space. For more information, see `FreeStorageSpace` .

We recommend using Amazon RDS Optimized Read instances for workloads involving multiple concurrent queries that increase the usage of temporary files. These instances use local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage to place the temporary files. For more information, see Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads.

You can use the following parameters and functions to manage the temporary files in your instance.

- **`temp_file_limit`** – This parameter cancels any query exceeding the size of temp_files in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the `log_temp_files` parameter. As a

best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```
postgres=>select * from pgbench_accounts, pg_class, big_table;
```

```
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

- **log_temp_files** – This parameter sends messages to the postgresql.log when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

  The following example shows that when the query successfully completes, the entries are logged in the postgresql.log file while the temporary files are cleaned up.

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
 temporary file: path "base/pgsql_tmp/pgsql_tmp31236.5", size 140353536
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
 a.bid limit 10;
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
 temporary file: path "base/pgsql_tmp/pgsql_tmp31236.4", size 180428800
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
 a.bid limit 10;
```

- **pg_ls_tmpdir** – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```
postgres=>select * from pg_ls_tmpdir();
```

```
      name       |    size    |      modification
-----------------+------------+------------------------
```

```
 pgsql_tmp8355.1 | 1072250880 | 2023-02-06 22:54:56+00
 pgsql_tmp8351.0 | 1072250880 | 2023-02-06 22:54:43+00
 pgsql_tmp8327.0 | 1072250880 | 2023-02-06 22:54:56+00
 pgsql_tmp8351.1 |  703168512 | 2023-02-06 22:54:56+00
 pgsql_tmp8355.0 | 1072250880 | 2023-02-06 22:54:00+00
 pgsql_tmp8328.1 |  835031040 | 2023-02-06 22:54:56+00
 pgsql_tmp8328.0 | 1072250880 | 2023-02-06 22:54:40+00
(7 rows)
```

```
postgres=>select query from pg_stat_activity where pid = 8355;

query
-------------------------------------------------------------------------------------
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
 a.bid
(1 row)
```

The file name includes the processing ID (PID) of the session that generated the temporary file. A more advanced query, such as in the following example, performs a sum of the temporary files for each PID.

```
postgres=>select replace(left(name, strpos(name, '.')-1),'pgsql_tmp','') as pid,
 count(*), sum(size) from pg_ls_tmpdir() group by pid;
```

```

 pid  | count |   sum
------+-------------------
 8355 |     2 | 2144501760
 8351 |     2 | 2090770432
 8327 |     1 | 1072250880
 8328 |     2 | 2144501760
(4 rows)
```

- **pg_stat_statements** – If you activate the pg_stat_statements parameter, then you can view the average temporary file usage per call. You can identify the query_id of the query and use it to examine the temporary file usage as shown in the following example.

```
postgres=>select queryid from pg_stat_statements where query like 'select a.aid from
 pgbench%';
```

```
       queryid
----------------------
 -7170349228837045701
(1 row)
```

```
postgres=>select queryid, substr(query,1,25), calls, temp_blks_read/calls
 temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from
 pg_stat_statements where queryid = -7170349228837045701;
```

```
       queryid        |          substr           | calls | temp_blks_read_per_call |
 temp_blks_written_per_call
----------------------+---------------------------+-------+-------------------------
+---------------------------
 -7170349228837045701 | select a.aid from pgbench |    50 |                  239226 |
                    388678
(1 row)
```

- **`Performance Insights`** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics **temp_bytes** and **temp_files**. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

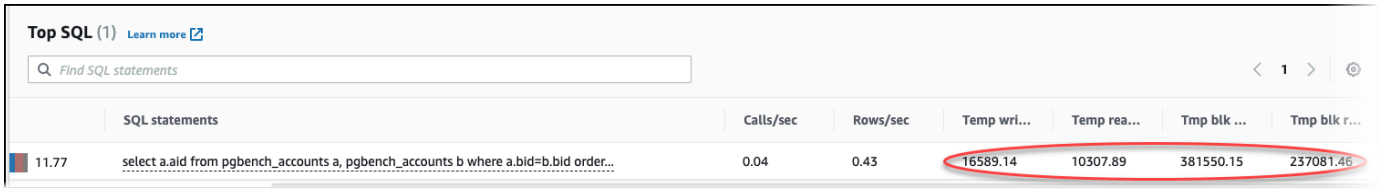
  For more information about how to analyze metrics and queries with Performance Insights, see Analyzing metrics with the Performance Insights dashboard.

  For an example of viewing temporary file usage with Performance Insights, see Viewing temporary file usage with Performance Insights

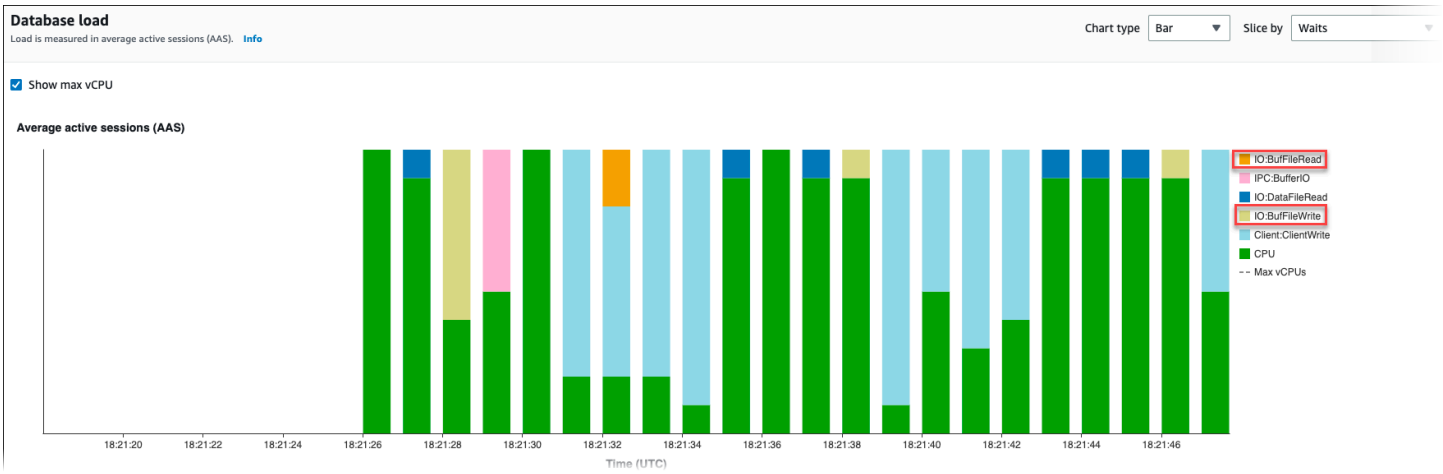
Viewing temporary file usage with Performance Insights

You can use Performance Insights to view temporary file usage by turning on the metrics **temp_bytes** and **temp_files**. The view in Performance Insights doesn't show the specific queries

that generate temporary files, however, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.



1. In the Performance Insights dashboard, choose **Manage Metrics**.
2. Choose **Database metrics**, and select the **temp_bytes** and **temp_files** metrics as shown in the following image.



3. In the **Top SQL** tab, choose the **Preferences** icon.
4. In the **Preferences** window, turn on the following statistics to appear in the **Top SQL**tab and choose **Continue**.

- Temp writes/sec
- Temp reads/sec
- Tmp blk write/call
- Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for `pg_ls_tmpdir`, as shown in the following example.

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on `IO:BufFileRead` and `IO:BufFileWrite` by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see Overview of the Top SQL tab. You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see IO:BufFileRead and IO:BufFileWrite.

> **Note**
>
> The `work_mem` parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this

parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.
As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the `SET work_mem` command. Then the change is only applied to the current session and doesn't change the value globally.

Using pgBadger for log analysis with PostgreSQL

You can use a log analyzer such as pgBadger to analyze PostgreSQL logs. The pgBadger documentation states that the %l pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS `log_line_prefix` as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```
./pgbadger -f stderr -p '%t:%r:%u@%d:[%p]:' postgresql.log.2014-02-04-00
```

Using PGSnapper for monitoring PostgreSQL

You can use PGSnapper to assist with periodic collection of Amazon RDS for PostgreSQL performance-related statistics and metrics. For more information, see Monitor Amazon RDS for PostgreSQL performance using PGSnapper.

Managing custom casts in RDS for PostgreSQL

Type casting in PostgreSQL is the process of converting a value from one data type to another. PostgreSQL provides built-in casts for many common conversions, but you can also create custom casts to define how specific type conversions should behave.

A cast specifies how to perform a conversion from one data type to another. For example, converting text `'123'` to integer 123, or numeric `45.67` to text `'45.67'`.

For comprehensive information about PostgreSQL casting concepts and syntax, refer to the PostgreSQL CREATE CAST Documentation.

Starting with RDS for PostgreSQL versions 13.23, 14.20, 15.15, 16.11, 17.7, and 18.1, you can use the rds_casts extension to install additional casts for built-in types, while still being able to create your own casts for custom types.

Topics

- Installing and using the rds_casts extension
- Supported casts
- Creating or dropping casts
- Creating custom casts with proper context strategy

Installing and using the rds_casts extension

To create the `rds_casts` extension, connect to your RDS for PostgreSQL DB instance as an `rds_superuser` and run the following command:

```
CREATE EXTENSION IF NOT EXISTS rds_casts;
```

Supported casts

Create the extension in each database where you want to use custom casts. After creating the extension, use the following command to view all available casts:

```
SELECT * FROM rds_casts.list_supported_casts();
```

This function lists the available cast combinations (source type, target type, coercion context, and cast function). For example, if you want to create `text` to `numeric` as an `implicit` cast. You can use the following query to find if the cast is available to create:

```
SELECT * FROM rds_casts.list_supported_casts()
WHERE source_type = 'text' AND target_type = 'numeric';
 id | source_type | target_type |          qualified_function          |
 coercion_context
----+-------------+-------------+--------------------------------------
+------------------
 10 | text        | numeric     | rds_casts.rds_text_to_numeric_custom | implicit
 11 | text        | numeric     | rds_casts.rds_text_to_numeric_custom | assignment
 13 | text        | numeric     | rds_casts.rds_text_to_numeric_custom | explicit
 20 | text        | numeric     | rds_casts.rds_text_to_numeric_inout  | implicit
```

```
 21 | text        | numeric     | rds_casts.rds_text_to_numeric_inout  | assignment
 23 | text        | numeric     | rds_casts.rds_text_to_numeric_inout  | explicit
```

The rds_casts extension provides two types of conversion functions for each cast:

- *_inout functions* - Use PostgreSQL's standard I/O conversion mechanism, behaving identically to casts created with the INOUT method
- *_custom functions* - Provide enhanced conversion logic that handles edge cases, such as converting empty strings to NULL values to avoid conversion errors

The `inout` functions replicate PostgreSQL's native casting behavior, while `custom` functions extend this functionality by handling scenarios that standard INOUT casts cannot accommodate, such as converting empty strings to integers.

Creating or dropping casts

You can create and drop supported casts using two methods:

Cast creation

Method 1: Using native CREATE CAST command

```
CREATE CAST (text AS numeric)
WITH FUNCTION rds_casts.rds_text_to_numeric_custom
AS IMPLICIT;
```

Method 2: Using the rds_casts.create_cast function

```
SELECT rds_casts.create_cast(10);
```

The `create_cast` function takes the ID from the `list_supported_casts()` output. This method is simpler and ensures you're using the correct function and context combination. This id is guaranteed to remain the same across different postgres versions.

To verify the cast was created successfully, query the pg_cast system catalog:

```
SELECT oid, castsource::regtype, casttarget::regtype, castfunc::regproc, castcontext,
 castmethod
FROM pg_cast
WHERE castsource = 'text'::regtype AND casttarget = 'numeric'::regtype;
```

```
  oid   | castsource | casttarget |               castfunc               | castcontext
 | castmethod
--------+------------+------------+--------------------------------------+-------------
+------------
 356372 | text       | numeric    | rds_casts.rds_text_to_numeric_custom | i
 | f
```

The `castcontext` column shows: `e` for EXPLICIT, `a` for ASSIGNMENT, or `i` for IMPLICIT.

Dropping casts

Method 1: Using DROP CAST command

```
DROP CAST IF EXISTS (text AS numeric);
```

Method 2: Using the rds_casts.drop_cast function

```
SELECT rds_casts.drop_cast(10);
```

The `drop_cast` function takes the same ID used when creating the cast. This method ensures you're dropping the exact cast that was created with the corresponding ID.

Creating custom casts with proper context strategy

When creating multiple casts for integer types, operator ambiguity errors can occur if all casts are created as IMPLICIT. The following example demonstrates this issue by creating two implicit casts from text to different integer widths:

```
-- Creating multiple IMPLICIT casts causes ambiguity
postgres=> CREATE CAST (text AS int4) WITH FUNCTION
 rds_casts.rds_text_to_int4_custom(text) AS IMPLICIT;
CREATE CAST
postgres=> CREATE CAST (text AS int8) WITH FUNCTION
 rds_casts.rds_text_to_int8_custom(text) AS IMPLICIT;
CREATE CAST

postgres=> CREATE TABLE test_cast(col int);
CREATE TABLE
postgres=> INSERT INTO test_cast VALUES ('123'::text);
INSERT 0 1
postgres=> SELECT * FROM test_cast WHERE col='123'::text;
```

```
ERROR:  operator is not unique: integer = text
LINE 1: SELECT * FROM test_cast WHERE col='123'::text;
                                            ^
HINT:  Could not choose a best candidate operator. You might need to add explicit type
 casts.
```

The error occurs because PostgreSQL cannot determine which implicit cast to use when comparing an integer column with a text value. Both the int4 and int8 implicit casts are valid candidates, creating ambiguity.

To avoid this operator ambiguity, use ASSIGNMENT context for smaller integer widths and IMPLICIT context for larger integer widths:

```
-- Use ASSIGNMENT for smaller integer widths
CREATE CAST (text AS int2)
WITH FUNCTION rds_casts.rds_text_to_int2_custom(text)
AS ASSIGNMENT;

CREATE CAST (text AS int4)
WITH FUNCTION rds_casts.rds_text_to_int4_custom(text)
AS ASSIGNMENT;

-- Use IMPLICIT for larger integer widths
CREATE CAST (text AS int8)
WITH FUNCTION rds_casts.rds_text_to_int8_custom(text)
AS IMPLICIT;

postgres=> INSERT INTO test_cast VALUES ('123'::text);
INSERT 0 1
postgres=> SELECT * FROM test_cast WHERE col='123'::text;
 col
-----
 123
(1 row)
```

With this strategy, only the int8 cast is implicit, so PostgreSQL can unambiguously determine which cast to use.

Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for

the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, `default.postgres13`.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see Parameter groups for Amazon RDS.

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL `pg_settings` table of your instance, as shown following.

```
SELECT name, setting, boot_val, reset_val, unit
 FROM pg_settings
 ORDER BY name;
```

To learn more about the values returned from this query, see `pg_settings` in the PostgreSQL documentation.

Be especially careful when changing the settings for `max_connections` and `shared_buffers` on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for `max_connections` or `shared_buffers` and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the `postgres.log`.

```
2018-09-18 21:13:15 UTC::@:[8097]:FATAL:  could not map anonymous shared memory: Cannot
 allocate memory
2018-09-18 21:13:15 UTC::@:[8097]:HINT:  This error usually means that PostgreSQL's
 request for a shared memory segment
exceeded available memory or swap space. To reduce the request size (currently
 3514134274048 bytes), reduce
PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or
 max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see Parameter groups for Amazon RDS.

There are two types of parameters in RDS for PostgreSQL.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

> **Note**
>
> If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the `ALTER DATABASE`, `ALTER ROLE`, and `SET` commands.

RDS for PostgreSQL DB instance parameter list

The following table lists some (but not all) parameters available in an RDS for PostgreSQL DB instance. To view all available parameters, you use the describe-db-parameters AWS CLI command. For example, to get the list of all parameters available in the default parameter group for RDS for PostgreSQL version 13, run the following.

```
aws rds describe-db-parameters --db-parameter-group-name default.postgres13
```

You can also use the Console. Choose **Parameter groups** from the Amazon RDS menu, and then choose the parameter group from those available in your AWS Region.

Parameter name	Apply_Type	Description
application_name	Dynamic	Sets the application name to be reported in statistics and logs.
archive_command	Dynamic	Sets the shell command that will be called to archive a WAL file.
array_nulls	Dynamic	Enables input of NULL elements in arrays.
authentication_timeout	Dynamic	Sets the maximum allowed time to complete client authentication.
autovacuum	Dynamic	Starts the autovacuum subprocess.
autovacuum_analyze_scale_factor	Dynamic	Number of tuple inserts, updates, or deletes before analyze as a fraction of reltuples.
autovacuum_analyze_threshold	Dynamic	Minimum number of tuple inserts, updates, or deletes before analyze.
autovacuum_freeze_max_age	Static	Age at which to autovacuum a table to prevent transaction ID wraparound.
autovacuum_naptime	Dynamic	Time to sleep between autovacuum runs.

Parameter name	Apply_Type	Description
autovacuum_max_workers	Static	Sets the maximum number of simultaneously running autovacuum worker processes.
autovacuum_vacuum_cost_delay	Dynamic	Vacuum cost delay, in milliseconds, for autovacuum.
autovacuum_vacuum_cost_limit	Dynamic	Vacuum cost amount available before napping, for autovacuum.
autovacuum_vacuum_scale_factor	Dynamic	Number of tuple updates or deletes before vacuum as a fraction of reltuples.
autovacuum_vacuum_threshold	Dynamic	Minimum number of tuple updates or deletes before vacuum.
backslash_quote	Dynamic	Sets whether a backslash (\) is allowed in string literals.
bgwriter_delay	Dynamic	Background writer sleep time between rounds.
bgwriter_lru_maxpages	Dynamic	Background writer maximum number of LRU pages to flush per round.
bgwriter_lru_multiplier	Dynamic	Multiple of the average buffer usage to free per round.
bytea_output	Dynamic	Sets the output format for bytes.
check_function_bodies	Dynamic	Checks function bodies during CREATE FUNCTION.
checkpoint_completion_target	Dynamic	Time spent flushing dirty buffers during checkpoint, as a fraction of the checkpoint interval.

Parameter name	Apply_Type	Description
checkpoint_segments	Dynamic	Sets the maximum distance in log segments between automatic write-ahead log (WAL) checkpoints.
checkpoint_timeout	Dynamic	Sets the maximum time between automatic WAL checkpoints.
checkpoint_warning	Dynamic	Enables warnings if checkpoint segments are filled more frequently than this.
client_connection_check_interval	Dynamic	Sets the time interval between checks for disconnection while running queries.
client_encoding	Dynamic	Sets the client's character set encoding.
client_min_messages	Dynamic	Sets the message levels that are sent to the client.
commit_delay	Dynamic	Sets the delay in microseconds between transaction commit and flushing WAL to disk.
commit_siblings	Dynamic	Sets the minimum concurrent open transactions before performing commit_delay.
constraint_exclusion	Dynamic	Enables the planner to use constraints to optimize queries.
cpu_index_tuple_cost	Dynamic	Sets the planner's estimate of the cost of processing each index entry during an index scan.
cpu_operator_cost	Dynamic	Sets the planner's estimate of the cost of processing each operator or function call.
cpu_tuple_cost	Dynamic	Sets the planner's estimate of the cost of processing each tuple (row).
cursor_tuple_fraction	Dynamic	Sets the planner's estimate of the fraction of a cursor's rows that will be retrieved.

Parameter name	Apply_Type	Description
datestyle	Dynamic	Sets the display format for date and time values.
deadlock_timeout	Dynamic	Sets the time to wait on a lock before checking for deadlock.
debug_pretty_print	Dynamic	Indents parse and plan tree displays.
debug_print_parse	Dynamic	Logs each query's parse tree.
debug_print_plan	Dynamic	Logs each query's execution plan.
debug_print_rewritten	Dynamic	Logs each query's rewritten parse tree.
default_statistics_target	Dynamic	Sets the default statistics target.
default_tablespace	Dynamic	Sets the default tablespace to create tables and indexes in.
default_transaction_deferrable	Dynamic	Sets the default deferrable status of new transactions.
default_transaction_isolation	Dynamic	Sets the transaction isolation level of each new transaction.
default_transaction_read_only	Dynamic	Sets the default read-only status of new transactions.
default_with_oids	Dynamic	Creates new tables with object IDs (OIDs) by default.
effective_cache_size	Dynamic	Sets the planner's assumption about the size of the disk cache.
effective_io_concurrency	Dynamic	Number of simultaneous requests that can be handled efficiently by the disk subsystem.

Parameter name	Apply_Type	Description
enable_bitmapscan	Dynamic	Enables the planner's use of bitmap-scan plans.
enable_hashagg	Dynamic	Enables the planner's use of hashed aggregation plans.
enable_hashjoin	Dynamic	Enables the planner's use of hash join plans.
enable_indexscan	Dynamic	Enables the planner's use of index-scan plans.
enable_material	Dynamic	Enables the planner's use of materialization.
enable_mergejoin	Dynamic	Enables the planner's use of merge join plans.
enable_nestloop	Dynamic	Enables the planner's use of nested-loop join plans.
enable_seqscan	Dynamic	Enables the planner's use of sequential-scan plans.
enable_sort	Dynamic	Enables the planner's use of explicit sort steps.
enable_tidscan	Dynamic	Enables the planner's use of TID scan plans.
escape_string_warning	Dynamic	Warns about backslash (\) escapes in ordinary string literals.
extra_float_digits	Dynamic	Sets the number of digits displayed for floating-point values.
from_collapse_limit	Dynamic	Sets the FROM-list size beyond which subqueries are not collapsed.
fsync	Dynamic	Forces synchronization of updates to disk.
full_page_writes	Dynamic	Writes full pages to WAL when first modified after a checkpoint.
geqo	Dynamic	Enables genetic query optimization.

Parameter name	Apply_Type	Description
geqo_effort	Dynamic	GEQO: effort is used to set the default for other GEQO parameters.
geqo_generations	Dynamic	GEQO: number of iterations of the algorithm.
geqo_pool_size	Dynamic	GEQO: number of individuals in the population.
geqo_seed	Dynamic	GEQO: seed for random path selection.
geqo_selection_bias	Dynamic	GEQO: selective pressure within the population.
geqo_threshold	Dynamic	Sets the threshold of FROM items beyond which GEQO is used.
gin_fuzzy_search_limit	Dynamic	Sets the maximum allowed result for exact search by GIN.
hot_standby_feedback	Dynamic	Determines whether a hot standby sends feedback messages to the primary or upstream standby.
intervalstyle	Dynamic	Sets the display format for interval values.
join_collapse_limit	Dynamic	Sets the FROM-list size beyond which JOIN constructs are not flattened.
lc_messages	Dynamic	Sets the language in which messages are displayed.
lc_monetary	Dynamic	Sets the locale for formatting monetary amounts.
lc_numeric	Dynamic	Sets the locale for formatting numbers.
lc_time	Dynamic	Sets the locale for formatting date and time values.

Parameter name	Apply_Type	Description
log_autovacuum_min_duration	Dynamic	Sets the minimum running time above which autovacuum actions will be logged.
log_checkpoints	Dynamic	Logs each checkpoint.
log_connections	Dynamic	Logs each successful connection.
log_disconnections	Dynamic	Logs end of a session, including duration.
log_duration	Dynamic	Logs the duration of each completed SQL statement.
log_error_verbosity	Dynamic	Sets the verbosity of logged messages.
log_executor_stats	Dynamic	Writes executor performance statistics to the server log.
log_filename	Dynamic	Sets the file name pattern for log files.
log_file_mode	Dynamic	Sets file permissions for log files. Default value is 0644.
log_hostname	Dynamic	Logs the host name in the connection logs. As of PostgreSQL 12 and later versions, this parameter is 'off' by default. When turned on, the connection uses DNS reverse-lookup to get the hostname that gets captured to the connection logs. If you turn on this parameter, you should monitor the impact that it has on the time it takes to establish connections.
log_line_prefix	Dynamic	Controls information prefixed to each log line.
log_lock_waits	Dynamic	Logs long lock waits.
log_min_duration_statement	Dynamic	Sets the minimum running time above which statements will be logged.

Parameter name	Apply_Type	Description
log_min_error_statement	Dynamic	Causes all statements generating an error at or above this level to be logged.
log_min_messages	Dynamic	Sets the message levels that are logged.
log_parser_stats	Dynamic	Writes parser performance statistics to the server log.
log_planner_stats	Dynamic	Writes planner performance statistics to the server log.
log_rotation_age	Dynamic	Automatic log file rotation will occur after N minutes.
log_rotation_size	Dynamic	Automatic log file rotation will occur after N kilobytes.
log_statement	Dynamic	Sets the type of statements logged.
log_statement_stats	Dynamic	Writes cumulative performance statistics to the server log.
log_temp_files	Dynamic	Logs the use of temporary files larger than this number of kilobytes.
log_timezone	Dynamic	Sets the time zone to use in log messages.
log_truncate_on_rotation	Dynamic	Truncate existing log files of same name during log rotation.
logging_collector	Static	Start a subprocess to capture stderr output and/or csvlogs into log files.
maintenance_work_mem	Dynamic	Sets the maximum memory to be used for maintenance operations.

Parameter name	Apply_Type	Description
max_connections	Static	Sets the maximum number of concurrent connections.
max_files_per_process	Static	Sets the maximum number of simultaneously open files for each server process.
max_locks_per_transaction	Static	Sets the maximum number of locks per transaction.
max_pred_locks_per_transaction	Static	Sets the maximum number of predicate locks per transaction.
max_prepared_transactions	Static	Sets the maximum number of simultaneously prepared transactions.
max_stack_depth	Dynamic	Sets the maximum stack depth, in kilobytes.
max_standby_archive_delay	Dynamic	Sets the maximum delay before canceling queries when a hot standby server is processing archived WAL data.
max_standby_streaming_delay	Dynamic	Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.

Parameter name	Apply_Type	Description

max_wal_size	Dynamic	Sets the WAL size (MB) that triggers a checkpoint.
		• For RDS for PostgreSQL 15 and earlier versions, it is 2 GB.
		• For RDS for PostgreSQL 16 and later versions, RDS for PostgreSQL automatically configures based on the allocated storage size of your instance:
		  • 6 GB for instances with allocated storage 100 GB and more.
		  • 2 GB for instances with allocated storage less than 100 GB.
		
		Use the following command on your Amazon RDS for PostgreSQL DB instance to see its current value:
		`SHOW max_wal_size;`

min_wal_size	Dynamic	Sets the minimum size to shrink the WAL to. For PostgreSQL version 9.6 and earlier, min_wal_size is in units of 16 MB. For PostgreSQL version 10 and later, min_wal_size is in units of 1 MB.
quote_all_identifiers	Dynamic	Adds quotes (") to all identifiers when generating SQL fragments.
random_page_cost	Dynamic	Sets the planner's estimate of the cost of a non-sequentially fetched disk page. This parameter has no value unless query plan management (QPM) is turned on. When QPM is on, the default value for this parameter 4.

Parameter name	Apply_Type	Description
rds.adaptive_autovacuum	Dynamic	Automatically tunes the autovacuum parameters whenever the transaction ID thresholds are exceeded.
rds.force_ssl	Dynamic	Requires the use of SSL connections. The default value is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value set to 0 (off).
rds.local_volume_spill_enabled	Static	Enables writing logical spill files to the local volume.
rds.log_retention_period	Dynamic	Sets log retention such that Amazon RDS deletes PostgreSQL logs that are older than *n* minutes.
rds.rds_superuser_reserved_connections	Static	Sets the number of connection slots reserved for rds_superusers. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation reserved_connections.
rds.replica_identity_full	Dynamic	When you set this parameter to on, it overrides the replica identity setting to FULL for all database tables. This means all column values are written to the write ahead log (WAL), regardless of your REPLICA IDENTITY FULL settings. **Note** Turning on this parameter may increase your database instance IOPS due to the additional WAL logging.

Parameter name	Apply_Type	Description
rds.restrict_password_commands	Static	Restricts who can manage passwords to users with the rds_password role. Set this parameter to 1 to enable password restriction. The default is 0.
search_path	Dynamic	Sets the schema search order for names that are not schema-qualified.
seq_page_cost	Dynamic	Sets the planner's estimate of the cost of a sequentially fetched disk page.
session_replication_role	Dynamic	Sets the sessions behavior for triggers and rewrite rules.
shared_buffers	Static	Sets the number of shared memory buffers used by the server.
shared_preload_libraries	Static	Lists the shared libraries to preload into the RDS for PostgreSQL DB instance. Supported values include auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_tle, pg_transport, plprofiler, and plrust.
ssl	Dynamic	Enables SSL connections.
sql_inheritance	Dynamic	Causes subtables to be included by default in various commands.
ssl_renegotiation_limit	Dynamic	Sets the amount of traffic to send and receive before renegotiating the encryption keys.
standard_conforming_strings	Dynamic	Causes ... strings to treat backslashes literally.

Parameter name	Apply_Type	Description
statement_timeout	Dynamic	Sets the maximum allowed duration of any statement.
synchronize_seqscans	Dynamic	Enables synchronized sequential scans.
synchronous_commit	Dynamic	Sets the current transactions synchronization level.
tcp_keepalives_count	Dynamic	Maximum number of TCP keepalive retransmits.
tcp_keepalives_idle	Dynamic	Time between issuing TCP keepalives.
tcp_keepalives_interval	Dynamic	Time between TCP keepalive retransmits.
temp_buffers	Dynamic	Sets the maximum number of temporary buffers used by each session.
temp_file_limit	Dynamic	Sets the maximum size in KB to which the temporary files can grow.
temp_tablespaces	Dynamic	Sets the tablespaces to use for temporary tables and sort files.

Parameter name	Apply_Type	Description
timezone	Dynamic	Sets the time zone for displaying and interpreting time stamps. The Internet Assigned Numbers Authority (IANA) publishes new time zones at https://www.iana.org/time-zones several times a year. Every time RDS releases a new minor maintenance release of PostgreSQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for PostgreSQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. You can't modify the time zone tables in PostgreSQL DB instances manually. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.
track_activities	Dynamic	Collects information about running commands.
track_activity_query_size	Static	Sets the size reserved for pg_stat_activity.current_query, in bytes.
track_counts	Dynamic	Collects statistics on database activity.
track_functions	Dynamic	Collects function-level statistics on database activity.
track_io_timing	Dynamic	Collects timing statistics on database I/O activity.
transaction_deferrable	Dynamic	Indicates whether to defer a read-only serializable transaction until it can be started with no possible serialization failures.

Parameter name	Apply_Type	Description
transaction_isolation	Dynamic	Sets the current transactions isolation level.
transaction_read_only	Dynamic	Sets the current transactions read-only status.
transform_null_equals	Dynamic	Treats expr=NULL as expr IS NULL.
update_process_title	Dynamic	Updates the process title to show the active SQL command.
vacuum_cost_delay	Dynamic	Vacuum cost delay in milliseconds.
vacuum_cost_limit	Dynamic	Vacuum cost amount available before napping.
vacuum_cost_page_dirty	Dynamic	Vacuum cost for a page dirtied by vacuum.
vacuum_cost_page_hit	Dynamic	Vacuum cost for a page found in the buffer cache.
vacuum_cost_page_miss	Dynamic	Vacuum cost for a page not found in the buffer cache.
vacuum_defer_cleanup_age	Dynamic	Number of transactions by which vacuum and hot cleanup should be deferred, if any.
vacuum_freeze_min_age	Dynamic	Minimum age at which vacuum should freeze a table row.
vacuum_freeze_table_age	Dynamic	Age at which vacuum should scan a whole table to freeze tuples.
wal_buffers	Static	Sets the number of disk-page buffers in shared memory for WAL.
wal_writer_delay	Dynamic	WAL writer sleep time between WAL flushes.

Parameter name	Apply_Type	Description
work_mem	Dynamic	Sets the maximum memory to be used for query workspaces.
xmlbinary	Dynamic	Sets how binary values are to be encoded in XML.
xmloption	Dynamic	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.

Amazon RDS uses the default PostgreSQL units for all parameters. The following table shows the PostgreSQL default unit for each parameter.

Parameter name	Unit
archive_timeout	s
authentication_timeout	s
autovacuum_naptime	s
autovacuum_vacuum_cost_delay	ms
bgwriter_delay	ms
checkpoint_timeout	s
checkpoint_warning	s
deadlock_timeout	ms
effective_cache_size	8 KB
lock_timeout	ms
log_autovacuum_min_duration	ms

Parameter name	Unit
log_min_duration_statement	ms
log_rotation_age	minutes
log_rotation_size	KB
log_temp_files	KB
maintenance_work_mem	KB
max_stack_depth	KB
max_standby_archive_delay	ms
max_standby_streaming_delay	ms
post_auth_delay	s
pre_auth_delay	s
segment_size	8 KB
shared_buffers	8 KB
statement_timeout	ms
ssl_renegotiation_limit	KB
tcp_keepalives_idle	s
tcp_keepalives_interval	s
temp_file_limit	KB
work_mem	KB
temp_buffers	8 KB
vacuum_cost_delay	ms

Parameter name	Unit
wal_buffers	8 KB
wal_receiver_timeout	ms
wal_segment_size	B
wal_sender_timeout	ms
wal_writer_delay	ms
wal_receiver_status_interval	s

Tuning with wait events for RDS for PostgreSQL

Wait events are an important tuning tool for RDS for PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. This section also discusses basic PostgreSQL tuning concepts.

The wait events in this section are specific to RDS for PostgreSQL.

- Timeout:VacuumDelay

Essential concepts for RDS for PostgreSQL tuning

Before you tune your RDS for PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of RDS for PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics

- RDS for PostgreSQL wait events
- RDS for PostgreSQL memory
- RDS for PostgreSQL processes

RDS for PostgreSQL wait events

A *wait event* is an indication that the session is waiting for a resource. For example, the wait event `Client:ClientRead` occurs when RDS for PostgreSQL is waiting to receive data from the client. Sessions typically wait for resources such as the following.

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

By itself, a single wait event doesn't indicate a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

On the other hand, large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now takes hours to run, you can identify the wait events that

contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

RDS for PostgreSQL memory

RDS for PostgreSQL memory is divided into shared and local.

Topics

- Shared memory in RDS for PostgreSQL
- Local memory in RDS for PostgreSQL

Shared memory in RDS for PostgreSQL

RDS for PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. The following sections provide descriptions of the most important ones.

Topics

- Shared buffers
- Write ahead log (WAL) buffers

Shared buffers

The *shared buffer pool* is an RDS for PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, RDS for PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data. The default value is set to `{DBInstanceClassMemory/32768}` bytes, based on the available memory for the DB instance.

Write ahead log (WAL) buffers

A *write-ahead log (WAL) buffer* holds transaction data that RDS for PostgreSQL later writes to persistent storage. Using the WAL mechanism, RDS for PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, RDS for PostgreSQL writes the changes to the WAL buffer. When the client issues a `COMMIT`, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL, with possible values such as `minimal`, `replica`, and `logical`.

Local memory in RDS for PostgreSQL

Every backend process allocates local memory for query processing.

Topics

- Work memory area
- Maintenance work memory area
- Temporary buffer area

Work memory area

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an `ORDER BY` clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files, measured in megabytes. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

Maintenance work memory area

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations, measured in megabytes. The default value is 64 MB. A database session can only run one maintenance operation at a time.

Temporary buffer area

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session, measured in megabytes. The default value is 8 MB. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

RDS for PostgreSQL processes

RDS for PostgreSQL uses multiple processes.

Topics

- Postmaster process
- Backend processes
- Background processes

Postmaster process

The *postmaster process* is the first process started when you start RDS for PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer

  RDS for PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows RDS for PostgreSQL to use the logs to recover the database after a failure.

- Background writer

  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- Autovacuum daemon

  The daemon consists of the following:

  - The autovacuum launcher
  - The autovacuum worker processes

  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:

  - Recover or reuse disk space occupied by updated or deleted rows
  - Update statistics used by the planner
  - Protect against loss of old data because of transaction ID wraparound

  The autovacuum feature automates the execution of `VACUUM` and `ANALYZE` commands. `VACUUM` has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. `VACUUM FULL` requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. `VACUUM` creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

RDS for PostgreSQL wait events

The following table lists the wait events for RDS for PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions..

Wait event	Definition
Client:ClientRead	This event occurs when RDS for PostgreSQL is waiting to receive data from the client.
Client:ClientWrite	This event occurs when RDS for PostgreSQL is waiting to write data to the client.
CPU	This event occurs when a thread is active in CPU or is waiting for CPU.
IO:BufFileRead and IO:BufFileWrite	These events occur when RDS for PostgreSQL creates temporary files.
IO:DataFileRead	This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.
IO:WALWrite	This event occurs when RDS for PostgreSQL is waiting for the write-ahead log (WAL) buffers to be written to a WAL file.
Lock:advisory	This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.
Lock:extend	This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Wait event	Definition
Lock:Relation	This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.
Lock:transactionid	This event occurs when a transaction is waiting for a row-level lock.
Lock:tuple	This event occurs when a backend process is waiting to acquire a lock on a tuple.
LWLock:BufferMapping (LWLock:buffer_mapping)	This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.
LWLock:BufferIO (IPC:BufferIO)	This event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.
LWLock:buffer_content (BufferContent)	This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.
LWLock:lock_manager (LWLock:lockmanager)	This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.
LWLock:SubtransSLRU (LWLock:SubtransControlLock)	This event occurs when a process is waiting to access the simple least-recently used (SLRU) cache for a subtransaction.
Timeout:PgSleep	This event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

Wait event	Definition
Timeout:VacuumDelay	This event indicates that the vacuum process is sleeping because the estimated cost limit has been reached.

Client:ClientRead

The `Client:ClientRead` event occurs when RDS for PostgreSQL is waiting to receive data from the client.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

Context

An RDS for PostgreSQL DB instance is waiting to receive data from the client. The RDS for PostgreSQL DB instance must receive the data from the client before it can send more data to the client. The time that the instance waits before receiving data from the client is a `Client:ClientRead` event.

Likely causes of increased waits

Common causes for the `Client:ClientRead` event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for DB instance to receive data from the client.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

Excessive network round trips

A large number of network round trips between the RDS for PostgreSQL DB instance and the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

Large copy operation

During a copy operation, the data is transferred from the client's file system to the RDS for PostgreSQL DB instance. Sending a large amount of data to the DB instance can delay transmission of data from the client to the DB instance.

Idle client connection

When a client connects to the RDS for PostgreSQL DB instance in an `idle in transaction` state, the DB instance might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in `Client:ClientRead` events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called `pkt_buf`, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the `pkt_buf` setting to 8,192. If the new setting doesn't decrease the number of `Client:ClientRead` events, we recommend increasing the `pkt_buf` setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the instance
- Scale your client
- Use current generation instances
- Increase network bandwidth

- Monitor maximums for network performance
- Monitor for transactions in the "idle in transaction" state

Place the clients in the same Availability Zone and VPC subnet as the instance

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance. Make sure that the clients are as geographically close to the DB instance as possible.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see DB instance classes. To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

Increase network bandwidth

Use `NetworkReceiveThroughput` and `NetworkTransmitThroughput` Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size. For more information, see DB instance class types.

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon RDS.

Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see Monitor network performance for your Amazon EC2 instance in the *Amazon EC2 User Guide* and Monitor network performance for your Amazon EC2 instance in the *Amazon EC2 User Guide*.

Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of `idle in transaction` connections. To do this, monitor the `state` column in the `pg_stat_activity` table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

Client:ClientWrite

The `Client:ClientWrite` event occurs when RDS for PostgreSQL is waiting to write data to the client.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

Context

A client process must read all of the data received from an RDS for PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a `Client:ClientWrite` event.

Reduced network throughput between the RDS for PostgreSQL DB instance and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. *CPU pressure* is when the CPU is fully utilized and there are tasks waiting for CPU time. *Network saturation* is when the network between the database and client is carrying more data than it can handle.

Likely causes of increased waits

Common causes for the `Client:ClientWrite` event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for the client to receive the data.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the RDS for PostgreSQL DB instance.

Large volume of data sent to the client

The RDS for PostgreSQL DB instance might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the cluster
- Use current generation instances
- Reduce the amount of data sent to the client

- Scale your client

Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see DB instance classes. To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the RDS for PostgreSQL DB instance sends to the client. Making such adjustments relieves CPU and network contention on the client.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics

- Supported engine versions
- Context

- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is relevant for all all versions of RDS for PostgreSQL.

Context

The *central processing unit (CPU)* is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. *CPU scheduling* is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics

- How to tell when this wait occurs
- DBLoadCPU metric
- os.cpuUtilization metrics
- Likely cause of CPU scheduling

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The `pg_stat_activity.state` column has the value `active`.
- The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both `null`.

To see the backend processes that are using or waiting on CPU, run the following query.

```
SELECT *
FROM   pg_stat_activity
WHERE  state = 'active'
AND    wait_event_type IS NULL
AND    wait_event IS NULL;
```

DBLoadCPU metric

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- os.cpuUtilization.nice.avg
- os.cpuUtilization.total.avg
- os.cpuUtilization.wait.avg
- os.cpuUtilization.idle.avg

Performance Insights reports the CPU usage by the database engine as os.cpuUtilization.nice.avg.

Likely cause of CPU scheduling

The operating system (OS) kernel handles scheduling for the CPU. When the CPU is *active*, a process might need to wait to get scheduled. The CPU is active while it's performing computations. It's also active while it has an idle thread that it's not running, that is, an idle thread that's waiting on memory I/O. This type of I/O dominates the typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch CPUUtilization metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the loadAverageMinute metric in the OS metrics section in Performance Insights.

Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

Topics

- Likely causes of sudden spikes

- Likely causes of long-term high frequency
- Corner cases

Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators
  - An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- The CPU might be managing page table entries if the *huge pages* feature has been turned off. This memory management feature is turned on by default for all DB instance classes other than

micro, small, and medium DB instance classes. For more information, see Huge pages for RDS for PostgreSQL.

Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics

- Investigate whether the database is causing the CPU increase
- Determine whether the number of connections increased
- Respond to workload changes

Investigate whether the database is causing the CPU increase

Examine the `os.cpuUtilization.nice.avg` metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the `DatabaseConnections` metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.

  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.
- The number of backend processes consuming CPU is greater than the number of vCPUs.

  In this case, consider the following options:

  - Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Amazon RDS Proxy.

- Upgrade your instance size to get a higher number of vCPUs.
- Redirect some read-only workloads to reader nodes, if applicable.

The connections didn't increase

Examine the `blks_hit` metrics in Performance Insights. Look for a correlation between an increase in `blks_hit` and CPU usage. The following scenarios are possible:

- CPU usage and `blks_hit` are correlated.

  In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:

  - Explain the plans manually and compare them to the expected execution plan.
  - Look for an increase in block hits per second and local block hits per second. In the **Top SQL** section of Performance Insights dashboard, choose **Preferences**.
- CPU usage and `blks_hit` aren't correlated.

  In this case, determine whether any of the following occurs:

  - The application is rapidly connecting to and disconnecting from the database.

    Diagnose this behavior by turning on `log_connections` and `log_disconnections`, then analyzing the PostgreSQL logs. Consider using the `pgbadger` log analyzer. For more information, see https://github.com/darold/pgbadger.
  - The OS is overloaded.

    In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights `os.cpuUtilization` metrics or the CloudWatch `CPUUtilization` metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.
  - Top SQL statements are consuming too much CPU.

    Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an `EXPLAIN` command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

Respond to workload changes

If your workload has changed, look for the following types of changes:

New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

An increase in the size of the data set

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

New operators

Check whether they perform as expected during the testing.

An increase in running parallel queries

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

IO:BufFileRead and IO:BufFileWrite

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when RDS for PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes

called *spilling to disk*. For more information about the temporary files and their usage, see Managing temporary files with PostgreSQL.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

`IO:BufFileRead` and `IO:BufFileWrite` relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Resource Consumption in the PostgreSQL documentation.

The default value for `work_mem` is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set `work_mem` carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, RDS for PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write

to temporary files. Common causes for the `IO:BufFileRead` and `IO:BufFileWrite` events include the following:

Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
- `GROUP BY` clause
- `DISTINCT`
- Window functions
- `CREATE TABLE AS SELECT`
- Materialized view refresh

Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

- `CREATE INDEX`
- `CLUSTER`

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the problem
- Examine your join queries
- Examine your ORDER BY and GROUP BY queries
- Avoid using the DISTINCT operation
- Consider using window functions instead of GROUP BY functions
- Investigate materialized views and CTAS statements
- Use pg_repack when you rebuild indexes
- Increase maintenance_work_mem when you cluster tables

- Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

Identify the problem

You can view temporary file usage directly in Performance Insights. For more information, see Viewing temporary file usage with Performance Insights. When Performance Insights is disabled, you might notice increased `IO:BufFileRead` and `IO:BufFileWrite` operations.

To identify the source of the problem, you can set the `log_temp_files` parameter to log all queries that generate more than your specified threshold KB of temporary files. By default, `log_temp_files` is set to `-1`, which turns off this logging feature. If you set this parameter to `0`, RDS for PostgreSQL logs all temporary files. If you set it to is `1024`, RDS for PostgreSQL logs all queries that produce temporary files larger than 1 MB. For more information about `log_temp_files`, see Error Reporting and Logging in the PostgreSQL documentation.

Examine your join queries

It's likely that your query uses joins. For example, the following query joins four tables.

```
SELECT *
       FROM "order"
 INNER JOIN order_item
       ON (order.id = order_item.order_id)
 INNER JOIN customer
       ON (customer.id = order.customer_id)
 INNER JOIN customer_address
       ON (customer_address.customer_id = customer.id AND
           order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```
SELECT *
       FROM "order"
 INNER JOIN order_item
       ON (order.id = order_item.order_id)
 INNER JOIN customer
       ON (customer.id = customer.id)
```

```
INNER JOIN customer_address
      ON (customer_address.customer_id = customer.id AND
          order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

Examine your ORDER BY and GROUP BY queries

In some cases, an `ORDER BY` clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an `ORDER BY` clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the `ORDER BY` clause.
- Considering creating indexes to accelerate `ORDER BY` clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

  If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use `WITH` clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

- If you don't need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

- COUNT
- AVG
- MIN
- MAX
- SUM
- STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

Avoid using the DISTINCT operation

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use RDS for PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

Consider using window functions instead of GROUP BY functions

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

- RANK
- ARRAY_AGG
- ROW_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
     , avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
  FROM empsalary;
```

You can rewrite the query with the `WINDOW` clause as follows.

```
SELECT sum(salary) OVER w as sum_salary
         , avg(salary) OVER w as_avg_salary
    FROM empsalary
  WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the RDS for PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

Investigate materialized views and CTAS statements

When a materialized view refreshes, it runs a query. This query can contain an operation such as `GROUP BY`, `ORDER BY`, or `DISTINCT`. During a refresh, you might observe large numbers of temporary files and the wait events `IO:BufFileWrite` and `IO:BufFileRead`. Similarly, when you create a table based on a `SELECT` statement, the `CREATE TABLE` statement runs a query. To reduce the temporary files needed, optimize the query.

Use pg_repack when you rebuild indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information about `maintenance_work_mem`, see

https://www.postgresql.org/docs/current/runtime-config-resource.html in the PostgreSQL documentation.

A possible workaround when recreating a large index is to use the pg_repack extension. For more information, see Reorganize tables in PostgreSQL databases with minimal locks in the pg_repack documentation. For information about setting up the extension in your RDS for PostgreSQL DB instance, see Reducing bloat in tables and indexes with the pg_repack extension.

Increase maintenance_work_mem when you cluster tables

The `CLUSTER` command clusters the table specified by *table_name* based on an existing index specified by *index_name*. RDS for PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the `CLUSTER` command and observe the wait events `IO:BufFileWrite` and `IO:BufFileRead`, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

In some situations, you need to tune memory. Your goal is to balance memory across the following areas of consumption using the appropriate parameters, as follows.

- The `work_mem` value
- The memory remaining after discounting the `shared_buffers` value
- The maximum connections opened and in use, which is limited by `max_connections`

For more information about tuning memory, see Resource Consumption in the PostgreSQL documentation.

Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value.

To find out how many temporary files a query generates, set `log_temp_files` to `0`. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`.

For example, assume that your RDS for PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 25 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the RDS for PostgreSQL automation services automatically restart.

Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

IO:DataFileRead

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include `SELECT`, `UPDATE`, and `DELETE`. For example, an `UPDATE` can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the `IO:DataFileRead` event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the `IO:DataFileRead` event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for `SELECT` queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see Resource Consumption in the PostgreSQL documentation.

Likely causes of increased waits

Common causes for the `IO:DataFileRead` event include the following:

Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in `IO:DataFileRead` events can occur.

SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater `seq_scan` value. Find them by querying `pg_stat_user_tables`. To track queries that are generating more read operations, use the extension `pg_stat_statements`.

CTAS and CREATE INDEX for large data sets

A *CTAS* is a `CREATE TABLE AS SELECT` statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the `IO:DataFileRead` event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates `IO:DataFile` reads when pages aren't in memory.

Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the `IO:DataFileRead` waits increase. After space is reclaimed, the vacuum time spent on `IO:DataFileRead` decreases.

Ingesting large amounts of data

When your application ingests large amounts of data, `ANALYZE` operations might occur more often. The `ANALYZE` process can be triggered by an autovacuum launcher or invoked manually.

The `ANALYZE` operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the `default_statistics_target` value. For more information, see the PostgreSQL documentation. The `default_statistics_target` parameter accepts values between 1 and 10,000, where the default is 100.

Resource starvation

If instance network bandwidth or CPU are consumed, the `IO:DataFileRead` event might occur more frequently.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Check predicate filters for queries that generate waits

- Minimize the effect of maintenance operations
- Respond to high numbers of connections

Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating `IO:DataFileRead` wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension `pg_stat_statements`
- The catalog view `pg_stat_all_tables`, if it periodically shows an increased number of physical reads
- The `pg_statio_all_tables` view, if it shows that `_read` counters are increasing

We recommend that you determine which filters are used in the predicate (`WHERE` clause) of these queries. Follow these guidelines:

- Run the `EXPLAIN` command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more `IO:DataFileRead` events when compared to queries that use filters.

  Find out whether the column listed in the `WHERE` clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the `IO:DataFileRead` events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.
- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your `WHERE` clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

Minimize the effect of maintenance operations

Maintenance operations such as `VACUUM` and `ANALYZE` are important. We recommend that you don't turn them off because you find `IO:DataFileRead` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

```
pg_stat_user_tables.n_dead_tup > (pg_class.reltuples x autovacuum_vacuum_scale_factor)
 + autovacuum_vacuum_threshold
```

The view `pg_stat_user_tables` and catalog `pg_class` have multiple rows. One row can correspond to one row in your table. This formula assumes that the `reltuples` are for a specific table. The parameters `autovacuum_vacuum_scale_factor` (0.20 by default) and `autovacuum_vacuum_threshold` (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

Topics

- Find tables consuming space unnecessarily
- Find indexes consuming space unnecessarily
- Find tables that are eligible to be autovacuumed

Find tables consuming space unnecessarily

To find tables consuming space unnecessarily, you can use functions from the PostgreSQL `pgstattuple` extension. This extension (module) is available by default on all RDS for PostgreSQL DB instances and can be instantiated on the instance with the following command.

```
CREATE EXTENSION pgstattuple;
```

For more information about this extension, see pgstattuple in the PostgreSQL documentation.

You can check for table and index bloat in your application. For more information, see Diagnosing table and index bloat.

Find indexes consuming space unnecessarily

To find bloated indexes and estimate the amount of space consumed unnecessarily on the tables for which you have read privileges, you can run the following query.

```
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not
 supported).
-- This query is compatible with PostgreSQL 8.2 and later.

SELECT current_database(), nspname AS schemaname, tblname, idxname,
 bs*(relpages)::bigint AS real_size,
  bs*(relpages-est_pages)::bigint AS extra_size,
  100 * (relpages-est_pages)::float / relpages AS extra_ratio,
  fillfactor, bs*(relpages-est_pages_ff) AS bloat_size,
  100 * (relpages-est_pages_ff)::float / relpages AS bloat_ratio,
  is_na
  -- , 100-(sub.pst).avg_leaf_density, est_pages, index_tuple_hdr_bm,
  -- maxalign, pagehdr, nulldatawidth, nulldatahdrwidth, sub.reltuples, sub.relpages
  -- (DEBUG INFO)
FROM (
  SELECT coalesce(1 +
       ceil(reltuples/floor((bs-pageopqdata-pagehdr)/(4+nulldatahdrwidth)::float)), 0
       -- ItemIdData size + computed avg size of a tuple (nulldatahdrwidth)
    ) AS est_pages,
    coalesce(1 +

    -- or 1 = 1
)
ORDER BY age(relfrozenxid) DESC;
```

Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the `DatabaseConnections` metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

  If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see Amazon RDS Proxy.

- Whenever possible, take advantage of read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the read replica(s). This technique reduces the I/O pressure on the primary (writer) node.
- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives RDS for PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating `IO:DataFileRead` wait events are writes.

IO:WALWrite

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL 10 and higher.

Context

Activity in the database that's generating write-ahead log data fills up the WAL buffers first and then writes to disk, asynchronously. The wait event `IO:WALWrite` is generated when the SQL session is waiting for the WAL data to complete writing to disk so that it can release the transaction's COMMIT call.

Likely causes of increased waits

If this wait event occurs often, you should review your workload and the type of updates that your workload performs and their frequency. In particular, look for the following types of activity.

Heavy DML activity

Changing data in database tables doesn't happen instantaneously. An insert to one table might need to wait for an insert or an update to the same table from another client. The data

manipulation language (DML) statements for changing data values (INSERT, UPDATE, DELETE, COMMIT, ROLLBACK TRANSACTION) can result in contention that causes the write-ahead logfile to be waiting for the buffers to be flushed. This situation is captured in the following Amazon RDS Performance Insights metrics that indicate heavy DML activity.

- `tup_inserted`
- `tup_updated`
- `tup_deleted`
- `xact_rollback`
- `xact_commit`

For more information about these metrics, see Performance Insights counters for Amazon RDS for PostgreSQL.

Frequent checkpoint activity

Frequent checkpoints contribute to a higher number of WAL files. In RDS for PostgreSQL, full page writes are always "on." Full page writes help protect against data loss. However, when checkpointing occurs too frequently, the system can suffer overall performance issues. This is especially true on systems with heavy DML activity. In some cases, you might find error messages in your `postgresql.log` stating that “checkpoints are occurring too frequently."

We recommend that when tuning checkpoints, you carefully balance performance against expected time need to recover in the event of an abnormal shutdown.

Actions

We recommend the following actions to reduce the numbers of this wait event.

Topics

- Reduce the number of commits
- Monitor your checkpoints
- Scale up IO
- Dedicated log volume (DLV)

Reduce the number of commits

To reduce the number of commits, you can combine statements into transaction blocks. Use Amazon RDS Performance Insights to examine the type of queries being run. You can also move large maintenance operations to off-peak hours. For example, create indexes or use `pg_repack` operations during non-production hours.

Monitor your checkpoints

There are two parameters that you can monitor to see how frequently your RDS for PostgreSQL DB instance is writing to the WAL file for checkpoints.

- `log_checkpoints` – This parameter is set to "on" by default. It causes a message to get sent to the PostgreSQL log for each checkpoint. These log messages include the number of buffers written, the time spent writing them, and the number of WAL files added, removed, or recycled for the given checkpoint.

  For more information about this parameter, see Error Reporting and Logging in the PostgreSQL documentation.
- `checkpoint_warning` – This parameter sets a threshold value (in seconds) for checkpoint frequency above which a warning is generated. By default, this parameter isn't set in RDS for PostgreSQL. You can set the value of this parameter to get a warning when the database changes in your RDS for PostgreSQL DB instance are written at a rate for which the WAL files are not sized to handle. For example, say you set this parameter to 30. If your RDS for PostgreSQL instance needs to write changes more often than every 30 seconds, the warning that "checkpoints are occurring too frequently" is sent to the PostgreSQL log. This can indicate that your `max_wal_size` value should be increased.

  For more information, see Write Ahead Log in the PostgreSQL documentation.

Scale up IO

This type of input/output (IO) wait event can remediated by scaling the input/output operations per second (IOPs) to provide faster IO. Scaling IO is preferable to scaling CPU, because scaling CPU can result in even more IO contention because the increased CPU can handle more work and thus make the IO bottleneck even worse. In general, we recommend that you consider tuning your workload before performing scaling operations.

Dedicated log volume (DLV)

You can use a dedicated log volume (DLV) for a DB instance that uses Provisioned IOPS (PIOPS) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. A DLV moves PostgreSQL database transaction logs to a storage volume that's separate from the volume containing the database tables. For more information, see Dedicated log volume (DLV).

IPC:parallel wait events

The following `IPC:parallel wait events` indicate that a session is waiting for inter-process communication related to parallel query execution operations.

- `IPC:BgWorkerStartup` - A process is waiting for a parallel worker process to complete its startup sequence. This happens when initializing workers for parallel query execution.
- `IPC:BgWorkerShutdown` - A process is waiting for a parallel worker process to complete its shutdown sequence. This occurs during the cleanup phase of parallel query execution.
- `IPC:ExecuteGather` - A process is waiting to receive data from parallel worker processes during query execution. This occurs when the leader process needs to gather results from its workers.
- `IPC:ParallelFinish` - A process is waiting for parallel workers to finish their execution and report their final results. This happens during the completion phase of parallel query execution.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

Parallel query execution in PostgreSQL involves multiple processes working together to process a single query. When a query is determined to be suitable for parallelization,

a leader process coordinates with one or more parallel worker processes based on the `max_parallel_workers_per_gather` parameter setting. The leader process divides the work among workers, each worker processes its portion of data independently, and results are gathered back to the leader process.

> **Note**
>
> Each parallel worker operates as a separate process with resource requirements similar to a full user session. This means a parallel query with 4 workers can consume up to 5 times the resources (CPU, memory, I/O bandwidth) compared to a non-parallel query, as both the leader process and each worker process maintain their own resource allocations. For instance, settings like `work_mem` are applied individually to each worker, potentially multiplying the total memory usage across all processes.

The parallel query architecture consists of three main components:

- Leader process: The main process that initiates the parallel operation, divides the workload, and coordinates with worker processes.
- Worker processes: Background processes that execute portions of the query in parallel.
- Gather/Gather merge: Operations that combine results from multiple worker processes back to the leader

During parallel execution, processes need to communicate with each other through Inter-Process Communication (IPC) mechanisms. These IPC wait events occur during different phases:

- Worker startup: When parallel workers are being initialized
- Data exchange: When workers are processing data and sending results to the leader
- Worker shutdown: When parallel execution completes and workers are being terminated
- Synchronization points: When processes need to coordinate or wait for other processes to complete their tasks

Understanding these wait events is crucial for diagnosing performance issues related to parallel query execution, especially in high-concurrency environments where multiple parallel queries may be executing simultaneously.

Likely causes of increased waits

Several factors can contribute to an increase in parallel-related IPC wait events:

High concurrency of parallel queries

When many parallel queries are running simultaneously, it can lead to resource contention and increased waiting times for IPC operations. This is particularly common in systems with high transaction volumes or analytical workloads.

Suboptimal parallel query plans

If the query planner chooses inefficient parallel plans, it may result in unnecessary parallelization or poor work distribution among workers. This can lead to increased IPC waits, especially for `IPC:ExecuteGather` and `IPC:ParallelFinish` events. These planning issues often stem from outdated statistics and table/index bloat.

Frequent startup and shutdown of parallel workers

Short-lived queries that frequently initiate and terminate parallel workers can cause an increase in `IPC:BgWorkerStartup` and `IPC:BgWorkerShutdown` events. This is often seen in OLTP workloads with many small, parallelizable queries.

Resource constraints

Limited CPU, memory, or I/O capacity can cause bottlenecks in parallel execution, leading to increased wait times across all IPC events. For example, if CPU is saturated, worker processes may take longer to start up or process their portion of work.

Complex query structures

Queries with multiple levels of parallelism (e.g., parallel joins followed by parallel aggregations) can lead to more complex IPC patterns and potentially increased wait times, especially for `IPC:ExecuteGather` events.

Large result sets

Queries that produce large result sets may cause increased `IPC:ExecuteGather` wait times as the leader process spends more time collecting and processing results from worker processes.

Understanding these factors can help in diagnosing and addressing performance issues related to parallel query execution in Aurora PostgreSQL.

Actions

When you see waits related to parallel query, it typically means that a backend process is coordinating or waiting on parallel worker processes. These waits are common during execution of parallel plans. You can investigate and mitigate the impact of these waits by monitoring parallel worker usage, reviewing the parameter settings, and tuning query execution and resource allocation.

Topics

- Analyze query plans for inefficient parallelism
- Monitor parallel query usage
- Review and adjust parallel query settings
- Optimize resource allocation
- Investigate connection management
- Review and optimize maintenance operations

Analyze query plans for inefficient parallelism

Parallel query execution can often lead to system instability, CPU spikes, and unpredictable query performance variance. It's crucial to thoroughly analyze whether parallelism actually improves your specific workload. Use EXPLAIN ANALYZE to review parallel query execution plans.

Temporarily disable parallelism at the session level to compare plan efficiency:

```
SET max_parallel_workers_per_gather = 0;
EXPLAIN ANALYZE <your_query>;
```

Re-enable parallelism and compare:

```
RESET max_parallel_workers_per_gather;
EXPLAIN ANALYZE <your_query>;
```

If disabling parallelism yields better or more consistent results, consider disabling it for specific queries at the session level using SET commands. For a broader impact, you might want to disable

parallelism at the instance level by adjusting the relevant parameters in your DB parameter group. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

Monitor parallel query usage

Use the following queries to gain visibility into parallel query activity and capacity:

Check active parallel worker processes:

```
SELECT
    COUNT(*)
FROM
    pg_stat_activity
WHERE
    backend_type = 'parallel worker';
```

This query shows the number of active parallel worker processes. A high value may indicate that your `max_parallel_workers` is configured with a high value and you might want to consider reducing it.

Check concurrent parallel queries:

```
SELECT
    COUNT(DISTINCT leader_pid)
FROM
    pg_stat_activity
WHERE
    leader_pid IS NOT NULL;
```

This query returns the number of distinct leader processes that have launched parallel queries. A high number here indicates that multiple sessions are running parallel queries concurrently, which can increase demand on CPU and memory.

Review and adjust parallel query settings

Review the following parameters to ensure they align with your workload:

- `max_parallel_workers`: Total number of parallel workers across all sessions.

- `max_parallel_workers_per_gather`: Max workers per query.

For OLAP workloads, increasing these values can improve performance. For OLTP workloads, lower values are generally preferred.

```
SHOW max_parallel_workers;
SHOW max_parallel_workers_per_gather;
```

Optimize resource allocation

Monitor CPU utilization and consider adjusting the number of vCPUs if consistently high and if your application benefits from parallel queries. Ensure adequate memory is available for parallel operations.

- Use Performance Insights metrics to determine if the system is CPU-bound.
- Each parallel worker uses its own `work_mem`. Ensure total memory usage is within instance limits.

The parallel queries may consume very substantially more resources than non-parallel queries, because each worker process is a completely separate process which has roughly the same impact on the system as an additional user session. This should be taken into account when choosing a value for this setting, as well as when configuring other settings that control resource utilization, such as `work_mem`. For more information, see the PostgreSQL documentation. Resource limits such as `work_mem` are applied individually to each worker, which means the total utilization may be much higher across all processes than it would normally be for any single process.

Consider increasing vCPUs or tuning memory parameters if your workload is heavily parallelized.

Investigate connection management

If experiencing connection exhaustion, review application connection pooling strategies. Consider implementing connection pooling at the application level if not already in use.

Review and optimize maintenance operations

Coordinate index creation and other maintenance tasks to prevent resource contention. Consider scheduling these operations during off-peak hours. Avoid scheduling heavy maintenance (e.g.,

parallel index builds) during periods of high user query load. These operations can consume parallel workers and impact performance for regular queries.

IPC:ProcArrayGroupUpdate

The `IPC:ProcArrayGroupUpdate` event occurs when a session is waiting for the group leader to update the transaction status at the end of that operation. While PostgreSQL generally associates IPC type wait events with parallel query operations, this particular wait event is not specific to parallel queries.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Understanding the process array – The process (proc) array is a shared memory structure in PostgreSQL. It holds information about all running processes, including transaction details. During transaction completion (`COMMIT` or `ROLLBACK`), the ProcArray needs to be updated to reflect the change and clear the transactionID from the array. The session attempting to finish its transaction must acquire an exclusive lock on the ProcArray. This prevents other processes from obtaining shared or exclusive locks on it.

Group update mechanism – While performing a COMMIT or ROLLBACK, if a backend process cannot obtain a ProcArrayLock in exclusive mode, it updates a special field called ProcArrayGroupMember. This adds the transaction to the list of sessions that intend to end. This backend process then sleeps and the time it sleeps is instrumented as the ProcArrayGroupUpdate wait event. The first process in the ProcArray with procArrayGroupMember, referred to as the leader process, acquires the ProcArrayLock in exclusive mode. It then clears the list of processes waiting for group transactionID clearing. Once this completes, the leader releases the ProcArrayLock and then wakes up all processes in this list, notifying them that their transaction is completed.

Likely causes of increased waits

The more processes that are running, the longer a leader will hold on to a procArrayLock in exclusive mode. Consequently, the more write transactions end up in a group update scenario causing a potential pile up of processes waiting on the `ProcArrayGroupUpdate` wait event. In Database Insights' Top SQL view, you will see that COMMIT is the statement with the majority of this wait event. This is expected but will require deeper investigation into the specific write SQL being run to determine what appropriate action to take.

Actions

We recommend different actions depending on the causes of your wait event. Identify `IPC:ProcArrayGroupUpdate` events by using Amazon RDS Performance Insights or by querying the PostgreSQL system view `pg_stat_activity`.

Topics

- Monitoring transaction commit and rollback operations
- Reducing concurrency
- Implementing connection pooling
- Using faster storage

Monitoring transaction commit and rollback operations

Monitor commits and rollbacks – An increased number of commits and rollbacks can lead to increased pressure on the ProcArray. For example, if a SQL statement begins to fail due to increased duplicate key violations, you may see an increase in rollbacks which can increase ProcArray contention and table bloat.

Amazon RDS Database Insights provides the PostgreSQL metrics `xact_commit` and `xact_rollback` to report the number of commits and rollbacks per second.

Reducing concurrency

Batching transactions – Where possible, batch operations in single transactions to reduce commit/rollback operations.

Limit concurrency – Reduce the number of concurrently active transactions to alleviate lock contention on the ProcArray. While it will require some testing, reducing the total number of concurrent connections can reduce contention and maintain throughput.

Implementing connection pooling

Connection pooling solutions – Use connection pooling to manage database connections efficiently, reducing the total number of backends and therefore the workload on the ProcArray. While it will require some testing, reducing the total number of concurrent connections can reduce contention and maintain throughput.

Reduce connection storms – Similarly, a pattern of frequently creating and terminating connections causes additional pressure on the ProcArray. By reducing this pattern, overall contention is reduced.

Using faster storage

Dedicated log volume – If the `IPC:ProcArrayGroupUpdate` wait event is accompanied with high `IO:WALWrite` wait events, setting up a dedicated log volume can reduce the bottleneck writing to WAL. In turn, this improves the performance of commits.

For more information, see Dedicated log volume.

Lock:advisory

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

Topics

- Relevant engine versions
- Context
- Causes
- Actions

Relevant engine versions

This wait event information is relevant for RDS for PostgreSQL versions 9.6 and higher.

Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full

control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a `CREATE INDEX` statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the `pg_locks` system view.

Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from Advisory Locks in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the `LIMIT` clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

Actions

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```
SELECT blocked_locks.pid AS blocked_pid,
         blocking_locks.pid AS blocking_pid,
         blocked_activity.usename AS blocked_user,
         blocking_activity.usename AS blocking_user,
         now() - blocked_activity.xact_start AS blocked_transaction_duration,
         now() - blocking_activity.xact_start AS blocking_transaction_duration,
         concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS
 blocked_wait_event,
         concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS
 blocking_wait_event,
         blocked_activity.state AS blocked_state,
         blocking_activity.state AS blocking_state,
         blocked_locks.locktype AS blocked_locktype,
         blocking_locks.locktype AS blocking_locktype,
         blocked_activity.query AS blocked_statement,
         blocking_activity.query AS blocking_statement
    FROM pg_catalog.pg_locks blocked_locks
    JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
 blocked_locks.pid
    JOIN pg_catalog.pg_locks blocking_locks
        ON blocking_locks.locktype = blocked_locks.locktype
        AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
        AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
        AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
        AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
        AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
        AND blocking_locks.transactionid IS NOT DISTINCT FROM
 blocked_locks.transactionid
        AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
        AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
        AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
```

```
        AND blocking_locks.pid != blocked_locks.pid
    JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
    WHERE NOT blocked_locks.GRANTED;
```

All of the advisory lock API functions have two sets of arguments, either one `bigint` argument or two `integer` arguments:

- For the API functions with one `bigint` argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two `integer` arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one `bigint` argument; 2 means two `integer` arguments.

Lock:extend

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. `INSERT`, `COPY`, and `UPDATE` operations can generate this event.

Likely causes of increased waits

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Reduce concurrent inserts and updates to the same relation
- Increase network bandwidth

Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see pg_stat_all_tables in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```
SELECT
    blocked.pid,
    blocked.usename,
    blocked.query,
    blocking.pid AS blocking_id,
```

```
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';

   pid  | usename  |            query             | blocking_id |
            blocking_query                          | blocking_wait_event |
 blocking_wait_event_type
  ------+----------+------------------------------+-------------
+-------------------------------------------------------------------
+---------------------+--------------------------
   7143 |  myuser  | insert into tab1 values (1); |        4600 | INSERT INTO tab1 (a)
 SELECT s FROM generate_series(1,1000000) s; | DataFileExtend      | IO
```

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see Managing PostgreSQL partitions with the pg_partman extension.
- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.

> **Important**
>
> We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

Increase network bandwidth

To see whether there's an increase in write latency, check the `WriteLatency` metric in CloudWatch. If there is, use the `WriteThroughput` and `ReadThroughput` Amazon CloudWatch

metrics to monitor the storage related traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch instance-level metrics for Amazon RDS. For information about network performance for each DB instance class, see Amazon CloudWatch instance-level metrics for Amazon RDS.

Lock:Relation

The `Lock:Relation` event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the `LOCK` command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, RDS for PostgreSQL generates a `Lock:Relation` event. Some common examples are the following:

- Exclusive locks such as `ACCESS EXCLUSIVE` can block all concurrent access. Data definition language (DDL) operations such as `DROP TABLE`, `TRUNCATE`, `VACUUM FULL`, and `CLUSTER` acquire `ACCESS EXCLUSIVE` locks implicitly. `ACCESS EXCLUSIVE` is also the default lock mode for `LOCK TABLE` statements that don't specify a mode explicitly.

- Using `CREATE INDEX (without CONCURRENT)` on a table conflicts with data manipulation language (DML) statements `UPDATE`, `DELETE`, and `INSERT`, which acquire `ROW EXCLUSIVE` locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a `ROLLBACK` or `COMMIT` statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

Likely causes of increased waits

When the `Lock:Relation` event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

Maintenance operations

Health maintenance operations such as `VACUUM` and `ANALYZE` can significantly increase the number of conflicting locks. `VACUUM FULL` acquires an `ACCESS EXCLUSIVE` lock, and `ANALYSE` acquires a `SHARE UPDATE EXCLUSIVE` lock. Both types of locks can cause a `Lock:Relation` wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only `ACCESS EXCLUSIVE` relation locks are replicated to reader instances. However, the

ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Reduce the impact of blocking SQL statements
- Minimize the effect of maintenance operations

Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the NOWAIT option – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

  For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.
- Use SET lock_timeout – Set a lock_timeout value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find Lock:Relation wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.

- To reduce `Lock:Relation` waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see Working with PostgreSQL autovacuum on Amazon RDS in the *Amazon RDS User Guide*.

Lock:transactionid

The `Lock:transactionid` event occurs when a transaction is waiting for a row-level lock.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:transactionid` occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the `Lock:transactionid` wait event is blocked because of this lock. After the blocking transaction ends in either a `COMMIT` or `ROLLBACK` statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of RDS for PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- `UPDATE`
- `SELECT … FOR UPDATE`
- `SELECT … FOR KEY SHARE`

The statement `SELECT … FOR KEY SHARE` is a special case. The database uses the clause `FOR KEY SHARE` to optimize the performance of referential integrity. A row-level lock on a row can block `INSERT`, `UPDATE`, and `DELETE` commands on other tables that reference the row.

Likely causes of increased waits

When this event appears more than normal, the cause is typically `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements combined with the following conditions.

Topics

- High concurrency
- Idle in transaction
- Long-running transactions

High concurrency

RDS for PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

Idle in transaction

Sometimes the `pg_stat_activity.state` column shows the value `idle in transaction`. This value appears for sessions that have started a transaction, but haven't yet issued a `COMMIT` or `ROLLBACK`. If the `pg_stat_activity.state` value isn't `active`, the query shown in `pg_stat_activity` is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event `Lock:transactionid`. To diagnose the issue, examine the output from `pg_stat_activity` and `pg_locks`.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics

- Respond to high concurrency
- Respond to idle transactions
- Respond to long-running transactions

Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see Amazon RDS Proxy.
- Design the application or data model to avoid contending `UPDATE` and `SELECT ... FOR UPDATE` statements. You can also decrease the number of foreign keys accessed by `SELECT ... FOR KEY SHARE` statements.

Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a `COMMIT` or `ROLLBACK`.
- Search for code paths that are missing `COMMIT`, `ROLLBACK`, or `END`.
- Make sure that the exception handling logic in your application always has a path to a valid `end of transaction`.
- Make sure that your application processes query results after ending the transaction with `COMMIT` or `ROLLBACK`.

Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

Lock:tuple

The `Lock:tuple` event occurs when a backend process is waiting to acquire a lock on a tuple.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

The event `Lock:tuple` indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the `Lock:tuple` event.

Time	Session 1	Session 2	Session 3
t1	Starts a transaction.		
t2	Updates row 1.		
t3		Updates row 1. The session acquires an exclusive lock on the tuple and then waits for	

Time	Session 1	Session 2	Session 3
		session 1 to release the lock by committing or rolling back.	
t4			Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.

Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see Explicit Locking in the PostgreSQL documentation. To learn more about pgbench, see pgbench in the PostgreSQL documentation.

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running `UPDATE` or `DELETE` statements.
- Highly concurrent sessions are running a `SELECT` statement using the `FOR UPDATE` or `FOR NO KEY UPDATE` lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and `Lock:tuple` can appear.

For more information, see Row-Level Locks in the PostgreSQL documentation.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Investigate your application logic

- Find the blocker session
- Reduce concurrency when it is high
- Troubleshoot bottlenecks

Investigate your application logic

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see SET AUTOCOMMIT in the PostgreSQL documentation.

Find the blocker session

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```
SELECT blocked_locks.pid AS blocked_pid,
         blocking_locks.pid AS blocking_pid,
         blocked_activity.usename AS blocked_user,
         blocking_activity.usename AS blocking_user,
         now() - blocked_activity.xact_start AS blocked_transaction_duration,
         now() - blocking_activity.xact_start AS blocking_transaction_duration,
         concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS
 blocked_wait_event,
         concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS
 blocking_wait_event,
```

```
         blocked_activity.state AS blocked_state,
         blocking_activity.state AS blocking_state,
         blocked_locks.locktype AS blocked_locktype,
         blocking_locks.locktype AS blocking_locktype,
         blocked_activity.query AS blocked_statement,
         blocking_activity.query AS blocking_statement
   FROM pg_catalog.pg_locks blocked_locks
   JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
blocked_locks.pid
   JOIN pg_catalog.pg_locks blocking_locks
       ON blocking_locks.locktype = blocked_locks.locktype
       AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
       AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
       AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
       AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
       AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
       AND blocking_locks.transactionid IS NOT DISTINCT FROM
blocked_locks.transactionid
       AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
       AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
       AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
       AND blocking_locks.pid != blocked_locks.pid
   JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
   WHERE NOT blocked_locks.GRANTED;
```

Reduce concurrency when it is high

The `Lock:tuple` event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the `NOWAIT` clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

Troubleshoot bottlenecks

The `Lock:tuple` can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

LWLock:BufferMapping (LWLock:buffer_mapping)

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

> **Note**
>
> This event is named `LWLock:BufferMapping` for RDS for PostgreSQL version 13 and higher versions. For RDS for PostgreSQL version 12 and older versions, this event is named `LWLock:buffer_mapping`.

Topics

- Supported engine versions
- Context
- Causes
- Actions

Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.

Context

The *shared buffer pool* is a PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The

`shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. .

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor buffer-related metrics
- Assess your indexing strategy
- Reduce the number of buffers that must be allocated quickly

Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

`blks_hit`

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

`blks_read`

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

LWLock:BufferIO (IPC:BufferIO)

The `LWLock:BufferIO` event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

Topics

- Relevant engine versions
- Context
- Causes
- Actions

Relevant engine versions

This wait event information is relevant for all RDS for PostgreSQL versions. For RDS for PostgreSQL 12 and earlier versions this wait event is named as lwlock:buffer_io whereas in RDS for PostgreSQL 13 version it is named as lwlock:bufferio. From RDS for PostgreSQL 14 version BufferIO wait event moved from `LWLock` to `IPC` wait event type (IPC:BufferIO).

Context

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

> **Note**
>
> The `LWLock:BufferIO` wait event precedes the IO:DataFileRead wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see Locking Overview.

Causes

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload

- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

Actions

We recommend different actions depending on the causes of your wait event:

- Tune `max_wal_size` and `checkpoint_timeout` based on your workload peak time if you see `LWLock:BufferIO` coinciding with `BufferCacheHitRatio` metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.
- Restrict the maximum number of connections to the database as a best practice.

LWLock:buffer_content (BufferContent)

The `LWLock:buffer_content` event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In RDS for PostgreSQL 13 and higher, this wait event is called `BufferContent`.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The `LWLock:buffer_content` (`BufferContent`) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the `LWLock:buffer_content` (`BufferContent`) event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify `LWLock:buffer_content` (`BufferContent`) events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

Topics

- Improve in-memory efficiency
- Reduce usage of foreign key constraints
- Remove unused indexes
- Increase the cache size when using sequences

Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see DB instance classes.

Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

Remove unused indexes

For workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events, identify unused indexes and remove them.

Increase the cache size when using sequences

If your tables uses sequences, increase the cache size to remove contention on sequence pages and index pages. Each sequence is a single page in shared memory. The pre-defined cache is per connection. This might not be enough to handle the workload when many concurrent sessions are getting a sequence value.

LWLock:lock_manager (LWLock:lockmanager)

This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

Topics

- Supported engine versions
- Context

- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.
For RDS for PostgreSQL releases older than version 13, the name of this wait event is `LWLock:lock_manager`. For RDS for PostgreSQL version 13 and higher, the name of this wait event is `LWLock:lockmanager`.

Context

When you issue a SQL statement, RDS for PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

To tune your queries for fast-path locking, you can use the following query.

```
SELECT count(*), pid, mode, fastpath
  FROM pg_locks
```

```
 WHERE fastpath IS NOT NULL
 GROUP BY 4,3,2
 ORDER BY pid, mode;
 count | pid  |      mode       | fastpath
-------+------+-----------------+----------
16 | 9185 | AccessShareLock | t
336 | 9185 | AccessShareLock | f
1 | 9185 | ExclusiveLock   | t
```

The following query shows only the total across the database.

```
SELECT count(*), mode, fastpath
  FROM pg_locks
 WHERE fastpath IS NOT NULL
 GROUP BY 3,2
 ORDER BY mode,1;
count |      mode       | fastpath
-------+-----------------+----------
16 | AccessShareLock | t
337 | AccessShareLock | f
1 | ExclusiveLock   | t
(3 rows)
```

For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

Example of a scaling problem for the lock manager

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands

of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the `LWLock:lock_manager` wait event appears.

> **Note**
>
> The `LWLock:lock_manager` wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non–fast path locks that the database must control.

Likely causes of increased waits

When the `LWLock:lock_manager` wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

Actions

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

Topics

- Use partition pruning
- Remove unnecessary indexes
- Tune your queries for fast path locking

- Tune for other wait events
- Reduce hardware bottlenecks
- Use a connection pooler
- Upgrade your RDS for PostgreSQL version

Use partition pruning

Partition pruning is a query optimization strategy for declaratively partitioned tables that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their `WHERE` clause contains the column used for the partitioning. For more information, see Partition Pruning in the PostgreSQL documentation.

Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading Unused Indexes in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see pg-collector in the AWS Labs GitHub repository.

Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

- Amazon RDS Proxy
- pgbouncer
- Connection Pools and Data Sources in the *PostgreSQL Documentation*

Upgrade your RDS for PostgreSQL version

If your current version of RDS for PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and later have an improved partition mechanism. For more information

about version 12, see PostgreSQL 12.0 Release Notes. For more information about upgrading RDS for PostgreSQL, see Upgrades of the RDS for PostgreSQL DB engine.

LWLock:pg_stat_statements

The LWLock:pg_stat_statements wait event occurs when the `pg_stat_statements` extension takes an exclusive lock on the hash table that tracks SQL statements. This happens in the following scenarios:

- When the number of tracked statements reaches the configured `pg_stat_statements.max` parameter value and there is a need to make room for more entries, the extension performs a sort on the number of calls, removes the 5% of the least-executed statements, and re-populates the hash with the remaining entries.
- When `pg_stat_statements` performs a `garbage collection` operation to the `pgss_query_texts.stat` file on disk and rewrites the file.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Understanding the pg_stat_statements extension – The pg_stat_statements extension tracks SQL statement execution statistics in a hash table. The extension tracks SQL statements up to the limit defined by the `pg_stat_statements.max` parameter. This parameter determines the maximum number of statements that can be tracked which corresponds to the maximum number of rows in the pg_stat_statements view.

Statement statistics persistence – The extension persists statement statistics across instance restarts by:

- Writing data to a file named pg_stat_statements.stat
- Using the pg_stat_statements.save parameter to control persistence behavior

When pg_stat_statements.save is set to:

- on (default): Statistics are saved at shutdown and reloaded at server start
- off: Statistics are neither saved at shutdown nor reloaded at server start

Query text storage – The extension stores the text of tracked queries in a file named `pgss_query_texts.stat`. This file can grow to double the average size of all tracked SQL statements before garbage collection occurs. The extension requires an exclusive lock on the hash table during cleanup operations and rewrite `pgss_query_texts.stat` file.

Statement deallocation process – When the number of tracked statements reaches the `pg_stat_statements.max` limit and new statements need to be tracked, the extension:

- Takes an exclusive lock (LWLock:pg_stat_statements) on the hash table.
- Loads existing data into local memory.
- Performs a quicksort based on the number of calls.
- Removes the least-called statements (bottom 5%).
- Re-populates the hash table with the remaining entries.

Monitoring statement deallocation – In PostgreSQL 14 and later, you can monitor statement deallocation using the pg_stat_statements_info view. This view includes a dealloc column that shows how many times statements were deallocated to make room for new ones

If the deallocation of statements occurs frequently, it will lead to more frequent garbage collection of the `pgss_query_texts.stat` file on disk.

Likely causes of increased waits

The typical causes of increased `LWLock:pg_stat_statements` waits include:

- An increase in the number of unique queries used by the application.
- The `pg_stat_statements.max` parameter value being small compared to the number of unique queries being used.

Actions

We recommend different actions depending on the causes of your wait event. You might identify `LWLock:pg_stat_statements` events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

Adjust the following `pg_stat_statements` parameters to control tracking behavior and reduce LWLock:pg_stat_ statements wait events.

Topics

- Disable pg_stat_statements.track parameter
- Increase pg_stat_statements.max parameter
- Disable pg_stat_statements.track_utility parameter

Disable pg_stat_statements.track parameter

If the LWLock:pg_stat_statements wait event is adversely impacting database performance, and a rapid solution is required before further analysis of the `pg_stat_statements` view to identify the root cause, the `pg_stat_statements.track` parameter can be disabled by setting it to none. This will disable the collection of statement statistics.

Increase pg_stat_statements.max parameter

To reduce deallocation and minimize garbage collection of the `pgss_query_texts.stat` file on disk, increase the value of the `pg_stat_statements.max` parameter. The default value is `5,000`.

> **Note**
>
> The `pg_stat_statements.max` parameter is static. You must restart your DB instance to apply any changes to this parameter.

Disable pg_stat_statements.track_utility parameter

You can analyze the pg_stat_statements view to determine which utility commands are consuming the most resources tracked by `pg_stat_statements`.

The pg_stat_statements.track_utility parameter controls whether the module tracks utility commands, which include all commands except SELECT, INSERT, UPDATE, DELETE, and MERGE. By default, this parameter is set to on.

For example, when your application uses many savepoint queries, which are inherently unique, it can increase statement deallocation. To address this, you can disable the pg_stat_statements.track_utility parameter to stop pg_stat_statements from tracking savepoint queries.

> **Note**
>
> The pg_stat_statements.track_utility parameter is a dynamic parameter. You can change its value without restarting your database instance.

Example of unique save point queries in pg_stat_statements

```
                    query                         |       queryid
--------------------------------------------------+---------------------
 SAVEPOINT JDBC_SAVEPOINT_495701                  | -7249565344517699703
 SAVEPOINT JDBC_SAVEPOINT_1320                    | -1572997038849006629
 SAVEPOINT JDBC_SAVEPOINT_26739                   |  54791337410474486
 SAVEPOINT JDBC_SAVEPOINT_1294466                 |  8170064357463507593
 ROLLBACK TO SAVEPOINT JDBC_SAVEPOINT_65016       | -33608214779996400
 SAVEPOINT JDBC_SAVEPOINT_14185                   | -2175035613806809562
 SAVEPOINT JDBC_SAVEPOINT_45837                   | -6201592986750645383
 SAVEPOINT JDBC_SAVEPOINT_1324                    |  6388797791882029332
```

PostgreSQL 17 introduces several enhancements for utility command tracking:

- Savepoint names are now displayed as constants.
- Global Transaction IDs (GIDs) of two-phase commit commands are now displayed as constants.
- Names of DEALLOCATE statements are shown as constants.
- CALL parameters are now displayed as constants.

LWLock:SubtransSLRU (LWLock:SubtransControlLock)

The `LWLock:SubtransSLRU` and `LWLock:SubtransBuffer` wait events indicate that a session is waiting to access the simple least-recently used (SLRU) cache for subtransaction information. This occurs when determining transaction visibility and parent-child relationships.

- `LWLock:SubtransSLRU`: A process is waiting to access the simple least-recently used (SLRU) cache for a subtransaction. In RDS for PostgreSQL prior to version 13, this wait event is called `SubtransControlLock`.
- `LWLock:SubtransBuffer`: A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a subtransaction. In RDS for PostgreSQL prior to version 13, this wait event is called `subtrans`.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

Understanding subtransactions – A subtransaction is a transaction within a transaction in PostgreSQL. It's also known as a nested transaction.

Subtransactions are typically created when you use:

- `SAVEPOINT` commands
- Exception blocks (`BEGIN/EXCEPTION/END`)

Subtransactions let you roll back parts of a transaction without affecting the entire transaction. This gives you fine-grained control over transaction management.

Implementation details – PostgreSQL implements subtransactions as nested structures within main transactions. Each subtransaction gets its own transaction ID.

Key implementation aspects:

- Transaction IDs are tracked in `pg_xact`
- Parent-child relationships are stored in `pg_subtrans` subdirectory under `PGDATA`
- Each database session can maintain up to 64 active subtransactions
- Exceeding this limit causes subtransaction overflow, which requires accessing the simple least-recently used (SLRU) cache for subtransaction information

Likely causes of increased waits

Common causes of subtransaction SLRU contention include:

- **Excessive use of SAVEPOINT and EXCEPTION handling** – PL/pgSQL procedures with `EXCEPTION` handlers automatically create implicit savepoints, regardless of whether exceptions occur. Each `SAVEPOINT` initiates a new subtransaction. When a single transaction accumulates more than 64 subtransactions, it triggers a subtransaction SLRU overflow.
- **Driver and ORM configurations** – `SAVEPOINT` usage can be explicit in application code or implicit through driver configurations. Many commonly used ORM tools and application frameworks support nested transactions natively. Here are some common examples:
  - The JDBC driver parameter `autosave`, if set to `always` or `conservative`, generates savepoints before each query.
  - Spring Framework transaction definitions when set to `propagation_nested`.
  - Rails when `requires_new: true` is set.
  - SQLAlchemy when `session.begin_nested` is used.
  - Django when nested `atomic()` blocks are used.
  - GORM when `Savepoint` is used.
  - psqlODBC when rollback level setting is set to statement-level rollback (for example, `PROTOCOL=7.4-2`).
- **High concurrent workloads with long-running transactions and subtransactions** – When subtransaction SLRU overflow occurs during high concurrent workloads and long-running transactions and subtransactions, PostgreSQL experiences increased contention. This manifests as elevated wait events for `LWLock:SubtransBuffer` and `LWLock:SubtransSLRU` locks.

Actions

We recommend different actions depending on the causes of your wait event. Some actions provide immediate relief, while others require investigation and long-term correction.

Topics

- Monitoring subtransaction usage
- Configuring memory parameters
- Long-term actions

Monitoring subtransaction usage

For PostgreSQL versions 16.1 and later, use the following query to monitor subtransaction counts and overflow status per backend. This query joins backend statistics with activity information to show which processes are using subtransactions:

```
SELECT a.pid, usename, query, state, wait_event_type,
       wait_event, subxact_count, subxact_overflowed
FROM (SELECT id, pg_stat_get_backend_pid(id) pid, subxact_count, subxact_overflowed
      FROM pg_stat_get_backend_idset() id
           JOIN LATERAL pg_stat_get_backend_subxact(id) AS s ON true
     ) a
JOIN pg_stat_activity b ON a.pid = b.pid;
```

For PostgreSQL versions 13.3 and later, monitor the `pg_stat_slru` view for subtransaction cache pressure. The following SQL query retrieves SLRU cache statistics for the Subtrans component:

```
SELECT * FROM pg_stat_slru WHERE name = 'Subtrans';
```

A consistently increasing `blks_read` value indicates frequent disk access for uncached subtransactions, signaling potential SLRU cache pressure.

Configuring memory parameters

For PostgreSQL 17.1 and later, you can configure the subtransaction SLRU cache size using the `subtransaction_buffers` parameter. The following configuration example shows how to set the subtransaction buffer parameter:

```
subtransaction_buffers = 128
```

This parameter specifies the amount of shared memory used to cache subtransaction contents (`pg_subtrans`). When specified without units, the value represents blocks of `BLCKSZ` bytes, typically 8KB each. For example, setting the value to 128 allocates 1MB (128 * 8kB) of memory for the subtransaction cache.

> **Note**
>
> You can set this parameter at the cluster level so that all instances remain consistent. Test and adjust the value to suit your specific workload requirements and instance class. You must reboot the writer instance for parameter changes to take effect.

Long-term actions

- **Examine application code and configurations** – Review your application code and database driver configurations for both explicit and implicit `SAVEPOINT` usage and subtransactions usage in general. Identify transactions potentially generating over 64 subtransactions.
- **Reduce savepoint usage** – Minimize the use of savepoints in your transactions:
  - Review PL/pgSQL procedures and functions with EXCEPTION blocks. EXCEPTION blocks automatically create implicit savepoints, which can contribute to subtransaction overflow. Each EXCEPTION clause creates a subtransaction, regardless of whether an exception actually occurs during execution.

    Example

    Example 1: Problematic EXCEPTION block usage

    The following code example shows problematic EXCEPTION block usage that creates multiple subtransactions:

```
CREATE OR REPLACE FUNCTION process_user_data()
RETURNS void AS $$
DECLARE
    user_record RECORD;
BEGIN
    FOR user_record IN SELECT * FROM users LOOP
        BEGIN
            -- This creates a subtransaction for each iteration
            INSERT INTO user_audit (user_id, action, timestamp)
            VALUES (user_record.id, 'processed', NOW());

            UPDATE users
            SET last_processed = NOW()
            WHERE id = user_record.id;

        EXCEPTION
            WHEN unique_violation THEN
                -- Handle duplicate audit entries
                UPDATE user_audit
                SET timestamp = NOW()
                WHERE user_id = user_record.id AND action = 'processed';
        END;
    END LOOP;
END;
$$ LANGUAGE plpgsql;
```

The following improved code example reduces subtransaction usage by using UPSERT instead of exception handling:

```
CREATE OR REPLACE FUNCTION process_user_data()
RETURNS void AS $$
DECLARE
    user_record RECORD;
BEGIN
    FOR user_record IN SELECT * FROM users LOOP
        -- Use UPSERT to avoid exception handling
        INSERT INTO user_audit (user_id, action, timestamp)
        VALUES (user_record.id, 'processed', NOW())
        ON CONFLICT (user_id, action)
        DO UPDATE SET timestamp = NOW();
```

```
        UPDATE users
        SET last_processed = NOW()
        WHERE id = user_record.id;
    END LOOP;
END;
$$ LANGUAGE plpgsql;
```

Example

Example 2: STRICT exception handler

The following code example shows problematic EXCEPTION handling with NO_DATA_FOUND:

```
CREATE OR REPLACE FUNCTION get_user_email(p_user_id INTEGER)
RETURNS TEXT AS $$
DECLARE
    user_email TEXT;
BEGIN
    BEGIN
        -- STRICT causes an exception if no rows or multiple rows found
        SELECT email INTO STRICT user_email
        FROM users
        WHERE id = p_user_id;

        RETURN user_email;

    EXCEPTION
        WHEN NO_DATA_FOUND THEN
            RETURN 'Email not found';
    END;
END;
$$ LANGUAGE plpgsql;
```

The following improved code example avoids subtransactions by using IF NOT FOUND instead of exception handling:

```
CREATE OR REPLACE FUNCTION get_user_email(p_user_id INTEGER)
RETURNS TEXT AS $$
```

```
DECLARE
    user_email TEXT;
BEGIN
     SELECT email INTO user_email
     FROM users
     WHERE id = p_user_id;

     IF NOT FOUND THEN
         RETURN 'Email not found';
     ELSE
         RETURN user_email;
     END IF;
END;
$$ LANGUAGE plpgsql;
```

  - JDBC driver – The `autosave` parameter, if set to `always` or `conservative`, generates savepoints before each query. Evaluate whether the `never` setting would be acceptable for your application.
  - PostgreSQL ODBC driver (psqlODBC) — The rollback level setting (for statement-level rollback) creates implicit savepoints to enable statement rollback functionality. Evaluate whether transaction-level or no rollback would be acceptable for your application.
  - Examine ORM transaction configurations
  - Consider alternative error handling strategies that don't require savepoints
- **Optimize transaction design** – Restructure transactions to avoid excessive nesting and reduce the likelihood of subtransaction overflow conditions.
- **Reduce long-running transactions** – Long-running transactions can exacerbate subtransaction issues by holding onto subtransaction information longer. Monitor Performance Insights metrics and configure the `idle_in_transaction_session_timeout` parameter to automatically terminate idle transactions.
- Monitor Performance Insights metrics – Track metrics including `idle_in_transaction_count` (number of sessions in idle in transaction state) and `idle_in_transaction_max_time` (duration of the longest running idle transaction) to detect long-running transactions.
- Configure `idle_in_transaction_session_timeout` – Set this parameter in your parameter group to automatically terminate idle transactions after a specified duration.
- Proactive monitoring – Monitor for high occurrences of `LWLock:SubtransBuffer` and `LWLock:SubtransSLRU` wait events to detect subtransaction-related contention before it becomes critical.

Timeout:PgSleep

The `Timeout:PgSleep` event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

Topics

- Supported engine versions
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- `pg_sleep`
- `pg_sleep_for`
- `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see Delaying Execution in the PostgreSQL documentation.

Actions

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

Timeout:VacuumDelay

The `Timeout:VacuumDelay` event indicates that the cost limit for vacuum I/O has been exceeded and that the vacuum process has been put to sleep. Vacuum operations stop for the

duration specified in the respective cost delay parameter and then it resumes its work. For the manual vacuum command, the delay is specified in the `vacuum_cost_delay` parameter. For the autovacuum daemon, the delay is specified in the `autovacuum_vacuum_cost_delay parameter.`

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

Context

PostgreSQL has both an autovacuum daemon and a manual vacuum command. The autovacuum process is "on" by default for RDS for PostgreSQL DB instances. The manual vacuum command is used on an as-needed basis, for example, to purge tables of dead tuples or generate new statistics.

When vacuuming is underway, PostgreSQL uses an internal counter to keep track of estimated costs as the system performs various I/O operations. When the counter reaches the value specified by the cost limit parameter, the process performing the operation sleeps for the brief duration specified in the cost delay parameter. It then resets the counter and continues operations.

The vacuum process has parameters that can be used to regulate resource consumption. The autovacuum and the manual vacuum command have their own parameters for setting the cost limit value. They also have their own parameters to specify a cost delay, an amount of time to put the vacuum to sleep when the limit is reached. In this way, the cost delay parameter works as a throttling mechanism for resource consumption. In the following lists, you can find description of these parameters.

Parameters that affect throttling of the autovacuum daemon

- `autovacuum_vacuum_cost_limit` – Specifies the cost limit value to use in automatic vacuum operations. Increasing the setting for this parameter allows the vacuum process to use more resources and decreases the `Timeout:VacuumDelay` wait event.

- `autovacuum_vacuum_cost_delay` – Specifies the cost delay value to use in automatic vacuum operations. The default value is 2 milliseconds. Setting the delay parameter to 0 turns off the throttling mechanism and thus, the `Timeout:VacuumDelay` wait event won't appear.

For more information, see Automatic Vacuuming in the PostgreSQL documentation.

Parameters that affect throttling of the manual vacuum process

- `vacuum_cost_limit` – The threshold at which the vacuuming process is put to sleep. By default, the limit is 200. This number represents the accumulated cost estimates for extra I/O needed by various resources. Increasing this value reduces the number of the `Timeout:VacuumDelay` wait event.
- `vacuum_cost_delay` – The amount of time that the vacuum process sleeps when the vacuum cost limit has been reached. The default setting is 0, which means that this feature is off. You can set this to an integer value to specify the number of milliseconds to turn on this feature, but we recommend that you leave it at its default setting.

For more information about the `vacuum_cost_delay` parameter, see Resource Consumption in the PostgreSQL documentation.

To learn more about how to configure and use the autovacuum with RDS for PostgreSQL, see Working with PostgreSQL autovacuum on Amazon RDS for PostgreSQL.

Likely causes of increased waits

The `Timeout:VacuumDelay` is affected by the balance between the cost limit parameter settings (`vacuum_cost_limit`, `autovacuum_vacuum_cost_limit`) and the cost delay parameters (`vacuum_cost_delay`, `autovacuum_vacuum_cost_delay`) that control the vacuum's sleep duration. Raising a cost limit parameter value allows more resources to be used by the vacuum before being put to sleep. That results in fewer `Timeout:VacuumDelay` wait events. Increasing either of the delay parameters causes the `Timeout:VacuumDelay` wait event to occur more frequently and for longer periods of time.

The `autovacuum_max_workers` parameter setting can also increase numbers of the `Timeout:VacuumDelay`. Each additional autovacuum worker process contributes to the internal counter mechanism, and thus the limit can be reached more quickly than with a single autovacuum worker process. As the cost limit is reached more quickly, the cost delay is put to effect more

frequently, resulting in more `Timeout:VacuumDelay` wait events. For more information, see autovacuum_max_workers in the PostgreSQL documentation.

Large objects, such as 500GB or larger, also raise this wait event because it can take some time for the vacuum to complete processing large objects.

Actions

If the vacuum operations complete as expected, no remediation is needed. In other words, this wait event doesn't necessarily indicate a problem. It indicates that the vacuum is being put to sleep for the period of time specified in the delay parameter so that resources can be applied to other processes that need to complete.

If you want vacuum operations to complete faster, you can lower the delay parameters. This shortens the time that the vacuum sleeps.

Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detects conditions on your RDS for PostgreSQL DB instances that can cause problems, and lets you know about them before they occur. Proactive insights can alert you to a long running idle in transaction connection. For more information about troubleshooting long running idle in transaction connections, see Database has long running idle in transaction connection

DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

For more information about Amazon DevOps Guru for Amazon RDS, see Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS.

Database has long running idle in transaction connection

A connection to the database has been in the `idle in transaction` state for more than 1800 seconds.

Topics

- Supported engine versions
- Context
- Likely causes for this issue
- Actions
- Relevant metrics

Supported engine versions

This insight information is supported for all versions of RDS for PostgreSQL.

Context

A transaction in the `idle in transaction` state can hold locks that block other queries. It can also prevent VACUUM (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

Likely causes for this issue

A transaction initiated in an interactive session with BEGIN or START TRANSACTION hasn't ended by using a COMMIT, ROLLBACK, or END command. This causes the transaction to move to `idle in transaction` state.

Actions

You can find idle transactions by querying `pg_stat_activity`.

In your SQL client, run the following query to list all connections in `idle in transaction` state and to order them by duration:

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
 xact_duration,*
FROM  pg_stat_activity
WHERE state  = 'idle in transaction'
AND   xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

Topics

- End transaction
- Terminate the connection
- Configure the idle_in_transaction_session_timeout parameter
- Check the AUTOCOMMIT status
- Check the transaction logic in your application code

End transaction

When you initiate a transaction in an interactive session with BEGIN or START TRANSACTION, it moves to `idle in transaction` state. It remains in this state until you end the transaction by issuing a COMMIT, ROLLBACK, END command or disconnect the connection completely to roll back the transaction.

Terminate the connection

Terminate the connection with an idle transaction using the following query:

```
SELECT pg_terminate_backend(pid);
```

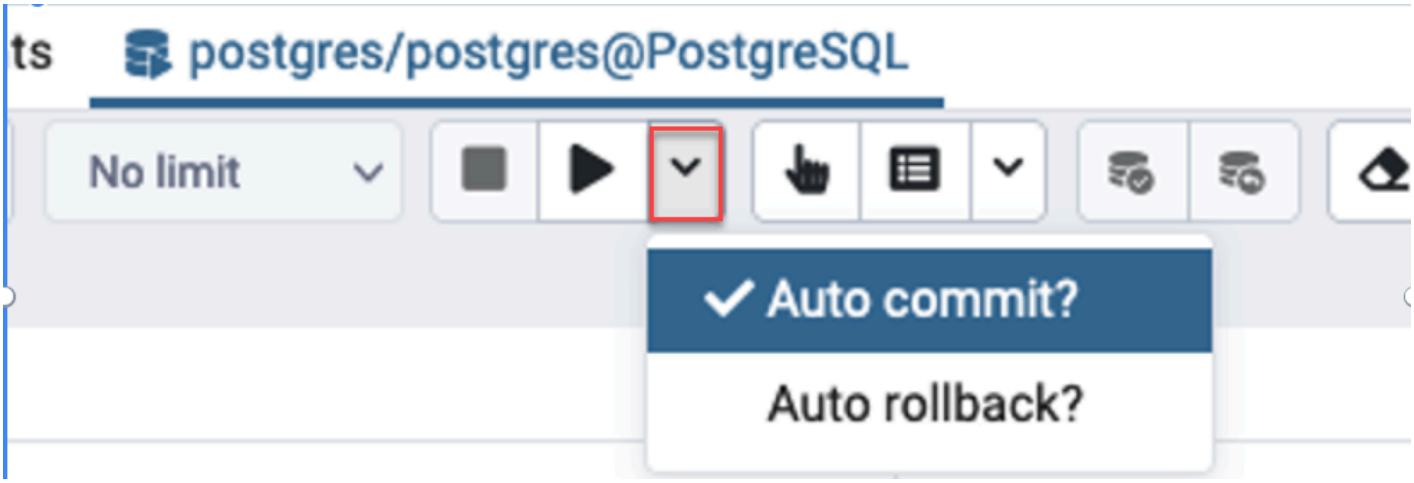
pid is the process ID of the connection.

Configure the idle_in_transaction_session_timeout parameter

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see the PostgreSQL documentation.

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the idle_in_transaction state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```



Check the AUTOCOMMIT status

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your psql client, run the following command:

  ```
  postgres=> \set AUTOCOMMIT on
  ```

- In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.

Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit `COMMIT` commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

Relevant metrics

The following PI metrics are related to this insight:

- idle_in_transaction_count - Number of sessions in `idle in transaction` state.
- idle_in_transaction_max_time - The duration of the longest running transaction in the `idle in transaction` state.

Using PostgreSQL extensions with Amazon RDS for PostgreSQL

You can extend the functionality of PostgreSQL by installing a variety of extensions and modules. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see Managing spatial data with the PostGIS extension. As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the `pg_partman` extension. To learn more, see Managing PostgreSQL partitions with the pg_partman extension.

> **Note**
>
> RDS for PostgreSQL supports Trusted Language Extensions for PostgreSQL through the `pg_tle` extension, which you can add to your DB instance. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements. To learn about RDS for PostgreSQL versions supporting `pg_tle` extension and for more information, see Working with Trusted Language Extensions for PostgreSQL.

In some cases, rather than installing an extension, you might add a specific module to the list of `shared_preload_libraries` in your RDS for PostgreSQL DB instance's custom DB parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in Scheduling maintenance with the PostgreSQL pg_cron extension. As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see Logging execution plans of queries in the AWS knowledge center.

Depending on your version of RDS for PostgreSQL, installing an extension might require `rds_superuser` permissions, as follows:

- For RDS for PostgreSQL versions 12 and earlier versions, installing extensions requires `rds_superuser` privileges.
- For RDS for PostgreSQL version 13 and higher versions, users (roles) with create permissions on a given database instance can install and use any *trusted extensions*. For a list of trusted extensions, see PostgreSQL trusted extensions.

You can also specify precisely which extensions can be installed on your RDS for PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see Restricting installation of PostgreSQL extensions.

To learn more about the `rds_superuser` role, see Understanding PostgreSQL roles and permissions.

Topics

- Using functions from the orafce extension
- Using Amazon RDS delegated extension support for PostgreSQL

- Using pgAudit to log database activity
- Scheduling maintenance with the PostgreSQL pg_cron extension
- Using pglogical to synchronize data across instances
- Using pgactive to support active-active replication
- Reducing bloat in tables and indexes with the pg_repack extension
- Upgrading and using the PLV8 extension
- Using PL/Rust to write PostgreSQL functions in the Rust language
- Managing spatial data with the PostGIS extension

Using functions from the orafce extension

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see orafce on GitHub.

> **Note**
>
> RDS for PostgreSQL doesn't support the `utl_file` package that is part of the orafce extension. This is because the `utl_file` schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.

To use the orafce extension

1. Connect to the DB instance with the primary user name that you used to create the DB instance.

   If you want to turn on orafce for a different database in the same DB instance, use the /c dbname psql command. Using this command, you change from the primary database after initiating the connection.
2. Turn on the orafce extension with the CREATE EXTENSION statement.

   ```
   CREATE EXTENSION orafce;
   ```
3. Transfer ownership of the oracle schema to the rds_superuser role with the ALTER SCHEMA statement.

   ```
   ALTER SCHEMA oracle OWNER TO rds_superuser;
   ```

   If you want to see the list of owners for the oracle schema, use the \dn psql command.

Using Amazon RDS delegated extension support for PostgreSQL

Using Amazon RDS delegated extension support for PostgreSQL, you can delegate the extension management to a user who need not be an `rds_superuser`. With this delegated extension support, a new role called `rds_extension` is created and you must assign this to a user to manage other extensions. This role can create, update, and drop extensions.

You can specify the extensions that can be installed on your RDS DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.

You can restrict the list of extensions available that can be managed by the user with the `rds_extension` role using `rds.allowed_delegated_extensions` parameter.

The delegated extension support is available in the following versions:

- All higher versions
- 16.4 and higher 16 versions
- 15.8 and higher 15 versions
- 14.13 and higher 14 versions
- 13.16 and higher 13 versions
- 12.20 and higher 12 versions

Topics

- Turning on delegate extension support to a user
- Configuration used in RDS delegated extension support for PostgreSQL
- Turning off the support for the delegated extension
- Benefits of using Amazon RDS delegated extension support
- Limitation of Amazon RDS delegated extension support for PostgreSQL
- Permissions required for certain extensions
- Security Considerations
- Drop extension cascade disabled
- Example extensions that can be added using delegated extension support

Turning on delegate extension support to a user

You must perform the following to enable delegate extension support to a user:

1. **Grant `rds_extension` role to a user** – Connect to the database as `rds_superuser` and execute the following command:

```
Postgres => grant rds_extension to user_name;
```

2. **Set the list of extensions available for delegated users to manage** – The `rds.allowed_delegated_extensions` allows you to specify a subset of the available extensions using `rds.allowed_extensions` in the DB cluster parameter. You can perform this at one of the following levels:

   - In the cluster or the instance parameter group, through the AWS Management Console or API. For more information, see Parameter groups for Amazon RDS.
   - Use the following command at the database level:

```
alter database database_name set rds.allowed_delegated_extensions =
 'extension_name_1,
                  extension_name_2,...extension_name_n';
```

   - Use the following command at the user level:

```
alter user user_name set rds.allowed_delegated_extensions = 'extension_name_1,
                  extension_name_2,...extension_name_n';
```

> **Note**
>
> You need not restart the database after changing the `rds.allowed_delegated_extensions` dynamic parameter.

3. **Allow access to the delegated user to objects created during the extension creation process** – Certain extensions create objects that require additional permissions to be granted before the user with `rds_extension` role can access them. The `rds_superuser` must grant the delegated user access to those objects. One of the options is to use an event trigger to automatically grant permission to the delegated user.

Example of event trigger

If you want to allow a delegated user with `rds_extension` to use extensions that require setting permissions on their objects created by the extension creation, you can customize the below example of an event trigger and add only the extensions for which you want the delegated users to have access to the full functionality. This event trigger can be created on template1 (the default template), therefore all database created from template1 will have that event trigger. When a delegated user installs the extension, this trigger will automatically grant ownership on the objects created by the extension.

```
CREATE OR REPLACE FUNCTION create_ext()

  RETURNS event_trigger AS $$

DECLARE

  schemaname TEXT;
  databaseowner TEXT;

  r RECORD;

BEGIN

  IF tg_tag = 'CREATE EXTENSION' and current_user != 'rds_superuser' THEN
    RAISE NOTICE 'SECURITY INVOKER';
    RAISE NOTICE 'user: %', current_user;
    FOR r IN SELECT * FROM pg_catalog.pg_event_trigger_ddl_commands()
    LOOP
        CONTINUE WHEN r.command_tag != 'CREATE EXTENSION' OR r.object_type !=
 'extension';

        schemaname = (
            SELECT n.nspname
            FROM pg_catalog.pg_extension AS e
            INNER JOIN pg_catalog.pg_namespace AS n
            ON e.extnamespace = n.oid
            WHERE e.oid = r.objid
        );

        databaseowner = (
```

```
            SELECT pg_catalog.pg_get_userbyid(d.datdba)
            FROM pg_catalog.pg_database d
            WHERE d.datname = current_database()
        );
        RAISE NOTICE 'Record for event trigger %, objid: %,tag: %, current_user: %,

  END IF;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;

CREATE EVENT TRIGGER log_create_ext ON ddl_command_end EXECUTE PROCEDURE
 create_ext();
```

Configuration used in RDS delegated extension support for PostgreSQL

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
`rds.allowed_delegated_extensions`	This parameter limits the extensions a rds_extension role can manage in a database. It must be a subset of rds.allowed_extensions.	empty string	• By default, this parameter is empty string, which means that no extensions have been delegated to users with `rds_extension` . • Any supported extension can be added if the user has permission to do so. To do this, set the `rds.allowed_delegated_extensions` parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that	rds_superuser

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
			the user with the `rds_extension` role can install. • When set to `*`, it means that all extensions listed in `rds_allowed_extensions` are delegated to users with `rds_extension` role. To learn more about setting up this parameter, see Turning on delegate extension support to a user.	

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
rds.allowed_extensions	This parameter lets the customer limit the extensions that can be installed in the RDS DB instance. For more information, see Restricting installation of PostgreSQL extensions	"*"	By default, this parameter is set to "*", which means that all extensions supported on RDS for PostgreSQL and Aurora PostgreSQL are allowed to be created by users with necessary privileges. Empty means no extensions can be installed in the RDS DB instance.	administrator

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
rds-delegated_extension_allow_drascac	This parameter controls the ability for user with rds_extension to drop the extension using a cascade option.	off	By default, rds-delegated_extension_allow_drop_cascade is set to off. This means that users with rds_extension are not allowed to drop an extension using the cascade option. To grant that ability, the rds.delegated_extension_allow_drop_cascade parameter should be set to on.	rds_superuser

Turning off the support for the delegated extension

Turning off partially

The delegated users can't create new extensions but can still update existing extensions.

- Reset rds.allowed_delegated_extensions to the default value in the DB cluster parameter group.
- Use the following command at the database level:

```
alter database database_name reset rds.allowed_delegated_extensions;
```

- Use the following command at the user level:

```
alter user user_name reset rds.allowed_delegated_extensions;
```

Turning off fully

Revoking `rds_extension` role from a user will revert the user to standard permissions. The user can no longer create, update, or drop extensions.

```
postgres => revoke rds_extension from user_name;
```

Benefits of using Amazon RDS delegated extension support

By using Amazon RDS delegated extension support for PostgreSQL, you securely delegate the extension management to users who do not have the `rds_superuser` role. This feature provides the following benefits:

- You can easily delegate extension management to users of your choice.
- This doesn't require `rds_superuser` role.
- Provides ability to support different set of extensions for different databases in the same DB cluster.

Limitation of Amazon RDS delegated extension support for PostgreSQL

- Objects created during the extension creation process may require additional privileges for the extension to function properly.
- Some extensions can't be managed by the delegated extension user by default, including the following: `log_fdw`, `pg_cron`, `pg_tle`, `pgactive`, `pglogical`, `postgis_raster`, `postgis_tiger_geocoder`, `postgis_topology`.

Permissions required for certain extensions

In order to create, use, or update the following extensions, the delegated user should have the necessary privileges on the following functions, tables, and schema.

Exte s that need owne or perm ns	Function	Tables	Schema	Text Search Dictionary	Comment
addr tand er_da s	none	us_gaz, us_lex, us_lex, I.us_rule s	none	none	none
amch	bt_index_ check, bt_index_ parent_check	none	none	none	none
dict_	none	none	none	intdict	none
pg_p n	none	custom_ti me_partit ions, part_conf ig, part_conf ig_sub	none	none	none

post aster	none	none	none	none	none
post opol	none	topology, layer	topology	none	the delegated user Must be

Exte s that need own or perm ns	Function	Tables	Schema	Text Search Dictionary	Comment
					the database owner
log_f	create_fo reign_tab le_for_log_file	none	none	none	none
rds_t	role_pass word_encr yption_type	none	none	none	none
post iger_ oder	none	geocode_s ettings_d efault, geocode_s ettings	tiger	none	none
pg_f acem	pg_freespace	none	none	none	none
pg_v lity	pg_visibility	none	none	none	none

Security Considerations

Keep in mind that a user with `rds_extension` role will be able to manage extensions on all databases they have the connect privilege on. If the intention is to have a delegated user manage extension on a single database, a good practice is to revoke all privileges from public on each database, then explicitly grant the connect privilege for that specific database to the delegate user.

There are several extensions that can allow a user to access information from multiple database. Ensure the users you grant `rds_extension` has cross database capabilities before adding these extensions to `rds.allowed_delegated_extensions`. For example, `postgres_fdw` and `dblink` provide functionality to query across databases on the same instance or remote instances. `log_fdw` reads the postgres engine log files, which are for all databases in the instance, potentially containing slow queries or error messages from multiple databases. `pg_cron` enables running scheduled background jobs on the DB instance and can configure jobs to run in a different database.

Drop extension cascade disabled

The ability to drop the extension with cascade option by a user with the `rds_extension` role is controlled by `rds.delegated_extension_allow_drop_cascade` parameter. By default, `rds-delegated_extension_allow_drop_cascade` is set to `off`. This means that users with the `rds_extension` role are not allowed to drop an extension using the cascade option as shown in the below query.

```
DROP EXTENSION CASCADE;
```

As this will automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. Attempting to use the cascade option will result in an error.

To grant that ability, the `rds.delegated_extension_allow_drop_cascade` parameter should be set to on.

Changing the `rds.delegated_extension_allow_drop_cascade` dynamic parameter doesn't require a database restart. You can do this at one of the following levels:

- In the cluster or the instance parameter group, through the AWS Management Console or API.
- Using the following command at the database level:

```
alter database database_name set rds.delegated_extension_allow_drop_cascade = 'on';
```

- Using the following command at the user level:

```
alter role tenant_user set rds.delegated_extension_allow_drop_cascade = 'on';
```

Example extensions that can be added using delegated extension support

- rds_tools

```
extension_test_db=> create extension rds_tools;
CREATE EXTENSION
extension_test_db=> SELECT * from rds_tools.role_password_encryption_type() where
 rolname = 'pg_read_server_files';
ERROR: permission denied for function role_password_encryption_type
```

- amcheck

```
extension_test_db=> CREATE TABLE amcheck_test (id int);
CREATE TABLE
extension_test_db=> INSERT INTO amcheck_test VALUES (generate_series(1,100000));
INSERT 0 100000
extension_test_db=> CREATE INDEX amcheck_test_btree_idx ON amcheck_test USING btree
 (id);
CREATE INDEX
extension_test_db=> create extension amcheck;
CREATE EXTENSION
extension_test_db=> SELECT bt_index_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_check
extension_test_db=> SELECT bt_index_parent_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_parent_check
```

- pg_freespacemap

```
extension_test_db=> create extension pg_freespacemap;
CREATE EXTENSION
extension_test_db=> SELECT * FROM pg_freespace('pg_authid');
ERROR: permission denied for function pg_freespace
extension_test_db=> SELECT * FROM pg_freespace('pg_authid',0);
ERROR: permission denied for function pg_freespace
```

- pg_visibility

```
extension_test_db=> create extension pg_visibility;
CREATE EXTENSION
extension_test_db=> select * from pg_visibility('pg_database'::regclass);
ERROR: permission denied for function pg_visibility
```

- postgres_fdw

```
extension_test_db=> create extension postgres_fdw;
CREATE EXTENSION
extension_test_db=> create server myserver foreign data wrapper postgres_fdw options
 (host 'foo', dbname 'foodb', port '5432');
ERROR: permission denied for foreign-data wrapper postgres_fdw
```

Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an `INSERT` or `UPDATE` SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the `WHERE` clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.
- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints

- References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

Topics

- Overview of the PostgreSQL pg_partman extension
- Enabling the pg_partman extension
- Configuring partitions using the create_parent function
- Configuring partition maintenance using the run_maintenance_proc function

Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the `pg_partman` documentation.

> **Note**
>
> The `pg_partman` extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The pg_partman extension also provides the run_maintenance_proc function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

Enabling the pg_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the pg_partman extension separately for each database. To enable the pg_partman extension for a specific database, create the partition maintenance schema and then create the pg_partman extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

> **Note**
>
> To create the pg_partman extension, make sure that you have rds_superuser privileges.

If you receive an error such as the following, grant the rds_superuser privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant rds_superuser privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the pg_partman extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:

- Primary keys event_id and created_at, which must have the column used to guide the partition.

- A check constraint `ck_valid_operation` to enforce values for an `operation` table column.
- Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
- Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL,
        org_name TEXT,
        CONSTRAINT pk_organization PRIMARY KEY (org_id)
    );

CREATE TABLE data_mart.events(
        event_id        BIGSERIAL,
        operation       CHAR(1),
        value           FLOAT(24),
        parent_event_id BIGINT,
        event_type      VARCHAR(25),
        org_id          BIGSERIAL,
        created_at      timestamp,
        CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
        CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
        CONSTRAINT fk_orga_membership
            FOREIGN KEY(org_id)
            REFERENCES data_mart.organization (org_id),
        CONSTRAINT fk_parent_event_id
            FOREIGN KEY(parent_event_id, created_at)
            REFERENCES data_mart.events (event_id,created_at)
    ) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

Configuring partitions using the create_parent function

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the `events` table

example created in Enabling the pg_partman extension. Call the `create_parent` function as follows.

```
SELECT partman.create_parent(
 p_parent_table => 'data_mart.events',
 p_control      => 'created_at',
 p_type         => 'range',
 p_interval     => '1 day',
 p_premake      => 30);
```

The parameters are as follows:

- `p_parent_table` – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- `p_control` – The column on which the partitioning is to be based. The data type must be an integer or time-based.
- `p_type` – The type is either `'range'` or `'list'`.
- `p_interval` – The time interval or integer range for each partition. Example values include `1 day`, `1 hour`, and so on.
- `p_premake` – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see Creation Functions in the `pg_partman` documentation.

Configuring partition maintenance using the run_maintenance_proc function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the `pg_partman` extension and the `pg_cron` extension, which initiates an internal scheduler. The `pg_cron` scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in Enabling the pg_partman extension to set partition maintenance operations to run automatically. As a prerequisite, add `pg_cron` to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```
CREATE EXTENSION pg_cron;
```

```
UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add `pg_cron` to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the `pg_cron` extension. For more information, see Scheduling maintenance with the PostgreSQL pg_cron extension.
3. Run the command `UPDATE partman.part_config` to adjust the `pg_partman` settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
   a. `infinite_time_partitions = true,` – Configures the table to be able to automatically create new partitions without any limit.
   b. `retention = '3 months',` – Configures the table to have a maximum retention of three months.
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule...` to make a `pg_cron` function call. This call defines how often the scheduler runs the `pg_partman` maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see Maintenance Functions in the `pg_partman` documentation.

Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep *audit logs* to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your RDS for PostgreSQL DB instance, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see RDS for PostgreSQL database log files.

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your RDS for PostgreSQL DB instance is configured to log data manipulation language (DML) statements as detailed in Turning on query logging for your RDS for PostgreSQL DB instance, you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging.

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

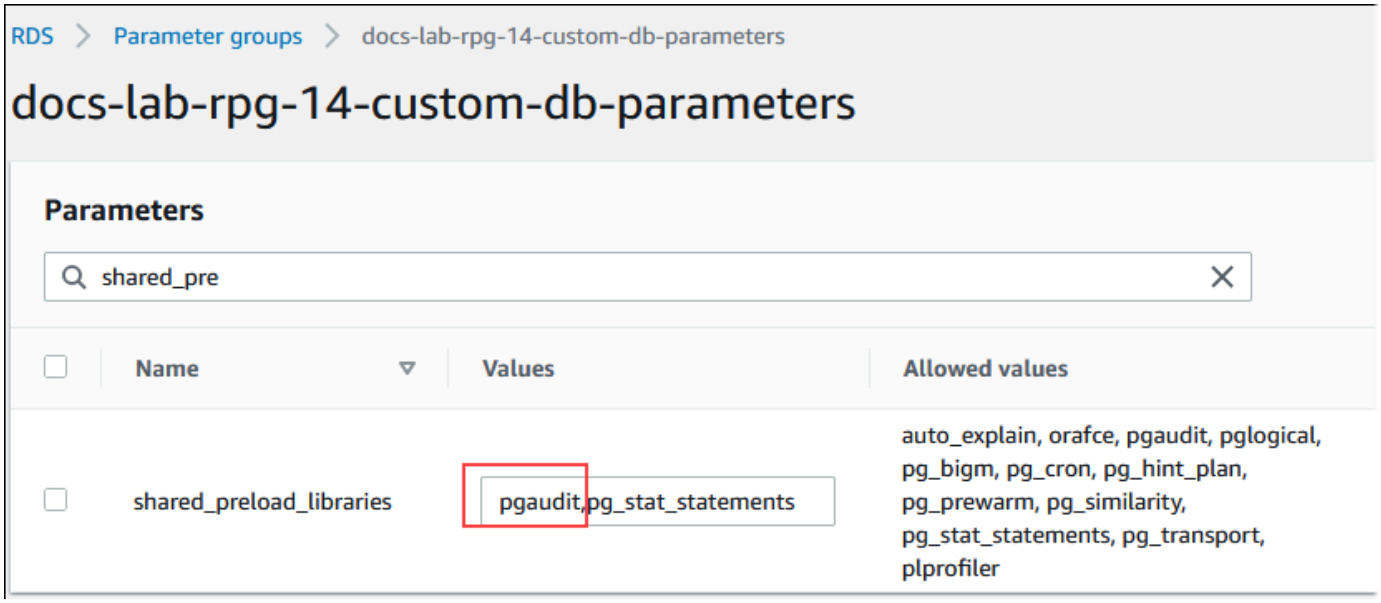
The pgAudit extension is supported on all available RDS for PostgreSQL versions. For a list of pgAudit versions supported by available RDS for PostgreSQL versions, see Extension versions for Amazon RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes.*

Topics

- Setting up the pgAudit extension
- Auditing database objects
- Excluding users or databases from audit logging
- Reference for the pgAudit extension

Setting up the pgAudit extension

To set up the pgAudit extension on your RDS for PostgreSQL DB instance , you first add pgAudit to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS. Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.



You must have permissions as the `rds_superuser` role to perform all these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group.

Console

To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pgaudit` to the list in the **Values** field. Use a comma to separate items in the list of values.

8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that pgAudit has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the `pgaudit` extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

11. Close the `psql` session.

```
labdb=> \q
```

12. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.

You can also choose one of the following values for the `pgaudit.log` parameter.

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
- ddl – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
- function – Logs function calls and `DO` blocks.
- misc – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
- read – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
- role – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
- write – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

14. Choose **Save changes**.
15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
16. Choose your RDS for PostgreSQL DB instance from the Databases list.

AWS CLI

To setup pgAudit

To setup pgAudit using the AWS CLI, you call the modify-db-parameter-group operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pgaudit library is initialized.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, you can verify that `pgaudit` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

   With pgAudit initialized, you can now create the extension.

```
CREATE EXTENSION pgaudit;
```

4. Close the `psql` session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the `pgaudit.log` parameter to `write`, which captures inserts, updates, and deletes to the log.

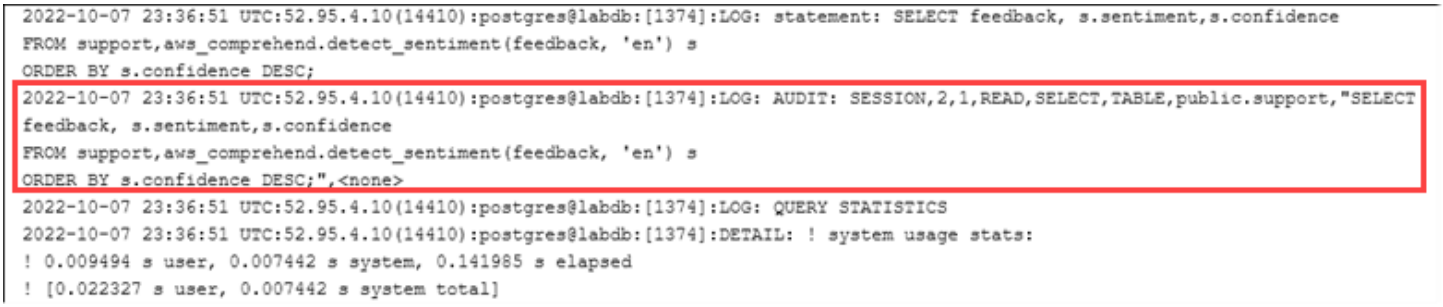
```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \
   --region aws-region
```

   You can also choose one of the following values for the `pgaudit.log` parameter.

   - none – This is the default. No database changes are logged.
   - all – Logs everything (read, write, function, role, ddl, misc).
   - ddl – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
   - function – Logs function calls and `DO` blocks.
   - misc – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
   - read – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
   - role – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
   - write – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

   Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```



Auditing database objects

With pgAudit set up on your RDS for PostgreSQL DB instance and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in

a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that `pgaudit` has been initialized and that you have created the `pgaudit` extension by following the procedure in Setting up the pgAudit extension.

```
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: statement: SELECT feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: AUDIT: SESSION,2,1,READ,SELECT,TABLE,public.support,"SELECT
feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;",<none>
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: QUERY STATISTICS
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:DETAIL: ! system usage stats:
! 0.009494 s user, 0.007442 s system, 0.141985 s elapsed
! [0.022327 s user, 0.007442 s system total]
```

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

To set up object auditing

1. Use `psql` to connect to the RDS for PostgreSQL DB instance.

   ```
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --
   username=postgrespostgres --password --dbname=labdb
   ```

2. Create a database role named `rds_pgaudit` using the following command.

   ```
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   labdb=>
   ```

3. Close the `psql` session.

   ```
   labdb=> \q
   ```

In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot"
 \
   --region aws-region
```

5. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that your changes to the parameters take effect.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```
SHOW pgaudit.role;
pgaudit.role
------------------
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
id
----
(0 rows)
```

The database logs should contain an entry similar to the following.

```
...
```

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT:
OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
...
```

For information on viewing the logs, see Monitoring Amazon RDS log files.

To learn more about the pgAudit extension, see pgAudit on GitHub.

Excluding users or databases from audit logging

As discussed in RDS for PostgreSQL database log files, PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your RDS for PostgreSQL DB instance.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

> **Note**
>
> Parameter settings at the session level take precedence over the settings in the custom DB parameter group for the RDS for PostgreSQL DB instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your RDS for PostgreSQL DB instance is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.

```
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the `user_specific_settings` column for `pgaudit.log` to confirm that the parameter is set to `NONE`.

```
SELECT
    usename AS user_name,
    useconfig AS user_specific_settings
FROM
    pg_user
WHERE
```

```
    usename = 'myuser';
```

You see output such as the following.

```
 user_name | user_specific_settings
-----------+-----------------------
 myuser    | {pgaudit.log=NONE}
(1 row)
```

You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```
SELECT
    usename AS "user_name",
    datname AS "database_name",
    pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
    pg_catalog.pg_db_role_setting s
    LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
    LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
    usename = 'myuser'
    AND datname = 'mydatabase'
ORDER BY
    1,
    2;
```

You see output similar to the following.

```
  user_name | database_name |     settings
-----------+---------------+------------------
 myuser    | mydatabase    | pgaudit.log=none
(1 row)
```

After turning off auditing for `myuser`, you decide that you don't want to track changes to `mydatabase`. You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

```
SELECT
a.datname AS database_name,
b.setconfig AS database_specific_settings
FROM
pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
a.datname = 'mydatabase';
```

You see output such as the following.

```
 database_name | database_specific_settings
---------------+----------------------------
 mydatabase    | {pgaudit.log=NONE}
(1 row)
```

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see List of allowable settings for the `pgaudit.log` parameter.

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
```

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

Parameter	Description
`pgaudit.log`	Specifies the statement classes that will be logged by session audit logging. Allowable values include ddl, function, misc, read, role, write, none, all. For more information, see List of allowable settings for the `pgaudit.log` parameter.
`pgaudit.log_catalog`	When turned on (set to 1), adds statements to audit trail if all relations in a statement are in pg_catalog.
`pgaudit.log_level`	Specifies the log level to use for log entries. Allowed values: debug5, debug4, debug3, debug2, debug1, info, notice, warning, log
`pgaudit.log_parameter`	When turned on (set to 1), parameters passed with the statement are captured in the audit log.
`pgaudit.log_relation`	When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.
`pgaudit.log_statement_once`	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.
`pgaudit.role`	Specifies the master role to use for object audit logging. The only allowable entry is `rds_pgaudit` .

List of allowable settings for the `pgaudit.log` parameter

Value	Description
none	This is the default. No database changes are logged.
all	Logs everything (read, write, function, role, ddl, misc).
ddl	Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
function	Logs function calls and `DO` blocks.
misc	Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
read	Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
role	Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
write	Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to `ALL`. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for `READ` operations on one or more tables.

Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL `pg_cron` extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The `pg_cron` extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

To learn more about using `pg_cron`, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.

> **Note**
>
> The `pg_cron` extension version is displayed as a two digit version, for example, 1.6, in the pg_available_extensions view. While you might see three digit versions, for example, 1.6.4 or 1.6.5, listed in some contexts, you must specify the two digit version when performing an extension upgrade.

Topics

- Setting up the pg_cron extension
- Granting database users permissions to use pg_cron
- Scheduling pg_cron jobs
- Reference for the pg_cron extension

Setting up the pg_cron extension

Set up the `pg_cron` extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding `pg_cron` to the `shared_preload_libraries` parameter value.
   - If your RDS for PostgreSQL DB instance uses the `rds.allowed_extensions` parameter to explicitly list extensions that can be installed, you need to add the `pg_cron` extension to the list. Only certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. By default, all available extensions are allowed. For more information, see Restricting installation of PostgreSQL extensions.

Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Modifying parameters in a DB parameter group in Amazon RDS.

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has `rds_superuser` permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user `postgres` and create the extension.

```
CREATE EXTENSION pg_cron;
```

   The `pg_cron` scheduler is set in the default PostgreSQL database named `postgres`. The `pg_cron` objects are created in this `postgres` database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database.

Granting database users permissions to use pg_cron

Installing the `pg_cron` extension requires the `rds_superuser` privileges. However, permissions to use the `pg_cron` can be granted (by a member of the `rds_superuser` group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the `cron` schema only as needed if it improves operations in your production environment.

To grant a database user permission in the `cron` schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives *db-user* permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@:[30647]:ERROR: permission denied for table table-name
```

```
2020-12-08 16:41:00 UTC::@:[27071]:LOG: background worker "pg_cron" (PID 30647) exited
 with exit code 1
```

In other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the `cron.job_run_details` table. For more information, see Tables for scheduling jobs and capturing status.

Scheduling pg_cron jobs

The following sections show how you can schedule various management tasks using `pg_cron` jobs.

> **Note**
>
> When you create `pg_cron` jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A `pg_cron` job fails if it runs out of background worker processes. The default number of `pg_cron` jobs is 5. For more information, see Parameters for managing the pg_cron extension.

Topics

- Vacuuming a table
- Purging the pg_cron history table
- Logging errors to the postgresql.log file only
- Scheduling a cron job for a database other than the default database

Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, Working with PostgreSQL autovacuum on Amazon RDS for PostgreSQL.

Following is an example of using the `cron.schedule` function to set up a job to use `VACUUM FREEZE` on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
 schedule
----------
1
(1 row)
```

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
jobid  | runid | job_pid | database | username | command                        |
 status    | return_message | start_time                    | end_time
-------+-------+---------+----------+----------+--------------------------------
+-----------+----------------+-------------------------------
+--------------------------------
 1     | 1     | 3395    | postgres | adminuser| vacuum freeze pgbench_accounts
 | succeeded | VACUUM         | 2020-12-04 21:10:00.050386+00 | 2020-12-04
 21:10:00.072028+00
(1 row)
```

Following is a query of the `cron.job_run_details` table to see the failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
jobid | runid | job_pid | database | username | command                        | status
 | return_message                                | start_time                    |
 end_time
------+-------+---------+----------+----------+--------------------------------+--------
+-----------------------------------------------+-------------------------------
+-------------------------------
 5    | 4     | 30339   | postgres | adminuser| vacuum freeze pgbench_account | failed
 | ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 |
 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see Tables for scheduling jobs and capturing status.

Purging the pg_cron history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the cron.schedule function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE
    FROM cron.job_run_details
    WHERE end_time < now() - interval '7 days'$$);
```

For more information, see Tables for scheduling jobs and capturing status.

Logging errors to the postgresql.log file only

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. The `pg_cron` extension no longer writes to the table and captures errors to the `postgresql.log` file only. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

Use the following command to check the value of the `cron.log_run` parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see Parameters for managing the pg_cron extension.

Scheduling a cron job for a database other than the default database

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

> **Note**
>
> Only users with `rds_superuser` role or `rds_superuser` privileges can list all cron jobs in the database. Other users can view only their own jobs in the `cron.job` table.

1. In the cron database, schedule the job as you normally do using the cron.schedule.

```
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum
 freeze test_table');
```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the `cron.job` table.

```
postgres=> SELECT * FROM cron.job;
jobid | schedule    | command                        | nodename  | nodeport |
 database | username  | active | jobname
------+-------------+--------------------------------+-----------+----------
+----------+----------+--------+-----------------------
106   | 29 03 * * * | vacuum freeze test_table       | localhost | 8192     |
 database1| adminuser | t      | database1 manual vacuum
  1   | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192     |
 postgres | adminuser | t      | manual vacuum
(2 rows)
```

> **Note**
>
> In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (`postgres`) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the `pg_cron` extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics

- Parameters for managing the pg_cron extension
- Function reference: cron.schedule
- Function reference: cron.unschedule
- Tables for scheduling jobs and capturing status

Parameters for managing the pg_cron extension

Following is a list of parameters that control the pg_cron extension behavior.

Parameter	Description
cron.database_name	The database in which pg_cron metadata is kept.
cron.host	The hostname to connect to PostgreSQL. You can't modify this value.
cron.log_run	Log every job that runs in the job_run_details table. Values are on or off. For more information, see Tables for scheduling jobs and capturing status.
cron.log_statement	Log all cron statements before running them. Values are on or off.
cron.max_running_jobs	The maximum number of jobs that can run concurrently.
cron.use_background_workers	Use background workers instead of client sessions. You can't modify this value.

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%'
 ORDER BY name;
```

Function reference: cron.schedule

This function schedules a cron job. The job is initially scheduled in the default postgres database. The function returns a bigint value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database.

The function has two syntax formats.

Syntax

```
cron.schedule (job_name,
    schedule,
    command
);

cron.schedule (schedule,
    command
);
```

Parameters

Parameter	Description
job_name	The name of the cron job.
schedule	Text indicating the schedule for the cron job. The format is the standard cron format.
command	Text of the command to run.

Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
 schedule
----------
      145
(1 row)

postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
 schedule
----------
      146
(1 row)
```

Function reference: cron.unschedule

This function deletes a cron job. You can specify either the `job_name` or the `job_id`. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

Syntax

```
cron.unschedule (job_id);

cron.unschedule (job_name);
```

Parameters

Parameter	Description
`job_id`	A job identifier that was returned from the `cron.schedule` function when the cron job was scheduled.
`job_name`	The name of a cron job that was scheduled with the `cron.schedule` function.

Examples

```
postgres=> SELECT cron.unschedule(108);
 unschedule
------------
 t
(1 row)

postgres=> SELECT cron.unschedule('test');
 unschedule
------------
 t
(1 row)
```

Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

Table	Description
`cron.job`	Contains the metadata about each scheduled job. Most interactions with this table should be done by using the `cron.schedule` and `cron.unschedule` functions. **Important** We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the `username` column to run as `rds-superuser` .
`cron.job_run_details`	Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran. **Note** To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see Purging the pg_cron history table.

Using pglogical to synchronize data across instances

All currently available RDS for PostgreSQL versions support the `pglogical` extension. The pglogical extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see Performing logical replication for Amazon RDS for PostgreSQL.

The `pglogical` extension supports logical replication between two or more RDS for PostgreSQL DB instances. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The `pglogical` extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The *publisher node* is the RDS for PostgreSQL DB instance that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- The *subscriber node* is the RDS for PostgreSQL DB instance that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the `pglogical` extension.

Topics

- Requirements and limitations for the pglogical extension
- Setting up the pglogical extension
- Setting up logical replication for RDS for PostgreSQL DB instance
- Reestablishing logical replication after a major upgrade
- Managing logical replication slots for RDS for PostgreSQL
- Parameter reference for the pglogical extension

Requirements and limitations for the pglogical extension

All currently available releases of RDS for PostgreSQL support the `pglogical` extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from a publisher to a subscriber must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

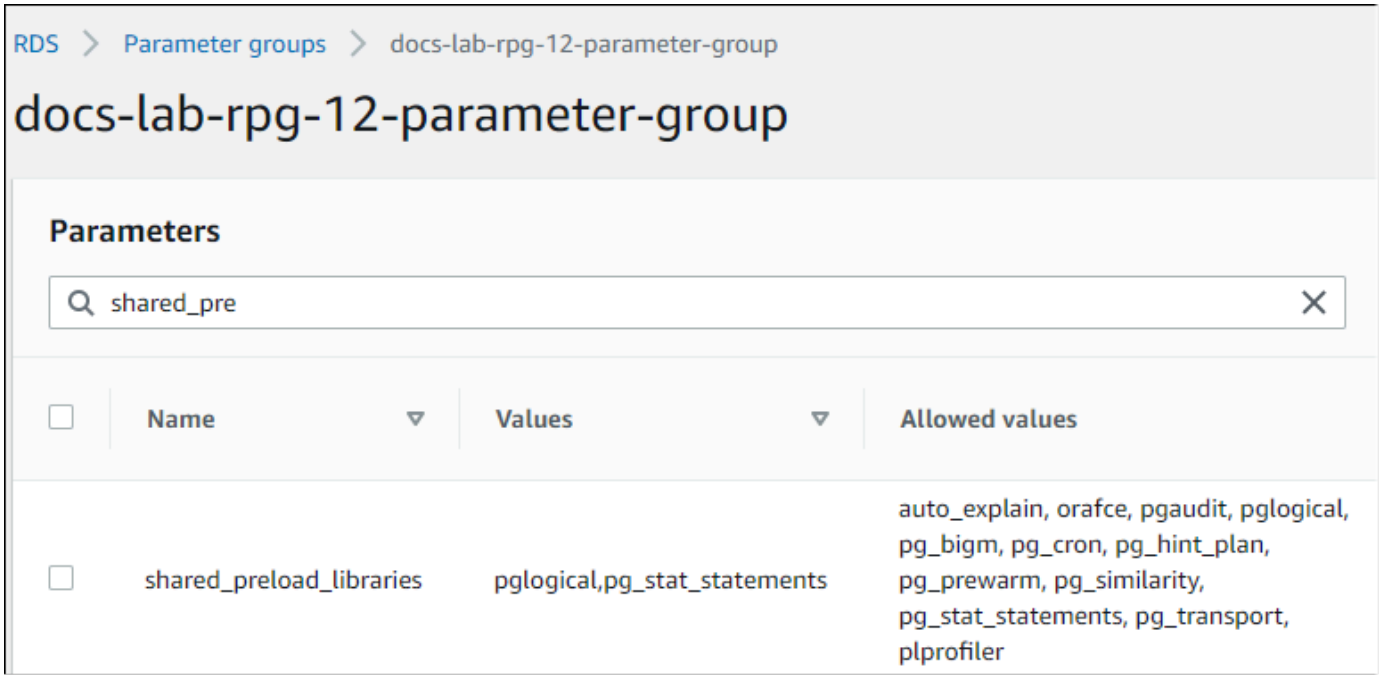
The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The `pglogical` extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see PostgreSQL bi-directional replication using pglogical.

Setting up the pglogical extension

To set up the `pglogical` extension on your RDS for PostgreSQL DB instance , you add `pglogical` to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. You also need to set the value of the `rds.logical_replication` parameter to `1`, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.



The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS.

Console

To set up the pglogical extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.

5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pglogical` to the list in the **Values** field. Use a comma to separate items in the list of values.

8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.
9. Reboot the RDS for PostgreSQL DB instance so that your changes take effect.
10. When the instance is available, you can use `psql` (or pgAdmin) to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

11. To verify that pglogical is initialized, run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pglogical
(1 row)
```

12. Verify the setting that enables logical decoding, as follows.

```
SHOW wal_level;
wal_level
-----------
 logical
(1 row)
```

13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose **Save changes**.
15. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

AWS CLI

To setup the pglogical extension

To setup pglogical using the AWS CLI, you call the modify-db-parameter-group operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add `pglogical` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the following AWS CLI command to set `rds.logical_replication` to 1 to turn on the logical decoding capability for the RDS for PostgreSQL DB instance.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
```

```
   --parameters
 "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-
reboot" \
   --region aws-region
```

3. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pglogical library is initialized.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

4. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

6. Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

Setting up logical replication for RDS for PostgreSQL DB instance

The following procedure shows you how to start logical replication between two RDS for PostgreSQL DB instances. The steps assume that both the source (publisher) and the target (subscriber) have the `pglogical` extension set up as detailed in Setting up the pglogical extension.

> **Note**
>
> The node_name of a subscriber node can't start with `rds`.

To create the publisher node and define the tables to replicate

These steps assume that your RDS for PostgreSQL DB instance has a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do that by using the `psql` metacommand `\d` *`tablename`* and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use `psql` to connect to the instance that has the table you want to use as a source for subscribers.

   ```
   psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --
   username=postgres --password --dbname=labdb
   ```

   If you don't have an existing table that you want to replicate, you can create a sample table as follows.

   a. Create an example table using the following SQL statement.

      ```
      CREATE TABLE docs_lab_table (a int PRIMARY KEY);
      ```

   b. Populate the table with generated data by using the following SQL statement.

      ```
      INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
      INSERT 0 5000
      ```

   c. Verify that data exists in the table by using the following SQL statement.

      ```
      SELECT count(*) FROM docs_lab_table;
      ```

2. Identify this RDS for PostgreSQL DB instance as the publisher node, as follows.

   ```
   SELECT pglogical.create_node(
       node_name := 'docs_lab_provider',
       dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
    dbname=labdb');
    create_node
   -------------
      3410995529
   ```

```
(1 row)
```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see Replication sets in the pglogical documentation.

```
SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true',
 NULL, NULL);
 replication_set_add_table
  --------------------------
  t
  (1 row)
```

The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

To set up the subscriber node and create a subscription to receive updates

These steps assume that the RDS for PostgreSQL DB instance has been set up with the `pglogical` extension. For more information, see Setting up the pglogical extension.

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```
psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. On the subscriber RDS for PostgreSQL DB instance,create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

3. Verify that this table is empty.

```
SELECT count(*) FROM docs_lab_table;
 count
-------
  0
(1 row)
```

4. Identify this RDS for PostgreSQL DB instance as the subscriber node, as follows.

```
SELECT pglogical.create_node(
```

```
    node_name := 'docs_lab_target',
    dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432
 sslmode=require dbname=labdb user=postgres password=********');
 create_node
-------------
   2182738256
(1 row)
```

5. Create the subscription.

```
SELECT pglogical.create_subscription(
   subscription_name := 'docs_lab_subscription',
   provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
 sslmode=require dbname=labdb user=postgres password=*******',
   replication_sets := ARRAY['default'],
   synchronize_data := true,
   forward_origins := '{}' );
 create_subscription
---------------------
1038357190
(1 row)
```

When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```
SELECT count(*) FROM docs_lab_table;
 count
-------
  5000
(1 row)
```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

Reestablishing logical replication after a major upgrade

Before you can perform a major version upgrade of an RDS for PostgreSQL DB instance that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the

publisher node, drop the replication slots, upgrade the RDS for PostgreSQL DB instance, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The RDS for PostgreSQL subscriber node in a logical replication scenario has no slots to drops, but it can't be upgraded to a major version while it's designated as a subscriber node with a subscription to the publisher. Before upgrading the RDS for PostgreSQL subscriber node, drop the subscription and the node. For more information, see Managing logical replication slots for RDS for PostgreSQL.

Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the active column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name,plugin,slot_type,active FROM pg_replication_slots;
                    slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
 pgl_labdb_docs_labcb4fa94_docs_lab3de412c | pglogical_output | logical   | f
(1 row)
```

To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@:[7361]:LOG: background worker "pglogical apply
 16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@:[7361]:LOG: background worker "pglogical apply
 16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```
SELECT * FROM pg_replication_origin;
 roident | roname
---------+--------
(0 rows)
```

  The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```
   roident |                       roname
  ---------+-------------------------------------------------
         1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
  (1 row)
```

- Query the `pglogical.show_subscription_status` function as shown in the following example.

```
SELECT subscription_name,status,slot_name FROM pglogical.show_subscription_status();
     subscription_name | status |              slot_name
---====----------------+--------+-------------------------------------
 docs_lab_subscription | down   | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

  This output shows that replication has been disrupted. Its status is `down`. Normally, the output shows the status as `replicating`.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

To reestablish logical replication between publisher and subscriber nodes

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

```
psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

```
SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
 alter_subscription_disable
----------------------------
 t
(1 row)
```

3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```
SELECT * FROM pg_replication_origin;
 roident |               roname
---------+-------------------------------------
       1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

```
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
  pg_replication_origin_create
------------------------------
                             1
(1 row)
```

5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
  alter_subscription_enable
---------------------------
 t
(1 row)
```

Check the status of the node. Its status should be `replicating` as shown in this example.

```
SELECT subscription_name,status,slot_name
  FROM pglogical.show_subscription_status();
            subscription_name |   status    |              slot_name
------------------------------+-------------+-------------------------------------
 docs_lab_subscription         | replicating |
 pgl_labdb_docs_lab98f517b_docs_lab3de412c
(1 row)
```

Check the status of the subscriber's replication slot on the publisher node. The slot's `active` column should return `t` (true), indicating that replication has been re-established.

```
SELECT slot_name,plugin,slot_type,active
  FROM pg_replication_slots;
                   slot_name              |      plugin      | slot_type | active
------------------------------------------+------------------+-----------+--------
 pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical   | t
(1 row)
```

Managing logical replication slots for RDS for PostgreSQL

Before you can perform a major version upgrade on an RDS for PostgreSQL DB instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To drop slots from your RDS for PostgreSQL DB instance, first drop the subscription and then drop the slot.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```
SELECT * FROM pglogical.node;
node_id   |     node_name
------------+-------------------
 2182738256 | docs_lab_target
 3410995529 | docs_lab_provider
(2 rows)
```

You can get the details about the subscription with the following query.

```
SELECT sub_name,sub_slot_name,sub_target
  FROM pglogical.subscription;
 sub_name |         sub_slot_name          | sub_target
----------+--------------------------------+------------
  docs_lab_subscription     | pgl_labdb_docs_labcb4fa94_docs_lab3de412c | 2182738256
(1 row)
```

You can now drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
 drop_subscription
-------------------
                 1
(1 row)
```

After dropping the subscription, you can delete the node.

```
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
 drop_node
-----------
 t
(1 row)
```

You can verify that the node no longer exists, as follows.

```
SELECT * FROM pglogical.node;
 node_id | node_name
---------+-----------
(0 rows)
```

Parameter reference for the pglogical extension

In the table you can find parameters associated with the `pglogical` extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see PostgreSQL bi-directional replication using pglogical.

Parameter	Description
pglogical.batch_inserts	Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.
pglogical.conflict_log_level	Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.
pglogical.conflict_resolution	Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are error, apply_remote, keep_local, last_update_wins, first_update_wins.
pglogical.extra_connection_options	Connection options to add to all peer node connections.
pglogical.synchronous_commit	pglogical specific synchronous commit value
pglogical.use_spi	Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see Server Programming Interface in the PostgreSQL documentation.

Using pgactive to support active-active replication

The `pgactive` extension uses active-active replication to support and coordinate write operations on multiple RDS for PostgreSQL databases. Amazon RDS for PostgreSQL supports the `pgactive` extension on the following versions:

- RDS for PostgreSQL 17.0 and all higher versions
- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.4-R2 and higher 15 versions
- RDS for PostgreSQL 14.10 and higher 14 versions
- RDS for PostgreSQL 13.13 and higher 13 versions
- RDS for PostgreSQL 12.17 and higher 12 versions
- RDS for PostgreSQL 11.22

> **Note**
>
> When there are write operations on more than one database in a replication configuration, conflicts are possible. For more information, see Handling conflicts in active-active replication

Topics

- Limitations for the pgactive extension
- Initializing the pgactive extension capability
- Setting up active-active replication for RDS for PostgreSQL DB instances
- Measuring replication lag among pgactive members
- Configuring parameter settings for the pgactive extension
- Understanding active-active conflicts
- Understanding the pgactive schema
- pgactive functions reference
- Handling conflicts in active-active replication
- Handling sequences in active-active replication

Limitations for the pgactive extension

- All tables require a Primary Key, otherwise Update's and Delete's aren't allowed. The values in the Primary Key column shouldn't be updated.
- Sequences may have gaps and sometimes might not follow an order. Sequences are not replicated. For more information, see Handling sequences in active-active replication.
- DDL and large objects are not replicated.
- Secondary unique indexes can cause data divergence.
- Collation needs to be identical on all node in the group.
- Load balancing across nodes is an anti-pattern.
- Large transactions can cause replication lag.

Initializing the pgactive extension capability

To initialize the `pgactive` extension capability on your RDS for PostgreSQL DB instance, set the value of the `rds.enable_pgactive` parameter to `1` and then create the extension in the database. Doing so automatically turns on the parameters `rds.logical_replication` and `track_commit_timestamp` and sets the value of `wal_level` to `logical`.

You must have permissions as the `rds_superuser` role to perform these tasks.

You can use the AWS Management Console or the AWS CLI to create the required RDS for PostgreSQL DB instances. The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS.

Console

To initialize the pgactive extension capability

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. In the instance details, find the **DB instance parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.

5. Find the `rds.enable_pgactive` parameter, and set it to 1 to initialize the `pgactive` capability.
6. Choose **Save changes**.
7. In the navigation pane of the Amazon RDS console, choose **Databases**.
8. Select your RDS for PostgreSQL DB instance, and then choose **Reboot** from the **Actions** menu.
9. Confirm the DB instance reboot so that your changes take effect.
10. When the DB instance is available, you can use `psql` or any other PostgreSQL client to connect to the RDS for PostgreSQL DB instance.

    The following example assumes that your RDS for PostgreSQL DB instance has a default database named *`postgres`*.

    ```
    psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --
    username=postgres --password=PASSWORD --dbname=postgres
    ```

11. To verify that pgactive is initialized, run the following command.

    ```
    postgres=>SELECT setting ~ 'pgactive'
    FROM pg_catalog.pg_settings
    WHERE name = 'shared_preload_libraries';
    ```

    If `pgactive` is in `shared_preload_libraries`, the preceding command will return the following:

    ```
    ?column?
    ----------
     t
    ```

AWS CLI

To initialize the pgactive extension capability

To initialize the `pgactive` using the AWS CLI, call the modify-db-parameter-group operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to set `rds.enable_pgactive` to 1 to initialize the `pgactive` capability for the RDS for PostgreSQL DB instance.

```
postgres=>aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=rds.enable_pgactive,ParameterValue=1,ApplyMethod=pending-reboot" \
   --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the `pgactive` library is initialized.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=master user --password=PASSWORD --dbname=postgres
```

4. To verify that pgactive is initialized, run the following command.

```
postgres=>SELECT setting ~ 'pgactive'
FROM pg_catalog.pg_settings
WHERE name = 'shared_preload_libraries';
```

If `pgactive` is in `shared_preload_libraries`, the preceding command will return the following:

```
?column?
----------
 t
```

Setting up active-active replication for RDS for PostgreSQL DB instances

The following procedure shows you how to start active-active replication between two RDS for PostgreSQL DB instances where `pgactive` is available. To run the multi-region high availability example, you need to deploy Amazon RDS for PostgreSQL instances in two different regions and set up VPC Peering. For more information, see VPC peering.

> **Note**
>
> Sending traffic between multiple regions may incur additional costs.

These steps assume that the RDS for PostgreSQL DB instance has been enabled with the `pgactive` extension. For more information, see Initializing the pgactive extension capability.

To configure the first RDS for PostgreSQL DB instance with the `pgactive` extension

The following example illustrates how the `pgactive` group is created, along with other steps required to create the `pgactive` extension on the RDS for PostgreSQL DB instance.

1. Use `psql` or another client tool to connect to your first RDS for PostgreSQL DB instance.

```
psql --host=firstinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password=PASSWORD --dbname=postgres
```

2. Create a database on the RDS for PostgreSQL instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. Create and populate a sample table using the following SQL statements:

   a. Create an example table using the following SQL statement.

```
app=> CREATE SCHEMA inventory;
CREATE TABLE inventory.products (
id int PRIMARY KEY, product_name text NOT NULL,
created_at timestamptz NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

   b. Populate the table with some sample data by using the following SQL statement.

```
app=> INSERT INTO inventory.products (id, product_name)
VALUES (1, 'soap'), (2, 'shampoo'), (3, 'conditioner');
```

   c. Verify that data exists in the table by using the following SQL statement.

```
 app=>SELECT count(*) FROM inventory.products;

 count
-------
 3
```

5. Create `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

6. To securely create and initialize the pgactive group use the following commands:

```
app=>
-- connection info for endpoint1
CREATE SERVER pgactive_server_endpoint1
    FOREIGN DATA WRAPPER pgactive_fdw
    OPTIONS (host '<endpoint1>', dbname 'app');
CREATE USER MAPPING FOR postgres
    SERVER pgactive_server_endpoint1
    OPTIONS (user 'postgres', password '<password>');
      -- connection info for endpoint2
CREATE SERVER pgactive_server_endpoint2
    FOREIGN DATA WRAPPER pgactive_fdw
    OPTIONS (host '<endpoint2>', dbname 'app');
CREATE USER MAPPING FOR postgres
    SERVER pgactive_server_endpoint2
    OPTIONS (user 'postgres', password '<password>');
```

Now you can initialize the replication group and add this first instance:

```
SELECT pgactive.pgactive_create_group(
    node_name := 'endpoint1-app',
    node_dsn := 'user_mapping=postgres
 pgactive_foreign_server=pgactive_server_endpoint1'

);
```

Use the following commands as an alternate but less secure method to create and initialize the pgactive group:

```
app=> SELECT pgactive.pgactive_create_group(
    node_name := 'node1-app',
    node_dsn := 'dbname=app host=firstinstance.111122223333.aws-
region.rds.amazonaws.com user=postgres password=PASSWORD');
```

node1-app is the name that you assign to uniquely identify a node in the `pgactive` group.

> **Note**
>
> To perform this step successfully on a DB instance that is publicly accessible, you must turn on the `rds.custom_dns_resolution` parameter by setting it to 1.

7. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
-----------------------------
(1 row)
```

To configure the second RDS for PostgreSQL instance and join it to the `pgactive` group

The following example illustrates how you can join an RDS for PostgreSQL DB instance to the `pgactive` group, along with other steps that are required to create the `pgactive` extension on the DB instance.

These steps assume that another RDS for PostgreSQL DB instances has been set up with the `pgactive` extension. For more information, see Initializing the pgactive extension capability.

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```
psql --host=secondinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password=PASSWORD --dbname=postgres
```

2. Create a database on the second RDS for PostgreSQL DB instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. Create the `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

5. Join the RDS for PostgreSQL second DB instance to the `pgactive` group in a more secure way using the following commands:

```

-- connection info for endpoint1
CREATE SERVER pgactive_server_endpoint1
    FOREIGN DATA WRAPPER pgactive_fdw
    OPTIONS (host '<endpoint1>', dbname 'app');
CREATE USER MAPPING FOR postgres
    SERVER pgactive_server_endpoint1
    OPTIONS (user 'postgres', password '<password>');

-- connection info for endpoint2
CREATE SERVER pgactive_server_endpoint2
    FOREIGN DATA WRAPPER pgactive_fdw
    OPTIONS (host '<endpoint2>', dbname 'app');
CREATE USER MAPPING FOR postgres
    SERVER pgactive_server_endpoint2
    OPTIONS (user 'postgres', password '<password>');

```

```

SELECT pgactive.pgactive_join_group(
    node_name := 'endpoint2-app',
```

```
    node_dsn := 'user_mapping=postgres
 pgactive_foreign_server=pgactive_server_endpoint2',
    join_using_dsn := 'user_mapping=postgres
 pgactive_foreign_server=pgactive_server_endpoint1'
);
```

Use the following commands as an alternate but less secure method to join the RDS for PostgreSQL second DB instance to the `pgactive` group

```
app=> SELECT pgactive.pgactive_join_group(
node_name := 'node2-app',
node_dsn := 'dbname=app host=secondinstance.111122223333.aws-
region.rds.amazonaws.com user=postgres password=PASSWORD',
join_using_dsn := 'dbname=app host=firstinstance.111122223333.aws-
region.rds.amazonaws.com user=postgres password=PASSWORD');
```

node2-app is the name that you assign to uniquely identify a node in the `pgactive` group.

6. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
-----------------------------
(1 row)
```

If the first RDS for PostgreSQL database is relatively large, you can see `pgactive.pgactive_wait_for_node_ready()` emitting the progress report of the restore operation. The output looks similar to the following:

```
NOTICE:  restoring database 'app', 6% of 7483 MB complete
NOTICE:  restoring database 'app', 42% of 7483 MB complete
NOTICE:  restoring database 'app', 77% of 7483 MB complete
NOTICE:  restoring database 'app', 98% of 7483 MB complete
NOTICE:  successfully restored database 'app' from node node1-app in
 00:04:12.274956
 pgactive_wait_for_node_ready
```

```
------------------------------
(1 row)
```

From this point forward, `pgactive` synchronizes the data between the two DB instances.

7. You can use the following command to verify if the database of the second DB instance has the data:

```
app=> SELECT count(*) FROM inventory.products;
```

If the data is successfully synchronized, you'll see the following output:

```
 count
-------
 3
```

8. Run the following command to insert new values:

```
app=> INSERT INTO inventory.products (id, product_name) VALUES (4, 'lotion');
```

9. Connect to the database of the first DB instance and run the following query:

```
app=> SELECT count(*) FROM inventory.products;
```

If the active-active replication is initialized, the output is similar to the following:

```
count
-------
 4
```

To detach and remove a DB instance from the `pgactive` group

You can detach and remove a DB instance from the `pgactive` group using these steps:

1. You can detach the second DB instance from the first DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_detach_nodes(ARRAY['node2-app']);
```

2. Remove the pgactive extension from the second DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_remove();
```

   To forcefully remove the extension:

```
app=> SELECT * FROM pgactive.pgactive_remove(true);
```

3. Drop the extension using the following command:

```
app=> DROP EXTENSION pgactive;
```

Measuring replication lag among pgactive members

You can use the following query to view the replication lag among the pgactive members. Run this query on every pgactive node to get the full picture.

```
app=> SELECT * FROM pgactive.pgactive_get_replication_lag_info();
#-[ RECORD 1 ]--------+-----------------------------------------
#node_name            | node2-app
#node_sysid           | 7481018224801653637

#flush_lsn            | 0/214EF68
#replay_lsn           | 0/214EF68
```

Monitor the following diagnostics at a minimum:

active

Set up alerts when active is false, which indicates that the slot isn't currently in use (the subscriber instance has disconnected from the publisher).

pending_wal_decoding

In PostgreSQL's logical replication, WAL files are stored in binary format. The publisher must decode these WAL changes and convert them into logical changes (such as insert, update, or delete operations).

The metric pending_wal_decoding shows the number of WAL files waiting to be decoded on the publisher side.

This number can increase due to these factors:

- When the subscriber isn't connected, active status will be false and pending_wal_decoding will increase
- The slot is active, but the publisher can't keep up with the volume of WAL changes

pending_wal_to_apply

The metric pending_wal_apply indicates the number of WAL files waiting to be applied on the subscriber side.

Several factors can prevent the subscriber from applying changes and potentially cause a disk full scenario:

- Schema differences - for example, when you have changes in the WAL stream for a table named sample, but that table doesn't exist on the subscriber side
- Values in the primary key columns were updated
- Secondary unique indexes can cause data divergence

Configuring parameter settings for the pgactive extension

You can use the following query to view all the parameters associated with `pgactive` extension.

```
app=> SELECT * FROM pg_settings WHERE name LIKE 'pgactive.%';
```

You can configure the `pgactive` extension using various parameters. These parameters can be set through either the AWS Management Console or the AWS CLI interface.

Main pgactive extension parameters

The following table provides a reference for the main parameters of the `pgactive` extension:

Parameter	Unit	Default	Description
`pgactive.conflict_logging_include_tuples`	`boolean`	–	Logs complete tuple information for the `pgactive` extension. **Note** A server restart is required for changes to take effect.
`pgactive.log_conflicts_to_table`	`boolean`	–	Determines whether the `pgactive` extension logs the detected conflicts to the `pgactive.`

Parameter	Unit	Default	Description
			`pgactive_conflict_history` table. For more information, see Conflict logging for details. **Note** A server restart is required for changes to take effect.

Parameter	Unit	Default	Description
pgactive.log_conflicts_to_logfile	boolean	–	Determines whether the pgactive extension logs the detected conflicts to the PostgreSQL log file. For more information, see Conflict logging for details. **Note** A server restart is required for changes to take effect.

Parameter	Unit	Default	Description
pgactive.synchronous_commit	boolean	off	Determines the commit behavior for pgactive apply workers. When disabled(off), apply workers perform asynchronous commits, which improves PostgreSQL throughput during apply operations but delays replay confirmations to the upstream. Setting it to off is always safe and won't cause transaction loss or skipping. This setting only affects the timing of disk flushes on the downstream node and when confirmations are sent upstream. The system delays sending replay flush

Parameter	Unit	Default	Description
			confirmations until commits are flushed to disk through unrelated operations like checkpoints or periodic work. However, if the upstream has the downstream listed in `synchronous_standby_names`, setting it to `off` causes synchronous commits on the upstream to take longer to report success to the client. In this case, set the parameter to on. **Note** Even when this parameter is set to on with nodes

Parameter	Unit	Default	Description
			listed in `synchronous_standby_names`, replication conflicts can still occur in active-active configurations. This is because the system lacks inter-node locking and global snapshot management, allowing concurrent transactions on different nodes to modify the same

Parameter	Unit	Default	Description
			tuple. Additionally, transactions only begin replication after committing on the upstream node. Enabling synchronous commit doesn't transform the pgactive extension into an always-consistent system.

Parameter	Unit	Default	Description
pgactive.temp_dump_directory	string	–	Defines the temporary storage path required for database cloning operations during initial setup. This directory must be writable by the postgres user and have sufficient storage space to contain a complete database dump. The system uses this location only during initial database setup with logical copy operations. This parameter isn't used by the pgactive_init_copy command.

Parameter	Unit	Default	Description
pgactive.max_ddl_lock_delay	milliseconds	-1	Specifies the maximum wait time for DDL lock before forcibly aborting concurrent write transactions. The default value is -1, which adopts the value set in max_standby_streaming_delay . This parameter accepts time units. For example, you can set it to 10s for 10 seconds. During this wait period, the system attempts to acquire DDL locks while waiting for ongoing write transactions to either commit or roll back. For more information, see the DDL Locking.

Parameter	Unit	Default	Description
pgactive.ddl_lock_timeout	milliseconds	-1	Specifies how long a DDL lock attempt waits to obtain the lock. The default value is -1, which uses the value specified in lock_timeout. You can set this parameter using time units such as 10s for 10 seconds. This timer only controls the waiting period for obtaining a DDL lock. Once the system obtains the lock and begins the DDL operation, the timer stops. This parameter doesn't limit the total duration a DDL lock can be held or the overall DDL operation time. To control the total duration of the operation,

Parameter	Unit	Default	Description
			use `statement_timeout` instead. For more information, see DDL Locking.

Parameter	Unit	Default	Description
pgactive.debug_trace_ddl_locks_level	boolean	–	Overrides the default debug log level for DDL locking operations in the pgactive extension. When configured, this setting causes DDL lock-related messages to be emitted at the LOG debug level instead of their default level. Use this parameter to monitor DDL locking activity without enabling the verbose DEBUG1 or DEBUG2 log levels across your entire server. Available log levels, in increasing order of verbosity: • **none** - DDL lock messages appear only at

Parameter	Unit	Default	Description
			DEBUG1 and lower server log levels. • **statement** - Adds LOG output for DDL lock acquisition attempts. • **acquire_release** - Records lock acquisition, release, declination events, and peer node applications of remote DDL locks. • **peers** - Provides additional details about DDL lock negotiations between peer nodes. • **debug** - Logs all DDL lock-related activities at LOG level.

Parameter	Unit	Default	Description
			For more information about monitoring options, see Monitoring global DDL locks. **Note** Changes to this setting take effect when you reload the configuration. You don't need to restart the server.

Additional pgactive extension parameters

The following table presents less frequently used and internal configuration options available for the `pgactive` extension.

Parameter	Unit	Default	Description
pgactive.debug_apply_delay	integer	–	Sets an apply delay (in milliseconds) for configured connections that don't have an explicit apply delay in their pgactive.pgactive_connections entry. This delay is set during node creation or join time, and pgactive won't replay a transaction on peer nodes until at least the specified number of milliseconds have elapsed since it was committed. Primarily used to simulate high-latency networks in testing environme

Parameter	Unit	Default	Description
			nts to make it easier to create conflicts. For example, with a 500ms delay on nodes A and B, you have at least 500ms to perform a conflicting insert on node B after inserting a value on node A. **Note** Requires a server reload or restart of apply workers to take effect.

Parameter	Unit	Default	Description
pgactive.connectability_check_duration	integer	–	Specifies the duration (in seconds) that a database worker attempts to establish connections during failed attempts. The worker makes one connection attempt per second until it succeeds or reaches this timeout value. This setting is useful when the database engine starts before the worker is ready to establish connections.

Parameter	Unit	Default	Description
pgactive.skip_ddl_replication	boolean	on	Controls how DDL changes are replicated or handled in Amazon RDS with pgactive enabled. When set to on, the node processes DDL changes like a non-pgcctive node. The following requirements apply when working with this parameter: • New nodes can't join a pgactive group if their skip_ddl_replication value differs from the upstream node. • Existing nodes can't start pgactive workers if their parameter

Parameter	Unit	Default	Description
			value doesn't match the upstream node. • All pgactive members must use the same parameter value. You can modify this parameter in two ways with super user privileges: globally, locally (session level). **Note** Changing this parameter incorrectly can break your replication setups.

Parameter	Unit	Default	Description
pgactive.do_not_replicate	boolean	–	This parameter is for internal use only. When you set this parameter in a transaction, the changes are not replicated to other nodes in your DB cluster. **Note** Changing this parameter incorrectly can break your replication setups.

Parameter	Unit	Default	Description
pgactive.discard_mismatched_row_attributes	boolean	–	This parameter is intended for specialist use only. We recommend using this parameter only when troubleshooting specific replication issues. Use this parameter when: • The incoming replication stream contains rows with more columns than your local table. • These remote rows contain non-null values. This setting overrides the following error message and allows data divergence to arise to

Parameter	Unit	Default	Description
			let replicati on continue: `cannot right-pad mismatched attributes; attno %u is missing in local table and remote row has non-null, non-dropp ed value for this attribute` **Note** Changing this parameter incorrect ly can break your replicati on setups.

Parameter	Unit	Default	Description
pgactive.debug_trace_replay	boolean	–	When set to on, it emits a log message for each remote action that downstream apply workers process. The logs include: • Change type • Affected table name • Number of changes since transaction start • Transaction commit LSN • Commit timestamp • Upstream node identifier • Forwarding node identifier (if applicable) The logs also capture queued DDL commands and table drops. para>

Parameter	Unit	Default	Description
			By default, the logs do not include row field contents. To include row values in the logs, you must recompile with the following flags enabled: • VERBOSE_INSERT • VERBOSE_UPDATE • VERBOSE_DELETE **Note** Enabling this logging setting can impact performance. We recommend enabling it only when needed for

Parameter	Unit	Default	Description
			troubleshooting. Changes to this setting take effect when you reload the configuration. You don't need to restart the server.

Parameter	Unit	Default	Description
pgactive.extra_apply_connection_options		–	You can configure connection parameters for all peer node connections with pgactive nodes. These parameters control settings such as keepalives and SSL modes. By default, pgactive uses the following connection parameters: • connect_timeout=30 • keepalives=1 • keepalives_idle=20 • keepalives_interval=20 • keepalives_count=5 To override the default parameters, use the following similar command:

Parameter	Unit	Default	Description
			`pgactive.extra_apply_connection_options = 'keepalives=0'` Individual node connection strings take precedence over both these settings and pgactive's built-in connection options. For more information about connection string formats, see libpq connection strings. We recommend keeping the default keepalive settings enabled. Only disable keepalives if you experience issues with

Parameter	Unit	Default	Description
			large transactions completing over unreliable networks. **Note** We recommend keeping the default keepalive settings enabled. Only disable keepalives if you experience issues with large transactions completing over unreliable networks. Changes to this setting take effect

Parameter	Unit	Default	Description
			when you reload the configuration. You don't need to restart the server.
`pgactive.init_node_parallel_jobs (int)`		–	Specifies the number of parallel jobs that `pg_dump` and `pg_restore` can use during logical node joins with the `pgactive.pgactive_join_group` function. Changes to this setting take effect when you reload the configuration. You don't need to restart the server.

Parameter	Unit	Default	Description
pgactive.max_nodes	int	4	Specifies the maximum number of nodes allowed in a pgactive extension group. The default value is 4 nodes. You must consider the following when setting the value of this parameter: • All nodes in a pgactive extension group must use the same parameter value. • A new node can't join if its parameter value differs from the upstream node. • Existing nodes can't start pgactive extension workers

Parameter	Unit	Default	Description
			if their parameter value differs from the upstream node. • Larger groups require additional monitoring and maintenance effort, so the value of this parameter wisely. You can set this parameter in two ways: in the configuration file, using the `ALTER SYSTEM SET` command Default value for this parameter is 4, meaning, there can be maximum of 4 nodes allowed in the `pgactive` extension group at any point of time.

Parameter	Unit	Default	Description
			Note The change takes effect after you restart the server.
`pgactive.permit_node_identifier_getter_function_creation`	`boolean`	–	This parameter is intended for internal use only. When enabled, `pgactive` extension allows creation of pgactive node identifier getter function.

Understanding active-active conflicts

When you use pgactive in active-active mode, writing to the same tables from multiple nodes can create data conflicts. While some clustering systems use distributed locks to prevent concurrent access, pgactive takes an optimistic approach that's better suited for geographically distributed applications.

Some database clustering systems prevent concurrent data access by using distributed locks. While this approach works when servers are in close proximity, it doesn't support geographically distributed applications because it requires extremely low latency for good performance. Instead

of using distributed locks (a pessimistic approach), the pgactive extension uses an optimistic approach. This means it:

- Helps you avoid conflicts when possible.
- Allows certain types of conflicts to occur.
- Provides conflict resolution when conflicts happen.

This approach gives you more flexibility when building distributed applications.

How conflicts happen

Inter-node conflicts arise from sequences of events that could not happen if all the involved transactions occurred concurrently on the same node. Because the nodes only exchange changes after transactions commit, each transaction is individually valid on the node it committed on but would not be valid if run on another node that has done other work in the meantime. Since pgactive apply essentially replays the transaction on the other nodes, the replay operation can fail if there is a conflict between a transaction being applied and a transaction that was committed on the receiving node.

The reason most conflicts can't happen when all transactions run on a single node is that PostgreSQL has inter-transaction communication mechanisms to prevent it, including:

- UNIQUE indexes
- SEQUENCEs
- Row and relation locking
- SERIALIZABLE dependency tracking

All of these mechanisms are ways to communicate between transactions to prevent undesirable concurrency issues

pgactive achieves low latency and handles network partitions well because it doesn't use a distributed transaction manager or lock manager. However, this means transactions on different nodes run in complete isolation from each other. While isolation typically improves database consistency, in this case, you need to reduce isolation to prevent conflicts.

Types of conflicts

Conflicts that can occur include:

Topics

- PRIMARY KEY or UNIQUE conflicts
- INSERT/INSERT conflicts
- INSERTs that violate multiple UNIQUE constraints
- UPDATE/UPDATE conflicts
- UPDATE conflicts on the PRIMARY KEY
- UPDATEs that violate multiple UNIQUE constraints
- UPDATE/DELETE conflicts
- INSERT/UPDATE conflicts
- DELETE/DELETE conflicts
- Foreign Key Constraint conflicts
- Exclusion constraint conflicts
- Global data conflicts
- Lock conflicts and deadlock aborts
- Divergent conflicts

PRIMARY KEY or UNIQUE conflicts

Row conflicts occur when multiple operations attempt to modify the same row key in ways not possible on a single node. These conflicts represent the most common type of data conflicts.

pgactive resolves detected conflicts through last-update-wins handling or your custom conflict handler.

Row conflicts include:

- INSERT vs INSERT
- INSERT vs UPDATE
- UPDATE vs DELETE
- INSERT vs DELETE
- DELETE vs DELETE
- INSERT vs DELETE

INSERT/INSERT conflicts

This most common conflict occurs when INSERTs on two different nodes create a tuple with the same PRIMARY KEY values (or identical UNIQUE constraint values when no PRIMARY KEY exists).

pgactivelink resolves INSERT conflicts by using the timestamp from the originating host to keep the most recent tuple. You can override this default behavior with your custom conflict handler. While this process requires no special administrator action, be aware that pgactivelink discards one of the INSERT operations across all nodes. No automatic data merging occurs unless your custom handler implements it.

The pgactivelink can only resolve conflicts involving a single constraint violation. If an INSERT violates multiple UNIQUE constraints, you must implement additional conflict resolution strategies.

INSERTs that violate multiple UNIQUE constraints

An INSERT/INSERT conflict can violate multiple UNIQUE constraints, including the PRIMARY KEY. pgactivelink can only handle conflicts that involve a single UNIQUE constraint. When conflicts violate multiple UNIQUE constraints, the apply worker fails and returns the following error:

```
multiple unique constraints violated by remotely INSERTed tuple.
```

In older versions, this situation generated a 'diverging uniqueness conflict' error instead.

To resolve these conflicts, you must take manual action. Either DELETE the conflicting local tuples or UPDATE them to remove conflicts with the new remote tuple. Be aware that you might need to address multiple conflicting tuples. Currently, pgactivelink provides no built-in functionality to ignore, discard, or merge tuples that violate multiple unique constraints.

> **Note**
>
> For more information, see UPDATEs that violate multiple UNIQUE constraints.

UPDATE/UPDATE conflicts

This conflict occurs when two nodes concurrently modify the same tuple without changing its PRIMARY KEY. pgactivelink resolves these conflicts using last-update-wins logic or your custom conflict handler, if defined. A PRIMARY KEY is essential for tuple matching and conflict resolution.

For tables without a PRIMARY KEY, pgactivelink rejects UPDATE operations with the following error:

```
Cannot run UPDATE or DELETE on table (tablename) because it does not have a primary key.
```

UPDATE conflicts on the PRIMARY KEY

pgactive has limitations when handling PRIMARY KEY updates. While you can perform UPDATE operation on a PRIMARY KEY, pgactive can't automatically resolve conflicts using last-update-wins logic for these operations. You must ensure that your PRIMARY KEY updates don't conflict with existing values. If conflicts occur during PRIMARY KEY updates, they become divergent conflicts that require your manual intervention. For more information about handling these situations, see Divergent conflicts.

UPDATEs that violate multiple UNIQUE constraints

pgactivelink cannot apply last-update-wins conflict resolution when an incoming UPDATE violates multiple UNIQUE constraints or PRIMARY KEY values. This behavior is similar to INSERT operations with multiple constraint violations. These situations create divergent conflicts that require your manual intervention. For more information, see Divergent conflicts.

UPDATE/DELETE conflicts

This conflicts occur when one node UPDATEs a row while another node simultaneously DELETEs it. In this case a UPDATE/DELETE conflict occurs on replay. The resolution is to discard any UPDATE that arrives after a DELETE, unless your custom conflict handler specifies otherwise.

pgactivelink requires a PRIMARY KEY to match tuples and resolve conflicts. For tables without a PRIMARY KEY, it rejects DELETE operations with the following error:

```
Cannot run UPDATE or DELETE on table (tablename) because it does not have a primary key.
```

> **Note**
>
> pgactivelink cannot distinguish between UPDATE/DELETE and INSERT/UPDATE conflicts. In both cases, an UPDATE affects a nonexistent row. Due to asynchronous replication and lack of replay ordering between nodes, pgactivelink can't determine if the UPDATE is for a new

row (INSERT not yet received) or a deleted row. In both scenarios, pgactivelink discards the UPDATE.

INSERT/UPDATE conflicts

This conflict can occur in multi-node environments. It happens when one node INSERTs a row, a second node UPDATEs it, and a third node receives the UPDATE before the original INSERT. By default, pgactivelink resolves these conflicts by discarding the UPDATE, unless your custom conflict trigger specifies otherwise. Be aware that this resolution method can result in data inconsistencies across nodes. For more information about similar scenarios and their handling, see UPDATE/DELETE conflicts.

DELETE/DELETE conflicts

This conflict occurs when two different nodes concurrently delete the same tuple. pgactivelink considers these conflicts harmless because both DELETE operations have the same end result. In this scenario, pgactivelink safely ignores one of the DELETE operations without affecting data consistency.

Foreign Key Constraint conflicts

FOREIGN KEY constraints can cause conflicts when applying remote transactions to existing local data. These conflicts typically occur when transactions are applied in a different sequence than their logical order on the originating nodes.

By default, pgactive applies changes with session_replication_role as `replica`, which bypasses foreign key checks during replication. In active-active configurations, this can lead to foreign key violations. Most violations are temporary and resolve once replication catches up. However, dangling foreign keys can occur because pgactive doesn't support cross-node row locking.

This behavior is inherent to partition-tolerant asynchronous active-active systems. For example, node A might insert a new child row while node B simultaneously deletes its parent row. The system can't prevent this type of concurrent modification across nodes.

To minimize foreign key conflicts, we recommend the following:

- Limit foreign key relationships to closely related entities.
- Modify related entities from a single node when possible.
- Choose entities that rarely require modification.

- Implement application-level concurrency control for modifications.

Exclusion constraint conflicts

pgactive link doesn't support exclusion constraints and restricts their creation.

> **Note**
>
> If you convert an existing standalone database to a pgactivelink database, manually drop all exclusion constraints.

In a distributed asynchronous system, it's not possible to guarantee that no set of rows violates the constraint. This is because all transactions on different nodes are fully isolated. Exclusion constraints can lead to replay deadlocks, where replay can't progress from any node to another due to exclusion constraint violations.

If you force pgactive Link to create an exclusion constraint, or if you don't drop existing ones when converting a standalone database to pgactive Link, replication is likely to break. To restore replication progress, remove or alter the local tuples that conflict with an incoming remote tuple so that the remote transaction can be applied.

Global data conflicts

When using pgactivelink, conflicts can occur when nodes have different global PostgreSQL system-wide data, such as roles. These conflicts can cause operations—primarily DDL—to succeed and commit on one node but fail to apply to other nodes.

If a user exists on one node but not another, replication issues can occur:

- Node1 has a user named `fred`, but this user doesn't exist on Node2
- When `fred` creates a table on Node1, the table is replicated with `fred` as the owner
- When this DDL command is applied to Node2, it fails because user `fred` doesn't exist
- This failure generates an ERROR in the PostgreSQL logs on Node2 and increments the `pgactive.pgactive_stats.nr_rollbacks` counter

Resolution: Create the user `fred` on Node2. The user doesn't need identical permissions but must exist on both nodes.

If a table exists on one node but not another, data modification operations will fail:

- Node1 has a table named `foo` that doesn't exist on Node2
- Any DML operations on the `foo` table on Node1 will fail when replicated to Node2

Resolution: Create the table `foo` on Node2 with the same structure.

> **Note**
>
> pgactivelink doesn't currently replicate CREATE USER commands or DDL operations. DDL replication is planned for a future release.

Lock conflicts and deadlock aborts

Because pgactive apply processes operate like normal user sessions, they follow standard row and table locking rules. This can result in pgactivelink apply processes waiting on locks held by user transactions or by other apply processes.

The following types of locks can affect apply processes:

- Explicit table-level locking (LOCK TABLE ...) by user sessions
- Explicit row-level locking (SELECT ... FOR UPDATE/FOR SHARE) by user sessions
- Locking from foreign keys
- Implicit locking due to row UPDATEs, INSERTs, or DELETEs, either from local activity or apply from other servers

Deadlocks can occur between:

- A pgactivelink apply process and a user transaction
- Two apply processes

When deadlocks occur, PostgreSQL's deadlock detector terminates one of the problem transactions. If the pgactivelink apply worker's process is terminated, it automatically retries and typically succeeds.

Note

- These issues are temporary and generally don't require administrator intervention. If an apply process is blocked for an extended period by a lock on an idle user session, you can terminate the user session to resume replication. This situation is similar to when a user holds a long lock that affects another user session.
- To identify locking-related replay delays, enable the `log_lock_waits` facility in PostgreSQL.

Divergent conflicts

Divergent conflicts occur when data that should be identical across nodes differs unexpectedly. While these conflicts shouldn't happen, not all can be reliably prevented in the current implementation.

Note

Modifying a row's PRIMARY KEY can cause divergent conflicts if another node changes the same row's key before all nodes process the change. Avoid changing primary keys, or restrict changes to one designated node. For more information, see the section called "UPDATE conflicts on the PRIMARY KEY".

Divergent conflicts involving row data typically require administrator intervention. To resolve these conflicts, you must manually adjust data on one node to match another while temporarily disabling replication using `pgactive.pgactive_do_not_replicate`. These conflicts shouldn't occur when you use pgactive as documented and avoid settings or functions marked as unsafe.

As an administrator, you must manually resolve these conflicts. Depending on the conflict type, you'll need to use advanced options like `pgactive.pgactive_do_not_replicate`. Use these options with caution, as improper use can worsen the situation. Due to the variety of possible conflicts, we can't provide universal resolution instructions.

Divergent conflicts occur when data that should be identical across different nodes unexpectedly differs. While these conflicts shouldn't happen, not all such conflicts can be reliably prevented in the current implementation.

Avoiding or tolerating conflicts

In most cases, you can use appropriate application design to avoid conflicts or make your application tolerant of conflicts.

Conflicts only occur when simultaneous operations happen on multiple nodes. To avoid conflicts:

- Write to only one node
- Write to independent database subsets on each node (for example, assign each node a separate schema)

For INSERT vs INSERT conflicts, use Global sequences to prevent conflicts entirely.

If conflicts are not acceptable for your use case, consider implementing distributed locking at the application level. Often, the best approach is to design your application to work with pgactive's conflict resolution mechanisms rather than trying to prevent all conflicts. For more information, see the section called “Types of conflicts”.

Conflict logging

pgactivelink logs conflict incidents in the `pgactive.pgactive_conflict_history` table to help you diagnose and handle active-active conflicts. Conflict logging to this table only occurs when you set `pgactive.log_conflicts_to_table` to true. The pgactive extension also logs conflicts to the PostgreSQL log file when log_min_messages is set to `LOG` or `lower`, regardless of the `pgactive.log_conflicts_to_table` setting.

Use the conflict history table to:

- Measure how frequently your application creates conflicts
- Identify where conflicts occur
- Improve your application to reduce conflict rates
- Detect cases where conflict resolutions don't produce desired results
- Determine where you need user-defined conflict triggers or application design changes

For row conflicts, you can optionally log row values. This is controlled by the `pgactive.log_conflicts_to_table` setting. Note that:

- This is a global database-wide option

- There is no per-table control over row value logging
- No limits are applied to field numbers, array elements, or field lengths
- Enabling this feature may not be advisable if you work with multi-megabyte rows that might trigger conflicts

Since the conflict history table contains data from every table in the database (each with potentially different schemas), logged row values are stored as JSON fields. The JSON is created using `row_to_json`, similar to calling it directly from SQL. PostgreSQL doesn't provide a `json_to_row` function, so you'll need table-specific code (in PL/pgSQL, PL/Python, PL/Perl, etc.) to reconstruct a composite-typed tuple from the logged JSON.

> **Note**
>
> Support for user-defined conflicts is planned as a future extension feature.

Understanding the pgactive schema

The pgactive schema manages active-active replication in RDS for PostgreSQL. This schema contains tables that store replication configuration and status information.

> **Note**
>
> The pgactive schema is evolving and subject to change. Don't modify the data in these tables directly.

The key tables in the pgactive schema include:

- `pgactive_nodes` – Stores information about nodes in the active-active replication group.
- `pgactive_connections` – Stores connection details for each node.

pgactive_nodes

The pgactive_nodes stores information about the nodes participating in the active-active replication group.

Column	Type	Collation	Nullable	Default
node_sysid	text	–	not null	–
node_time line	oid	–	not null	–
node_dboid	oid	–	not null	–
node_status	char	–	not null	–
node_name	text	–	not null	–
node_dsn	text	–	not null	–
node_init _from_dsn	text	–	not null	–
node_read _only	boolean	–	–	false
node_seq_id	smallint	–	not null	–

node_sysid

Unique ID for a node, generated during `pgactive_create_group` or `pgactive_join_group`

node_status

Readiness of the node:

- **b** - beginning setup
- **i** - initializing
- **c** - catchup
- **o** - creating outbound slots
- **r** - ready
- **k** - killed

> **Note**
>
> This column doesn't indicate if a node is connected or disconnected.

node_name

User-provided unique node name.

node_dsn

Connection string or user mapping name

node_init_from_dsn

DSN from which this node was created.

pgactive_connection

The pgactive_connections stores connection details for each node.

Column	Type	Collation	Nullable	Default
conn_sysid	text	none	not null	none
conn_timeline	oid	none	not null	none
conn_dboid	oid	none	not null	none
conn_dsn	text	none	not null	none
conn_apply_delay	integer	none	none	none
conn_replication_sets	text	none	none	none

conn_sysid

Node identifier for the node this entry refers to.

conn_dsn

Same as pgactive.pgactive_nodes node_dsn.

conn_apply_delay

If set, milliseconds to wait before applying each transaction from the remote node. Mainly for debugging. If null, the global default applies.

Working with replication sets

Replication sets determine which tables to include or exclude from replication operations. By default, all tables are replicated unless you specify otherwise using the following functions:

- `pgactive_exclude_table_replication_set()` - Excludes specified tables from replication
- `pgactive_include_table_replication_set()` - Includes specified tables in replication

> **Note**
>
> Before you configure replication sets, consider the following:
>
> - You can configure table inclusion or exclusion only after running `pgactive_create_group()` but before `pgactive_join_group()`.
> - After you use `pgactive_exclude_table_replication_set()`, you can't use `pgactive_include_table_replication_set()`.
> - After you use `pgactive_include_table_replication_set()`, you can't use `pgactive_exclude_table_replication_set()`.

The system handles newly created tables differently based on your initial configuration:

- If you excluded tables: Any new tables created after `pgactive_join_group()` are automatically included in replication
- If you included tables: Any new tables created after `pgactive_join_group()` are automatically excluded from replication.

To view the replication set configuration for a specific table, use the `pgactive.pgactive_get_table_replication_sets()` function.

pgactive functions reference

Following, you can find a list of pgactive functions with their parameters, return values, and practical usage notes to help you effectively use them:

get_last_applied_xact_info

Retrieves the last applied transaction information for a specified node.

Arguments

- sysid (text) - timeline OID
- dboid (OID)

Return type

It records the following:

- last_applied_xact_id (OID)
- last_applied_xact_committs (timestamp with time zone)
- last_applied_xact_at (timestamp with time zone)

Usage notes

Use this function to retrieve the last applied transaction information for a specified node.

pgactive_apply_pause

Pauses the replication apply process.

Arguments

None

Return type

boolean

Usage notes

Call this function to pause the replication apply process.

pgactive_apply_resume

Resumes the replication apply process.

Arguments

None

Return type

void

Usage notes

Call this function to resume the replication apply process.

pgactive_is_apply_paused

Checks if replication apply is currently paused.

Arguments

None

Return type

boolean

Usage notes

Use this function to check if replication apply is currently paused.

pgactive_create_group

Creates a pgactive group by converting a standalone database into the initial node.

Arguments

- node_name (text)
- node_dsn (text)
- apply_delay integer DEFAULT NULL::integer - replication_sets text[] DEFAULT ARRAY['default'::text]

Return type

void

Usage notes

Creates a pgactive group by converting a standalone database into the initial node. The function performs sanity checks before transforming the node into a pgactive node. Before using this function, ensure that your PostgreSQL cluster has sufficient `max_worker_processes` available to support pgactive background workers.

pgactive_detach_nodes

Removes specified nodes from the pgactive group.

Arguments

- p_nodes (text[])

Return type

void

Usage notes

Use this function to remove specified nodes from the pgactive group.

pgactive_exclude_table_replication_set

Excludes a specific table from replication.

Arguments

- p_relation (regclass)

Return type

void

Usage notes

Use this function to exclude a specific table from replication.

pgactive_get_replication_lag_info

Retrieves detailed replication lag information, including node details, WAL status, and LSN values.

Arguments

None

Return type

SETOF record - node_name text - node_sysid text - application_name text - slot_name text - active boolean - active_pid integer - pending_wal_decoding bigint - Approximate size of WAL in bytes to be decoded on the sender node - pending_wal_to_apply bigint - Approximate size of WAL in bytes to be applied on receiving node - restart_lsn pg_lsn - confirmed_flush_lsn pg_lsn - sent_lsn pg_lsn - write_lsn pg_lsn - flush_lsn pg_lsn - replay_lsn pg_lsn

Usage notes

Call this function to retrieve replication lag information, including node details, WAL status, and LSN values.

pgactive_get_stats

Retrieves pgactive replication statistics.

Arguments

None

Return type

SETOF record - rep_node_id oid - rilocalid oid - riremoteid text - nr_commit bigint - nr_rollback bigint - nr_insert bigint - nr_insert_conflict bigint - nr_update bigint - nr_update_conflict bigint - nr_delete bigint - nr_delete_conflict bigint - nr_disconnect bigint

Usage notes

Use this function to retrieve pgactive replication statistics.

pgactive_get_table_replication_sets

Gets replication set configuration for a specific relation.

Arguments

- relation (regclass)

Return type

SETOF record

Usage notes

Call this function to get replication set configuration for a specific relation.

pgactive_include_table_replication_set

Includes a specific table in replication.

Arguments

- p_relation (regclass)

Return type

void

Usage notes

Use this function to include a specific table in replication.

pgactive_join_group

Adds a node to an existing pgactive group.

Arguments

- node_name (text)
- node_dsn (text)
- join_using_dsn (text)
- apply_delay (integer, optional)
- replication_sets (text[], default: ['default'])
- bypass_collation_check (boolean, default: false)
- bypass_node_identifier_creation (boolean, default: false)
- bypass_user_tables_check (boolean, default: false)

Return type

void

Usage notes

Call this function to add a node to an existing pgactive group. Ensure your PostgreSQL cluster has sufficient max_worker_processes for pgactive background workers.

pgactive_remove

Removes all pgactive components from the local node.

Arguments

- force (boolean, default: false)

Return type

void

Usage notes

Call this function to remove all pgactive components from the local node.

pgactive_snowflake_id_nextval

Generates node-specific unique sequence values.

Arguments

- regclass

Return type

bigint

Usage notes

Use this function to generate node-specific unique sequence values.

pgactive_update_node_conninfo

Updates connection information for a pgactive node.

Arguments

- node_name_to_update (text)
- node_dsn_to_update (text)

Return type

void

Usage notes

Use this function to update connection information for a pgactive node.

pgactive_wait_for_node_ready

Monitors the progress of group creation or joining operations.

Arguments

- timeout (integer, default: 0)
- progress_interval (integer, default: 60)

Return type

void

Usage notes

Call this function to monitor the progress of group creation or joining operations.

Handling conflicts in active-active replication

The `pgactive` extension works per database and not per cluster. Each DB instance that uses `pgactive` is an independent instance and can accept data changes from any source. When a change is sent to a DB instance, PostgreSQL commits it locally and then uses `pgactive` to replicate the change asynchronously to other DB instances. When two PostgreSQL DB instances update the same record at nearly the same time, a conflict can occur.

The `pgactive` extension provides mechanisms for conflict detection and automatic resolution. It tracks the time stamp when the transaction was committed on both the DB instances and automatically applies the change with the latest time stamp. The `pgactive` extension also logs when a conflict occurs in the `pgactive.pgactive_conflict_history` table.

The `pgactive.pgactive_conflict_history` will keep growing. You may want to define a purging policy. This can be done by deleting some records on a regular basis or defining a partitioning scheme for this relation (and later detach, drop, truncate partitions of interest). To implement the purging policy on a regular basis, one option is to use the `pg_cron` extension. See

the following information of an example for the pg_cron history table, Scheduling maintenance with the PostgreSQL pg_cron extension.

Handling sequences in active-active replication

An RDS for PostgreSQL DB instance with the pgactive extension uses two different sequence mechanisms to generate unique values.

Global Sequences

To use a global sequence, create a local sequence with the CREATE SEQUENCE statement. Use pgactive.pgactive_snowflake_id_nextval(seqname) instead of usingnextval(seqname) to get the next unique value of the sequence.

The following example creates a global sequence:

```
app=> CREATE TABLE gstest (
      id bigint primary key,
      parrot text
    );
```

```
app=>CREATE SEQUENCE gstest_id_seq OWNED BY gstest.id;
```

```
app=> ALTER TABLE gstest \
      ALTER COLUMN id SET DEFAULT \
      pgactive.pgactive_snowflake_id_nextval('gstest_id_seq');
```

Partitioned sequences

In split-step or partitioned sequences, a normal PostgreSQL sequence is used on each node. Each sequence increments by the same amount and starts at different offsets. For example, with step 100, the node 1 generates sequence as 101, 201, 301, and so on and the node 2 generates sequence as 102, 202, 302, and so on. This scheme works well even if the nodes can't communicate for extended periods, but requires that the designer specify a maximum number of nodes when establishing the schema and requires per-node configuration. Mistakes can easily lead to overlapping sequences.

It is relatively simple to configure this approach with pgactive by creating the desired sequence on a node as follows:

```
CREATE TABLE some_table (generated_value bigint primary key);
```

```
app=> CREATE SEQUENCE some_seq INCREMENT 100 OWNED BY some_table.generated_value;
```

```
app=> ALTER TABLE some_table ALTER COLUMN generated_value SET DEFAULT
 nextval('some_seq');
```

Then call `setval` on each node to give a different offset starting value as follows.

```
app=>
-- On node 1
SELECT setval('some_seq', 1);

-- On node 2
SELECT setval('some_seq', 2);
```

Reducing bloat in tables and indexes with the pg_repack extension

You can use the pg_repack extension to remove bloat from tables and indexes as an alternative to VACUUM FULL. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the pg_repack extension and the full table repack, see the GitHub project documentation.

Unlike VACUUM FULL, the pg_repack extension requires an exclusive lock (AccessExclusiveLock) only for a short period of time during the table rebuild operation in the following cases:

- Initial creation of log table – A log table is created to record changes that occur during initial copy of the data, as shown in the following example:

```
postgres=>\dt+ repack.log_*
List of relations
-[ RECORD 1 ]-+----------
Schema        | repack
Name          | log_16490
Type          | table
Owner         | postgres
Persistence   | permanent
Access method | heap
Size          | 65 MB
Description   |
```

- Final swap-and-drop phase.

For the rest of the rebuild operation, it only needs an ACCESS SHARE lock on the original table to copy rows from it to the new table. This helps the INSERT, UPDATE, and DELETE operations to proceed as usual.

Recommendations

The following recommendations apply when you remove bloat from the tables and indexes using the pg_repack extension:

- Perform repack during non-business hours or over a maintenance window to minimize its impact on performance of other database activities.
- Closely monitor blocking sessions during the rebuild activity and ensure that there is no activity on the original table that could potentially block pg_repack, specifically during the final swap-

and-drop phase when it needs an exclusive lock on the original table. For more information, see Identifying what is blocking a query.

When you see a blocking session, you can terminate it using the following command after careful consideration. This helps in the continuation of pg_repack to finish the rebuild:

```
SELECT pg_terminate_backend(pid);
```

- While applying the accrued changes from the pg_repack's log table on systems with a very high transaction rate, the apply process might not be able to keep up with the rate of changes. In such cases, pg_repack would not be able to complete the apply process. For more information, see Monitoring the new table during the repack. If indexes are severely bloated, an alternative solution is to perform an index only repack. This also helps VACUUM's index cleanup cycles to finish faster.

  You can skip the index cleanup phase using manual VACUUM from PostgreSQL version 12, and it is skipped automatically during emergency autovacuum from PostgreSQL version 14. This helps VACUUM complete faster without removing the index bloat and is only meant for emergency situations such as preventing wraparound VACUUM. For more information, see Avoiding bloat in indexes in the Amazon Aurora User Guide.

Pre-requisites

- The table must have PRIMARY KEY or not-null UNIQUE constraint.
- The extension version must be the same for both the client and the server.
- Ensure that the RDS instance has more FreeStorageSpace than the total size of the table without the bloat. As an example, consider the total size of the table including TOAST and indexes as 2TB, and total bloat in the table as 1TB. The required FreeStorageSpace must be more than value returned by the following calculation:

  2TB (Table size) - 1TB (Table bloat) = 1TB

  You can use the following query to check the total size of the table and use pgstattuple to derive bloat. For more information, see Diagnosing table and index bloat in the Amazon Aurora User Guide

```
SELECT pg_size_pretty(pg_total_relation_size('table_name')) AS total_table_size;
```

This space is reclaimed after the completion of the activity.

- Ensure that the RDS instance has enough compute and IO capacity to handle the repack operation. You might consider to scale up the instance class for optimal balance of performance.

To use the pg_repack extension

1. Install the pg_repack extension on your RDS for PostgreSQL DB instance by running the following command.

```
CREATE EXTENSION pg_repack;
```

2. Run the following commands to grant write access to temporary log tables created by pg_repack.

```
ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO
 PUBLIC;
```

3. Connect to the database using the pg_repack client utility. Use an account that has rds_superuser privileges. As an example, assume that rds_test role has rds_superuser privileges. The following syntax performs pg_repack for full tables including all the table indexes in the postgres database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
 -k postgres
```

> **Note**
>
> You must connect using the -k option. The -a option is not supported.

The response from the pg_repack client provides information on the tables on the DB instance that are repacked.

```
INFO: repacking table "pgbench_tellers"
INFO: repacking table "pgbench_accounts"
INFO: repacking table "pgbench_branches"
```

4. The following syntax repacks a single table `orders` including indexes in `postgres` database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
 --table orders -k postgres
```

The following syntax repacks only indexes for `orders` table in `postgres` database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
 --table orders --only-indexes -k postgres
```

Monitoring the new table during the repack

- The size of the database is increased by the total size of the table minus bloat, until swap-and-drop phase of repack. You can monitor the growth rate of the database size, calculate the speed of the repack, and roughly estimate the time it takes to complete initial data transfer.

  As an example, consider the total size of the table as 2TB, the size of the database as 4TB, and total bloat in the table as 1TB. The database total size value returned by the calculation at the end of the repack operation is the following:

  `2TB (Table size) + 4 TB (Database size) - 1TB (Table bloat) = 5TB`

  You can roughly estimate the speed of the repack operation by sampling the growth rate in bytes between two points in time. If the growth rate is 1GB per minute, it can take 1000 minutes or 16.6 hours approximately to complete the initial table build operation. In addition to the initial table build, `pg_repack` also needs to apply accrued changes. The time it takes depends on the rate of applying ongoing changes plus accrued changes.

  > **Note**
  >
  > You can use `pgstattuple` extension to calculate the bloat in the table. For more information, see pgstattuple .

- The number of rows in the `pg_repack's` log table, under the repack schema represents the volume of changes pending to be applied to the new table after the initial load.

You can check the pg_repack's log table in pg_stat_all_tables to monitor the changes applied to the new table. pg_stat_all_tables.n_live_tup indicates the number of records that are pending to be applied to the new table. For more information, see pg_stat_all_tables.

```
postgres=>SELECT relname,n_live_tup FROM pg_stat_all_tables WHERE schemaname =
 'repack' AND relname ILIKE '%log%';

-[ RECORD 1 ]---------
relname    | log_16490
n_live_tup | 2000000
```

- You can use the pg_stat_statements extension to find out the time taken by each step in the repack operation. This is helpful in preparation for applying the same repack operation in a production environment. You may adjust the LIMIT clause for extending the output further.

```
postgres=>SELECT
     SUBSTR(query, 1, 100) query,
     round((round(total_exec_time::numeric, 6) / 1000 / 60),4)
 total_exec_time_in_minutes
 FROM
     pg_stat_statements
 WHERE
     query ILIKE '%repack%'
 ORDER BY
     total_exec_time DESC LIMIT 5;

 query                                                                |
 total_exec_time_in_minutes
----------------------------------------------------------------------
+---------------------------
 CREATE UNIQUE INDEX index_16493 ON repack.table_16490 USING btree (a) |
        6.8627
 INSERT INTO repack.table_16490 SELECT a FROM ONLY public.t1           |
        6.4150
 SELECT repack.repack_apply($1, $2, $3, $4, $5, $6)                    |
        0.5395
 SELECT repack.repack_drop($1, $2)                                     |
        0.0004
 SELECT repack.repack_swap($1)                                         |
        0.0004
(5 rows)
```

Repacking is completely an out-of-place operation so the original table is not impacted and we do not anticipate any unexpected challenges that require recovery of the original table. If repack fails unexpectedly, you must inspect the cause of the error and resolve it.

After the issue is resolved, drop and recreate the `pg_repack` extension in the database where the table exists, and retry the `pg_repack` step. In addition, the availability of compute resources and concurrent accessibility of the table plays a crucial role in the timely completion of the repack operation.

Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that's callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use PLV8 and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see Creating a DB snapshot for a Single-AZ DB instance for Amazon RDS.

Important

Starting with PostgreSQL version 18, Amazon RDS for PostgreSQL will deprecate the `plcoffee` and `plls` PostgreSQL extensions. We recommend that you stop using CoffeeScript and LiveScript in your applications to ensure you have an upgrade path for future engine version upgrades.

To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

   ```
   SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
   ```

   If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

   ```
   name    | default_version | installed_version |                      comment
   --------+-----------------+-------------------
   +-------------------------------------------------
   plls    | 2.1.0           | 1.5.3             | PL/LiveScript (v8) trusted
    procedural language
   ```

```
plcoffee| 2.1.0           | 1.5.3             | PL/CoffeeScript (v8) trusted
 procedural language
plv8    | 2.1.0           | 1.5.3             | PL/JavaScript (v8) trusted
 procedural language
(3 rows)
```

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven't done so yet. You can continue with the following steps while the snapshot is being created.
3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

```
SELECT proname, nspname, lanname
FROM pg_proc p, pg_language l, pg_namespace n
WHERE p.prolang = l.oid
AND n.oid = p.pronamespace
AND lanname IN ('plv8','plcoffee','plls');
```

4. Use pg_dump to create a schema-only dump file. For example, create a file on your client machine in the `/tmp` directory.

```
./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp
```

This example uses the following options:

- `-Fc` – Custom format
- --schema-only – Dump only the commands necessary to create schema (functions in this case)
- `-U` – The RDS master user name
- `database` – The database name for our DB instance

For more information on pg_dump, see pg_dump in the PostgreSQL documentation.

5. Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the `grep` command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list
```

For more information on pg_restore, see pg_restore in the PostgreSQL documentation.

6. Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION plv8 CASCADE;
```

If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

7. Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

8. Create the functions using the dump file and "driver" file.

The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

9. Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

The PLV8 version 2 adds the following extra row to your result set:

```
    proname    |  nspname   | lanname
---------------+------------+----------
 plv8_version  | pg_catalog | plv8
```

Using PL/Rust to write PostgreSQL functions in the Rust language

PL/Rust is a trusted Rust language extension for PostgreSQL. You can use it for stored procedures, functions, and other procedural code that's callable from SQL. The PL/Rust language extension is available in the following versions:

- RDS for PostgreSQL 17.1 and higher 17 versions

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.2-R2 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see PL/Rust on GitHub.

Topics

- Setting up PL/Rust
- Creating functions with PL/Rust
- Using crates with PL/Rust
- PL/Rust limitations

Setting up PL/Rust

To install the plrust extension on your DB instance, add plrust to the `shared_preload_libraries` parameter in the DB parameter group associated with your DB instance. With the plrust extension installed, you can create functions.

To modify the `shared_preload_libraries` parameter, your DB instance must be associated with a custom parameter group. For information about creating a custom DB parameter group, see Parameter groups for Amazon RDS.

You can install the plrust extension using the AWS Management Console or the AWS CLI.

The following steps assume that your DB instance is associated with a custom DB parameter group.

Console

Install the plrust extension in the `shared_preload_libraries` parameter

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

3. Choose the name of your DB instance to display its details.
4. Open the **Configuration** tab for your DB instance and find the DB instance parameter group link.
5. Choose the link to open the custom parameters associated with your DB instance.
6. In the **Parameters** search field, type `shared_pre` to find the **`shared_preload_libraries`** parameter.
7. Choose **Edit parameters** to access the property values.
8. Add plrust to the list in the **Values** field. Use a comma to separate items in the list of values.
9. Reboot the DB instance so that your change to the `shared_preload_libraries` parameter takes effect. The initial reboot may require additional time to complete.
10. When the instance is available, verify that plrust has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
--------------------------
rdsutils,plrust
(1 row)
```

AWS CLI

Install the plrust extension in the shared_preload_libraries parameter

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Use the modify-db-parameter-group AWS CLI command to add plrust to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=plrust,ApplyMethod=pending-
reboot" \
```

```
    --region aws-region
```

2. Use the reboot-db-instance AWS CLI command to reboot the DB instance and initialize the plrust library. The initial reboot may require additional time to complete.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, you can verify that plrust has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
--------------------------
rdsutils,plrust
(1 row)
```

Creating functions with PL/Rust

PL/Rust will compile the function as a dynamic library, load it, and execute it.

The following Rust function filters multiples out of an array.

```
postgres=> CREATE LANGUAGE plrust;
CREATE EXTENSION
```

```
CREATE OR REPLACE FUNCTION filter_multiples(a BIGINT[], multiple BIGINT) RETURNS
 BIGINT[]
    IMMUTABLE STRICT
    LANGUAGE PLRUST AS
$$
    Ok(Some(a.into_iter().filter(|x| x.unwrap() % multiple != 0).collect()))
$$;

WITH gen_values AS (
SELECT ARRAY(SELECT * FROM generate_series(1,100)) as arr)
```

```
SELECT filter_multiples(arr, 3)
from gen_values;
```

Using crates with PL/Rust

In RDS for PostgreSQL versions 16.3-R2 and higher, 15.7-R2 and higher 15 versions, 14.12-R2 and higher 14 versions, and 13.15-R2 and higher 13 versions, PL/Rust supports additional crates:

- `url`
- `regex`
- `serde`
- `serde_json`

In RDS for PostgreSQL versions 15.5-R2 and higher, 14.10-R2 and higher 14 versions, and 13.13-R2 and higher 13 versions, PL/Rust supports two additional crates:

- `croaring-rs`
- `num-bigint`

Starting with Amazon RDS for PostgreSQL versions 15.4, 14.9, and 13.12, PL/Rust supports the following crates:

- `aes`
- `ctr`
- `rand`

Only the default features are supported for these crates. New RDS for PostgreSQL versions might contain updated versions of crates, and older versions of crates may no longer be supported.

Follow the best practices for performing a major version upgrade to test whether your PL/Rust functions are compatible with the new major version. For more information, see the blog Best practices for upgrading Amazon RDS to major and minor versions of PostgreSQL and Upgrading the PostgreSQL DB engine for Amazon RDS in the Amazon RDS User Guide.

Examples of using dependencies when creating a PL/Rust function are available at Use dependencies.

PL/Rust limitations

By default, database users can't use PL/Rust. To provide access to PL/Rust, connect as a user with rds_superuser privilege, and run the following command:

```
postgres=> GRANT USAGE ON LANGUAGE PLRUST TO user;
```

Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see PostGIS.net.

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

Topics

- Step 1: Create a user (role) to manage the PostGIS extension
- Step 2: Load the PostGIS extensions
- Step 3: Transfer ownership of the extension schemas
- Step 4: Transfer ownership of the PostGIS tables
- Step 5: Test the extensions
- Step 6: Upgrade the PostGIS extension
- PostGIS extension versions
- Upgrading PostGIS 2 to PostGIS 3

Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres
 --password
```

Create a separate role (user) to administer the PostGIS extension.

```
postgres=>  CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
CREATE ROLE
```

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```
postgres=> GRANT rds_superuser TO gis_admin;
GRANT
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres=> CREATE DATABASE lab_gis;
CREATE DATABASE
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
GRANT
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```
postgres=> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

Step 2: Load the PostGIS extensions

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION
CREATE EXTENSION postgis_raster;
CREATE EXTENSION
CREATE EXTENSION fuzzystrmatch;
CREATE EXTENSION
```

```
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION
CREATE EXTENSION postgis_topology;
CREATE EXTENSION
CREATE EXTENSION address_standardizer_data_us;
CREATE EXTENSION
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
  pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
  FROM pg_catalog.pg_namespace n
  WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
  ORDER BY 1;
List of schemas
     Name     |   Owner
--------------+-----------
 public       | postgres
 tiger        | rdsadmin
 tiger_data   | rdsadmin
 topology     | rdsadmin
(4 rows)
```

Step 3: Transfer ownership of the extension schemas

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the `gis_admin` role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA topology OWNER TO gis_admin;
ALTER SCHEMA
```

You can confirm the ownership change by running the following SQL query. Or you can use the \dn metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
  pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
```

```
  FROM pg_catalog.pg_namespace n
  WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
  ORDER BY 1;

      List of schemas
    Name     |     Owner
-------------+--------------
 public      | postgres
 tiger       | gis_admin
 tiger_data  | gis_admin
 topology    | gis_admin
(4 rows)
```

Step 4: Transfer ownership of the PostGIS tables

> **Note**
>
> Do not change ownership of the PostGIS functions. Proper operation and future upgrades of PostGIS require these functions to retain original ownership. For more information about PostGIS permissions, see PostgreSQL Security.

Use the following function to transfer ownership of the PostGIS tables to the `gis_admin` role. Run the following statement from the psql prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$ BEGIN EXECUTE
 $1; RETURN $1; END; $f$;
CREATE FUNCTION
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname)
 || ' OWNER TO gis_admin;')
  FROM (
    SELECT nspname, relname
    FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
    WHERE nspname in ('tiger','topology') AND
    relkind IN ('r','S','v') ORDER BY relkind = 'S')
s;
```

Step 5: Test the extensions

To avoid needing to specify the schema name, add the `tiger` schema to your search path using the following command.

```
SET search_path=public,tiger;
SET
```

Test the `tiger` schema by using the following SELECT statement.

```
SELECT address, streetname, streettypeabbrev, zip
 FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
address | streetname | streettypeabbrev |  zip
---------+------------+------------------+-------
       1 | Devonshire | Pl               | 02109
(1 row)
```

To learn more about this extension, see Tiger Geocoder in the PostGIS documentation.

Test access to the `topology` schema by using the following `SELECT` statement. This calls the `createtopology` function to register a new topology object (my_new_topo) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see CreateTopology in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
 createtopology
----------------
              1
(1 row)
```

Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see PostGIS extension versions.

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information

about upgrading the PostgreSQL engine, see How to perform a major version upgrade for RDS for PostgreSQL.

You can check for available PostGIS extension version updates on your RDS for PostgreSQL DB instance at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see Upgrading PostGIS 2 to PostGIS 3.

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see How to perform a major version upgrade for RDS for PostgreSQL.

PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in Extension versions for Amazon RDS for PostgreSQL in the *Amazon RDS for PostgreSQL Release Notes.* To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the *Amazon RDS for PostgreSQL Release Notes*:

- PostgreSQL version 16 extensions supported on Amazon RDS

- PostgreSQL version 15 extensions supported on Amazon RDS
- PostgreSQL version 14 extensions supported on Amazon RDS
- PostgreSQL version 13 extensions supported on Amazon RDS
- PostgreSQL version 12 extensions supported on Amazon RDS
- PostgreSQL version 11 extensions supported on Amazon RDS
- PostgreSQL version 10 extensions supported on Amazon RDS
- PostgreSQL version 9.6.x extensions supported on Amazon RDS

Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis` extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postgis_raster` to the new version.

To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your RDS for PostgreSQL DB instance. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
    WHERE default_version > installed_version;
  name   | default_version | installed_version |                          comment
---------+-----------------+-------------------
+------------------------------------------------------------
 postgis | 3.1.4           | 2.3.7             | PostGIS geometry and geography
 spatial types and functions
(1 row)
```

2. Identify the versions of PostGIS installed in each database on your RDS for PostgreSQL DB instance. In other words, query each user database as follows.

```
SELECT
```

```
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
  Name   | Version | Schema |                            Description
---------+---------+--------
+------------------------------------------------------------------------
 postgis | 2.3.7   | public | PostGIS geometry, geography, and raster spatial types
 and functions
(1 row)
```

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```

3. Run the following query to verify that the raster functionality is now in its own package.

```
SELECT
    probin,
    count(*)
FROM
    pg_proc
WHERE
    probin LIKE '%postgis%'
GROUP BY
    probin;
          probin          | count
--------------------------+-------
 $libdir/rtpostgis-2.3    | 107
 $libdir/postgis-3        | 487
```

```
(2 rows)
```

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```
SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
        AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
      Name      | Version | Schema |                            Description
----------------+---------+--------
+------------------------------------------------------------------------
 postgis        | 3.1.5   | public | PostGIS geometry, geography, and raster
 spatial types and functions
 postgis_raster | 3.1.5   | public | PostGIS raster types and functions
(2 rows)
```

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```
DROP EXTENSION postgis_raster;
```

Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native `postgres_fdw` extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

Topics

- Using the log_fdw extension to access the DB log using SQL
- Using the postgres_fdw extension to access external data
- Working with MySQL databases by using the mysql_fdw extension
- Working with Oracle databases by using the oracle_fdw extension
- Working with SQL Server databases by using the tds_fdw extension

Using the log_fdw extension to access the DB log using SQL

RDS for PostgreSQL DB instance supports the `log_fdw` extension, which you can use to access your database engine log using a SQL interface. The `log_fdw` extension provides two functions that make it easy to create foreign tables for database logs:

- `list_postgres_log_files` – Lists the files in the database log directory and the file size in bytes.
- `create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text)` – Builds a foreign table for the specified file in the current database.

All functions created by `log_fdw` are owned by `rds_superuser`. Members of the `rds_superuser` role can grant access to these functions to other database users.

By default, the log files are generated by Amazon RDS in `stderr` (standard error) format, as specified in `log_destination` parameter. There are only two options for this parameter, `stderr` and `csvlog` (comma-separated values, CSV). If you add the `csvlog` option to the parameter, Amazon RDS generates both `stderr` and `csvlog` logs. This can affect the storage capacity on

your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see Setting the log destination (`stderr, csvlog`).

One benefit of generating `csvlog` logs is that the `log_fdw` extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for `log_destination`. For more information about how to do so, see Working with parameters on your RDS for PostgreSQL DB instance.

The following example assumes that the `log_destination` parameter includes `cvslog`.

To use the log_fdw extension

1. Install the `log_fdw` extension.

```
postgres=> CREATE EXTENSION log_fdw;
CREATE EXTENSION
```

2. Create the log server as a foreign data wrapper.

```
postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
CREATE SERVER
```

3. Select all from a list of log files.

```
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

   A sample response is as follows.

```
          file_name           | file_size_bytes
------------------------------+-----------------
 postgresql.log.2023-08-09-22.csv |            1111
 postgresql.log.2023-08-09-23.csv |            1172
 postgresql.log.2023-08-10-00.csv |            1744
 postgresql.log.2023-08-10-01.csv |            1102
(4 rows)
```

4. Create a table with a single 'log_entry' column for the selected file.

```
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log',
     'log_server', 'postgresql.log.2023-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
----------------------------------
(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

```
            log_time             |                                  message
---------------------------------
+-------------------------------------------------------------------------------
Tue Aug 09 15:45:18.172 2023 PDT | ending log output to stderr
Tue Aug 09 15:45:18.175 2023 PDT | database system was interrupted; last known up
 at 2023-08-09 22:43:34 UTC
Tue Aug 09 15:45:18.223 2023 PDT | checkpoint record is at 0/90002E0
Tue Aug 09 15:45:18.223 2023 PDT | redo record is at 0/90002A8; shutdown FALSE
Tue Aug 09 15:45:18.223 2023 PDT | next transaction ID: 0/1879; next OID: 24578
Tue Aug 09 15:45:18.223 2023 PDT | next MultiXactId: 1; next MultiXactOffset: 0
Tue Aug 09 15:45:18.223 2023 PDT | oldest unfrozen transaction ID: 1822, in
 database 1
(7 rows)
```

Using the postgres_fdw extension to access external data

You can access data in a table on a remote database server with the postgres_fdw extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

To use postgres_fdw to access a remote database server

1. Install the postgres_fdw extension.

```
CREATE EXTENSION postgres_fdw;
```

2. Create a foreign data server using CREATE SERVER.

```
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
```

3. Create a user mapping to identify the role to be used on the remote server.

> **Important**
>
> To redact the password so that it doesn't appear in the logs, set `log_statement=none` at the session level. Setting at the parameter level doesn't redact the password.

```
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

4. Create a table that maps to the table on the remote server.

```
CREATE FOREIGN TABLE foreign_table (
        id integer NOT NULL,
        data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

Working with MySQL databases by using the mysql_fdw extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL DB instance to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see Using encryption in transit with the extension.

The `mysql_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

Topics

- Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension
- Example: Working with an RDS for MySQL database from RDS for PostgreSQL
- Using encryption in transit with the extension

Setting up your RDS for PostgreSQL DB to use the mysql_fdw extension

Setting up the `mysql_fdw` extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-
region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the `rds_superuser` account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

To use mysql_fdw to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance , the user name is `postgres`, and you can connect using the `psql` command line tool as follows:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --
   username=postgres --password
   ```

2. Install the `mysql_fdw` extension as follows:

```
postgres=> CREATE EXTENSION mysql_fdw;
CREATE EXTENSION
```

After the extension is installed on your RDS for PostgreSQL DB instance , you set up the foreign server that provides the connection to a MySQL database.

To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance . The steps assume that you're connected as a user with `rds_superuser` privileges, such as `postgres`.

1. Create a foreign server in the RDS for PostgreSQL DB instance :

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-
name.111122223333.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the `rds_superuser` role.

```
postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
GRANT
```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

Example: Working with an RDS for MySQL database from RDS for PostgreSQL

Suppose that you have a simple table on an RDS for PostgreSQL DB instance . Your RDS for PostgreSQL users want to query (`SELECT`), `INSERT`, `UPDATE`, and `DELETE` items on that table. Assume that the `mysql_fdw` extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:

```
test=> CREATE SERVER mysqldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-
DB.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant usage to a user who doesn't have `rds_superuser` permissions, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER mysqldb TO user1;
GRANT
```

3. Connect as *user1*, and then create a mapping to the MySQL user:

```
test=> CREATE USER MAPPING FOR user1 SERVER mysqldb OPTIONS (username 'myuser',
 password 'mypassword');
CREATE USER MAPPING
```

4. Create a foreign table linked to the MySQL table:

```
test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqldb OPTIONS (dbname
 'test', table_name '');
CREATE FOREIGN TABLE
```

5. Run a simple query against the foreign table:

```
test=> SELECT * FROM mytab;
a |   b
---+-------
1 | apple
(1 row)
```

6. You can add, change, and remove data from the MySQL table. For example:

```
test=> INSERT INTO mytab values (2, 'mango');
INSERT 0 1
```

Run the SELECT query again to see the results:

```
test=> SELECT * FROM mytab ORDER BY 1;
 a |   b
---+-------
1 | apple
2 | mango
```

```
(2 rows)
```

Using encryption in transit with the extension

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration differ. You can enforce encryption for all outgoing connections by specifying the `REQUIRE SSL` option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to `REQUIRE SSL`, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the `ALTER USER` command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see ALTER USER in *MySQL Reference Manual*.

MySQL 5.7, MySQL 8.0	MySQL 5.6
`ALTER USER 'user'@'%' REQUIRE SSL;`	`GRANT USAGE ON *.* to 'user'@'%' REQUIRE SSL;`

For more information about the `mysql_fdw` extension, see the mysql_fdw documentation.

Working with Oracle databases by using the oracle_fdw extension

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the `oracle_fdw` extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the oracle_fdw documentation.

The `oracle_fdw` extension is supported on RDS for PostgreSQL 12.7, 13.3, and higher versions.

Topics

- Turning on the oracle_fdw extension
- Example: Using a foreign server linked to an Amazon RDS for Oracle database
- Working with encryption in transit
- Understanding the pg_user_mappings view and permissions

Turning on the oracle_fdw extension

To use the oracle_fdw extension, perform the following procedure.

To turn on the oracle_fdw extension

- Run the following command using an account that has `rds_superuser` permissions.

```
CREATE EXTENSION oracle_fdw;
```

Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name
2. Create a foreign server.

```
test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver
 '//endpoint:port/DB_name');
CREATE SERVER
```

3. Grant usage to a user who doesn't have `rds_superuser` privileges, for example `user1`.

```
test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
GRANT
```

4. Connect as `user1`, and create a mapping to an Oracle user.

```
test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser',
 password 'mypassword');
CREATE USER MAPPING
```

5. Create a foreign table linked to an Oracle table.

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
CREATE FOREIGN TABLE
```

6. Query the foreign table.

```
test=>  SELECT * FROM mytab;
a
---
1
(1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see About the Values for Negotiating Encryption and Integrity in the Oracle documentation. The client used for oracle_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration and it uses Oracle Security Library (libnnz) for encryption.

If your database is on RDS for Oracle, see Oracle native network encryption to configure the encryption.

Understanding the pg_user_mappings view and permissions

The PostgreSQL catalog `pg_user_mapping` stores the mapping from an RDS for PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the `pg_user_mappings` view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users `rdssu1` and `rdssu2` are members of the `rds_superuser` role, and `user1` isn't. The example uses the `psql` metacommand `\du` to list existing roles.

```
test=>  \du
                                                              List of roles
    Role name    |                          Attributes                          |
                 Member of
-----------------+------------------------------------------------------------
+-----------------------------------------------------------
 rdssu1          |                                                              |
 {rds_superuser}
 rdssu2          |                                                              |
 {rds_superuser}
 user1           |                                                              | {}
```

All users, including users that have `rds_superuser` privileges, are allowed to view their own user mappings (`umoptions`) in the `pg_user_mappings` table. As shown in the following example, when `rdssu1` tries to obtain all user mappings, an error is raised even though `rdssu1rds_superuser` privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```
test=> SET SESSION AUTHORIZATION rdssu1;
SET
test=> SELECT * FROM pg_user_mappings;
 umid  | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+---------------------------------
 16414 | 16411 | oradb   |  16412 | user1      |
 16423 | 16411 | oradb   |  16421 | rdssu1     | {user=oracleuser,password=mypwd}
 16424 | 16411 | oradb   |  16422 | rdssu2     |
 (3 rows)

test=> SET SESSION AUTHORIZATION rdssu2;
SET
test=> SELECT * FROM pg_user_mappings;
 umid  | srvid | srvname | umuser | usename    |            umoptions
-------+-------+---------+--------+------------+---------------------------------
 16414 | 16411 | oradb   |  16412 | user1      |
 16423 | 16411 | oradb   |  16421 | rdssu1     |
 16424 | 16411 | oradb   |  16422 | rdssu2     | {user=oracleuser,password=mypwd}
 (3 rows)
```

```
test=> SET SESSION AUTHORIZATION user1;
SET
test=> SELECT * FROM pg_user_mappings;
 umid  | srvid | srvname | umuser | usename    |           umoptions
-------+-------+---------+--------+------------+-------------------------------
 16414 | 16411 | oradb   |  16412 | user1      | {user=oracleuser,password=mypwd}
 16423 | 16411 | oradb   |  16421 | rdssu1     |
 16424 | 16411 | oradb   |  16422 | rdssu2     |
 (3 rows)
```

Because of implementation differences between `information_schema._pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema._pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the `USAGE` privilege on it.
- The current user is the server owner and the mapping is for `PUBLIC`.

Working with SQL Server databases by using the tds_fdw extension

You can use the PostgreSQL `tds_fdw` extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see tds-fdw/tds_fdw documentation on GitHub.

The `tds_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

Setting up your Aurora PostgreSQL DB to use the tds_fdw extension

In the following procedures, you can find an example of setting up and using the `tds_fdw` with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using `tds_fdw`, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect:
Adaptive Server is unavailable or does not exist (mssql2019.aws-
region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

To use tds_fdw to connect to a SQL Server database

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --
   username=test --password
   ```

2. Install the `tds_fdw` extension:

   ```
   test=> CREATE EXTENSION tds_fdw;
   CREATE EXTENSION
   ```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has `rds_superuser` privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS
 (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database
 'tds_fdw_testing');
CREATE SERVER
```

To access non-ASCII data on the SQLServer side, create a server link with the character_set option in the RDS for PostgreSQL DB instance:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername
 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing',
 character_set 'UTF-8');
CREATE SERVER
```

2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as user1 and create a mapping to a SQL Server user:

```
test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username
 'sqlserveruser', password 'password');
CREATE USER MAPPING
```

4. Create a foreign table linked to a SQL Server table:

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table
 'MYTABLE');
CREATE FOREIGN TABLE
```

5. Query the foreign table:

```
test=> SELECT * FROM mytab;
 a
---
 1
(1 row)
```

Using encryption in transit for the connection

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see Forcing connections to your DB instance to use SSL. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.

Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your RDS for PostgreSQL DB instances.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on the following RDS for PostgreSQL versions:

- Version 18.1 and higher 18 versions
- Version 17.1 and higher 17 versions
- Version 16.1 and higher 16 versions
- Version 15.2 and higher 15 versions
- Version 14.5 and higher 14 versions
- Version 13.12 and higher 13 versions

The Trusted Language Extensions development environment and runtime are packaged as the `pg_tle` PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the `pg_tle` extension in your RDS for PostgreSQL DB instance in the same way that you install other PostgreSQL extensions. After the `pg_tle` is set up, developers can use it to create new PostgreSQL extensions, known as *TLE extensions*.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

Topics

- Terminology
- Requirements for using Trusted Language Extensions for PostgreSQL
- Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance
- Overview of Trusted Language Extensions for PostgreSQL
- Creating TLE extensions for RDS for PostgreSQL
- Dropping your TLE extensions from a database
- Uninstalling Trusted Language Extensions for PostgreSQL
- Using PostgreSQL hooks with your TLE extensions
- Using Custom Data Types in TLE
- Function reference for Trusted Language Extensions for PostgreSQL
- Hooks reference for Trusted Language Extensions for PostgreSQL

Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is the official name of the open source development kit that's packaged as the `pg_tle` extension. It's available for use on any PostgreSQL system. For more information, see aws/pg_tle on GitHub.

Trusted Language Extensions

Trusted Language Extensions is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

trusted language

A *trusted language* is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create

trusted or untrusted extensions. For an example, see Trusted and Untrusted PL/Perl in the PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

TLE extension

A *TLE extension* is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **RDS for PostgreSQL versions** – Trusted Language Extensions is supported on RDS for PostgreSQL versions 13.12 and higher 13 versions, 14.5 and higher 14 versions, and 15.2 and higher versions only.
  - If you need to upgrade your RDS for PostgreSQL instance, see Upgrades of the RDS for PostgreSQL DB engine.
  - If you don't yet have an Amazon RDS DB instance running PostgreSQL, you can create one. For more information, see RDS for PostgreSQL DB instance, see Creating and connecting to a PostgreSQL DB instance.
- **Requires `rds_superuser` privileges** – To set up and configure the `pg_tle` extension, your database user role must have the permissions of the `rds_superuser` role. By default, this role is granted to the `postgres` user that creates the RDS for PostgreSQL DB instance.
- **Requires a custom DB parameter group** – Your RDS for PostgreSQL DB instance must be configured with a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance isn't configured with a custom DB parameter group, you should create one and associate it with your RDS for PostgreSQL DB instance. For a short summary of steps, see Creating and applying a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your RDS for PostgreSQL DB instance to use it.

Console

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose **Create parameter group**.
4. In the **Parameter group details** page, enter the following information.
   - For **Parameter group family**, choose postgres14.
   - For **Type**, choose DB Parameter Group.
   - For **Group name**, give your parameter group a meaningful name in the context of your operations.
   - For **Description**, enter a useful description so that others on your team can easily find it.
5. Choose **Create**. Your custom DB parameter group is created in your AWS Region. You can now modify your RDS for PostgreSQL DB instance to use it by following the next steps.
6. Choose **Databases** from the Amazon RDS menu.
7. Choose the RDS for PostgreSQL DB instance that you want to use with TLE from among those listed, and then choose **Modify.**
8. In the Modify DB instance settings page, find **Database options** in the Additional configuration section and choose your custom DB parameter group from the selector.
9. Choose **Continue** to save the change.
10. Choose **Apply immediately** so that you can continue setting up the RDS for PostgreSQL DB instance to use TLE.

To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

For more information working with DB parameter groups, see DB parameter groups for Amazon RDS DB instances.

AWS CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the *AWS Command Line Interface User Guide*.

To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Use the create-db-parameter-group AWS CLI command to create a custom DB parameter group based on postgres14 for your AWS Region.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-parameter-group \
     --region aws-region \
     --db-parameter-group-name custom-params-for-pg-tle \
     --db-parameter-group-family postgres14 \
     --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   For Windows:

   ```
   aws rds create-db-parameter-group ^
     --region aws-region ^
     --db-parameter-group-name custom-params-for-pg-tle ^
     --db-parameter-group-family postgres14 ^
     --description "My custom DB parameter group for Trusted Language Extensions"
   ```

   Your custom DB parameter group is available in your AWS Region, so you can modify RDS for PostgreSQL DB instance to use it.

2. Use the modify-db-instance AWS CLI command to apply your custom DB parameter group to your RDS for PostgreSQL DB instance. This command immediately reboots the active instance.

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-instance \
     --region aws-region \
     --db-instance-identifier your-instance-name \
     --db-parameter-group-name custom-params-for-pg-tle \
     --apply-immediately
   ```

For Windows:

```
aws rds modify-db-instance ^
  --region aws-region ^
  --db-instance-identifier your-instance-name ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --apply-immediately
```

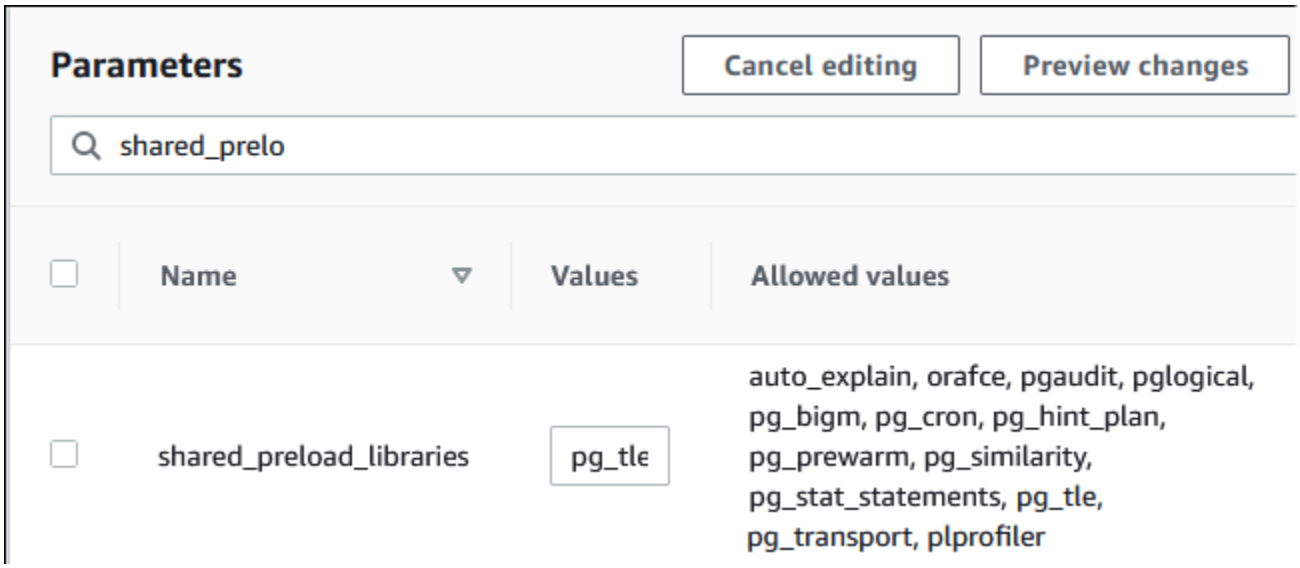
To continue setting up your system for Trusted Language Extensions, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

For more information, see Parameter groups for Amazon RDS.

Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance

The following steps assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your RDS for PostgreSQL DB instance, you install it in a specific database for use by the database users who have permissions on that database.



Console

To set up Trusted Language Extensions

Perform the following steps using an account that's a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.

6. Choose **Edit parameters** to access the property values.
7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.

8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pg_tle
(1 row)
```

10. With the `pg_tle` extension initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

You can verify that the extension is installed by using the following `psql` metacommand.

```
labdb=> \dx
                          List of installed extensions
  Name   | Version |   Schema   |                Description
---------+---------+------------+-------------------------------------------
 pg_tle  | 1.0.1   | pgtle      | Trusted-Language Extensions for PostgreSQL
 plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
```

11. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the `psql` metacommand as shown in the following example. Only the `pgtle_admin` and `postgres` roles are shown in the output. For more information, see Understanding the rds_superuser role.

```
labdb=> \du
                          List of roles
    Role name    |           Attributes            |               Member of
-----------------+---------------------------------
+-----------------------------------
pgtle_admin     | Cannot login                     | {}
postgres        | Create role, Create DB          +| {rds_superuser,pgtle_admin}
                | Password valid until infinity    |...
```

12. Close the `psql` session using the `\q` metacommand.

```
\q
```

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL.

AWS CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see Configuration basics in the *AWS Command Line Interface User Guide*.

To set up Trusted Language Extensions

1. Use the modify-db-parameter-group AWS CLI command to add `pg_tle` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
```

```
   --parameters
 "ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-
reboot" \
   --region aws-region
```

2. Use the reboot-db-instance AWS CLI command to reboot the RDS for PostgreSQL DB instance and initialize the `pg_tle` library.

```
aws rds reboot-db-instance \
    --db-instance-identifier your-instance \
    --region aws-region
```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

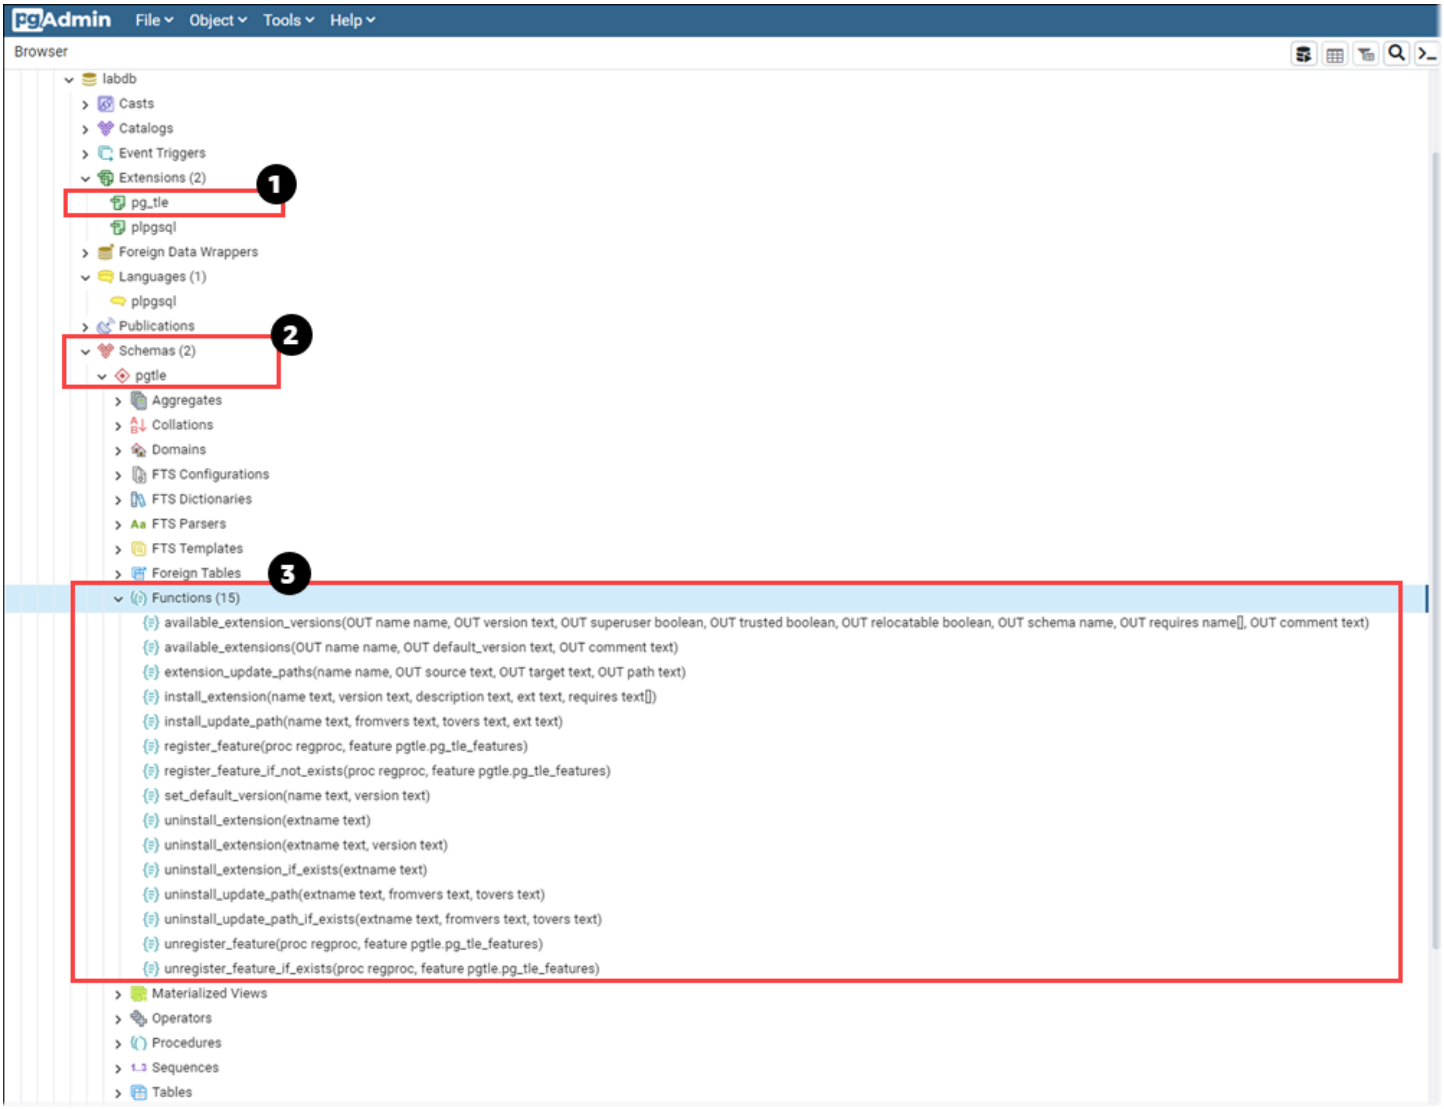
```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pg_tle
(1 row)
```

   With `pg_tle` initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

4. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
GRANT pgtle_admin TO postgres;
GRANT ROLE
```



5. Close the `psql` session as follows.

```
labdb=> \q
```

To get started creating TLE extensions, see Example: Creating a trusted language extension using SQL.

Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your RDS for PostgreSQL DB instance in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the `pg_tle` extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the `pg_tle` extension. As such, `pg_tle` is added to the available extensions for the database in which it's installed.
2. TLE has its own schema, `pgtle`. This schema contains helper functions (3) for installing and managing the extensions that you create.

3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see Function reference for Trusted Language Extensions for PostgreSQL.

Other components of the `pg_tle` extension include the following:

- **The `pgtle_admin` role** – The `pgtle_admin` role is created when the `pg_tle` extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of *least privilege* when granting the `pgtle_admin` role to database users. In other words, grant the `pgtle_admin` role only to database users that are allowed to create, install, and manage new TLE extensions, such as `postgres`.
- **The `pgtle.feature_info` table** – The `pgtle.feature_info` table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have `pgtle_admin` privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  - pgtle.register_feature
  - pgtle.register_feature_if_not_exists
  - pgtle.unregister_feature
  - pgtle.unregister_feature_if_exists

Creating TLE extensions for RDS for PostgreSQL

You can install any extensions that you create with TLE in any RDS for PostgreSQL DB instance that has the `pg_tle` extension installed. The `pg_tle` extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various `pgtle` functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the `pgtle_admin` role.

- pgtle.install_extension
- pgtle.install_update_path
- pgtle.register_feature
- pgtle.register_feature_if_not_exists
- pgtle.set_default_version
- pgtle.uninstall_extension(name)

- pgtle.uninstall_extension(name, version)
- pgtle.uninstall_extension_if_exists
- pgtle.uninstall_update_path
- pgtle.uninstall_update_path_if_exists
- pgtle.unregister_feature
- pgtle.unregister_feature_if_exists

Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named `pg_distance` that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see Taxicab geometry and Euclidean geometry in Wikipedia.

You can use this example in your own RDS for PostgreSQL DB instance if you have the `pg_tle` extension set up as detailed in Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

> **Note**
>
> You need to have the privileges of the `pgtle_admin` role to follow this procedure.

To create the example TLE extension

The following steps use an example database named `labdb`. This database is owned by the `postgres` primary user. The `postgres` role also has the permissions of the `pgtle_admin` role.

1. Use `psql` to connect to RDS for PostgreSQL DB instance.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Create a TLE extension named `pg_distance` by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_extension
```

```
(
 'pg_distance',
 '0.1',
  'Distance functions for two points',
$_pg_tle_$
    CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
    RETURNS float8
    AS $$
      SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
    $$ LANGUAGE SQL;

    CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 1);
    $$ LANGUAGE SQL;

    CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 2);
    $$ LANGUAGE SQL;
$_pg_tle_$
);
```

You see the output, such as the following.

```
install_extension
---------------
 t
(1 row)
```

The artifacts that make up the `pg_distance` extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the `CREATE EXTENSION` command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the `CREATE EXTENSION` command as you do for any other extension. As with other extensions, the database user needs to have the `CREATE` permissions in the database.

```
CREATE EXTENSION pg_distance;
```

4. To test the pg_distance TLE extension, you can use it to calculate the Manhattan distance between four points.

```
labdb=> SELECT manhattan_dist(1, 1, 5, 5);
8
```

To calculate the Euclidean distance between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);
5.656854249492381
```

The pg_distance extension loads the functions in the database and makes them available to any users with permissions on the database.

Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- IMMUTABLE – The IMMUTABLE attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see Function Volatility Categories in the PostgreSQL documentation.
- PARALLEL SAFE – The PARALLEL SAFE attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see CREATE FUNCTION in the PostgreSQL documentation.

In the following example, you can see how the pgtle.install_update_path function is used to add these attributes to each function to create a version 0.2 of the pg_distance TLE extension. For more information about this function, see pgtle.install_update_path. You need to have the pgtle_admin role to perform this task.

To update an existing TLE extension and specify the default version

1. Connect to RDS for PostgreSQL DB instance using psql or another client tool, such as pgAdmin.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Modify the existing TLE extension by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_update_path
(
 'pg_distance',
 '0.1',
 '0.2',
$_pg_tle_$
    CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8,
 norm int)
    RETURNS float8
    AS $$
      SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
    $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

    CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2
 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 1);
    $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

    CREATE OR REPLACE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2
 float8)
    RETURNS float8
    AS $$
      SELECT dist(x1, y1, x2, y2, 2);
    $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
$_pg_tle_$
);
```

You see a response similar to the following.

```
install_update_path
---------------------
 t
(1 row)
```

You can make this version of the extension the default version, so that database users don't have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see pgtle.set_default_version.

4. With the code in place, you can update the installed TLE extension in the usual way, by using `ALTER EXTENSION ... UPDATE` command, as shown here:

```
ALTER EXTENSION pg_distance UPDATE;
```

Dropping your TLE extensions from a database

You can drop your TLE extensions by using the `DROP EXTENSION` command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn't remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

To drop the TLE extension and remove its installation files

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=dbname
```

2. Drop the extension as you would any PostgreSQL extension.

```
DROP EXTENSION your-TLE-extension
```

For example, if you create the `pg_distance` extension as detailed in Example: Creating a trusted language extension using SQL, you can drop the extension as follows.

```
DROP EXTENSION pg_distance;
```

You see output confirming that the extension has been dropped, as follows.

```
DROP EXTENSION
```

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
- If you want to remove all files that make up the extension, continue to the next step.

3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
 uninstall_extension
---------------------
 t
(1 row)
```

Uninstalling Trusted Language Extensions for PostgreSQL

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

To drop the `pg_tle` extension and its schema from a database

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=dbname
```

2. Drop the pg_tle extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the CASCADE keyword, as shown in the following.

```
DROP EXTENSION pg_tle CASCADE;
```

   If the pg_tle extension isn't still active in the database, you don't need to use the CASCADE keyword.

3. Drop the pgtle schema. This action removes all the management functions from the database.

```
DROP SCHEMA pgtle CASCADE;
```

   The command returns the following when the process completes.

```
DROP SCHEMA
```

   The pg_tle extension, its schema and functions, and all artifacts are removed. To create new extensions using TLE, go through the setup process again. For more information, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

Using PostgreSQL hooks with your TLE extensions

A *hook* is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the pg_tle extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with pg_tle. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to on, off, or require. For more

information about specific requirements for available pg_tle hooks, see Hooks reference for Trusted Language Extensions for PostgreSQL.

Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the password_check.bad_passwords table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your RDS for PostgreSQL DB instance, you must have already installed Trusted Language Extensions. For details, see Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance.

To set up the password-check hook example

1. Use psql to connect to RDS for PostgreSQL DB instance.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Copy the code from the Password-check hook code listing and paste it into your database.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
$_pgtle_$
  CREATE SCHEMA password_check;
  REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
  GRANT USAGE ON SCHEMA password_check TO PUBLIC;

  CREATE TABLE password_check.bad_passwords (plaintext) AS
  VALUES
    ('123456'),
    ('password'),
    ('12345678'),
    ('qwerty'),
    ('123456789'),
    ('12345'),
    ('1234'),
    ('111111'),
```

```
    ('1234567'),
    ('dragon');
  CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

  CREATE FUNCTION password_check.passcheck_hook(username text, password text,
 password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
  RETURNS void AS $$
    DECLARE
      invalid bool := false;
    BEGIN
      IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common password
 dictionary';
        END IF;
      ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common password
 dictionary';
        END IF;
      END IF;
    END
  $$ LANGUAGE plpgsql SECURITY DEFINER;

  GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

  SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);
```

When the extension has been loaded into your database, you see the output such as the following.

```
 install_extension
-------------------
 t
(1 row)
```

3. While still connected to the database, you can now create the extension.

```
CREATE EXTENSION my_password_check_rules;
```

4. You can confirm that the extension has been created in the database by using the following `psql` metacommand.

```
\dx
                        List of installed extensions
          Name           | Version |   Schema   |
 Description
------------------------+---------+------------
+-------------------------------------------------------------
 my_password_check_rules | 1.0     | public     | Prevent use of any of the top-ten
 most common bad passwords
 pg_tle                  | 1.0.1   | pgtle      | Trusted-Language Extensions for
 PostgreSQL
 plpgsql                 | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the modify-db-parameter-group CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
    --region aws-region \
    --db-parameter-group-name your-custom-parameter-group \
    --parameters
 "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

When the parameter is successfully turned on, you see the output such as the following.

```
(
    "DBParameterGroupName": "docs-lab-parameters-for-tle"
}
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the RDS for PostgreSQL DB instance for the setting to take effect.

6. Open the `psql` session and query the database to verify that the password_check hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
----------------------------
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
 password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
 zone,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(
    $1::pg_catalog.text,
    $2::pg_catalog.text,
    $3::pgtle.password_types,
    $4::pg_catalog.timestamptz,
    $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that `pgsql` interactive metacommand `\password` behavior is also affected by the password_check hook.

```
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
ERROR:  Cannot use passwords from the common password dictionary
```

```
CONTEXT:  PL/pgSQL function
 password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
 zone,boolean) line 12 at RAISE
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text,
 $2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestamptz,
 $5::pg_catalog.bool)"
```

You can drop this TLE extension and uninstall its source files if you want. For more information, see Dropping your TLE extensions from a database.

Password-check hook code listing

The example code shown here defines the specification for the `my_password_check_rules` TLE extension. When you copy this code and paste it into your database, the code for the `my_password_check_rules` extension is loaded into the database, and the `password_check` hook is registered for use by the extension.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
$_pgtle_$
  CREATE SCHEMA password_check;
  REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
  GRANT USAGE ON SCHEMA password_check TO PUBLIC;

  CREATE TABLE password_check.bad_passwords (plaintext) AS
  VALUES
    ('123456'),
    ('password'),
    ('12345678'),
    ('qwerty'),
    ('123456789'),
    ('12345'),
    ('1234'),
    ('111111'),
    ('1234567'),
    ('dragon');
  CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

  CREATE FUNCTION password_check.passcheck_hook(username text, password text,
 password_type pgtle.password_types, valid_until timestamptz, valid_null boolean)
  RETURNS void AS $$
```

```
    DECLARE
      invalid bool := false;
    BEGIN
      IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
      ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
          SELECT 1
          FROM password_check.bad_passwords bp
          WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
          RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
      END IF;
    END
  $$ LANGUAGE plpgsql SECURITY DEFINER;

  GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

  SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);
```

Using Custom Data Types in TLE

PostgreSQL supports commands to register new base types (also known as scalar types) for efficiently handling complex data structures in your database. A base type allows you to customize how the data is stored internally, and how to convert it to and from an external textual representation. These custom data types are helpful when extending PostgreSQL to support functional domains where a built-in type such as number or text can't provide sufficient search semantics.

RDS for PostgreSQL enables you to create custom data types in your trusted language extension and define functions that support SQL and index operations for these new data types. Custom data types are available for the following versions:

- RDS for PostgreSQL 15.4 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see Trusted Language Base types.

Function reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your *TLE extensions*, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

Functions

- pgtle.available_extensions
- pgtle.available_extension_versions
- pgtle.extension_update_paths
- pgtle.install_extension
- pgtle.install_update_path
- pgtle.register_feature
- pgtle.register_feature_if_not_exists
- pgtle.set_default_version
- pgtle.uninstall_extension(name)
- pgtle.uninstall_extension(name, version)
- pgtle.uninstall_extension_if_exists
- pgtle.uninstall_update_path
- pgtle.uninstall_update_path_if_exists
- pgtle.unregister_feature
- pgtle.unregister_feature_if_exists

pgtle.available_extensions

The `pgtle.available_extensions` function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

Function prototype

```
pgtle.available_extensions()
```

Role

None.

Arguments

None.

Output

- `name` – The name of the TLE extension.
- `default_version` – The version of the TLE extension to use when `CREATE EXTENSION` is called without a version specified.
- `description` – A more detailed description about the TLE extension.

Usage example

```
SELECT * FROM pgtle.available_extensions();
```

pgtle.available_extension_versions

The `available_extension_versions` function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

Function prototype

```
pgtle.available_extension_versions()
```

Role

None.

Arguments

None.

Output

- `name` – The name of the TLE extension.
- `version` – The version of the TLE extension.
- `superuser` – This value is always `false` for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- `trusted` – This value is always `false` for a TLE extension.
- `relocatable` – This value is always `false` for a TLE extension.
- `schema` – Specifies the name of the schema in which the TLE extension is installed.
- `requires` – An array containing the names of other extensions needed by this TLE extension.
- `description` – A detailed description of the TLE extension.

For more information about output values, see Packaging Related Objects into an Extension > Extension Files in the PostgreSQL documentation.

Usage example

```
SELECT * FROM pgtle.available_extension_versions();
```

pgtle.extension_update_paths

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

Function prototype

```
pgtle.extension_update_paths(name)
```

Role

None.

Arguments

name – The name of the TLE extension from which to get upgrade paths.

Output

- source – The source version for an update.
- target – The target version for an update.
- path – The upgrade path used to update a TLE extension from source version to target version, for example, 0.1--0.2.

Usage example

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

pgtle.install_extension

The install_extension function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the CREATE EXTENSION command.

Function prototype

```
pgtle.install_extension(name text, version text, description text, ext text, requires
 text[] DEFAULT NULL::text[])
```

Role

None.

Arguments

- name – The name of the TLE extension. This value is used when calling CREATE EXTENSION.
- version – The version of the TLE extension.
- description – A detailed description about the TLE extension. This description is displayed in the comment field in pgtle.available_extensions().
- ext – The contents of the TLE extension. This value contains objects such as functions.

- `requires` – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the Extension Files in Packaging Related Objects into an Extension in the PostgreSQL documentation.

Output

This functions returns `OK` on success and `NULL` on error.

- `OK` – The TLE extension has been successfully installed in the database.
- `NULL` – The TLE extension hasn't been successfully installed in the database.

Usage example

```
SELECT pgtle.install_extension(
 'pg_tle_test',
 '0.1',
 'My first pg_tle extension',
$_pgtle_$
  CREATE FUNCTION my_test()
  RETURNS INT
  AS $$
    SELECT 42;
  $$ LANGUAGE SQL IMMUTABLE;
$_pgtle_$
);
```

pgtle.install_update_path

The `install_update_path` function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the `ALTER EXTENSION ... UPDATE` syntax.

Function prototype

```
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

Role

`pgtle_admin`

Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension for the upgrade.
- `tovers` – The destination version of the TLE extension for the upgrade.
- `ext` – The contents of the update. This value contains objects such as functions.

Output

None.

Usage example

```
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',
  $_pgtle_$
    CREATE OR REPLACE FUNCTION my_test()
    RETURNS INT
    AS $$
      SELECT 21;
    $$ LANGUAGE SQL IMMUTABLE;
  $_pgtle_$
);
```

pgtle.register_feature

The `register_feature` function adds the specified internal PostgreSQL feature to the `pgtle.feature_info` table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- `passcheck` – Registers the password-check hook with your procedure or function that customizes PostgreSQL's password-check behavior.

Function prototype

```
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

Role

pgtle_admin

Arguments

- proc – The name of a stored procedure or function to use for the feature.
- feature – The name of the pg_tle feature (such as passcheck) to register with the function.

Output

None.

Usage example

```
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

pgtle.register_feature_if_not_exists

The pgtle.register_feature_if_not_exists function adds the specified PostgreSQL feature to the pgtle.feature_info table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see Using PostgreSQL hooks with your TLE extensions.

Function prototype

```
pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)
```

Role

pgtle_admin

Arguments

- proc – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the pw_hook code.

- `feature` – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the `passcheck` hook. For more information, see Password-check hook (passcheck).

Output

Returns `true` after registering the feature for the specified extension. Returns `false` if the feature is already registered.

Usage example

```
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

pgtle.set_default_version

The `set_default_version` function lets you specify a `default_version` for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the `CREATE EXTENSION` and `ALTER EXTENSION ... UPDATE` commands, that version of your TLE extension is created in the database for that user.

This function returns `true` on success. If the TLE extension specified in the `name` argument doesn't exist, the function returns an error. Similarly, if the `version` of the TLE extension doesn't exist, it returns an error.

Function prototype

```
pgtle.set_default_version(name text, version text)
```

Role

`pgtle_admin`

Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to set the default.

Output

- `true` – When setting default version succeeds, the function returns `true`.
- ERROR – Returns an error message if a TLE extension with the specified name or version doesn't exist.

Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```

pgtle.uninstall_extension(name)

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of `CREATE EXTENSION` from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call `DROP EXTENSION` to remove it.

Function prototype

```
pgtle.uninstall_extension(extname text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with `CREATE EXTENSION` to load the TLE extension for use in a given database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```

pgtle.uninstall_extension(name, version)

The `uninstall_extension(name, version)` function removes the specified version of the TLE extension from the database. This function prevents `CREATE EXTENSION` and `ALTER EXTENSION` from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call `DROP EXTENSION` to remove the TLE extension. To uninstall all versions of a TLE extension, see pgtle.uninstall_extension(name).

Function prototype

```
pgtle.uninstall_extension(extname text, version text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to uninstall from the database.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');
```

pgtle.uninstall_extension_if_exists

The `uninstall_extension_if_exists` function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call `DROP EXTENSION` to remove the TLE extension before using this function to uninstall its artifacts.

Function prototype

```
pgtle.uninstall_extension_if_exists(extname text)
```

Role

pgtle_admin

Arguments

- extname – The name of the TLE extension. This value is used when calling CREATE EXTENSION.

Output

The uninstall_extension_if_exists function returns true after uninstalling the specified extension. If the specified extension doesn't exist, the function returns false.

- true – Returns true after uninstalling the TLE extension.
- false – Returns false when the TLE extension doesn't exist in the database.

Usage example

```
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

pgtle.uninstall_update_path

The uninstall_update_path function removes the specific update path from a TLE extension. This prevents ALTER EXTENSION ... UPDATE TO from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

Function prototype

```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

Role

pgtle_admin

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

Output

None.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

pgtle.uninstall_update_path_if_exists

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns `false`.

Function prototype

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

Role

`pgtle_admin`

Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

Output

- `true` – The function has successfully updated the path for the TLE extension.

- `false` – The function wasn't able to update the path for the TLE extension.

Usage example

```
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

pgtle.unregister_feature

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For information about registering a feature, see pgtle.register_feature.

Function prototype

```
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

Role

`pgtle_admin`

Arguments

- `proc` – The name of a stored function to register with a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature to register with the function. For example, `passcheck` is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see Password-check hook (passcheck).

Output

None.

Usage example

```
SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');
```

pgtle.unregister_feature_if_exists

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For more information, see Using PostgreSQL hooks with your

TLE extensions. Returns `true` after successfully unregistering the feature. Returns `false` if the feature wasn't registered.

For information about registering `pg_tle` features for your TLE extensions, see pgtle.register_feature.

Function prototype

```
pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')
```

Role

`pgtle_admin`

Arguments

- `proc` – The name of the stored function that was registered to include a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature that was registered with the trusted language extension.

Output

Returns `true` or `false`, as follows.

- `true` – The function has successfully unregistered the feature from extension.
- `false` – The function wasn't able to unregister the feature from the TLE extension.

Usage example

```
SELECT * FROM pgtle.unregister_feature_if_exists('pw_hook', 'passcheck');
```

Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A *hook* is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you

can use a passcheck hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the passcheck hook available for your TLE extensions. To learn more about the available hooks including the client authentication hook, see Trusted Language Extensions hooks.

Password-check hook (passcheck)

The passcheck hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and psql metacommand.

- CREATE ROLE *username* ...PASSWORD – For more information, see CREATE ROLE in the PostgreSQL documentation.
- ALTER ROLE *username*...PASSWORD – For more information, see ALTER ROLE in the PostgreSQL documentation.
- \password *username* – This interactive psql metacommand securely changes the password for the specified user by hashing the password before transparently using the ALTER ROLE ... PASSWORD syntax. The metacommand is a secure wrapper for the ALTER ROLE ... PASSWORD command, thus the hook applies to the behavior of the psql metacommand.

For an example, see Password-check hook code listing.

Contents

- Function prototype
- Arguments
- Configuration
- Usage notes

Function prototype

```
passcheck_hook(username text, password text, password_type pgtle.password_types,
 valid_until timestamptz, valid_null boolean)
```

Arguments

A passcheck hook function takes the following arguments.

- `username` – The name (as text) of the role (username) that's setting a password.
- `password` – The plaintext or hashed password. The password entered should match the type specified in `password_type`.
- `password_type` – Specify the `pgtle.password_type` format of the password. This format can be one of the following options.
  - `PASSWORD_TYPE_PLAINTEXT` – A plaintext password.
  - `PASSWORD_TYPE_MD5` – A password that's been hashed using MD5 (message digest 5) algorithm.
  - `PASSWORD_TYPE_SCRAM_SHA_256` – A password that's been hashed using SCRAM-SHA-256 algorithm.
- `valid_until` – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a `timestamptz` value.
- `valid_null` – If this Boolean is set to `true`, the `valid_until` option is set to `NULL`.

Configuration

The function `pgtle.enable_password_check` controls whether the passcheck hook is active. The passcheck hook has three possible settings.

- `off` – Turns off the `passcheck` password-check hook. This is the default value.
- on – Turns on the `passcode` password-check hook so that passwords are checked against the table.
- `require` – Requires a password check hook to be defined.

Usage notes

To turn the `passcheck` hook on or off, you need to modify the custom DB parameter group for your RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --region aws-region \
    --db-parameter-group-name your-custom-parameter-group \
    --parameters
 "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --region aws-region ^
    --db-parameter-group-name your-custom-parameter-group ^
    --parameters
 "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

Code examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with an AWS software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Hello Amazon RDS

The following code examples show how to get started using Amazon RDS.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using System;
using System.Threading.Tasks;
using Amazon.RDS;
using Amazon.RDS.Model;

namespace RDSActions;

public static class HelloRds
{
    static async Task Main(string[] args)
    {
        var rdsClient = new AmazonRDSClient();

        Console.WriteLine($"Hello Amazon RDS! Following are some of your DB
 instances:");
        Console.WriteLine();

        // You can use await and any of the async methods to get a response.
        // Let's get the first twenty DB instances.
        var response = await rdsClient.DescribeDBInstancesAsync(
            new DescribeDBInstancesRequest()
            {
```

```
                MaxRecords = 20 // Must be between 20 and 100.
            });

        foreach (var instance in response.DBInstances)
        {
            Console.WriteLine($"\tDB name: {instance.DBName}");
            Console.WriteLine($"\tArn: {instance.DBInstanceArn}");
            Console.WriteLine($"\tIdentifier: {instance.DBInstanceIdentifier}");
            Console.WriteLine();
        }
    }
}
```

- For API details, see DescribeDBInstances in *AWS SDK for .NET API Reference*.

end
```

- For API details, see DescribeDBInstances in *AWS SDK for Ruby API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Learn the basics of Amazon RDS with an AWS SDK

The following code examples show how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.
- Take a snapshot of the instance.
- Delete the instance and parameter group.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
/// <summary>
/// Scenario for RDS DB instance example.
/// </summary>
public class RDSInstanceScenario
{
    /*
    Before running this .NET code example, set up your development environment,
 including your credentials.

    This .NET example performs the following tasks:
    1.  Returns a list of the available DB engine families using the
 DescribeDBEngineVersionsAsync method.
    2.  Selects an engine family and creates a custom DB parameter group using
 the CreateDBParameterGroupAsync method.
    3.  Gets the parameter groups using the DescribeDBParameterGroupsAsync
 method.
    4.  Gets parameters in the group using the DescribeDBParameters method.
```

```
   5.  Parses and displays parameters in the group.
   6.  Modifies both the auto_increment_offset and auto_increment_increment
parameters
       using the ModifyDBParameterGroupAsync method.
   7.  Gets and displays the updated parameters using the DescribeDBParameters
method with a source of "user".
   8.  Gets a list of allowed engine versions using the
DescribeDBEngineVersionsAsync method.
   9.  Displays and selects from a list of micro instance classes available for
the selected engine and version.
   10. Creates an RDS DB instance that contains a MySql database and uses the
parameter group
       using the CreateDBInstanceAsync method.
   11. Waits for DB instance to be ready using the DescribeDBInstancesAsync
method.
   12. Prints out the connection endpoint string for the new DB instance.
   13. Creates a snapshot of the DB instance using the CreateDBSnapshotAsync
method.
   14. Waits for DB snapshot to be ready using the DescribeDBSnapshots method.
   15. Deletes the DB instance using the DeleteDBInstanceAsync method.
   16. Waits for DB instance to be deleted using the DescribeDbInstances method.
   17. Deletes the parameter group using the DeleteDBParameterGroupAsync.

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
```

```
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
 * 5. Modifies the auto_increment_offset parameter.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions.
 * 8. Gets a list of micro instance classes available for the selected engine.
 * 9. Creates an RDS database instance that contains a MySql database and uses
 * the parameter group.
 * 10. Waits for the DB instance to be ready and prints out the connection
 * endpoint value.
 * 11. Creates a snapshot of the DB instance.
 * 12. Waits for an RDS DB snapshot to be ready.
 * 13. Deletes the RDS DB instance.
 * 14. Deletes the parameter group.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
Before running this code example, set up your development environment, including
 your credentials.

For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

This example requires an AWS Secrets Manager secret that contains the database
 credentials. If you do not create a
secret, this example will not work. For more details, see:

https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html

This example performs the following tasks:

1. Returns a list of the available DB engines by invoking the
 DescribeDbEngineVersions method.
2. Selects an engine family and create a custom DB parameter group by invoking
 the createDBParameterGroup method.
3. Gets the parameter groups by invoking the DescribeDbParameterGroups method.
4. Gets parameters in the group by invoking the DescribeDbParameters method.
5. Modifies both the auto_increment_offset and auto_increment_increment
 parameters by invoking the modifyDbParameterGroup method.
6. Gets and displays the updated parameters.
7. Gets a list of allowed engine versions by invoking the
 describeDbEngineVersions method.
8. Gets a list of micro instance classes available for the selected engine.
9. Creates an Amazon Relational Database Service (Amazon RDS) database instance
 that contains a MySQL database and uses the parameter group.
```

```
10. Waits for DB instance to be ready and prints out the connection endpoint
 value.
11. Creates a snapshot of the DB instance.
12. Waits for the DB snapshot to be ready.
13. Deletes the DB instance.
14. Deletes the parameter group.

Actions for Amazon RDS using AWS SDKs

The following code examples demonstrate how to perform individual Amazon RDS actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Amazon RDS API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for Amazon RDS using AWS SDKs.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Relational Database Service API Reference.

Examples

- Use CreateDBInstance with an AWS SDK or CLI
- Use CreateDBParameterGroup with an AWS SDK or CLI
- Use CreateDBSnapshot with an AWS SDK or CLI
- Use DeleteDBInstance with an AWS SDK or CLI
- Use DeleteDBParameterGroup with an AWS SDK or CLI
- Use DescribeAccountAttributes with an AWS SDK or CLI
- Use DescribeDBEngineVersions with an AWS SDK or CLI
- Use DescribeDBInstances with an AWS SDK or CLI
- Use DescribeDBParameterGroups with an AWS SDK or CLI
- Use DescribeDBParameters with an AWS SDK or CLI
- Use DescribeDBSnapshots with an AWS SDK or CLI
- Use DescribeOrderableDBInstanceOptions with an AWS SDK or CLI
- Use GenerateRDSAuthToken with an AWS SDK
- Use ModifyDBInstance with an AWS SDK or CLI
- Use ModifyDBParameterGroup with an AWS SDK or CLI
- Use RebootDBInstance with an AWS SDK or CLI

Use `CreateDBInstance` with an AWS SDK or CLI

The following code examples show how to use `CreateDBInstance`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

CLI

AWS CLI

To create a DB instance

The following `create-db-instance` example uses the required options to launch a new DB instance.

```
aws rds create-db-instance \
    --db-instance-identifier test-mysql-instance \
    --db-instance-class db.t3.micro \
    --engine mysql \
    --master-username admin \
    --master-user-password secret99 \
    --allocated-storage 20
```

Output:

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "test-mysql-instance",
        "DBInstanceClass": "db.t3.micro",
        "Engine": "mysql",

CLI

AWS CLI

To create a DB parameter group

The following `create-db-parameter-group` example creates a DB parameter group.

```
aws rds create-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --db-parameter-group-family MySQL5.6 \
    --description "My new parameter group"
```

Output:

```
{
    "DBParameterGroup": {
        "DBParameterGroupName": "mydbparametergroup",
        "DBParameterGroupFamily": "mysql5.6",
        "Description": "My new parameter group",
        "DBParameterGroupArn": "arn:aws:rds:us-
east-1:123456789012:pg:mydbparametergroup"
    }
}
```

For more information, see Creating a DB Parameter Group in the *Amazon RDS User Guide*.

Use `DeleteDBInstance` with an AWS SDK or CLI

The following code examples show how to use `DeleteDBInstance`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/// <summary>
/// Delete a particular DB instance.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <returns>DB instance object.</returns>
public async Task<DBInstance> DeleteDBInstance(string dbInstanceIdentifier)
{
    var response = await _amazonRDS.DeleteDBInstanceAsync(
        new DeleteDBInstanceRequest()
        {
            DBInstanceIdentifier = dbInstanceIdentifier,
            SkipFinalSnapshot = true,
            DeleteAutomatedBackups = true
        });

    return response.DBInstance;
}
```

- For API details, see DeleteDBInstance in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>

```
    Aws::Client::ClientConfiguration clientConfig;
    // Optional: Set to the AWS Region (overrides config file).
    // clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

        Aws::RDS::Model::DeleteDBInstanceRequest request;
        request.SetDBInstanceIdentifier(dbInstanceIdentifier);
        request.SetSkipFinalSnapshot(true);
        request.SetDeleteAutomatedBackups(true);

        Aws::RDS::Model::DeleteDBInstanceOutcome outcome =
                client.DeleteDBInstance(request);

        if (outcome.IsSuccess()) {
            std::cout << "DB instance deletion has started."
                      << std::endl;
        }
        else {
            std::cerr << "Error with RDS::DeleteDBInstance. "
                      << outcome.GetError().GetMessage()
                      << std::endl;
            result = false;
        }
```

- For API details, see DeleteDBInstance in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To delete a DB instance

The following `delete-db-instance` example deletes the specified DB instance after creating a final DB snapshot named `test-instance-final-snap`.

```
aws rds delete-db-instance \
    --db-instance-identifier test-instance \
    --final-db-snapshot-identifier test-instance-final-snap
```

Output:

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "test-instance",
        "DBInstanceStatus": "deleting",
        ...some output truncated...
    }
}
```

- For API details, see DeleteDBInstance in *AWS CLI Command Reference*.

Use `DescribeAccountAttributes` with an AWS SDK or CLI

The following code examples show how to use `DescribeAccountAttributes`.

CLI

AWS CLI

To describe account attributes

The following `describe-account-attributes` example retrieves the attributes for the current AWS account.

```
aws rds describe-account-attributes
```

Output:

```
{
    "AccountQuotas": [
        {
            "Max": 40,
            "Used": 4,
            "AccountQuotaName": "DBInstances"
        },
        {
            "Max": 40,
            "Used": 0,
            "AccountQuotaName": "ReservedDBInstances"
        },
        {
            "Max": 100000,
            "Used": 40,
            "AccountQuotaName": "AllocatedStorage"
        },
        {
            "Max": 25,
            "Used": 0,
            "AccountQuotaName": "DBSecurityGroups"
        },
        {
            "Max": 20,
            "Used": 0,
            "AccountQuotaName": "AuthorizationsPerDBSecurityGroup"
```

```
        },
        {
            "Max": 50,
            "Used": 1,
            "AccountQuotaName": "DBParameterGroups"
        },
        {
            "Max": 100,
            "Used": 3,
            "AccountQuotaName": "ManualSnapshots"
        },
        {
            "Max": 20,
            "Used": 0,

CLI

AWS CLI

To describe a DB instance

The following `describe-db-instances` example retrieves details about the specified DB instance.

```
aws rds describe-db-instances \
    --db-instance-identifier mydbinstancecf
```

Output:

```
{
    "DBInstances": [
        {
            "DBInstanceIdentifier": "mydbinstancecf",
            "DBInstanceClass": "db.t3.small",
            "Engine": "mysql",
            "DBInstanceStatus": "available",
            "MasterUsername": "masterawsuser",
            "Endpoint": {
                "Address": "mydbinstancecf.abcexample.us-
east-1.rds.amazonaws.com",
                "Port": 3306,
                "HostedZoneId": "Z2R2ITUGPM61AM"
```

```
            },
            ...some output truncated...
        }
    ]
}
```

- For API details, see DescribeDBInstances in *AWS CLI Command Reference*.

CLI

AWS CLI

To describe the parameters in a DB parameter group

The following `describe-db-parameters` example retrieves the details of the specified DB parameter group.

```
aws rds describe-db-parameters \
    --db-parameter-group-name mydbpg
```

Output:

```
{
    "Parameters": [
        {
            "ParameterName": "allow-suspicious-udfs",
            "Description": "Controls whether user-defined functions that have
 only an xxx symbol for the main function can be loaded",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": false,
            "ApplyMethod": "pending-reboot"
        },
        {
            "ParameterName": "auto_generate_certs",
            "Description": "Controls whether the server autogenerates SSL key and
 certificate files in the data directory, if they do not already exist.",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": false,
            "ApplyMethod": "pending-reboot"
        },
        ...some output truncated...
    ]
}
```

```

For more information, see Creating a DB Snapshot in the *Amazon RDS User Guide*.

Example 2: To find the number of manual snapshots taken

The following `describe-db-snapshots` example uses the `length` operator in the `--query` option to return the number of manual snapshots that have been taken in a particular AWS Region.

```
aws rds describe-db-snapshots \
    --snapshot-type manual \
    --query "length(*[].{DBSnapshots:SnapshotType})" \
    --region eu-central-1
```

Output:

```
35
```

For more information, see Creating a DB Snapshot in the *Amazon RDS User Guide*.

Use `GenerateRDSAuthToken` with an AWS SDK

The following code example shows how to use `GenerateRDSAuthToken`.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use the RdsUtilities class to generate an authentication token.

```
public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        final String usage = """

                Usage:
                    <dbInstanceIdentifier> <masterUsername>

                Where:
                    dbInstanceIdentifier - The database instance identifier.\s
                    masterUsername - The master user name.\s
                """;

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String dbInstanceIdentifier = args[0];
        String masterUsername = args[1];
        Region region = Region.US_WEST_2;
        RdsClient rdsClient = RdsClient.builder()
                .region(region)
                .build();

        String token = getAuthToken(rdsClient, dbInstanceIdentifier,
 masterUsername);
```

```
        System.out.println("The token response is " + token);
    }

    public static String getAuthToken(RdsClient rdsClient, String
 dbInstanceIdentifier, String masterUsername) {

        RdsUtilities utilities = rdsClient.utilities();
        try {
            GenerateAuthenticationTokenRequest tokenRequest =
 GenerateAuthenticationTokenRequest.builder()
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .username(masterUsername)
                    .port(3306)
                    .hostname(dbInstanceIdentifier)
                    .build();

            return utilities.generateAuthenticationToken(tokenRequest);

        } catch (RdsException e) {
            System.out.println(e.getLocalizedMessage());
            System.exit(1);
        }
        return "";
    }
}
```

- For API details, see GenerateRDSAuthToken in *AWS SDK for Java 2.x API Reference*.

Use `ModifyDBInstance` with an AWS SDK or CLI

The following code examples show how to use `ModifyDBInstance`.

CLI

AWS CLI

Example 1: To modify a DB instance

The following `modify-db-instance` example associates an option group and a parameter group with a compatible Microsoft SQL Server DB instance. The `--apply-immediately` parameter causes the option and parameter groups to be associated immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-instance \
    --db-instance-identifier database-2 \
    --option-group-name test-se-2017 \
    --db-parameter-group-name test-sqlserver-se-2017 \
    --apply-immediately
```

Output:

```
{
    "DBInstance": {
        "DBInstanceIdentifier": "database-2",
        "DBInstanceClass": "db.r4.large",
        "Engine": "sqlserver-se",
        "DBInstanceStatus": "available",

        ...output omitted...

        "DBParameterGroups": [
            {
                "DBParameterGroupName": "test-sqlserver-se-2017",
                "ParameterApplyStatus": "applying"
            }
        ],
        "AvailabilityZone": "us-west-2d",

        ...output omitted...

        "MultiAZ": true,
        "EngineVersion": "14.00.3281.6.v1",
        "AutoMinorVersionUpgrade": false,
        "ReadReplicaDBInstanceIdentifiers": [],
        "LicenseModel": "license-included",
        "OptionGroupMemberships": [
            {
                "OptionGroupName": "test-se-2017",
                "Status": "pending-apply"
            }
```

```
        ],
        "CharacterSetName": "SQL_Latin1_General_CP1_CI_AS",
        "SecondaryAvailabilityZone": "us-west-2c",
        "PubliclyAccessible": true,
        "StorageType": "gp2",

        ...output omitted...

        "DeletionProtection": false,
        "AssociatedRoles": [],
        "MaxAllocatedStorage": 1000
    }
}
```

For more information, see Modifying an Amazon RDS DB Instance in the *Amazon RDS User Guide*.

Example 2: To associate VPC security group with a DB instance

The following `modify-db-instance` example associates a specific VPC security group and removes DB security groups from a DB instance:

```
aws rds modify-db-instance \
    --db-instance-identifier dbName \
    --vpc-security-group-ids sg-ID
```

Output:

```
{
"DBInstance": {
    "DBInstanceIdentifier": "dbName",
    "DBInstanceClass": "db.t3.micro",
    "Engine": "mysql",
    "DBInstanceStatus": "available",
    "MasterUsername": "admin",
    "Endpoint": {
        "Address": "dbName.abcdefghijk.us-west-2.rds.amazonaws.com",
        "Port": 3306,
        "HostedZoneId": "ABCDEFGHIJK1234"
    },
    "AllocatedStorage": 20,
    "InstanceCreateTime": "2024-02-15T00:37:58.793000+00:00",
    "PreferredBackupWindow": "11:57-12:27",
```

```
    "BackupRetentionPeriod": 7,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
        {
            "VpcSecurityGroupId": "sg-ID",
            "Status": "active"
        }
    ],
    ... output omitted ...
    "MultiAZ": false,
    "EngineVersion": "8.0.35",
    "AutoMinorVersionUpgrade": true,
    "ReadReplicaDBInstanceIdentifiers": [],
    "LicenseModel": "general-public-license",

    ... output omitted ...
    }
}
```

For more information, see Controlling access with security groups in the *Amazon RDS User Guide*.

- For API details, see ModifyDBInstance in *AWS CLI Command Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    Aws::Client::ClientConfiguration clientConfig;
    // Optional: Set to the AWS Region (overrides config file).
    // clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

    Aws::RDS::Model::ModifyDBParameterGroupRequest request;
    request.SetDBParameterGroupName(PARAMETER_GROUP_NAME);
    request.SetParameters(updateParameters);

    Aws::RDS::Model::ModifyDBParameterGroupOutcome outcome =
            client.ModifyDBParameterGroup(request);

    if (outcome.IsSuccess()) {
        std::cout << "The DB parameter group was successfully modified."
```

```
                    << std::endl;
        }
        else {
            std::cerr << "Error with RDS::ModifyDBParameterGroup. "
                      << outcome.GetError().GetMessage()
                      << std::endl;
        }
```

- For API details, see ModifyDBParameterGroup in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To modify a DB parameter group

The following `modify-db-parameter-group` example changes the value of the `clr enabled` parameter in a DB parameter group. The `--apply-immediately` parameter causes the DB parameter group to be modified immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name test-sqlserver-se-2017 \
    --parameters "ParameterName='clr
 enabled',ParameterValue=1,ApplyMethod=immediate"
```

Output:

```
{
    "DBParameterGroupName": "test-sqlserver-se-2017"
}
```

For more information, see Modifying Parameters in a DB Parameter Group in the *Amazon RDS User Guide*.

- For API details, see ModifyDBParameterGroup in *AWS CLI Command Reference*.

Scenarios for Amazon RDS using AWS SDKs

The following code examples show you how to implement common scenarios in Amazon RDS with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Amazon RDS or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Create an Aurora Serverless work item tracker

Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

SDK for .NET

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.

- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

PHP

SDK for PHP

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with AWS services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service

- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Serverless examples for Amazon RDS

The following code examples show how to use Amazon RDS with AWS SDKs.

Examples

- Connecting to an Amazon RDS database in a Lambda function

Connecting to an Amazon RDS database in a Lambda function

The following code examples show how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

.NET

SDK for .NET

> **Note**

Connecting to an Amazon RDS database in a Lambda function using .NET.

```
using System.Data;
using System.Text.Json;
using Amazon.Lambda.APIGatewayEvents;
using Amazon.Lambda.Core;
using MySql.Data.MySqlClient;

// Assembly attribute to enable the Lambda function's JSON input to be converted
 into a .NET class.
[assembly:
 LambdaSerializer(typeof(Amazon.Lambda.Serialization.SystemTextJson.DefaultLambdaJsonSeri

namespace aws_rds;

public class InputModel
{
    public string key1 { get; set; }
    public string key2 { get; set; }
}

public class Function
{
    /// <summary>
    // Handles the Lambda function execution for connecting to RDS using IAM
 authentication.
    /// </summary>
```

```
    /// <param name="input">The input event data passed to the Lambda function</
param>
    /// <param name="context">The Lambda execution context that provides runtime
 information</param>
    /// <returns>A response object containing the execution result</returns>

    public async Task<APIGatewayProxyResponse>
 FunctionHandler(APIGatewayProxyRequest request, ILambdaContext context)
    {
        // Sample Input: {"body": "{\"key1\":\"20\", \"key2\":\"25\"}"}
        var input = JsonSerializer.Deserialize<InputModel>(request.Body);

        /// Obtain authentication token
        var authToken = RDSAuthTokenGenerator.GenerateAuthToken(
            Environment.GetEnvironmentVariable("RDS_ENDPOINT"),
            Convert.ToInt32(Environment.GetEnvironmentVariable("RDS_PORT")),
            Environment.GetEnvironmentVariable("RDS_USERNAME")
        );

        /// Build the Connection String with the Token
        string connectionString =
 $"Server={Environment.GetEnvironmentVariable("RDS_ENDPOINT")};" +

 $"Port={Environment.GetEnvironmentVariable("RDS_PORT")};" +

 $"Uid={Environment.GetEnvironmentVariable("RDS_USERNAME")};" +
                                  $"Pwd={authToken};";

        try
        {
            await using var connection = new MySqlConnection(connectionString);
            await connection.OpenAsync();

            const string sql = "SELECT @param1 + @param2 AS Sum";

            await using var command = new MySqlCommand(sql, connection);
            command.Parameters.AddWithValue("@param1", int.Parse(input.key1 ??
 "0"));
            command.Parameters.AddWithValue("@param2", int.Parse(input.key2 ??
 "0"));

            await using var reader = await command.ExecuteReaderAsync();
            if (await reader.ReadAsync())
```

```
            {
                int result = reader.GetInt32("Sum");

                //Sample Response: {"statusCode":200,"body":"{\"message\":\"The
 sum is: 45\"}","isBase64Encoded":false}
                return new APIGatewayProxyResponse
                {
                    StatusCode = 200,
                    Body = JsonSerializer.Serialize(new { message = $"The sum is:
 {result}" })
                };
            }

        }
        catch (Exception ex)
        {
            Console.WriteLine($"Error: {ex.Message}");
        }

        return new APIGatewayProxyResponse

> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Connecting to an Amazon RDS database in a Lambda function using Python.

```
import json
import os
import boto3
import pymysql

# RDS settings
proxy_host_name = os.environ['PROXY_HOST_NAME']
port = int(os.environ['PORT'])
db_name = os.environ['DB_NAME']
db_user_name = os.environ['DB_USER_NAME']
aws_region = os.environ['AWS_REGION']

# Fetch RDS Auth Token
def get_auth_token():
    client = boto3.client('rds')
    token = client.generate_db_auth_token(
        DBHostname=proxy_host_name,
        Port=port
        DBUsername=db_user_name
        Region=aws_region
    )
    return token

def lambda_handler(event, context):
    token = get_auth_token()
```

```
    try:
        connection = pymysql.connect(
            host=proxy_host_name,
            user=db_user_name,
            password=token,
            db=db_name,
            port=port,
            ssl={'ca': 'Amazon RDS'}  # Ensure you have the CA bundle for SSL
connection
        )

        with connection.cursor() as cursor:
            cursor.execute('SELECT %s + %s AS sum', (3, 2))
            result = cursor.fetchone()

        return result

    except Exception as e:
        return (f"Error: {str(e)}")  # Return an error message if an exception
occurs
```

        db_hostname = db_hostname,
        port = port,
        db_user = db_username
    );

    let signable_request =
        SignableRequest::new("GET", &url, std::iter::empty(),
 SignableBody::Bytes(&[]))
            .expect("signable request");

    let (signing_instructions, _signature) =
        sign(signable_request, &signing_params.into())?.into_parts();

    let mut url = url::Url::parse(&url).unwrap();
    for (name, value) in signing_instructions.params() {
        url.query_pairs_mut().append_pair(name, &value);
    }

    let response = url.to_string().split_off("https://".len());

    Ok(response)
}

#[tokio::main]
async fn main() -> Result<(), Error> {
    run(service_fn(handler)).await
}
```

```
async fn handler(_event: LambdaEvent<Value>) -> Result<Value, Error> {
    let db_host = env::var("DB_HOSTNAME").expect("DB_HOSTNAME must be set");
    let db_port = env::var("DB_PORT")
        .expect("DB_PORT must be set")
        .parse::<u16>()
        .expect("PORT must be a valid number");
    let db_name = env::var("DB_NAME").expect("DB_NAME must be set");
    let db_user_name = env::var("DB_USERNAME").expect("DB_USERNAME must be set");

    let token = generate_rds_iam_token(&db_host, db_port, &db_user_name).await?;

    let opts = PgConnectOptions::new()
        .host(&db_host)
        .port(db_port)
        .username(&db_user_name)
        .password(&token)
        .database(&db_name)
        .ssl_root_cert_from_pem(RDS_CERTS.to_vec())
        .ssl_mode(sqlx::postgres::PgSslMode::Require);

    let pool = sqlx::postgres::PgPoolOptions::new()
        .connect_with(opts)
        .await?;

    let result: i32 = sqlx::query_scalar("SELECT $1 + $2")
        .bind(3)
        .bind(2)
        .fetch_one(&pool)
        .await?;

    println!("Result: {:?}", result);

    Ok(json!({
        "statusCode": 200,
        "content-type": "text/plain",
        "body": format!("The selected sum is: {result}")
    }))
}
```

For a complete list of AWS SDK developer guides and code examples, see Using this service with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon RDS , see AWS services in scope by compliance program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS . The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance . The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS :

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see Amazon VPC and Amazon RDS .
- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances , tag resources, or modify security groups.

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance . When you first create a DB instance , its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the Db2, MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance , see Using SSL/TLS to encrypt a connection to a DB instance or cluster .
- Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance . For more information, see Encrypting Amazon RDS resources .
- Use network encryption and transparent data encryption with Oracle DB instances; for more information, see Oracle native network encryption and Oracle Transparent Data Encryption
- Use the security features of your DB engine to control who can log in to the databases on a DB instance . These features work just as if the database was on your local network.

> **Note**
>
> You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.

For more information on managing access to Amazon RDS resources and your databases on a DB instance , see the following topics.

Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

> **Important**
>
> We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Topics

- Password authentication

- IAM database authentication
- Kerberos authentication

Password authentication

With *password authentication,* your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER` *`name`* `IDENTIFIED BY` *`password`*, while in PostgreSQL, the statement is `CREATE USER` *`name`* `WITH PASSWORD` *`password`*.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS , see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the *AWS Secrets Manager User Guide*.

IAM database authentication

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB instance . Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL .

Kerberos authentication

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances .

To use credentials from your self-managed Active Directory, you need to setup a trust relationship to the Directory Service for Microsoft Active Directory that the DB instance is joined to.

RDS for PostgreSQL and RDS for MySQL support one-way and two-way forest trust relationships with forest-wide authentication or selective authentication.

In some scenarios, you can configure Kerberos authentication over an external trust relationship. This requires your self-managed Active Directory to have additional settings. This includes but is not limited to Kerberos Forest Search Order.

Microsoft SQL Server and PostgreSQL DB instances support one-way and two-way forest trust relationships. Oracle DB instances support one-way and two-way external and forest trust relationships. For more information, see When to create a trust relationship in the *Directory Service Administration Guide*.

For information about Kerberos authentication with a specific DB engine, see the following:

- Working with AWS Managed Active Directory with RDS for SQL Server
- Using Kerberos authentication for Amazon RDS for MySQL
- Configuring Kerberos authentication for Amazon RDS for Oracle
- Using Kerberos authentication with Amazon RDS for PostgreSQL
- Using Kerberos authentication for Amazon RDS for Db2 .

> **Note**
>
> Currently, Kerberos authentication isn't supported for MariaDB DB instances.

Password management with Amazon RDS and AWS Secrets Manager

Amazon RDS integrates with Secrets Manager to manage master user passwords for your DB instances and Multi-AZ DB clusters.

Topics

- Limitations for Secrets Manager integration with Amazon RDS
- Overview of managing master user passwords with AWS Secrets Manager
- Benefits of managing master user passwords with Secrets Manager
- Permissions required for Secrets Manager integration
- Enforcing RDS management of the master user password in AWS Secrets Manager
- Managing the master user password for a DB instance with Secrets Manager
- Managing the master user password for an RDS for Oracle tenant database with Secrets Manager
- Managing the master user password for a Multi-AZDB cluster with Secrets Manager
- Rotating the master user password secret for a DB instance
- Rotating the master user password secret for a Multi-AZDB cluster
- Viewing the details about a secret for a DB instance
- Viewing the details about a secret for a Multi-AZDB cluster
- Viewing the details about a secret for a tenant database
- Region and version availability

Limitations for Secrets Manager integration with Amazon RDS

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Creating a read replica when the source DB or DB cluster manages credentials with Secrets Manager. This applies to all DB engines except RDS for SQL Server.
- Amazon RDS Blue/Green Deployments
- Amazon RDS Custom
- Oracle Data Guard switchover

Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the AWS Secrets Manager User Guide.

When you store database secrets in Secrets Manager, your AWS account incurs charges. For information about pricing, see AWS Secrets Manager Pricing.

You can specify that RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster when you perform one of the following operations:

- Create a DB instance
- Create a Multi-AZ DB cluster
- Create a tenant database in an RDS for Oracle CDB
- Modify a DB instance
- Modify a Multi-AZ DB cluster
- Modify a tenant database (RDS for Oracle only)
- Restore a DB instance from Amazon S3
- Restore a DB instance from a snapshot or to a point in time (RDS for Oracle only)

When you specify that RDS manages the master user password in Secrets Manager, RDS generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

RDS manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB instance that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB instance or Multi-AZ DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from AWS Secrets Manager and Connect to a SQL database with credentials in an AWS Secrets Manager secret in the *AWS Secrets Manager User Guide*.

Benefits of managing master user passwords with Secrets Manager

Managing RDS master user passwords with Secrets Manager provides the following benefits:

- RDS automatically generates database credentials.
- RDS automatically stores and manages database credentials in AWS Secrets Manager.
- RDS rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the AWS Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon RDS.

For create, modify, or restore operations, the user who specifies that Amazon RDS manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

The `kms:DescribeKey` permission is required to access your customer-managed key for the `MasterUserSecretKmsKeyId` and to describe `aws/secretsmanager`.

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`
- `kms:CreateGrant`

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- `secretsmanager:RotateSecret`

Enforcing RDS management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce RDS management of the master user password in AWS Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters or create or modify tenant databases unless the master user password is managed by RDS in Secrets Manager.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
 "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3",
                       "rds:RestoreDBInstanceFromDBSnapshot",
 "rds:RestoreDBInstanceToPointInTime", "rds:CreateTenantDatabase",
                       "rds:ModifyTenantDatabase"],
            "Resource": "*",
            "Condition": {
                "Bool": {
```

```
                    "rds:ManageMasterUserPassword": false
                }
            }
        }
    ]
}
```

> **Note**
>
> This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the instance.
> To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing instances that don't have Secrets Manager integration enabled.

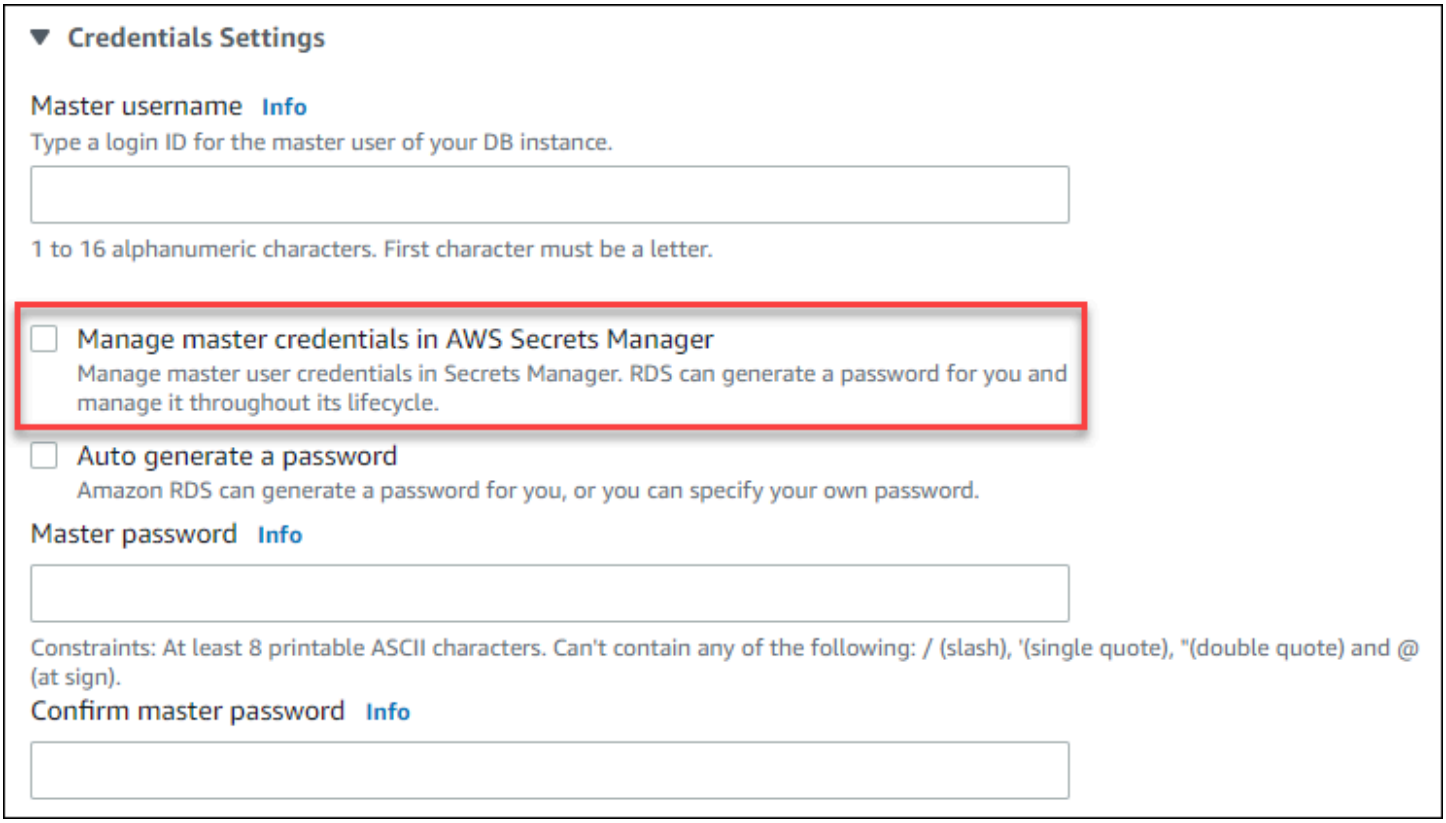
For more information about using condition keys in IAM policies, see Policy condition keys for Amazon RDS and Example policies: Using condition keys.

Managing the master user password for a DB instance with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

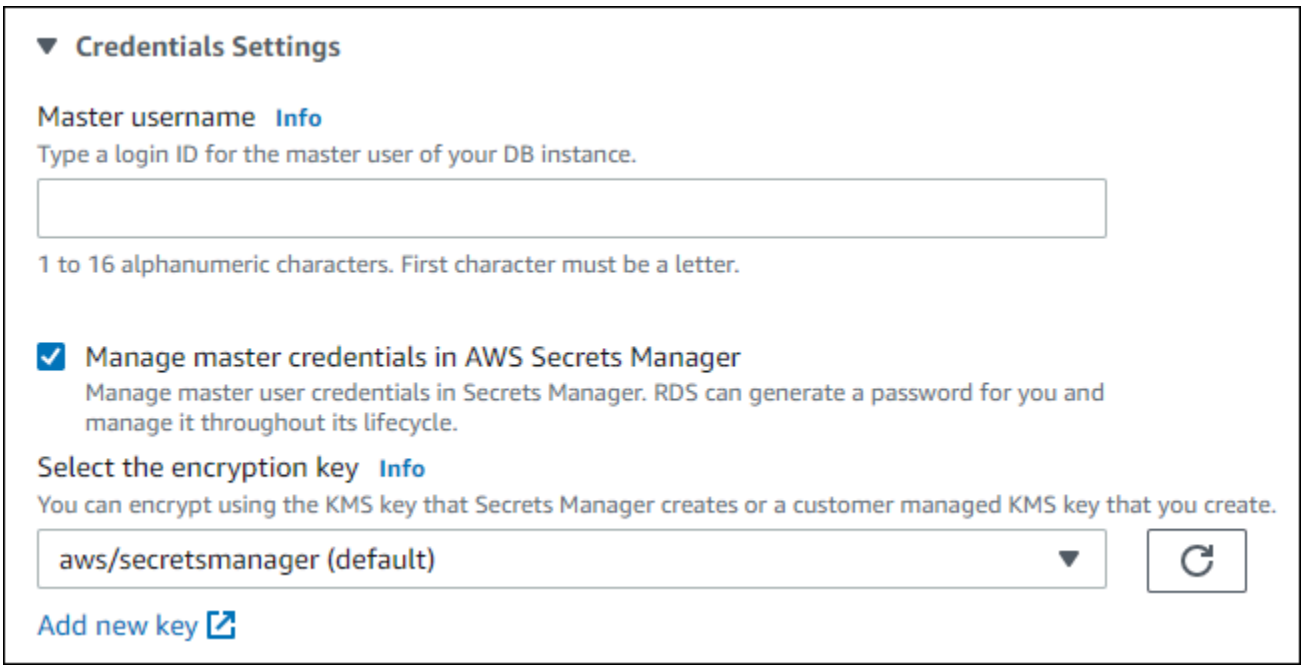
- Creating an Amazon RDS DB instance
- Modifying an Amazon RDS DB instance
- Restoring a backup into an Amazon RDS for MySQL DB instance
- Restoring to a DB instance (RDS for Oracle only)
- Restoring a DB instance to a specified time for Amazon RDS (RDS for Oracle only)

You can perform the preceding operations using the RDS console, the AWS CLI, or the RDS API.



Console

Follow the instructions for creating or modifying a DB instance with the RDS console:



- Creating a DB instance
- Modifying an Amazon RDS DB instance
- Importing data from Amazon S3 to a new MySQL DB instance

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. When you're creating or restoring a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you're modifying a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating or restoring a DB instance.

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB instance, you can't change the KMS key used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you're creating a DB instance, see Settings for DB instances. For more information about the available settings when you're modifying a DB instance, see Settings for DB instances.

AWS CLI

To manage the master user password with RDS in Secrets Manager, specify the `--manage-master-user-password` option in one of the following AWS CLI commands:

- create-db-instance
- modify-db-instance
- restore-db-instance-from-s3
- restore-db-instance-from-db-snapshot (RDS for Oracle only)
- restore-db-instance-to-point-in-time (RDS for Oracle only)

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see Settings for DB instances. For more information about the available settings when you are modifying a DB instance, see Settings for DB instances.

The following example creates a DB instance and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --engine mysql \
    --engine-version 8.0.39 \
    --db-instance-class db.r5b.large \
    --allocated-storage 200 \
    --master-username testUser \
    --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --engine mysql ^
    --engine-version 8.0.39 ^
    --db-instance-class db.r5b.large ^
    --allocated-storage 200 ^
    --master-username testUser ^
    --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following RDS API operations:

- CreateDBInstance
- ModifyDBInstance
- RestoreDBInstanceFromS3
- RestoreDBInstanceFromSnapshot (RDS for Oracle only)
- RestoreDBInstanceToPointInTime (RDS for Oracle only)

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

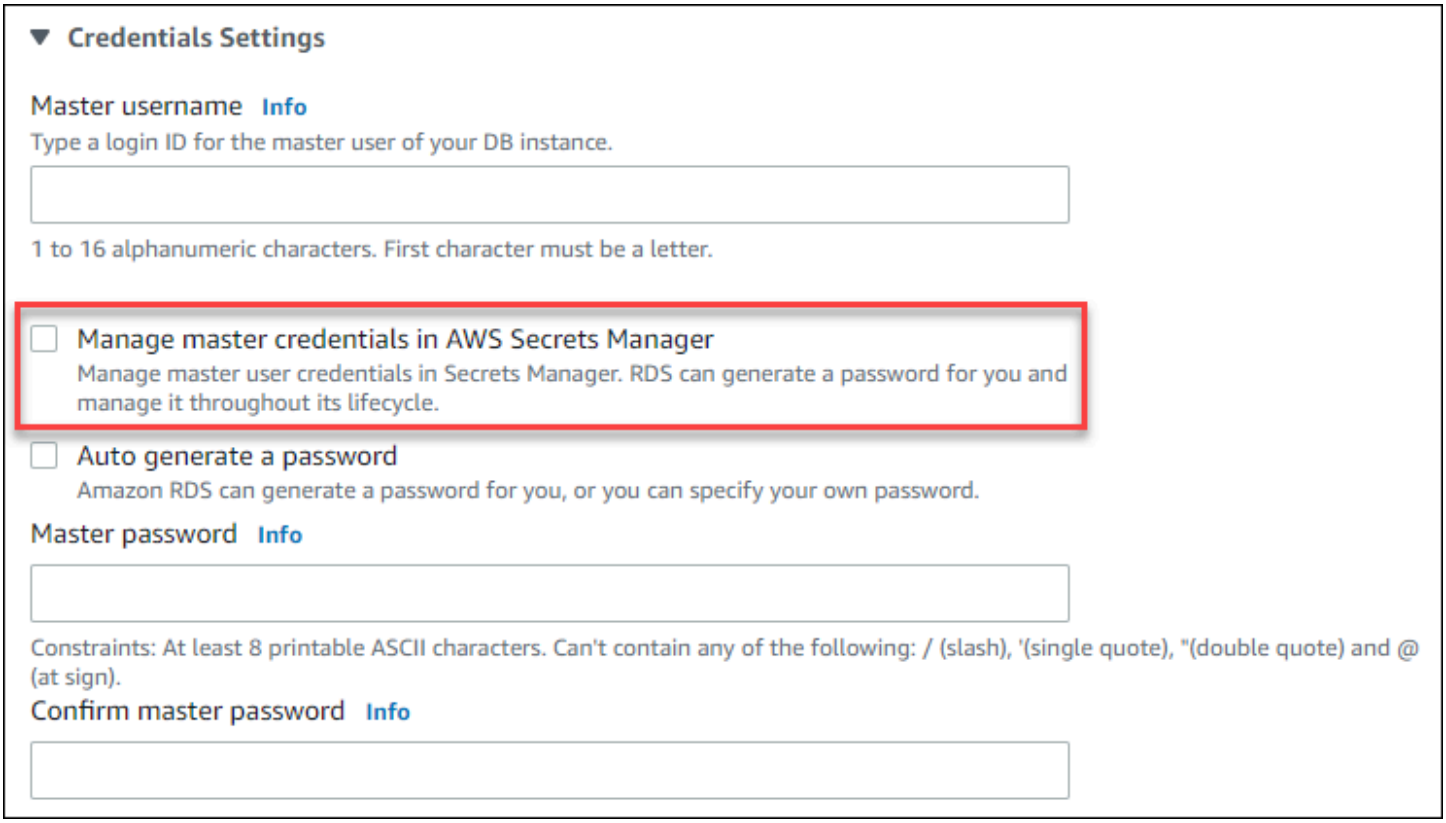
To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

Managing the master user password for an RDS for Oracle tenant database with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

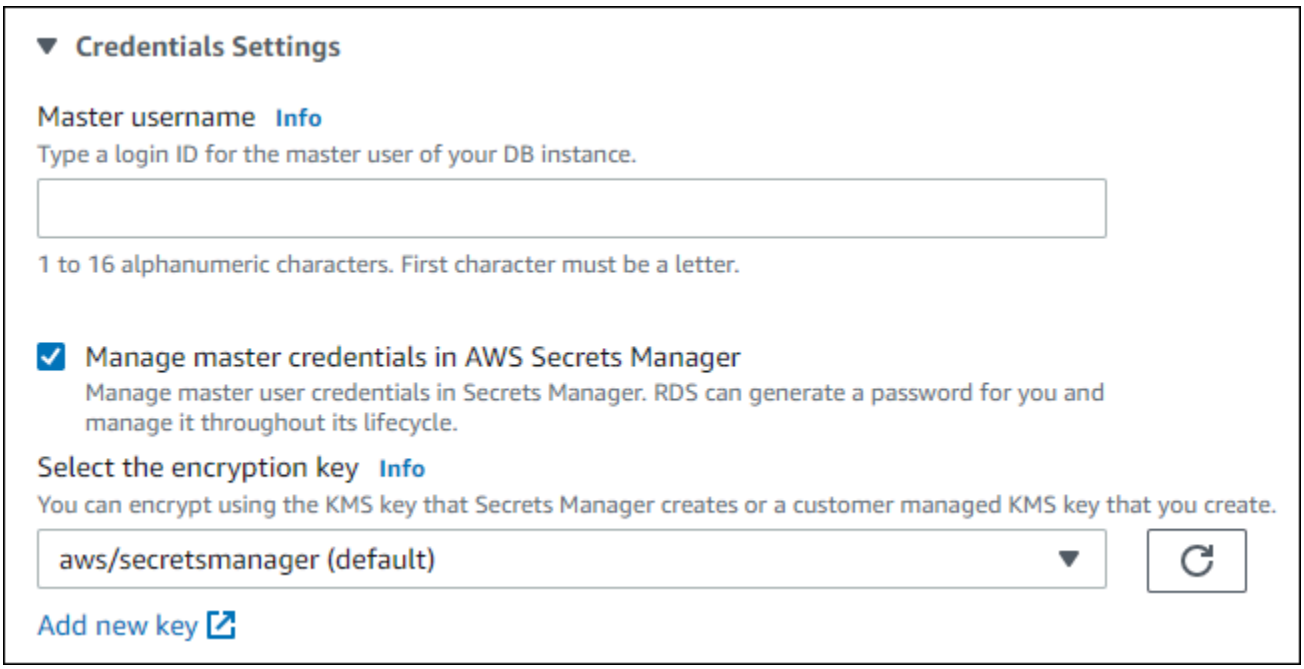
- Adding an RDS for Oracle tenant database to your CDB instance
- Modifying an RDS for Oracle tenant database

You can use the RDS console, the AWS CLI, or the RDS API to perform the preceding actions.



Console

Follow the instructions for creating or modifying an RDS for Oracle tenant database with the RDS console:



- Adding an RDS for Oracle tenant database to your CDB instance
- Modifying an RDS for Oracle tenant database

When you use the RDS console to perform one of the preceding operations, you can specify that RDS manage the master password in Secrets Manager. When you create a tenant database, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you modify a tenant database, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating a tenant database.

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a tenant database, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a tenant database, see Settings for DB instances. For more information about the available settings when you are modifying a tenant database, see Settings for DB instances.

AWS CLI

To manage the master user password with RDS in Secrets Manager, specify the `--manage-master-user-password` option in one of the following AWS CLI commands:

- create-tenant-database
- modify-tenant-database

When you specify the `--manage-master-user-password` option in the preceding commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a

customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a tenant database, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a tenant database, see create-tenant-database. For more information about the available settings when you are modifying a tenant database, see modify-tenant-database.

The following example creates an RDS for Oracle tenant database and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-tenant-database --region us-east-1 \
    --db-instance-identifier my-cdb-inst \
    --tenant-db-name mypdb2 \
    --master-username mypdb2-admin \
    --character-set-name UTF-16 \
    --manage-master-user-password
```

For Windows:

```
aws rds create-tenant-database --region us-east-1 ^
    --db-instance-identifier my-cdb-inst ^
    --tenant-db-name mypdb2 ^
    --master-username mypdb2-admin ^
    --character-set-name UTF-16 ^
    --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following RDS API operations:

- CreateTenantDatabase
- ModifyTenantDatabase

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

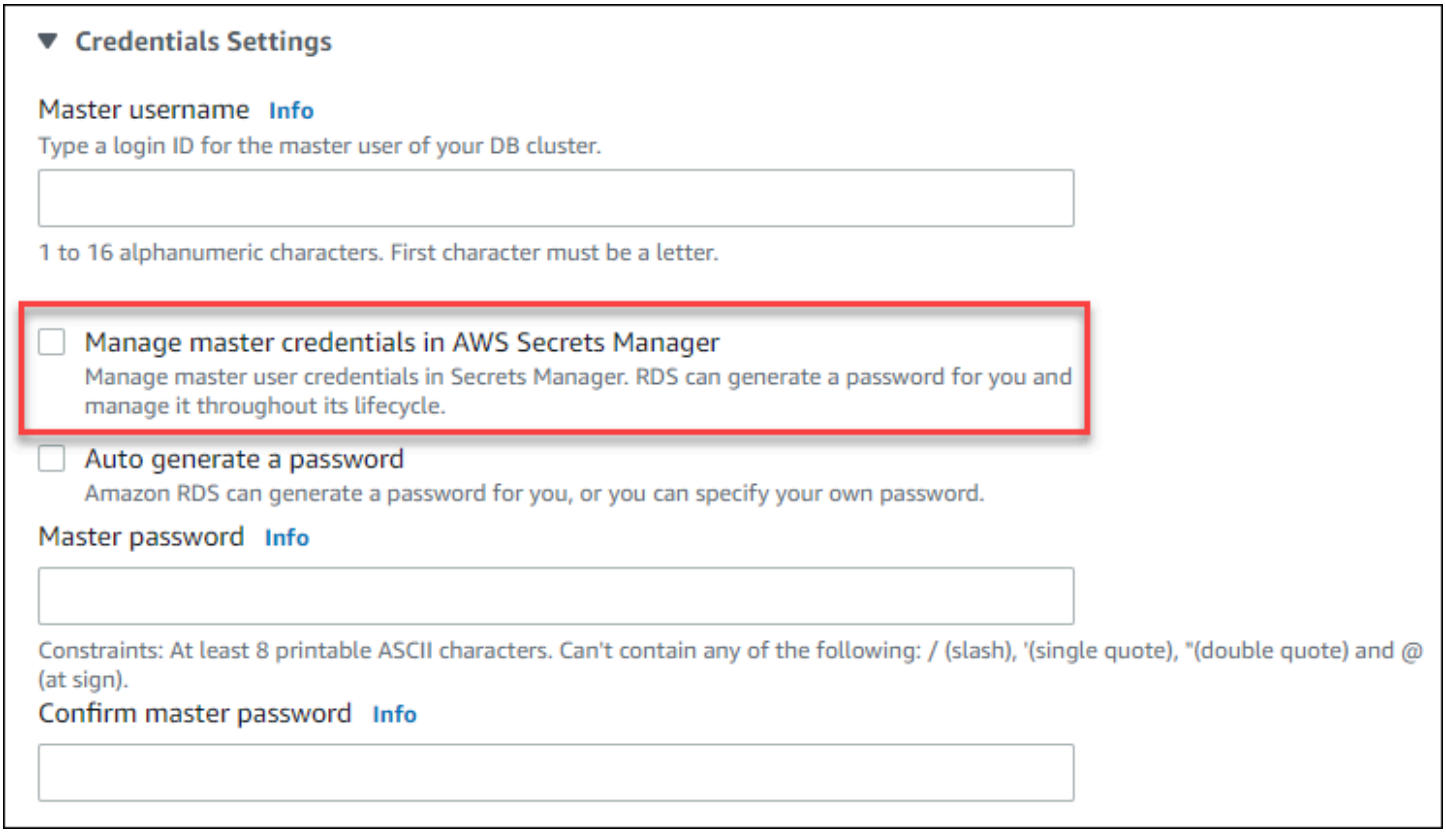
To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a tenant database, you can't change the KMS key that is used to encrypt the secret.

Managing the master user password for a Multi-AZDB cluster with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

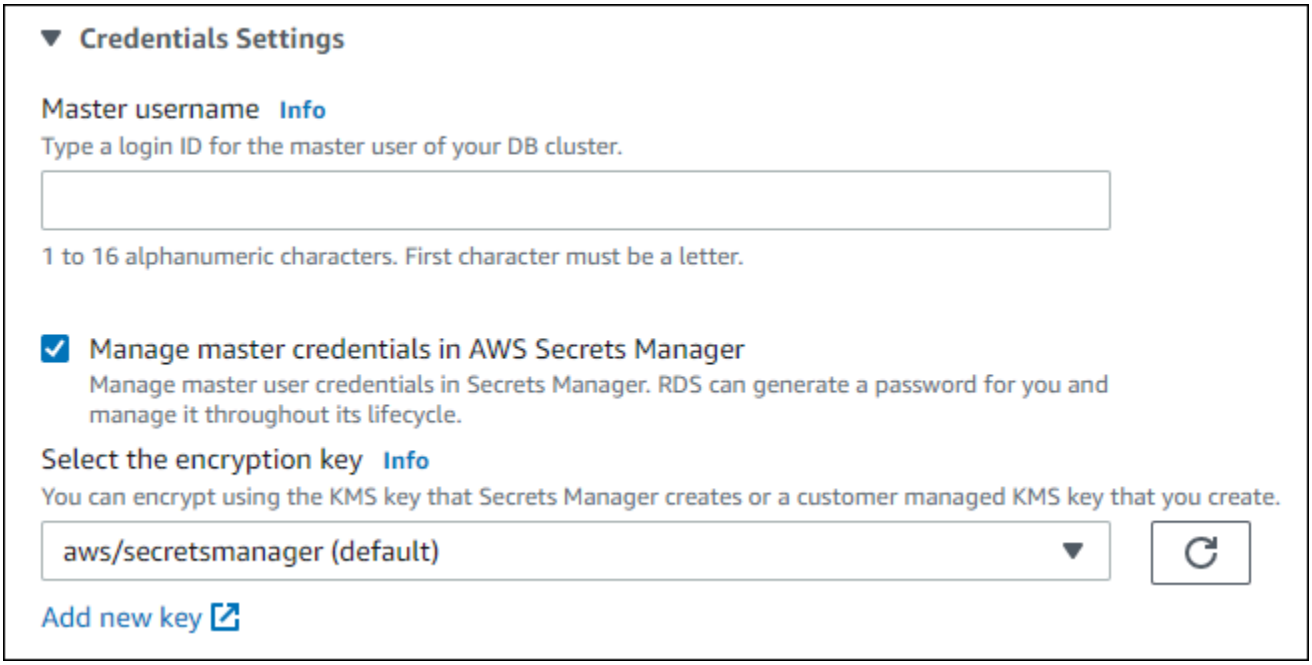
- Creating a Multi-AZ DB cluster for Amazon RDS
- Modifying a Multi-AZ DB cluster for Amazon RDS

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.



Console

Follow the instructions for creating or modifying a Multi-AZ DB cluster with the RDS console:



- Creating a DB cluster
- Modifying a Multi-AZ DB cluster for Amazon RDS

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating a DB cluster.

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters. For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters.

AWS CLI

To specify that RDS manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- create-db-cluster
- modify-db-cluster

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see Settings for creating Multi-AZ DB clusters. For more information about the available settings when you are modifying a Multi-AZ DB cluster, see Settings for modifying Multi-AZ DB clusters.

This example creates a Multi-AZ DB cluster and specifies that RDS manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
   --db-cluster-identifier mysql-multi-az-db-cluster \
   --engine mysql \
   --engine-version 8.0.39  \
   --backup-retention-period 1  \
   --allocated-storage 4000 \
   --storage-type io1 \
   --iops 10000 \
   --db-cluster-instance-class db.r6gd.xlarge \
   --master-username testUser \
   --manage-master-user-password
```

For Windows:

```
aws rds create-db-cluster ^
   --db-cluster-identifier mysql-multi-az-db-cluster ^
   --engine mysql ^
   --engine-version 8.0.39 ^
   --backup-retention-period 1 ^
   --allocated-storage 4000 ^
   --storage-type io1 ^
   --iops 10000 ^
   --db-cluster-instance-class db.r6gd.xlarge ^
   --master-username testUser ^
   --manage-master-user-password
```

RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

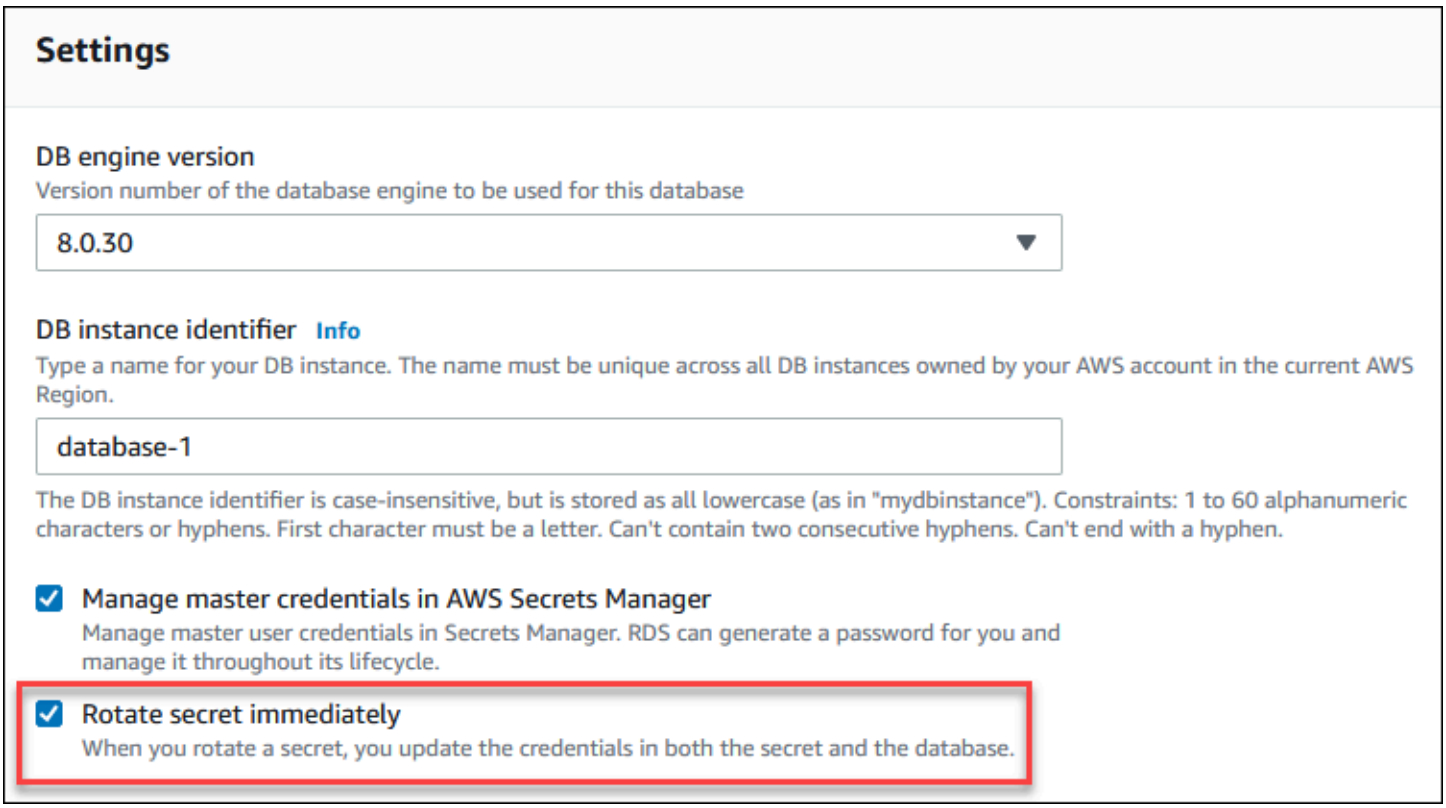
- CreateDBCluster
- ModifyDBCluster

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a

customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

Rotating the master user password secret for a DB instance



When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the DB instance to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB instance. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the DB instance and select **Rotate secret immediately** in **Settings**.

Follow the instructions for modifying a DB instance with the RDS console in Modifying an Amazon RDS DB instance. You must choose **Apply immediately** on the confirmation page.

AWS CLI

To rotate a master user password secret using the AWS CLI, use the modify-db-instance command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --rotate-master-user-password \
    --apply-immediately
```

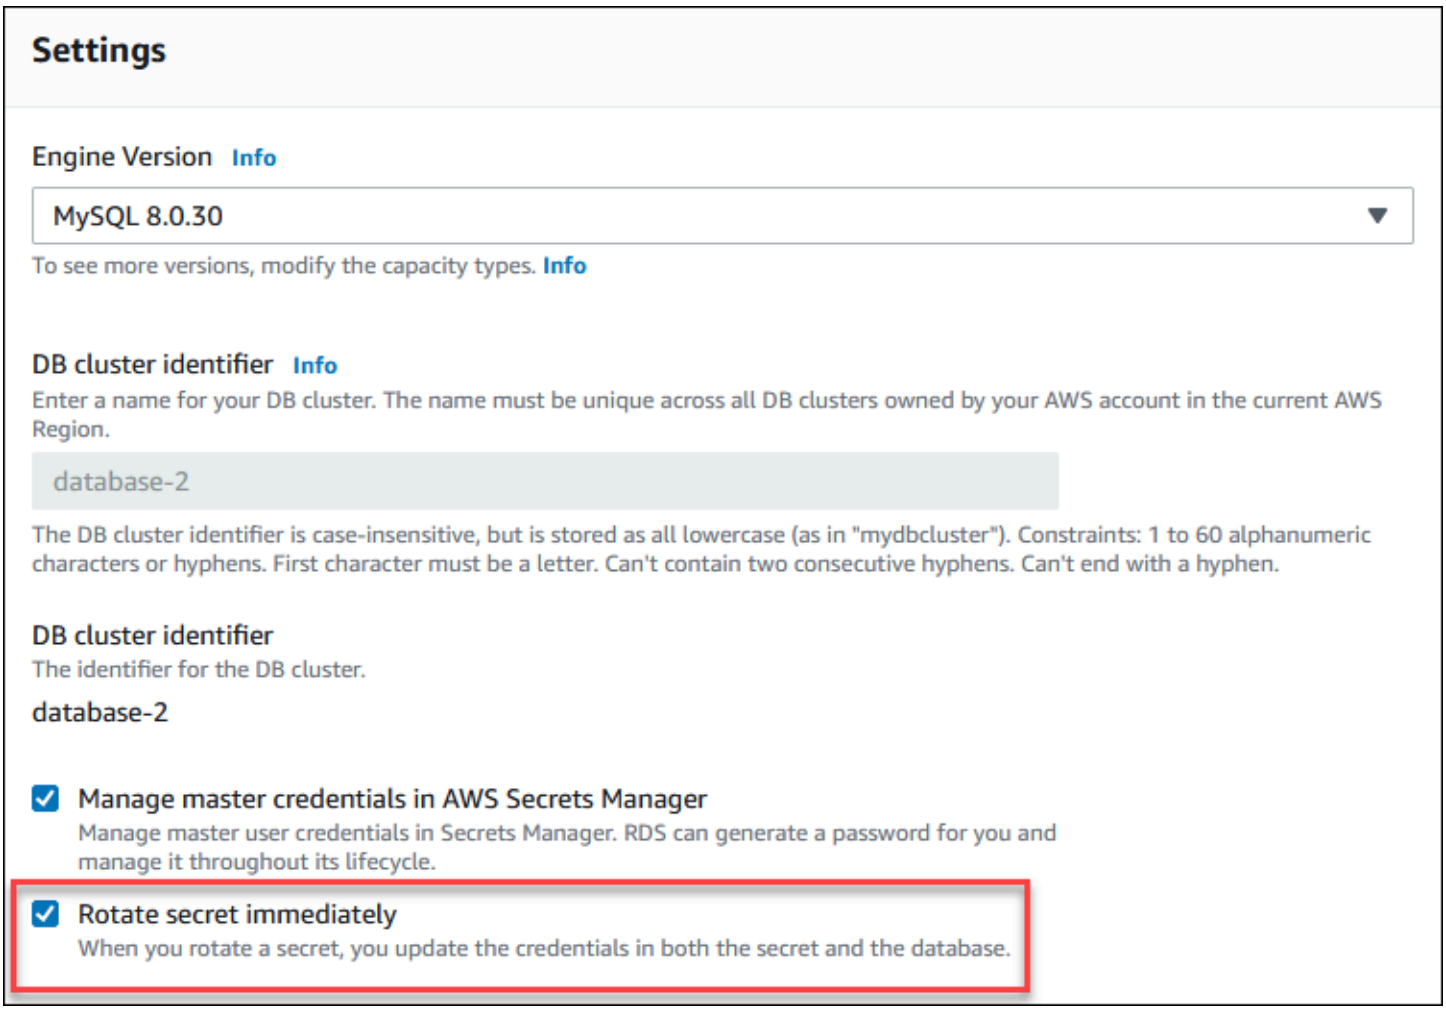
For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --rotate-master-user-password ^
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the ModifyDBInstance operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Rotating the master user password secret for a Multi-AZDB cluster



When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the Multi-AZ DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the Multi-AZ DB cluster. For information about modifying a Multi-AZ DB cluster, see Modifying a Multi-AZ DB cluster for Amazon RDS.

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains atleast one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the Multi-AZ DB cluster and select **Rotate secret immediately** in **Settings**.

Follow the instructions for modifying a Multi-AZ DB cluster with the RDS console in Modifying a Multi-AZ DB cluster for Amazon RDS. You must choose **Apply immediately** on the confirmation page.

AWS CLI

To rotate a master user password secret using the AWS CLI, use the modify-db-cluster command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```

```
    --db-cluster-identifier mydbcluster \
    --rotate-master-user-password \
    --apply-immediately
```

For Windows:

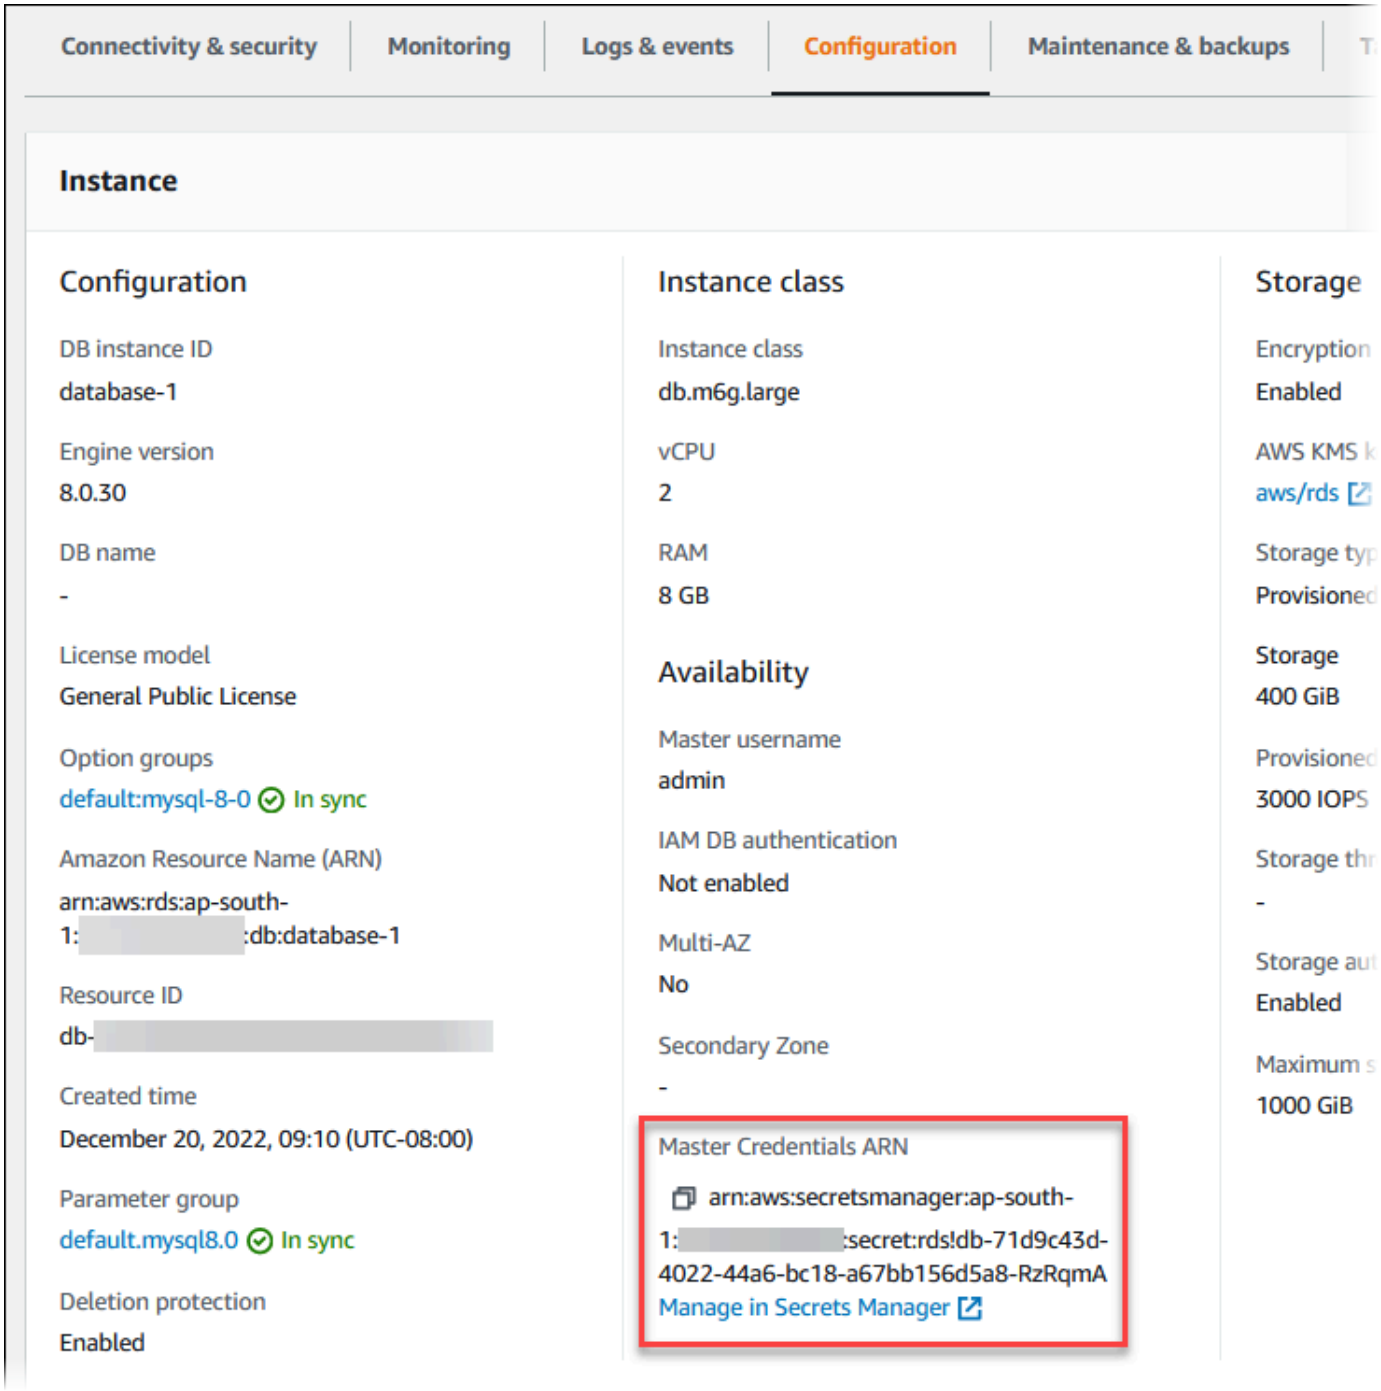
```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --rotate-master-user-password ^
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the ModifyDBCluster operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Viewing the details about a secret for a DB instance

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).



You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the describe-db-instances RDS CLI command to find the following information about a secret managed by RDS in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

    When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB instance to turn off automatic management of database credentials, and then modify the DB instance again to turn on automatic management of database credentials. To modify the DB instance, use the `--manage-master-user-password` option in the modify-db-instance command.
- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-instance-identifier` option to show output for a specific DB instance. This example shows the output for a secret that is used by a DB instance.

Example

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

Following is sample output for a secret:

```
"MasterUserSecret": {
                "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
                "SecretStatus": "active",
                "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
            }
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

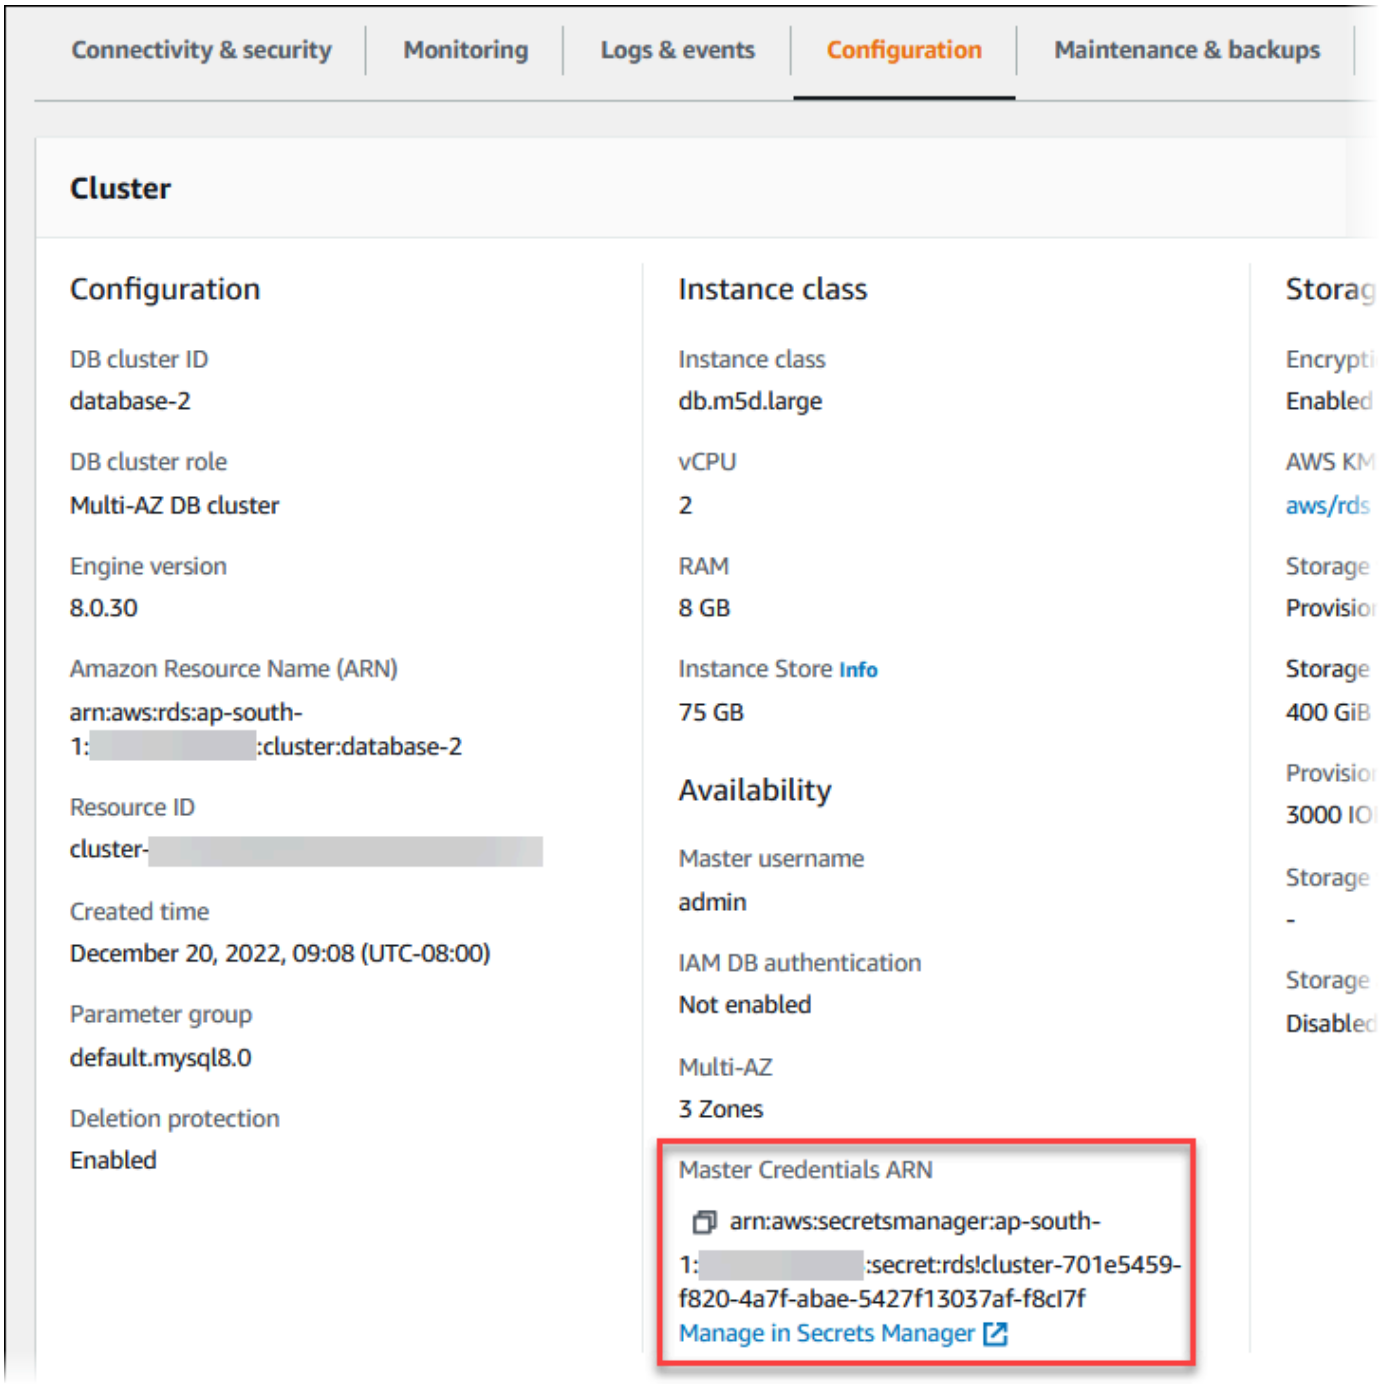
You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager by using the DescribeDBInstances operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Viewing the details about a secret for a Multi-AZDB cluster

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.



Console

To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose **Databases**.
3. Choose the name of the Multi-AZ DB cluster to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the RDS AWS CLI describe-db-clusters command to find the following information about a secret managed by RDS in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

    When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the modify-db-cluster command.
- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
                "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
                "SecretStatus": "active",
                "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
            }
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager using the DescribeDBClusters RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Viewing the details about a secret for a tenant database

You can retrieve your secrets using the console (https://console.aws.amazon.com/secretsmanager/) or the AWS CLI (get-secret-value Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by Amazon RDS in AWS Secrets Manager with the Amazon RDS console, the AWS CLI, or the Amazon RDS API.

Console

To view the details about a secret managed by Amazon RDS in AWS Secrets Manager for a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that contains the tenant database to show its details.
4. Choose the **Configuration** tab.

   In the **Tenant databases** section, find the tenant database and view its **Master Credentials ARN**.

   You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

AWS CLI

You can use the describe-tenant-databases Amazon RDS AWS CLI command to find the following information about a secret managed by Amazon RDS in AWS Secrets Manager for a tenant database:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that Amazon RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the tenant database to turn off automatic management of database credentials, and then modify the tenant database again to turn on automatic management of database credentials. To modify the tenant database, use the `--manage-master-user-password` option in the modify-tenant-database command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-instance-identifier` option to show output for tenant databases in a specific DB instance. You can also specify the `--tenant-db-name` option to show output for a specific tenant database. This example shows the output for a secret that is used by a tenant database.

Example

```
aws rds describe-tenant-databases \
    --db-instance-identifier database-3 \
    --query "TenantDatabases[0].MasterUserSecret"
```

Following is sample output for a secret:

```
{
    "SecretArn": "arn:aws:secretsmanager:us-east-2:123456789012:secret:rds!db-ABC123",
    "SecretStatus": "active",
    "KmsKeyId": "arn:aws:kms:us-east-2:123456789012:key/aa11bb22-####-####-####-
fedcba123456"
}
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager AWS CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
```

```
    --secret-id 'arn:aws:secretsmanager:us-east-2:123456789012:secret:rds!db-ABC123'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:us-east-2:123456789012:secret:rds!db-ABC123'
```

Amazon RDS API

You can view the ARN, status, and KMS key for a secret managed by Amazon RDS in AWS Secrets Manager by using the DescribeTenantDatabases operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. You can also set the `TenantDBName` parameter to a specific tenant database name. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager integration with Amazon RDS, see Supported Regions and DB engines for the Secrets Manager integration with Amazon RDS.

Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM).

That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics

- Protecting data using encryption
- Internetwork traffic privacy

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB instances.

Topics

- Encrypting Amazon RDS resources
- AWS KMS key management
- Using SSL/TLS to encrypt a connection to a DB instance or cluster

- Rotating your SSL/TLS certificate

Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its logs, automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances.

After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

> **Note**
>
> For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

Topics

- Overview of encrypting Amazon RDS resources
- Encrypting a DB instance
- Determining whether encryption is turned on for a DB instance
- Availability of Amazon RDS encryption
- Encryption in transit
- Limitations of Amazon RDS encrypted DB instances

Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest. For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. For more information about the availability and limitations of encryption, see Availability of Amazon RDS encryption and Limitations of Amazon RDS encrypted DB instances.

Amazon RDS uses an AWS Key Management Service key to encrypt these resources. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. You can use an AWS managed key, or you can create customer managed keys.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the AWS Key Management Service (AWS KMS).

Using AWS KMS, you can create customer managed keys and define the policies that control the use of these customer managed keys. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration. Some considerations about using KMS keys:

- Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

  If you must change the encryption key for your DB instance, create a manual snapshot of your instance and enable encryption while copying the snapshot. For more information, see re:Post Knowledge article.
- If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.
- A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region.
- If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.
- You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.
- Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with RDS encryption at rest, although using TDE and RDS encryption at rest simultaneously might slightly affect the performance of your database.

You must manage different keys for each encryption method. For more information on TDE, see Oracle Transparent Data Encryption or Support for Transparent Data Encryption in SQL Server.

Important

Amazon RDS loses access to the KMS key for a DB instance when you disable the KMS key. If you lose access to a KMS key, the encrypted DB instance goes into the `inaccessible-encryption-credentials-recoverable` state 2 hours after detection in instances where backups are enabled. The DB instance remains in this state for seven days, during which the instance is stopped. API calls made to the DB instance during this time might not succeed. To recover the DB instance, enable the KMS key and restart this DB instance. Enable the KMS key from the AWS Management Console, AWS CLI, or RDS API. Restart the DB instance using the AWS CLI command start-db-instance or AWS Management Console. The `inaccessible-encryption-credentials-recoverable` state only applies to DB instances that can stop. This recoverable state is not applicable to instances that can't stop, such as read replicas and instances with read replicas. For more information, see Limitations of stopping your DB instance.

If the DB instance isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB instance is not usable anymore and you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

During the creation of a DB instance, Amazon RDS checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the DB instance. Revoking the calling principal's access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB instance from the snapshot without specifying a different KMS key, the new instance uses the KMS key from the source account. Revoking access to the key after you create the DB instance does not affect the instance. However, disabling the key impacts all DB instances encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

DB instances with disabled backups remain available until the volumes are detached from the host during an instance modification or a recovery. RDS moves the instances into

`inaccessible-encryption-credentials-recoverable` state or `inaccessible-encryption-credentials` state as applicable.

For more information about KMS keys, see AWS KMS keys in the *AWS Key Management Service Developer Guide* and AWS KMS key management.

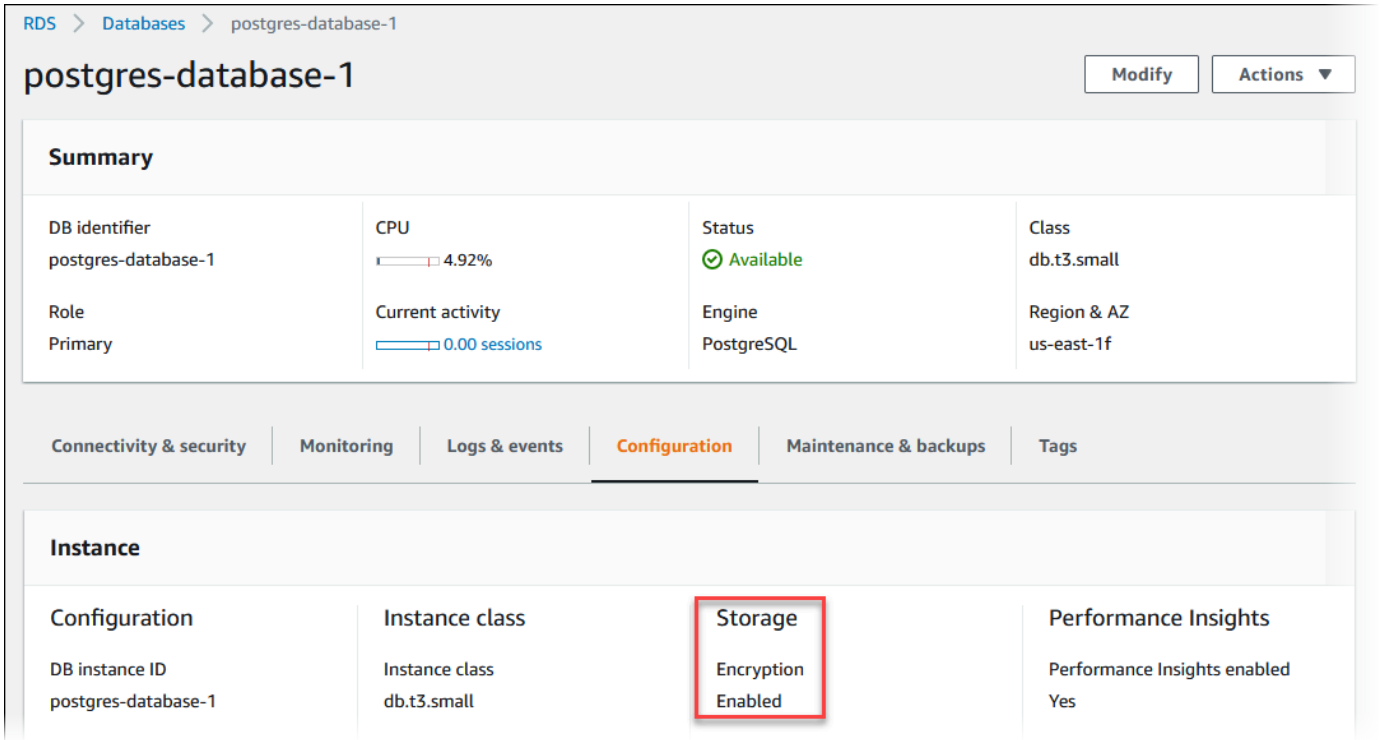
Encrypting a DB instance

To encrypt a new DB instance, choose **Enable encryption** on the Amazon RDS console. For information on creating a DB instance, see Creating an Amazon RDS DB instance.

If you use the create-db-instance AWS CLI command to create an encrypted DB instance, set the `--storage-encrypted` parameter. If you use the CreateDBInstance API operation, set the `StorageEncrypted` parameter to true.

If you use the AWS CLI `create-db-instance` command to create an encrypted DB instance with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

Determining whether encryption is turned on for a DB instance



You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.

Console

To determine whether encryption at rest is turned on for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the **Configuration** tab, and check the **Encryption** value under **Storage**.

   It shows either **Enabled** or **Not enabled**.

AWS CLI

To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the describe-db-instances command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB instance.

Example

```
aws rds describe-db-instances --db-instance-identifier mydb --query "*[].
{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the DescribeDBInstances operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

Availability of Amazon RDS encryption

Amazon RDS encryption is currently available for all database engines and storage types.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that *don't support* Amazon RDS encryption:

Instance type	Instance class
General purpose (M1)	db.m1.small db.m1.medium db.m1.large db.m1.xlarge
Memory optimized (M2)	db.m2.xlarge db.m2.2xlarge db.m2.4xlarge
Burstable (T2)	db.t2.micro

Encryption in transit

Encryption at the physical layer

All data flowing accross AWS Regions over the AWS global network is automatically encrypted at the physical layer before it leaves AWS secured facilities. All traffic between AZs is encrypted. Additional layers of encryption, including those listed in this section may provide additional protections.

Encryption provided by Amazon VPC peering and Transit Gateway cross-Region peering

All cross-Region traffic that uses Amazon VPC and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves AWS secured facilities.

Encryption between instances

AWS provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose**: M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized**: R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same AWS Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.

  However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see Copying a DB snapshot for Amazon RDS.
- You can't turn off encryption on an encrypted DB instance.
- You can't create an encrypted snapshot of an unencrypted DB instance.
- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.

- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

  The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.
- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

AWS KMS key management

Amazon RDS automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

You can use two types of AWS KMS keys to encrypt your DB instances .

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see Customer managed keys in the *AWS Key Management Service Developer Guide*.
- *AWS managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (`aws/rds`) is used for encryption. You can't manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see AWS managed keys in the *AWS Key Management Service Developer Guide*.

To manage KMS keys used for Amazon RDS encrypted DB instances , use the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use AWS CloudTrail. For more information about key rotation, see Rotating AWS KMS keys.

Authorizing use of a customer managed key

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To create an RDS resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

Important

When you use explicit deny statements for all resources (*) in AWS KMS key policies with managed services like Amazon RDS, you must specify a condition to allow the resource owning account. Operations might fail without this condition, even if the deny rule includes exceptions for your IAM user.

Tip

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the kms:ViaService condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in RDS , use the kms:ViaService condition key with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the Amazon RDS encryption context as a condition for using the customer managed key for encryption.

For more information, see Allowing users in other accounts to use a KMS key in the *AWS Key Management Service Developer Guide* and Key policies in AWS KMS.

Amazon RDS encryption context

When RDS uses your KMS key, or when Amazon EBS uses the KMS key on behalf of RDS , the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an

encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your AWS CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Amazon RDS always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

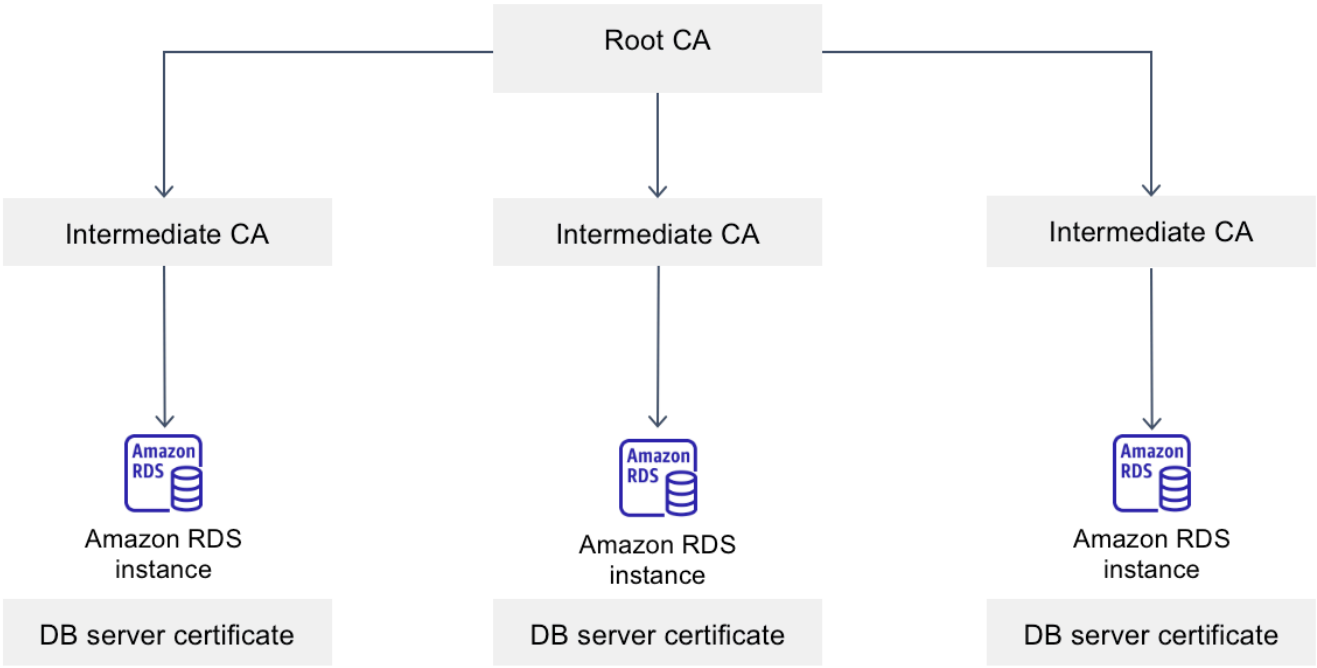
When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

Using SSL/TLS to encrypt a connection to a DB instance or cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a database running Db2, MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB instance or cluster . Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:



1. Choose the **certificate authority (CA)** that signs the **DB server certificate,** for your database. For more information about certificate authorities, see Certificate authorities .
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see Certificate bundles by AWS Region .

> **Note**
>
> All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
   - Using SSL/TLS with an Amazon RDS for Db2 DB instance
   - SSL/TLS support for MariaDB DB instances on Amazon RDS
   - Using SSL with a Microsoft SQL Server DB instance
   - SSL/TLS support for MySQL DB instances on Amazon RDS
   - Using SSL with an RDS for Oracle DB instance
   - Using SSL with a PostgreSQL DB instance

Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate,** which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.

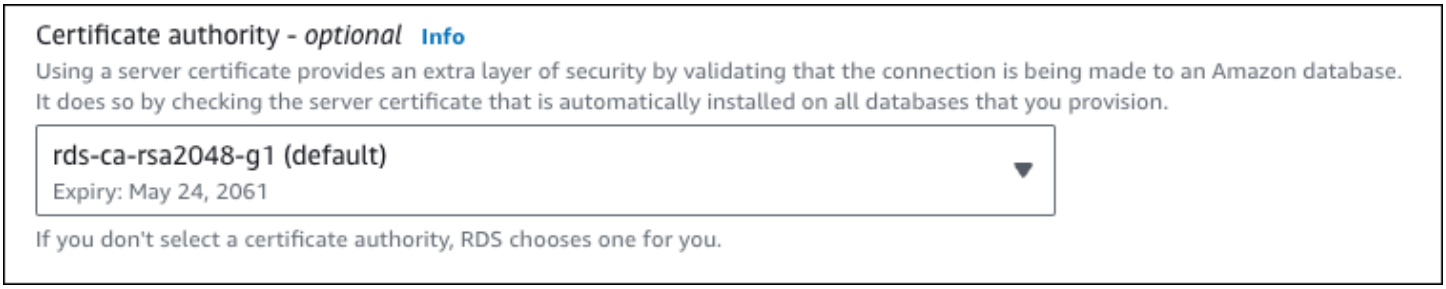
Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description	Common name (CN)
rds-ca-rsa2048-g1	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions. In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* Root CA RSA2048 G1
rds-ca-rsa4096-g1	Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* Root CA RSA4096 G1
rds-ca-ecc384-g1	Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* Root CA ECC384 G1

Note

If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using describe-certificates.

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.



Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create a DB instance or Multi-AZ DB cluster – You can set the CA when you create a DB instance or cluster. For instructions, see the section called "Creating a DB instance" or the section called "Creating a Multi-AZ DB cluster" .
- Modify a DB instance or Multi-AZ DB cluster – You can set the CA for a DB instance or cluster by modifying it. For instructions, see the section called "Modifying a DB instance" or the section called "Modifying a Multi-AZ DB cluster" .

> **Note**
>
> The default CA is set to rds-ca-rsa2048-g1. You can override the default CA for your AWS account by using the modify-certificates command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the AWS CLI, you can set the CA for a DB instance using the create-db-instance or modify-db-instance command. You can set the CA for a Multi-AZ DB cluster using the create-db-cluster or modify-db-cluster command.

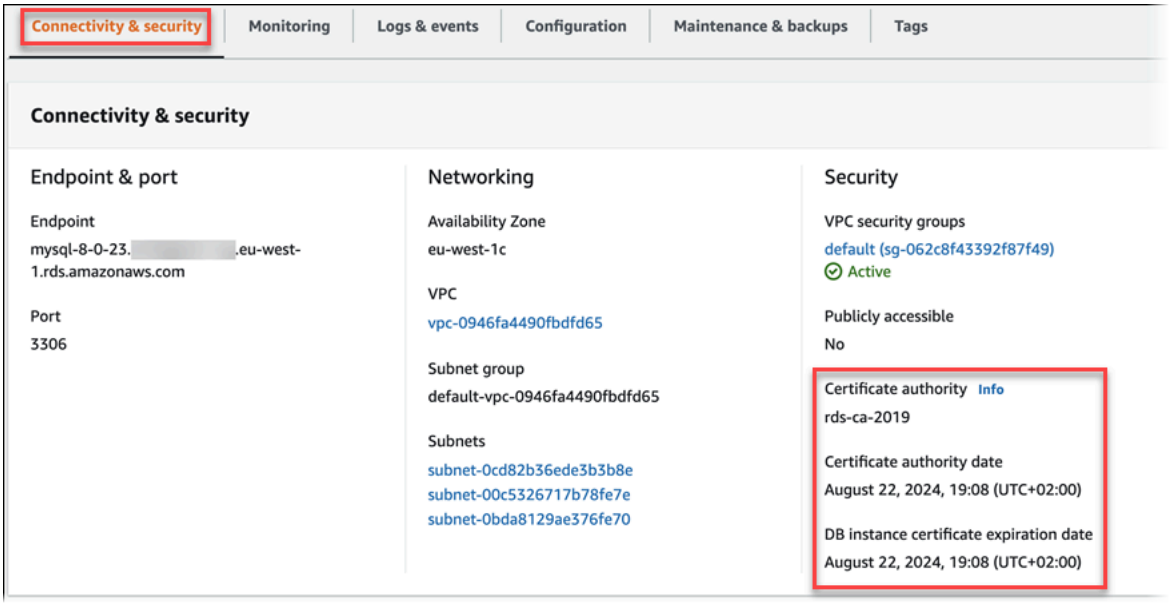
If you're using the AWS CLI, you can see the available CAs for your account by using the describe-certificates command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the describe-db-engine-versions command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
    "DBEngineVersions": [
        {
            "Engine": "postgres",
            "MajorEngineVersion": "13",
            "EngineVersion": "13.4",
            "DBParameterGroupFamily": "postgres13",
            "DBEngineDescription": "PostgreSQL",
            "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": true,
            "SupportedFeatureNames": [
                "Lambda"
            ],
            "Status": "available",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "SupportsBabelfish": false,
            "SupportsCertificateRotationWithoutRestart": true,
            "SupportedCACertificateIdentifiers": [
                "rds-ca-rsa2048-g1",
                "rds-ca-ecc384-g1",
                "rds-ca-rsa4096-g1"
            ]
        }
    ]
}
```



DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see Automatic server certificate rotation .

Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the **Connectivity & security** tab in the console, as in the following image.

If you're using the AWS CLI, you can view the details about the CA for a DB instance by using the describe-db-instances command. You can view the details about the CA for a Multi-AZ DB cluster by using the describe-db-clusters command.

Download certificate bundles for Amazon RDS

When you connect to your database with SSL or TLS, the database instance requires a trust certificate from Amazon RDS. Select the appropriate link in the following table to download the bundle that corresponds with the AWS Region where you host your database.

Certificate bundles by AWS Region

The certificate bundles for all AWS Regions and GovCloud (US) Regions contain the following root CA certificates:

- `rds-ca-rsa2048-g1`
- `rds-ca-rsa4096-g1`
- `rds-ca-ecc384-g1`

The `rds-ca-rsa4096-g1` and `rds-ca-ecc384-g1` certificates are not available in the following Regions:

- Asia Pacific (Mumbai)
- Asia Pacific (Melbourne)
- Canada West (Calgary)
- Europe (Zurich)
- Europe (Spain)
- Israel (Tel Aviv)

Your application trust store needs to only register the root CA certificate. Do not register the intermediate CA certificates to your trust store as this might cause connection issues when RDS automatically rotates your DB server certificate.

> **Note**
>
> Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy .

To download a certificate bundle for an AWS Region, select the link for the AWS Region that hosts your database in the following table.

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Any commercial AWS Region	global-bundle.pem	global-bundle.p7b
US East (N. Virginia)	us-east-1-bundle.pem	us-east-1-bundle.p7b
US East (Ohio)	us-east-2-bundle.pem	us-east-2-bundle.p7b

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
US West (N. California)	us-west-1-bundle.pem	us-west-1-bundle.p7b
US West (Oregon)	us-west-2-bundle.pem	us-west-2-bundle.p7b
Africa (Cape Town)	af-south-1-bundle.pem	af-south-1-bundle.p7b
Asia Pacific (Hong Kong)	ap-east-1-bundle.pem	ap-east-1-bundle.p7b
Asia Pacific (Hyderabad)	ap-south-2-bundle.pem	ap-south-2-bundle.p7b
Asia Pacific (Jakarta)	ap-southeast-3-bundle.pem	ap-southeast-3-bundle.p7b
Asia Pacific (Malaysia)	ap-southeast-5-bundle.pem	ap-southeast-5-bundle.p7b
Asia Pacific (Melbourne)	ap-southeast-4-bundle.pem	ap-southeast-4-bundle.p7b
Asia Pacific (Mumbai)	ap-south-1-bundle.pem	ap-south-1-bundle.p7b
Asia Pacific (Osaka)	ap-northeast-3-bundle.pem	ap-northeast-3-bundle.p7b
Asia Pacific (Thailand)	ap-southeast-7-bundle.pem	ap-southeast-7-bundle.p7b
Asia Pacific (Tokyo)	ap-northeast-1-bundle.pem	ap-northeast-1-bundle.p7b
Asia Pacific (Seoul)	ap-northeast-2-bundle.pem	ap-northeast-2-bundle.p7b
Asia Pacific (Singapore)	ap-southeast-1-bundle.pem	ap-southeast-1-bundle.p7b
Asia Pacific (Sydney)	ap-southeast-2-bundle.pem	ap-southeast-2-bundle.p7b
Canada (Central)	ca-central-1-bundle.pem	ca-central-1-bundle.p7b
Canada West (Calgary)	ca-west-1-bundle.pem	ca-west-1-bundle.p7b
Europe (Frankfurt)	eu-central-1-bundle.pem	eu-central-1-bundle.p7b
Europe (Ireland)	eu-west-1-bundle.pem	eu-west-1-bundle.p7b
Europe (London)	eu-west-2-bundle.pem	eu-west-2-bundle.p7b

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Europe (Milan)	eu-south-1-bundle.pem	eu-south-1-bundle.p7b
Europe (Paris)	eu-west-3-bundle.pem	eu-west-3-bundle.p7b
Europe (Spain)	eu-south-2-bundle.pem	eu-south-2-bundle.p7b
Europe (Stockholm)	eu-north-1-bundle.pem	eu-north-1-bundle.p7b
Europe (Zurich)	eu-central-2-bundle.pem	eu-central-2-bundle.p7b
Israel (Tel Aviv)	il-central-1-bundle.pem	il-central-1-bundle.p7b
Mexico (Central)	mx-central-1-bundle.pem	mx-central-1-bundle.p7b
Middle East (Bahrain)	me-south-1-bundle.pem	me-south-1-bundle.p7b
Middle East (UAE)	me-central-1-bundle.pem	me-central-1-bundle.p7b
South America (São Paulo)	sa-east-1-bundle.pem	sa-east-1-bundle.p7b
Any AWS GovCloud (US) Regions	global-bundle.pem	global-bundle.p7b
AWS GovCloud (US-East)	us-gov-east-1-bundle.pem	us-gov-east-1-bundle.p7b
AWS GovCloud (US-West)	us-gov-west-1-bundle.pem	us-gov-west-1-bundle.p7b

Viewing the contents of your CA certificate

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates rds-ca-2019 expired in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances or Multi-AZ DB clusters,consider using one of the new CA

certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1 or rds-ca-ecc384-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

To update the CA certificate for your database, use the following methods:

- Updating your CA certificate by modifying your DB instance or cluster
- Updating your CA certificate by applying maintenance

Before you update your DB instances or Multi-AZ DB clusters to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Considerations for rotating certificates

Consider the following situations before rotating your certificate:

- Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy .
- If you're using a Go version 1.15 application with a DB instance or Multi-AZ DB cluster that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 depending on your engine .

  Use the `modify-db-instance` command for a DB instance, or the `modify-db-cluster` command for a Multi-AZ DB cluster, using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

  If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Updating your CA certificate by modifying your DB instance or cluster

The following example updates your CA certificate from *rds-ca-2019* to *rds-ca-rsa2048-g1*.You can choose a different certificate. For more information, see Certificate authorities .

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see Automatic server certificate rotation .

To update your CA certificate by modifying your DB instance or cluster

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance or cluster .
2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   - Updating applications to connect to MariaDB instances using new SSL/TLS certificates
   - Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates
   - Updating applications to connect to MySQL DB instances using new SSL/TLS certificates
   - Updating applications to connect to Oracle DB instances using new SSL/TLS certificates
   - Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store .

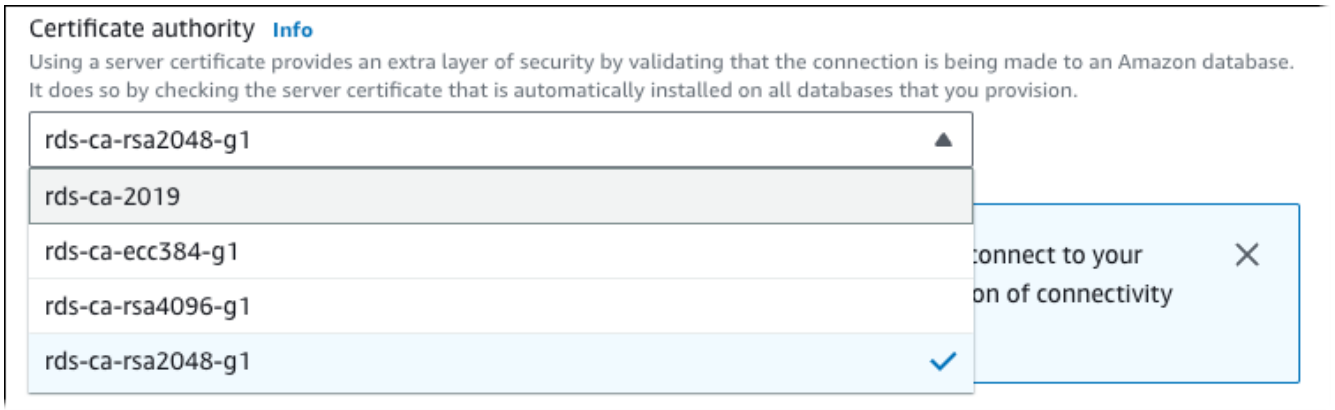
   > **Note**
   >
   > The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB

instance or cluster , we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance or Multi-AZ DB cluster to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the `SupportsCertificateRotationWithoutRestart` flag.

   Important

   If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.
   For RDS for Oracle DB instances, we recommend that you restart your Oracle DB to prevent any connection errors.
   For RDS for SQL Server Multi-AZ instances with AlwaysOn or Mirroring option enabled, a failover is expected when instance is rebooted after the certificate rotation.
   To set an override for your instance CA that's different from the default RDS CA, use the modify-certificates CLI command.



You can use the AWS Management Console or the AWS CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance or Multi-AZ DB cluster.

Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.

4. In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.

5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** or **Modify cluster** to save your changes.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To use the AWS CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance or Multi-AZ DB cluster, call the modify-db-instance or modify-db-cluster command. Specify the DB instance or cluster identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

DB instance

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

> **Note**
>
> If your instance requires reboot, you can use the modify-db-instance CLI command and specify the `--no-certificate-rotation-restart` option.

Example

Multi-AZ DB cluster

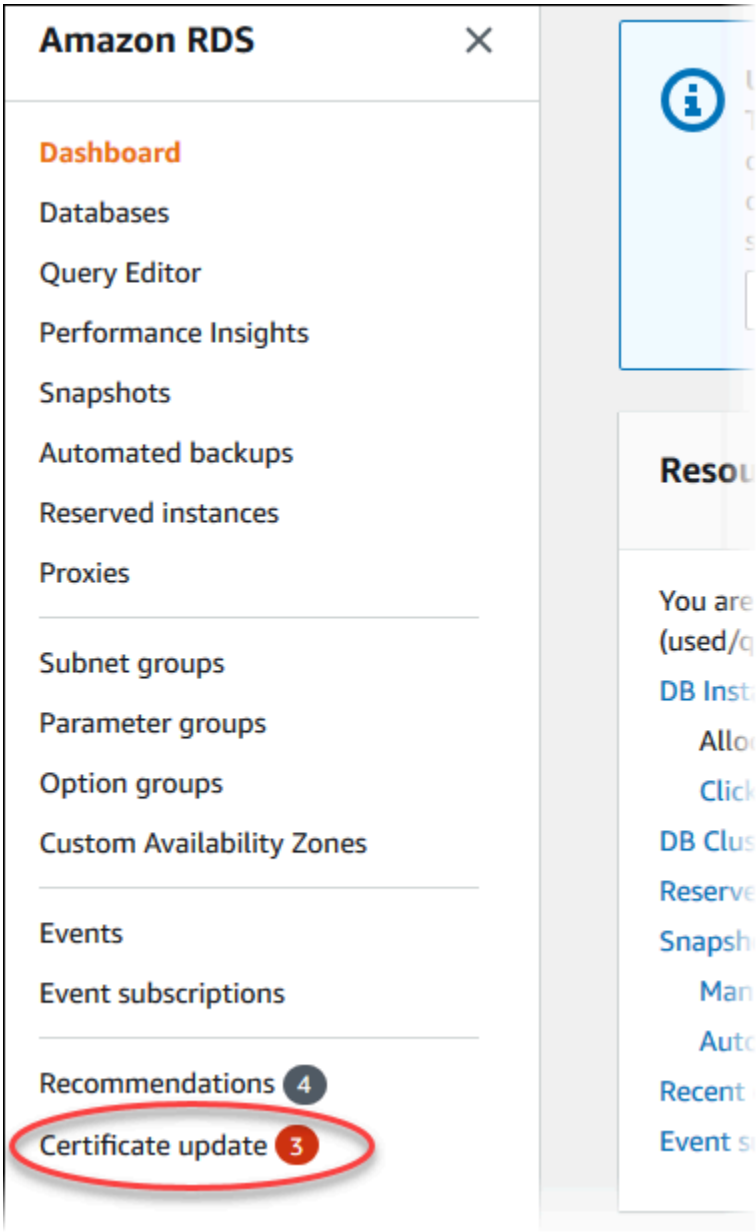
The following example modifies `mydbcluster` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbcluster \
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

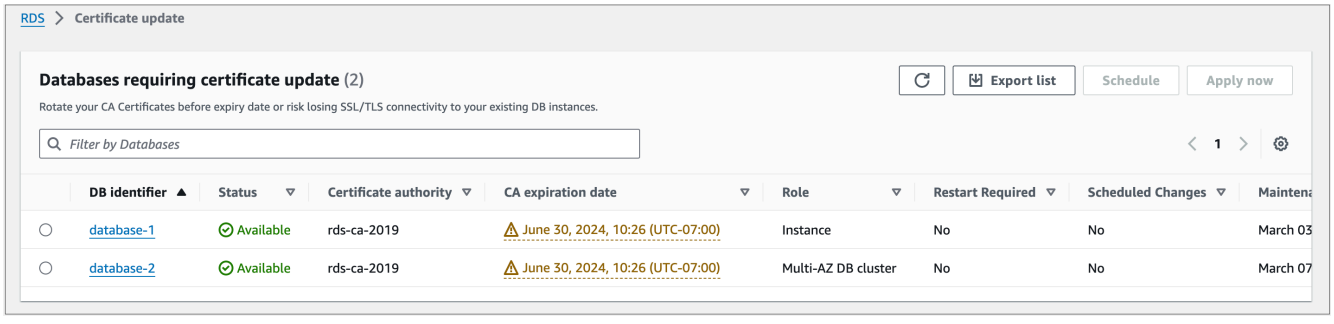
For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --ca-certificate-identifier rds-ca-rsa2048-g1
```



Updating your CA certificate by applying maintenance

Perform the following steps to update your CA certificate by applying maintenance.

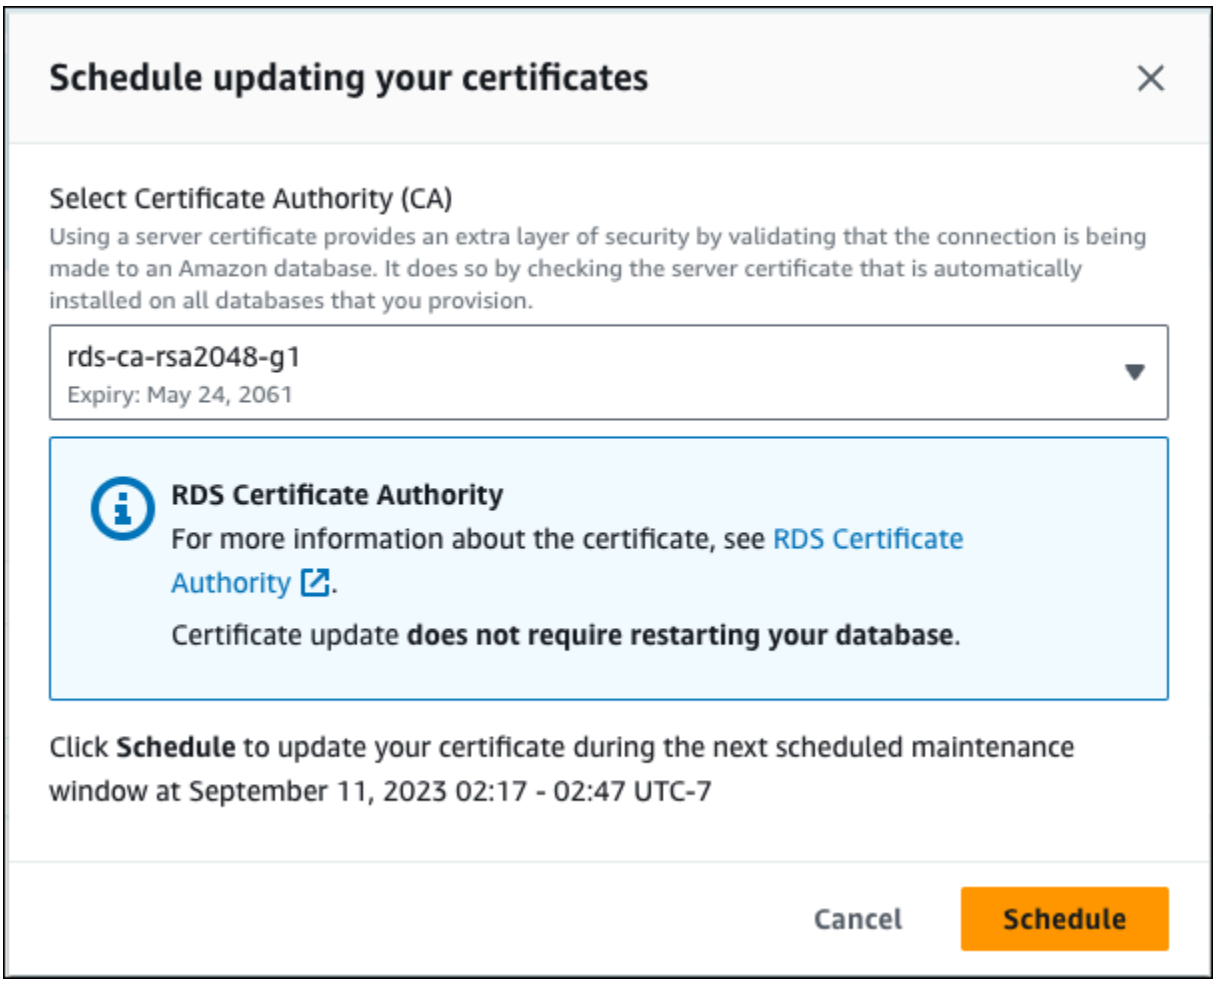


Console

To update your CA certificate by applying maintenance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Certificate update**.

The **Databases requiring certificate update** page appears.



> **Note**
>
> This page only shows the DB instances and clusters for the current AWS Region. If you have databases in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance or Multi-AZ DB cluster that you want to update.

   You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

   > **Important**
   >
   > If you experience connectivity issues after certificate expiry, use the **Apply now** option.

4. a. If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

b. If you choose **Apply now**, you are prompted to confirm the CA certificate rotation.

> **Important**
>
> Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance and cluster that you want to update.

Automatic server certificate rotation

If your root CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities .

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, Amazon RDS makes a `server-certificate-rotation` Pending Maintenance Action visible via Describe-pending-maintenance-actions API, at the half life of the certificate, or at least 3 months before expiry. You can apply the rotation using the apply-pending-maintenance-action API. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database .

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
```

```
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem">
 ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/
 {split_after=1}{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
 cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem">
 ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-
```

```
for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
 cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

Internetwork traffic privacy

Connections are protected both between Amazon RDS and on-premises applications and between Amazon RDS and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An Direct Connect connection. For more information, see What is Direct Connect?

You get access to Amazon RDS through the network by using AWS-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Identity and access management for Amazon RDS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How Amazon RDS works with IAM
- Identity-based policy examples for Amazon RDS
- AWS managed policies for Amazon RDS
- Amazon RDS updates to AWS managed policies
- Preventing cross-service confused deputy problems
- IAM database authenticationfor MariaDB, MySQL, and PostgreSQL
- Troubleshooting Amazon RDS identity and access

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon RDS.

Service user – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see Troubleshooting Amazon RDS identity and access.

Service administrator – If you're in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It's your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your administrator

to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see How Amazon RDS works with IAM.

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon RDS.

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access AWS using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see IAM database authenticationfor MariaDB, MySQL, and PostgreSQL.

IAM roles

An *IAM role* is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Create a role for a third-party identity provider (federation) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates

the permission set to a role in IAM. For information about permissions sets, see Permission sets in the *AWS IAM Identity Center User Guide*.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
  - **Forward access sessions** – Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.
  - **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.
  - **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Use an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the *IAM User Guide*.

For information about AWS managed policies that are specific to Amazon RDS, see AWS managed policies for Amazon RDS.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon RDS works with IAM

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are available to use with Amazon RDS.

The following table lists IAM features you can use with Amazon RDS:

IAM feature	Amazon RDS support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
Attribute-based access control (ABAC) (tags in policies)	Yes
Temporary credentials	Yes
Forward access sessions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how Amazon RDS and other AWS services work with IAM, see AWS services that work with IAM in the *IAM User Guide*.

Topics

- Amazon RDS identity-based policies
- Resource-based policies within Amazon RDS
- Policy actions for Amazon RDS
- Policy resources for Amazon RDS
- Policy condition keys for Amazon RDS
- Access control lists (ACLs) in Amazon RDS
- Attribute-based access control (ABAC) in policies with Amazon RDS tags

- Using temporary credentials with Amazon RDS
- Forward access sessions for Amazon RDS
- Service roles for Amazon RDS
- Service-linked roles for Amazon RDS

Amazon RDS identity-based policies

Supports identity-based policies: Yes.

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Amazon RDS

To view examples of Amazon RDS identity-based policies, see Identity-based policy examples for Amazon RDS.

Resource-based policies within Amazon RDS

Supports resource-based policies: No.

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for Amazon RDS

Supports policy actions: Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
      "rds:action1",
      "rds:action2"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Policy resources for Amazon RDS

Supports policy resources: Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't

support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the `dbtest` DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
      "resource1",
      "resource2"
```

To see a list of Amazon RDS resource types and their ARNs, see Resources Defined by Amazon RDS in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

Policy condition keys for Amazon RDS

Supports service-specific policy condition keys: Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Amazon RDS condition keys, see Condition Keys for Amazon RDS in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

Access control lists (ACLs) in Amazon RDS

Supports access control lists (ACLs): No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Amazon RDS tags

Supports attribute-based access control (ABAC) tags in policies: Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/`*`key-name`*, `aws:RequestTag/`*`key-name`*, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

For more information about tagging Amazon RDS resources, see Specifying conditions: Using custom tags. To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values.

Using temporary credentials with Amazon RDS

Supports temporary credentials: Yes.

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Forward access sessions for Amazon RDS

Supports forward access sessions: Yes.

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for Amazon RDS

Supports service roles: Yes.

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Amazon RDS functionality. Edit service roles only when Amazon RDS provides guidance to do so.

Service-linked roles for Amazon RDS

Supports service-linked roles: Yes.

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Amazon RDS service-linked roles, see Using service-linked roles for Amazon RDS.

Identity-based policy examples for Amazon RDS

By default, permission sets and roles don't have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the *IAM User Guide*.

Topics

- Policy best practices
- Using the Amazon RDS console
- Permissions required to use the console
- Allow users to view their own permissions
- Permission policies to create, modify and, delete resources in Amazon RDS
- Example policies: Using condition keys

- Specifying conditions: Using custom tags
- Grant permission to tag Amazon RDS resources during creation

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon RDS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see Adding permissions to a user in the *IAM User Guide*.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the `AmazonRDSReadOnlyAccess` managed policy to the user, as described in Managing access using policies.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

```
AmazonRDSFullAccess
```

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",

                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Permission policies to create, modify and, delete resources in Amazon RDS

The following sections present examples of permission policies that grant and restrict access to resources:

Allow a user to create DB instances in an AWS account

The following is an example policy that allows the account with the ID `123456789012` to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the `default` subnet group.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "AllowCreateDBInstanceOnly",
         "Effect": "Allow",
         "Action": [
            "rds:CreateDBInstance"
         ],
         "Resource": [
            "arn:aws:rds:*:123456789012:db:test*",
            "arn:aws:rds:*:123456789012:og:default*",
            "arn:aws:rds:*:123456789012:pg:default*",
            "arn:aws:rds:*:123456789012:subgrp:default"
         ],
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql",
               "rds:DatabaseClass": "db.t2.micro"
            }
         }
      }
   ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the account to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance AWS CLI command and the AWS Management Console).

- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (`rds`), the AWS Region (`*` indicates any region in this example), the AWS account number (`123456789012` is the account number in this example), and the type of resource. For more information about creating ARNs, see Amazon Resource Names (ARNs) in Amazon RDS.

  The `Resource` element in the example specifies the following policy constraints on resources for the user:

  - The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
  - The option group for the new DB instance must begin with `default`.
  - The DB parameter group for the new DB instance must begin with `default`.
  - The subnet group for the new DB instance must be the `default` subnet group.
- The `Condition` element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The `Condition` element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the `Condition` element. For more information about specifying conditions, see Policy condition keys for Amazon RDS. This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the `Engine` parameter in CreateDBInstance. For information about the valid condition values for `rds:DatabaseClass`, see Supported DB engines for DB instance classes .

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the `Resource` element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "AllowRDSDescribe",
         "Effect": "Allow",
         "Action": "rds:Describe*",
         "Resource": "*"
      }
   ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": [
            "arn:aws:rds:*:*:pg:mydbpg",
            "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
         ]
      }
   ]
}
```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource": [
            "arn:aws:rds:*:123456789012:pg:*",
            "arn:aws:rds:*:123456789012:secgrp:*",
            "arn:aws:rds:*:123456789012:og:*"
         ]
      },
      {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "DenyDelete1",
         "Effect": "Deny",
         "Action": "rds:DeleteDBInstance",
         "Resource": "arn:aws:rds:us-west-2:123456789012:db:my-mysql-instance"
      }
   ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "rds:*",
         "Resource": "arn:aws:rds:us-east-1:123456789012:db:mydb"
      }
   ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The `Condition` element indicates the requirement that the database engine is MySQL.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "AllowMySQLCreate",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql"
            },
            "Bool": {
               "rds:MultiAz": false
            }
         }
      }
   ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance

classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "DenyLargeCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseClass": [
                  "db.r3.8xlarge",
                  "db.m4.10xlarge"
               ]
            }
         }
      },
      {
         "Sid": "DenyPIOPSCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "NumericNotEquals": {
               "rds:Piops": "0"
            }
         }
      }
   ]
}
```

Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowTagEdits",
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws:rds:us-east-1:123456789012:db:db-123456",
      "Condition": {
        "StringEquals": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

> **Note**
>
> Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

RDS tag identifier	Applies to
`db-tag`	DB instances, including read replicas
`snapshot-tag`	DB snapshots
`ri-tag`	Reserved DB instances
`og-tag`	DB option groups
`pg-tag`	DB parameter groups
`subgrp-tag`	DB subnet groups
`es-tag`	Event subscriptions
`cluster-tag`	DB clusters
`cluster-pg-tag`	DB cluster parameter groups
`cluster-snapshot-tag`	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":
["value"]} }
```

For example, the following `Condition` element applies to DB instances with a tag named `environment` and a tag value of `production`.

```
"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }
```

For information about creating tags, see Tagging Amazon RDS resources.

Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the `AddTagsToResource` and `RemoveTagsFromResource` actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyTagUpdates",
         "Effect":"Deny",
         "Action":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"*"
      }
   ]
}
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see Amazon Resource Names (ARNs) in Amazon RDS.

Note

All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
            ],
          "Resource": [
            "arn:aws:rds:*:123456789012:pg:*",
            "arn:aws:rds:*:123456789012:secgrp:*",
            "arn:aws:rds:*:123456789012:og:*"
            ]
       },
       {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
            ],
         "Resource":"arn:aws:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
               "rds:db-tag/stage":[
                  "development",
                  "test"
                  ]
               }
            }
       }
    ]
}
```

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use `Deny` are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyProductionCreate",
         "Effect":"Deny",
         "Action":"rds:CreateDBInstance",
         "Resource":"arn:aws:rds:*:123456789012:pg:*",
         "Condition":{
            "StringEquals":{
               "rds:pg-tag/usage":"prod"
            }
         }
      }
   ]
}
```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see Amazon Resource Names (ARNs) in Amazon RDS.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowFullDevAccessNoTags",
         "Effect":"Allow",
         "NotAction":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"arn:aws:rds:*:123456789012:db:${aws:username}*",
         "Condition":{
            "StringEqualsIfExists":{
               "rds:db-tag/stage":"devo"
            }
         }
      }
   ]
}
```

Grant permission to tag Amazon RDS resources during creation

Some RDS API operations allow you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see What is ABAC for AWS? and Controlling access to AWS resources using tags.

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as `rds:CreateDBInstance`. If tags are specified in the create action, RDS performs additional authorization on the `rds:AddTagsToResource` action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the `rds:AddTagsToResource` action.

In the IAM policy definition for the `rds:AddTagsToResource` action, you can use the `aws:RequestTag` condition key to require tags in a request to tag a resource.

For example, the following policy allows users to create DB instances and apply tags during DB instance creation, but only with specific tag keys (`environment` or `project`):

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "rds:CreateDBInstance"
           ],
           "Resource": "*"
       },
       {
           "Effect": "Allow",
           "Action": [
               "rds:AddTagsToResource"
           ],
           "Resource": "*",
           "Condition": {
               "StringEquals": {
                   "aws:RequestTag/environment": ["production", "development"],
                   "aws:RequestTag/project": ["dataanalytics", "webapp"]
               },
               "ForAllValues:StringEquals": {
                   "aws:TagKeys": ["environment", "project"]
               }
           }
       }
   ]
}
```

This policy denies any create DB instance request that includes tags other than the `environment` or `project` tags, or that doesn't specify either of these tags. Additionally, users must specify values for the tags that match the allowed values in the policy.

The following policy allows users to create DB clusters and apply any tags during creation except the `environment=prod` tag:

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "rds:CreateDBCluster"
           ],
           "Resource": "*"
       },
       {
           "Effect": "Allow",
           "Action": [
               "rds:AddTagsToResource"
           ],
           "Resource": "*",
           "Condition": {
               "StringNotEquals": {
                   "aws:RequestTag/environment": "prod"
               }
           }
       }
   ]
}
```

Supported RDS API actions for tagging on creation

The following RDS API actions support tagging when you create a resource. For these actions, you can specify tags when you create the resource:

- `CreateBlueGreenDeployment`
- `CreateCustomDBEngineVersion`
- `CreateDBCluster`
- `CreateDBClusterEndpoint`
- `CreateDBClusterParameterGroup`
- `CreateDBClusterSnapshot`
- `CreateDBInstance`

- CreateDBInstanceReadReplica
- CreateDBParameterGroup
- CreateDBProxy
- CreateDBProxyEndpoint
- CreateDBSecurityGroup
- CreateDBShardGroup
- CreateDBSnapshot
- CreateDBSubnetGroup
- CreateEventSubscription
- CreateGlobalCluster
- CreateIntegration
- CreateOptionGroup
- CreateTenantDatabase
- CopyDBClusterParameterGroup
- CopyDBClusterSnapshot
- CopyDBParameterGroup
- CopyDBSnapshot
- CopyOptionGroup
- RestoreDBClusterFromS3
- RestoreDBClusterFromSnapshot
- RestoreDBClusterToPointInTime
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime
- PurchaseReservedDBInstancesOffering

If you use the AWS CLI or API to create a resource with tags, the `Tags` parameter is used to apply tags to resources during creation.

For these API actions, if tagging fails, the resource is not created, and the request fails with an error. This ensures that resources are either created with tags or not created at all, preventing resources from being created without the intended tags.

AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the *IAM User Guide*.

Topics

- AWS managed policy: AmazonRDSReadOnlyAccess
- AWS managed policy: AmazonRDSFullAccess
- AWS managed policy: AmazonRDSDataFullAccess
- AWS managed policy: AmazonRDSEnhancedMonitoringRole
- AWS managed policy: AmazonRDSPerformanceInsightsReadOnly
- AWS managed policy: AmazonRDSPerformanceInsightsFullAccess
- AWS managed policy: AmazonRDSDirectoryServiceAccess
- AWS managed policy: AmazonRDSServiceRolePolicy
- AWS managed policy: AmazonRDSCustomServiceRolePolicy
- AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy
- AWS managed policy: AmazonRDSPreviewServiceRolePolicy
- AWS managed policy: AmazonRDSBetaServiceRolePolicy

AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `outposts` – Allows principals to get AWS Outposts instance types.

- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (`dbqms`) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see AmazonRDSEnhancedMonitoringRole in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsReadOnly in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.

- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsFullAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the Directory Service.

Permissions details

This policy includes the following permission:

- `ds` – Allows principals to describe Directory Service directories and control authorization to Directory Service directories.

For more information about this policy, including the JSON policy document, see AmazonRDSDirectoryServiceAccess in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSServiceRolePolicy

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon RDS.

AWS managed policy: AmazonRDSCustomServiceRolePolicy

You can't attach the `AmazonRDSCustomServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources.

This policy includes the following permissions:

- `ec2` - Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.

- `cloudwatch` - Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- `events`, `sqs` - Allows RDS Custom to send and receive status information about the DB instance.
- `cloudtrail` - Allows RDS Custom to recieve change events about the DB instance
- `servicequotas` - Allows RDS Custom to read service quotas related to the DB instance
- `ssm` - Allows RDS Custom to manage the DB instance's underlying EC2 instance.
- `rds` - Allows RDS Custom to manage RDS resources for your DB instance
- `iam` - Allows RDS Custom to validate and attach the instance profile to a DB instance's underlying EC2 instance.

For more information about this policy, including the JSON policy document, see AmazonRDSCustomServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy

You shouldn't attach `AmazonRDSCustomInstanceProfileRolePolicy` to your IAM entities. It should only be attached to an instance profile role that is used to grant permissions to your Amazon RDS Custom DB instance to perform various automation actions and database management tasks. Pass the instance profile as `custom-iam-instance-profile` parameter during the RDS Custom instance creation and RDS Custom associates this instance profile to your DB instance.

Permissions details

This policy includes the following permissions:

- `ssm`, `ssmmessages`, `ec2messages` - Allows RDS Custom to communicate, execute automation and maintain agents on the DB instance through Systems Manager.
- `ec2`, `s3` - Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.
- `cloudwatch`, `logs` - Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- `events`, `sqs` - Allows RDS Custom to send and receive status information about the DB instance.

- `kms` - Allows RDS Custom to use an instance-specific KMS key to perform encryption of secrets and S3 objects that RDS Custom manages.

For more information about this policy, including the JSON policy document, see AmazonRDSCustomInstanceProfileRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSPreviewServiceRolePolicy

You shouldn't attach `AmazonRDSPreviewServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources. For more information, see Service-linked role for Amazon RDS Preview.

Permissions details

This policy includes the following permissions:

- `ec2` - Allows principals to describe Availability Zones and networking resources.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.
- `cloudwatch`, `logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see AmazonRDSPreviewServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AmazonRDSBetaServiceRolePolicy

You shouldn't attach `AmazonRDSBetaServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources. For more information, see Service-linked role permissions for Amazon RDS Beta.

Permissions details

This policy includes the following permissions:

- `ec2` - Allows Amazon RDS to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows Amazon RDS to manage DB instance specific secrets created by Amazon RDS.

- `cloudwatch`, `logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see AmazonRDSBetaServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Change	Description	Date
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS updated permissions on the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. The update removes `ec2:CopySnapshot` from one statement and adds two new statements for source and destination snapshot permissions. These updates comply with a Change in EBS CopySnapshot authorization behavior while keeping effective permissions unchanged. For more information, see Service-linked role permissions for Amazon RDS Custom.	August 7, 2025
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These permissions allow	March 25, 2025

Change	Description	Date
	RDS Custom to manage EC2 key-pairs and allow RDS Custom to integrate with Amazon SQS. For more information, see Service-linked role permissions for Amazon RDS Custom.	
AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy – Update to existing policy	Amazon RDS added new permissions to the managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to allow the usage of RDS Custom managed secrets on an RDS Custom instance. For more information, see AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy.	March 20, 2025
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom to list and restore Secrets Manager secrets. For more information, see Service-linked role permissions for Amazon RDS Custom.	March 6, 2025

Change	Description	Date
AWS managed policy: AmazonRDSPreviewServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see AWS managed policy: AmazonRDSPreviewServiceRolePolicy.	August 7, 2024
AWS managed policy: AmazonRDSBetaServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSBetaServiceRolePolicy` of the `AWSServiceRoleForRDSBeta` service-linked role. For more information, see AWS managed policy: AmazonRDSBetaServiceRolePolicy.	August 7, 2024

Change	Description	Date
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. The permissions allow RDS Custom to communicate with Amazon RDS services in another AWS Region and copy EC2 images. For more information, see Service-linked role permissions for Amazon RDS Custom.	July 18, 2024
AWS managed policy: AmazonRDSServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see AWS managed policy: AmazonRDSServiceRolePolicy.	July 2, 2024

Change	Description	Date
Service-linked role permissions for Amazon RDS Custom – Update to existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. This new permission allow RDS Custom to associate a service-role as an instance profile to an RDS Custom instance. For more information, see Service-linked role permissions for Amazon RDS Custom.	April 19, 2024
AWS managed policies for Amazon RDS – Update to existing policy	Amazon RDS added a new permission to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role to allow RDS Custom for SQL Server to modify the underlying database host instance type. RDS also added the `ec2:DescribeInstanceTypes` permission to get instance type information for database host. For more information, see AWS managed policies for Amazon RDS.	April 8, 2024

Change	Description	Date
AWS managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see AWS managed policies for Amazon RDS.	February 27, 2024
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new statement IDs to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see Service-linked role permissions for Amazon RDS.	January 19, 2024

Change	Description	Date
AWS managed policies for Amazon RDS – Update to existing policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see AWS managed policy: AmazonRDSPerformanceInsightsReadOnly and AWS managed policy: AmazonRDSPerformanceInsightsFullAccess	October 23, 2023
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom for Oracle to create, modify, and delete EventBridge Managed Rules. For more information, see Service-linked role permissions for Amazon RDS Custom.	September 20, 2023

Change	Description	Date
AWS managed policies for Amazon RDS – Update to existing policy	Amazon RDS added new permissions to `AmazonRDSFullAccess` managed policy. The permissions allow you to generate, view, and delete the performance analysis report for a time period. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	August 17, 2023
AWS managed policies for Amazon RDS – New policy and update to existing policy	Amazon RDS added new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and a new managed policy named `AmazonRDSPerformanceInsightsFullAccess`. These permissions allow you to analyse the Performance Insights for a time period, view the analysis results along with the recommendations, and delete the reports. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	August 16, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom for Oracle to use DB snapshots. For more information, see Service-linked role permissions for Amazon RDS Custom.	June 23, 2023
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom for Oracle to use DB snapshots. For more information, see Service-linked role permissions for Amazon RDS Custom.	June 23, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom to create network interfaces. For more information, see Service-linked role permissions for Amazon RDS Custom.	May 30, 2023
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. These new permissions allow RDS Custom to call Amazon EBS to check the storage quota. For more information, see Service-linked role permissions for Amazon RDS Custom.	April 18, 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS Custom added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role for integration with Amazon SQS. RDS Custom requires integration with Amazon SQS to create and manage SQS queues in the customer account. The SQS queue names follow the format `do-not-delete-rds-custom-[identifier]` and are tagged with `Amazon RDS Custom`. The permission for `ec2:CreateSnapshot` was also added to allow RDS Custom to create backups for volumes attached to the instance. For more information, see Service-linked role permissions for Amazon RDS Custom.	April 6, 2023

Change	Description	Date
AWS managed policies for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace `ListMetrics` to `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess`. This namespace is required for Amazon RDS to list specific resource usage metrics. For more information, see Overview of managing access permissions to your CloudWatch resources in the *Amazon CloudWatch User Guide*.	April 4, 2023
AWS managed policies for Amazon RDS – Update to an existing policy	Amazon RDS added a new permission to `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` managed policies to allow the display of Amazon DevOps Guru findings in the RDS console. This permission is required to allow the display of DevOps Guru findings. For more information, see Amazon RDS updates to AWS managed policies.	March, 30 2023

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role for integration with AWS Secrets Manager. RDS requires integration with Secrets Manager for managing master user passwords in Secrets Manager. The secret uses a reserved naming convention and restricts customer updates. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	December 22, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role. RDS Custom supports DB clusters. These new permissions in the policy allow RDS Custom to call AWS services on behalf of your DB clusters. For more information, see Service-linked role permissions for Amazon RDS Custom.	November 9, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AWSServiceRoleForRDS` service-linked role for integration with AWS Secrets Manager. Integration with Secrets Manager is required for SQL Server Reporting Services (SSRS) Email to function on RDS. SSRS Email creates a secret on behalf of the customer. The secret uses a reserved naming convention and restricts customer updates. For more information, see Using SSRS Email to send reports.	August 26, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSPreviewServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSBetaServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AWSServiceRoleForRDS` for `PutMetricData` . This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	April 22, 2022
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new permissions to the `AWSServiceRoleForRDS` service-linked role to manage permissions for customer-owned IP pools and local gateway route tables (LGW-RTBs). These permissions are required for RDS on Outposts to perform Multi-AZ replication across the Outposts' local network. For more information, see Working with Multi-AZ deployments for Amazon RDS on AWS Outposts.	April 19, 2022

Change	Description	Date
Identity-based policies – Update to an existing policy	Amazon RDS added a new permission to the `AmazonRDSFullAccess` managed policy to describe permissions on LGW-RTBs. This permission is required to describe permissions for RDS on Outposts to perform Multi-AZ replication across the Outposts' local network. For more information, see Working with Multi-AZ deployments for Amazon RDS on AWS Outposts.	April 19, 2022
AWS managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSPerformanceInsightsReadOnly` to allow Amazon RDS to call AWS services on behalf of your DB instances. For more information about configuring access policies for Performance Insights, see Configuring access policies for Performance Insights	March 10, 2022

Change	Description	Date
Service-linked role permissions for Amazon RDS – Update to an existing policy	Amazon RDS added new Amazon CloudWatch namespaces to `AWSServiceRoleForRDS` for `PutMetricData` . These namespaces are required for Amazon DocumentDB (with MongoDB compatibility) and Amazon Neptune to publish CloudWatch metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	March 4, 2022
Service-linked role permissions for Amazon RDS Custom – New policy	Amazon RDS added a new service-linked role named `AWSServiceRoleForRDSCustom` to allow RDS Custom to call AWS services on behalf of your DB instances.	October 26, 2021
Amazon RDS started tracking changes	Amazon RDS started tracking changes for its AWS managed policies.	October 26, 2021

Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see Amazon Resource Names (ARNs) in Amazon RDS.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- Granting permissions to publish notifications to an Amazon SNS topic
- Manually creating an IAM role for native backup and restore
- Setting up Windows Authentication for SQL Server DB instances
- Prerequisites for integrating RDS for SQL Server with S3
- Manually creating an IAM role for SQL Server Audit
- Configuring IAM permissions for RDS for Oracle integration with Amazon S3
- Setting up access to an Amazon S3 bucket (PostgreSQL import)
- Setting up access to an Amazon S3 bucket (PostgreSQL export)

IAM database authenticationfor MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL, and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (AWS) JDBC Driver supports IAM database authentication. For more information, see AWS IAM Authentication Plugin in the Amazon Web Services (AWS) JDBC Driver GitHub repository.

The Amazon Web Services (AWS) Python Driver supports IAM database authentication. For more information, see AWS IAM Authentication Plugin in the Amazon Web Services (AWS) Python Driver GitHub repository.

Navigate through the following topics to learn the process to set IAM for DB authentication:

- Enabling and disabling IAM database authentication

- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
- Connecting to your DB instance using IAM authentication

Region and version availability

Feature availability and support varies across specific versions of each database engine. For more information on engine, version, and Region availability with Amazon RDS and IAM database authentication, see Supported Regions and DB engines for IAM database authentication in Amazon RDS.

CLI and SDK support

IAM database authentication is available for the AWS CLI and for the following language-specific AWS SDKs:

- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto3)
- AWS SDK for Ruby

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- Currently, IAM database authentication doesn't support all global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the *IAM User Guide*.
- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.

- For PostgreSQL, Amazon RDS does not support enabling both IAM and Kerberos authentication methods at the same time.
- For PostgreSQL, you can't use IAM authentication to establish a replication connection.
- You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.
- IAM DB authentication requires compute resources on the database instance. You must have between 300 and 1000 MiB extra memory on your database for reliable connectivity. To see the memory needed for your workload, compare the RES column for RDS processes in the Enhanced Monitoring processlist before and after enabling IAM DB authentication. See Viewing OS metrics in the RDS console.

  If you are using a burstable class instance, avoid running out of memory by reducing the memory used by other parameters like buffers and cache by the same amount.
-
- IAM DB authentication is not supported for RDS on Outposts for any engine.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

  The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

  Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See RDS Proxy pricing.

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see AWS global condition context keys in the *IAM User Guide*.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB instance with IAM database authentication enabled, see Creating an Amazon RDS DB instance.
- To modify a DB instance to enable IAM database authentication, see Modifying an Amazon RDS DB instance.

- To restore a DB instance from a snapshot with IAM database authentication enabled, see Restoring to a DB instance.
- To restore a DB instance to a point in time with IAM database authentication enabled, see Restoring a DB instance to a specified time for Amazon RDS.

Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.

   > **Note**
   >
   > Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. You can also choose to enable publishing IAM DB authentication logs to CloudWatch Logs. Under **Log exports**, choose the **iam-db-auth-error log** option. Publishing your logs to CloudWatch Logs consumes storage and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.
7. Choose **Continue**.
8. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
9. Choose **Modify DB instance** .

AWS CLI

To create a new DB instance with IAM authentication by using the AWS CLI, use the `create-db-instance` command. Specify the `--enable-iam-database-authentication` option, as shown in the following example.

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m3.medium \
    --engine MySQL \
    --allocated-storage 20 \
    --master-username masterawsuser \
    --manage-master-user-password \
    --enable-iam-database-authentication
```

To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command `modify-db-instance`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

> **Note**
>
> Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --apply-immediately \
    --enable-iam-database-authentication
```

If you are restoring a DB instance, use one of the following AWS CLI commands:

- `restore-db-instance-to-point-in-time`

- `restore-db-instance-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB instance to have IAM authentication, use the API operation `ModifyDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

> **Note**
>
> Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Region and version availability.

If you are restoring a DB instance, use one of the following API operations:

- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

> **Note**
>
> To learn more about IAM policies, see Identity and access management for Amazon RDS.

The following example policy allows a user to connect to a DB instance using IAM database authentication.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:111122223333:dbuser:db-
ABCDEFGHIJKL01234/db_user"
            ]
        }
    ]
}
```

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:111122223333:dbuser:cluster-
ABCDEFGHIJKL01234/db_user"
            ]
        }
    ]
}
```

Important

A user with administrator permissions can access DB instances without explicit permissions in an IAM policy. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- `Effect` – Specify `Allow` to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- `Action` – Specify `rds-db:connect` to allow connections to the DB instance.
- `Resource` – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name
```

In this format, replace the following:

- *`region`* is the AWS Region for the DB instance. In the example policy, the AWS Region is `us-east-2`.
- *`account-id`* is the AWS account number for the DB instance. In the example policy, the account number is `1234567890`. The user must be in the same account as the account for the DB instance.

  To perform cross-account access, create an IAM role with the policy shown above in the account for the DB instance and allow your other account to assume the role.

- *DbiResourceId* is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is db-ABCDEFGHIJKL01234.

  To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

  Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

  ```
  aws rds describe-db-instances --query "DBInstances[*].
  [DBInstanceIdentifier,DbiResourceId]"
  ```

  If you are using Amazon Aurora, specify a DbClusterResourceId instead of a DbiResourceId. For more information, see Creating and using an IAM policy for IAM database access in the *Amazon Aurora User Guide*.

  > **Note**
  >
  > If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as prx-ABCDEFGHIJKL01234. For information about using IAM database authentication with RDS Proxy, see Connecting to a database using IAM authentication.

- *db-user-name* is the name of the database account to associate with IAM authentication. In the example policy, the database account is db_user.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
```

```
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:db-ABCDEFGHIJKL01234/
jane_doe",
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:db-ABCDEFGHIJKL01234/
mary_roe"
         ]
      }
   ]
}
```

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-
ABCDEFGHIJKL01234/jane_doe",
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-
ABCDEFGHIJKL01234/mary_roe"
         ]
      }
   ]
}
```

The following policy uses the "*" character to match all DB instances and database accounts for a particular AWS account and AWS Region.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:111122223333:dbuser:*/*"
            ]
        }
    ]
}
```

The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a `jane_doe` database account.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
         ]
      }
   ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named *dev*, and another database named *test*. If the database user `jane_doe` has access only to *dev*, any users or roles that access that DB instance with the `jane_doe` user also have access only to *dev*. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon RDS.

Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

> **Note**
>
> You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.
>
> ```
> arn:aws:rds-db:us-east-2:123456789012:dbuser:db-12ABC34DEFG5HIJ6KLMNOP78QR/
> jane_doe
> ```
>
> If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB instance using the `jane_doe` database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

> **Note**
>
> The user name used for IAM authentication must match the case of the user name in the database.

Topics

- Using IAM authentication with MariaDB and MySQL
- Using IAM authentication with PostgreSQL

Using IAM authentication with MariaDB and MySQL

With MariaDB and MySQL, authentication is handled by `AWSAuthenticationPlugin`—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows MariaDB and MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access.

> **Note**
>
> If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.
> `ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded`
> To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see Region and version availability and Enabling and disabling IAM database authentication.

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access. You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the *AWS General Reference*.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Topics

- Connecting to your DB instance using IAM authentication with the AWS drivers
- Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client
- Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client
- Connecting to your DB instance using IAM authentication and the AWS SDK for .NET
- Connecting to your DB instance using IAM authentication and the AWS SDK for Go
- Connecting to your DB instance using IAM authentication and the AWS SDK for Java
- Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

Connecting to your DB instance using IAM authentication with the AWS drivers

The AWS suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM),

and Federated Identity. The AWS drivers rely on monitoring DB instance status and being aware of the instance topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the AWS drivers, see the corresponding language driver for your RDS for MariaDB, RDS for MySQL, or RDS for PostgreSQL DB instance.

> **Note**
>
> The only features supported for RDS for MariaDB are authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity.

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and `mysql` command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token
- Connecting to a DB instance

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
   --port 3306 \
   --region us-west-2 \
   --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to a DB instance

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-
cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance

- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

  For more information about SSL/TLS support for MariaDB, see SSL/TLS support for MariaDB DB instances on Amazon RDS.

  For more information about SSL/TLS support for MySQL, see SSL/TLS support for MySQL DB instances on Amazon RDS.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .
- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

  If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.
- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-
west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-
cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+---------------+-------------+
```

```
| Variable_name | Value

                                                                    |
+---------------+-------------+
| ...           | ...
| Ssl_cipher    | AES256-SHA

                                                                    |
| ...           | ...
| Ssl_version   | TLSv1.1

                                                                    |
| ...           | ...
+-----------------------------+
```

If you want to connect to a DB instance through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics

- Generating an IAM authentication token
- Connecting to an Amazon RDS PostgreSQL instance

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

Connecting to an Amazon RDS PostgreSQL instance

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full
 sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName
 password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB instance that you want to access
- `port` – The port number used for connecting to your DB instance
- `sslmode` – The SSL mode to use

  When you use `sslmode=verify-full`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- `sslrootcert` – The full path to the SSL certificate file that contains the public key

  For more information, see Using SSL with a PostgreSQL DB instance.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .
- dbname – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

```
psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB instance through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The `AWSSDK.CORE` and the `AWSSDK.RDS` packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB instance that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB instance
- `SslMode` – The SSL mode to use

When you use `SslMode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- `SslCa` – The full path to the SSL certificate for Amazon RDS

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
  class Program
  {
    static void Main(string[] args)
    {
      var pwd =
 Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
 "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
      // for debug only Console.Write("{0}\n", pwd);  //this verifies the token is
 generated

      MySqlConnection conn = new MySqlConnection($"server=mysqldb.123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
      conn.Open();

      // Define a query
      MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

      // Execute a query
      MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();
```

```
      // Read all rows and output the first column in each row
      while (mysqlDataRdr.Read())
        Console.WriteLine(mysqlDataRdr[0]);

      mysqlDataRdr.Close();
      // Close connection
      conn.Close();
    }
  }
}
```

This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- `Server` – The endpoint of the DB instance that you want to access
- `User ID` – The database account that you want to access
- `Database` – The database that you want to access
- `Port` – The port number used for connecting to your DB instance
- `SSL Mode` – The SSL mode to use

  When you use `SSL Mode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- `Root Certificate` – The full path to the SSL certificate for Amazon RDS

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
```

```
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
 RDSAuthTokenGenerator.GenerateAuthToken("postgresmydb.123456789012.us-
east-1.rds.amazonaws.com", 5432, "jane_doe");
// for debug only Console.Write("{0}\n", pwd);  //this verifies the token is generated

            NpgsqlConnection conn = new
 NpgsqlConnection($"Server=postgresmydb.123456789012.us-east-1.rds.amazonaws.com;User
 Id=jane_doe;Password={pwd};Database=mydb;SSL Mode=Require;Root
 Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
                   NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
 pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
                Console.Write("{0}\n", dr[0]);

            // Close connection
            conn.Close();
        }
    }
}
```

If you want to connect to a DB instance through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB instance that you want to access

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB instance
- `region` – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

> **Important**
>
> The examples in this section use the following code to provide credentials that access a database from a local environment:
> `creds := credentials.NewEnvCredentials()`
> If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:
> `sess := session.Must(session.NewSession())`
> `creds := sess.Config.Credentials`
> If you make this change, make sure you add the following import:
> `"github.com/aws/aws-sdk-go/aws/session"`

Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```
package main

import (
     "context"
     "database/sql"
     "fmt"

     "github.com/aws/aws-sdk-go-v2/config"
     "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
     _ "github.com/go-sql-driver/mysql"
)

func main() {

     var dbName string = "DatabaseName"
     var dbUser string = "DatabaseUser"
     var dbHost string = "mysqldb.123456789012.us-east-1.rds.amazonaws.com"
     var dbPort int = 3306
     var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
     var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
     panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
     context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
```

```
     panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authenticationToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

This code connects to a PostgreSQL DB instance.

```
package main

import (
     "context"
     "database/sql"
     "fmt"

     "github.com/aws/aws-sdk-go-v2/config"
     "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
     _ "github.com/lib/pq"
)

func main() {

     var dbName string = "DatabaseName"
     var dbUser string = "DatabaseUser"
     var dbHost string = "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
     var dbPort int = 5432
     var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
     var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
```

```
     panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
     context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
     panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
        dbHost, dbPort, dbUser, authenticationToken, dbName,
    )

    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

    if err != nil {
        panic(err)
    }
}
```

If you want to connect to a DB instance through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Java

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
- Set up the AWS SDK for Java

For examples on how to use the SDK for Java 2.x, see Amazon RDS examples using SDK for Java 2.x. You can also use the AWS Advanced JDBC Wrapper, see AWS Advanced JDBC Wrapper documentation.

Topics

- Generating an IAM authentication token
- Manually constructing an IAM authentication token
- Connecting to a DB instance

Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for users.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
```

```
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {

     String region = "us-west-2";
     String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
     String port = "3306";
     String username = "jane_doe";

     System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
 username) {

     RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
      .credentials(new DefaultAWSCredentialsProviderChain())
      .region(region)
      .build();

     String authToken = generator.getAuthToken(
      GetIamAuthTokenRequest.builder()
      .hostname(hostName)
      .port(Integer.parseInt(port))
      .userName(username)
      .build());

     return authToken;
    }

}
```

Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the *AWS General Reference.*

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {

        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new
 SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
```

```
       DefaultAWSCredentialsProviderChain creds = new
DefaultAWSCredentialsProviderChain();
    String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
    String awsSecretKey = creds.getCredentials().getAWSSecretKey();
       String expiryMinutes = "900";

       System.out.println("Step 1:  Create a canonical request:");
       String canonicalString = createCanonicalString(username, awsAccessKey, date,
dateTimeStamp, region, expiryMinutes, instanceName, port);
       System.out.println(canonicalString);
       System.out.println();

       System.out.println("Step 2:  Create a string to sign:");
       String stringToSign = createStringToSign(dateTimeStamp, canonicalString,
awsAccessKey, date, region);
       System.out.println(stringToSign);
       System.out.println();

       System.out.println("Step 3:  Calculate the signature:");
       String signature = BinaryUtils.toHex(calculateSignature(stringToSign,
newSigningKey(awsSecretKey, date, region, serviceName)));
       System.out.println(signature);
       System.out.println();

       System.out.println("Step 4:  Add the signing info to the request");

       System.out.println(appendSignature(signature));
       System.out.println();

   }

   //Step 1: Create a canonical request date should be in format YYYYMMDD and dateTime
should be in format YYYYMMDDTHHMMSSZ

    }

    public static byte[] hash(String s) throws Exception {
        try {
            MessageDigest md = MessageDigest.getInstance("SHA-256");
            md.update(s.getBytes(UTF8));
```

```
            return md.digest();
        } catch (Exception e) {
            throw new SdkClientException(
                    "Unable to compute hash while signing request: "
                            + e.getMessage(), e);
        }
    }
}
```

Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - `RDS_INSTANCE_HOSTNAME` – The host name of the DB instance that you want to access.
  - `RDS_INSTANCE_PORT` – The port number used for connecting to your PostgreSQL DB instance.
  - `REGION_NAME` – The AWS Region where the DB instance is running.
  - `DB_USER` – The database account that you want to access.
  - `SSL_CERTIFICATE` – An SSL certificate for Amazon RDS that is specific to an AWS Region.

    To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB instance or cluster . Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

Note

Specify a password for `DEFAULT_KEY_STORE_PASSWORD` other than the prompt shown here as a security best practice.

}
```

If you want to connect to a DB instance through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.

Modify the values of the following variables as needed:

- `ENDPOINT` – The endpoint of the DB instance that you want to access
- `PORT` – The port number used for connecting to your DB instance
- `USER` – The database account that you want to access
- `REGION` – The AWS Region where the DB instance is running
- `DBNAME` – The database that you want to access
- `SSLCERTIFICATE` – The full path to the SSL certificate for Amazon RDS

  For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance or cluster .

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install the PyMySQL driver by following the instructions in the Python Package Index.

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
```

```
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn =
 pymysql.connect(auth_plugin_map={'mysql_clear_password':None},host=ENDPOINT,
 user=USER, password=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE',
 ssl_verify_identity=True, ssl_verify_cert=True)
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to a PostgreSQL DB instance.

Before running this code, install `psycopg2` by following the instructions in Psycopg documentation.

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
```

```
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
 password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB instance through a proxy, see Connecting to a database using IAM authentication.

Troubleshooting for IAM DB authentication

Following, you can find troubleshooting ideas for some common IAM DB authentication issues and information on CloudWatch logs and metrics for IAM DB authentication.

Exporting IAM DB authentication error logs to CloudWatch Logs

IAM DB authentication error logs are stored on the database host, and you can export these logs your CloudWatch Logs account. Use the logs and remediation methods in this page to troubleshoot IAM DB authentication issues.

You can enable log exports to CloudWatch Logs from the console, AWS CLI, and RDS API. For console instructions, see Publishing database logs to Amazon CloudWatch Logs.

To export your IAM DB authentication error logs to CloudWatch Logs when creating a DB instance from the AWS CLI, use the following command:

```
aws rds create-db-instance --db-instance-identifier mydbinstance \
--region us-east-1 \
--db-instance-class db.t3.large \
--allocated-storage 50 \
```

```
--engine postgres \
--engine-version 16 \
--port 5432 \
--master-username master \
--master-user-password password \
--publicly-accessible \
--enable-iam-database-authentication \
--enable-cloudwatch-logs-exports=iam-db-auth-error
```

To export your IAM DB authentication error logs to CloudWatch Logs when modifying a DB instance from the AWS CLI, use the following command:

```
aws rds modify-db-instance --db-instance-identifier mydbinstance \
--region us-east-1 \
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["iam-db-auth-error"]}'
```

To verify if your DB instance is exporting IAM DB authentication logs to CloudWatch Logs, check if the `EnabledCloudwatchLogsExports` parameter is set to `iam-db-auth-error` in the output for the `describe-db-instances` command.

```
aws rds describe-db-instances --region us-east-1 --db-instance-identifier mydbinstance
            ...

             "EnabledCloudwatchLogsExports": [
                "iam-db-auth-error"
            ],
            ...
```

IAM DB authentication CloudWatch metrics

Amazon RDS delivers near-real time metrics about IAM DB authentication to your Amazon CloudWatch account. The following table lists the IAM DB authentication metrics available using CloudWatch:

Metric	Description
`IamDbAuthConnectionRequests`	Total number of connection requests made with IAM DB authentication.

Metric	Description
IamDbAuthConnectionSuccess	Total number of successful IAM DB authentic ation requests.
IamDbAuthConnectionFailure	Total number of failed IAM DB authentication requests.
IamDbAuthConnectionFailureI nvalidToken	Total number of failed IAM DB authentication requests due to invalid token.
IamDbAuthConnectionFailureI nsufficientPermissions	Total number of failed IAM DB authentication requests due to incorrect policies or permissio ns.
IamDbAuthConnectionFailureT hrottling	Total number of failed IAM DB authentic ation requests due to IAM DB authentication throttling.
IamDbAuthConnectionFailureS erverError	Total number of failed IAM DB authentication requests due to an internal server error in the IAM DB authentication feature.

Common issues and solutions

You might encounter the following issues when using IAM DB authention. Use the remediation steps in the table to solve the issues:

Error	Metric(s)	Cause	Solution
[ERROR] Failed to authenticate the connectio n request for user *db_user* because the provided token is malformed	IamDbAuth Connectio nFailure IamDbAuth Connectio nFailureI nvalidToken	The IAM DB authentia tion token in the connection request is either not a valid SigV4a token, or it is not formatted correctly.	Check your token generation strategy in your applicati on. In some cases, make sure you are passing the token with valid formatting. Truncating the token

Error	Metric(s)	Cause	Solution
or otherwise invalid. (Status Code: 400, Error Code: InvalidToken)			(or incorrect string formatting) will make the token invalid.
[ERROR] Failed to authenticate the connection request for user *db_user* because the token age is longer than 15 minutes. (Status Code: 400, Error Code:ExpiredToken)	IamDbAuthConnectionFailure IamDbAuthConnectionFailureInvalidToken	The IAM DB authentication token has expired. Tokens are only valid for 15 minutes.	Check your token caching and/or token re-use logic in your application. You should not re-use tokens that are older than 15 minutes.

Error	Metric(s)	Cause	Solution
[ERROR] Failed to authorize the connection request for user *db_user* because the IAM policy assumed by the caller 'arn:aws:sts::123456789012:assumed-role/ <RoleName>/ <RoleSession>' is not authorized to perform `rds-db:connect` on the DB instance. (Status Code: 403, Error Code:NotAuthorized)	IamDbAuthConnectionFailure IamDbAuthConnectionFailureInsufficientPermissions	This error might be due to the following reasons: • The IAM policy assumed by the application does not authorize the rds-db:connect action. • You are assuming the incorrect role/policy for *db_user* to connect to the database. • You are assuming the correct policy for *db_user*, but you are not connecting to the correct database.	Verify that the IAM role and/or policy you are assuming in your application. Make sure you assume the same policy to generate the token as to connect to the DB.
[ERROR] Failed to authorize the connection request for user *db_user* due to IAM DB authentication throttling. (Status Code: 429, Error Code: ThrottlingException)	IamDbAuthConnectionFailure IamDbAuthConnectionFailureThrottling	You are making too many connection requests to your DB in a short amount of time. IAM DB authentication throttling limit is 200 connections per second.	Reduce the rate of establishing new connections with IAM authentication. Consider implementing connection pooling using RDS Proxy in order to reuse established connections in your application.

Error	Metric(s)	Cause	Solution

`[ERROR] Failed to authorize the connection request for user db_user due to an internal IAM DB authentication error. (Status Code: 500, Error Code: InternalError)`	`IamDbAuthConnectionFailure`
	
	`IamDbAuthConnectionFailureThrottling`
		There was an internal error while authorizing the DB connecito n with IAM DB authentication.	Reach out to https://aws.amazon.com/premiumsupport/ to investigate the issue.

Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

Topics

- I'm not authorized to perform an action in Amazon RDS
- I'm not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Amazon RDS resources

I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a *widget* but does not have `rds:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *my-example-widget* resource using the `rds:GetWidget` action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

I want to allow people outside of my AWS account to access my Amazon RDS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon RDS supports these features, see How Amazon RDS works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.

- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.

Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS . CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS , the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail .

Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see Monitoring OS metrics with Enhanced Monitoring .

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance

Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see Monitoring DB load with Performance Insights on Amazon RDS .

Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see Monitoring Amazon RDS log files .

Amazon RDS Recommendations

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see Recommendations from Amazon RDS .

Amazon RDS Event Notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Working with Amazon RDS event notification .

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon RDS -related checks:

- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).

For more information about monitoring Amazon RDS , see Monitoring metrics in an Amazon RDS instance .

Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security and compliance quick start guides – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- Architecting for HIPAA Security and Compliance on Amazon Web Services – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- AWS compliance resources – This collection of workbooks and guides that might apply to your industry and location.
- AWS Config – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub CSPM – This AWS service provides a comprehensive view of your security state within AWS. Security Hub CSPM uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub CSPM controls reference.

Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see Backing up, restoring, and exporting data.

Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a

standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see Working with DB instance read replicas.

Failover

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS.

Infrastructure security in Amazon RDS

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

In addition, Amazon RDS offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups.

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see Hiding a DB instance in a VPC from the internet.

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the *Amazon EC2 User Guide.*

For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the *Amazon VPC User Guide*. For more information about RDS API operations, see Amazon RDS API Reference.

You don't need an interface VPC endpoint to connect to a DB instance. For more information, see Scenarios for accessing a DB instance in a VPC.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (New Zealand)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Taipei)
- Asia Pacific (Thailand)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Mexico (Central)
- Middle East (Bahrain)
- South America (São Paulo)

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see Accessing a service through an interface endpoint in the *Amazon VPC User Guide*.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
   "Statement":[
      {
         "Principal":"*",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBInstance",
            "rds:ModifyDBInstance",
            "rds:CreateDBSnapshot"
         ],
         "Resource":"*"
      }
   ]
}
```

Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
     }
   ]
}
```

Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources. Such

resources include DB instances , security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances .

- Create an individual user for each person who manages Amazon RDS resources, including yourself. Don't use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS . For more information, see Rotating your AWS Secrets Manager secrets in the *AWS Secrets Manager User Guide*. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the *AWS Secrets Manager User Guide*.

For more information about Amazon RDS security, see Security in Amazon RDS . For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.

AWS Security Hub CSPM uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub CSPM to evaluate RDS resources, see Amazon Relational Database Service controls in the AWS Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub CSPM. For more information, see What is AWS Security Hub CSPM?.

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB instance . By default, network access is turned off for a DB instance . You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

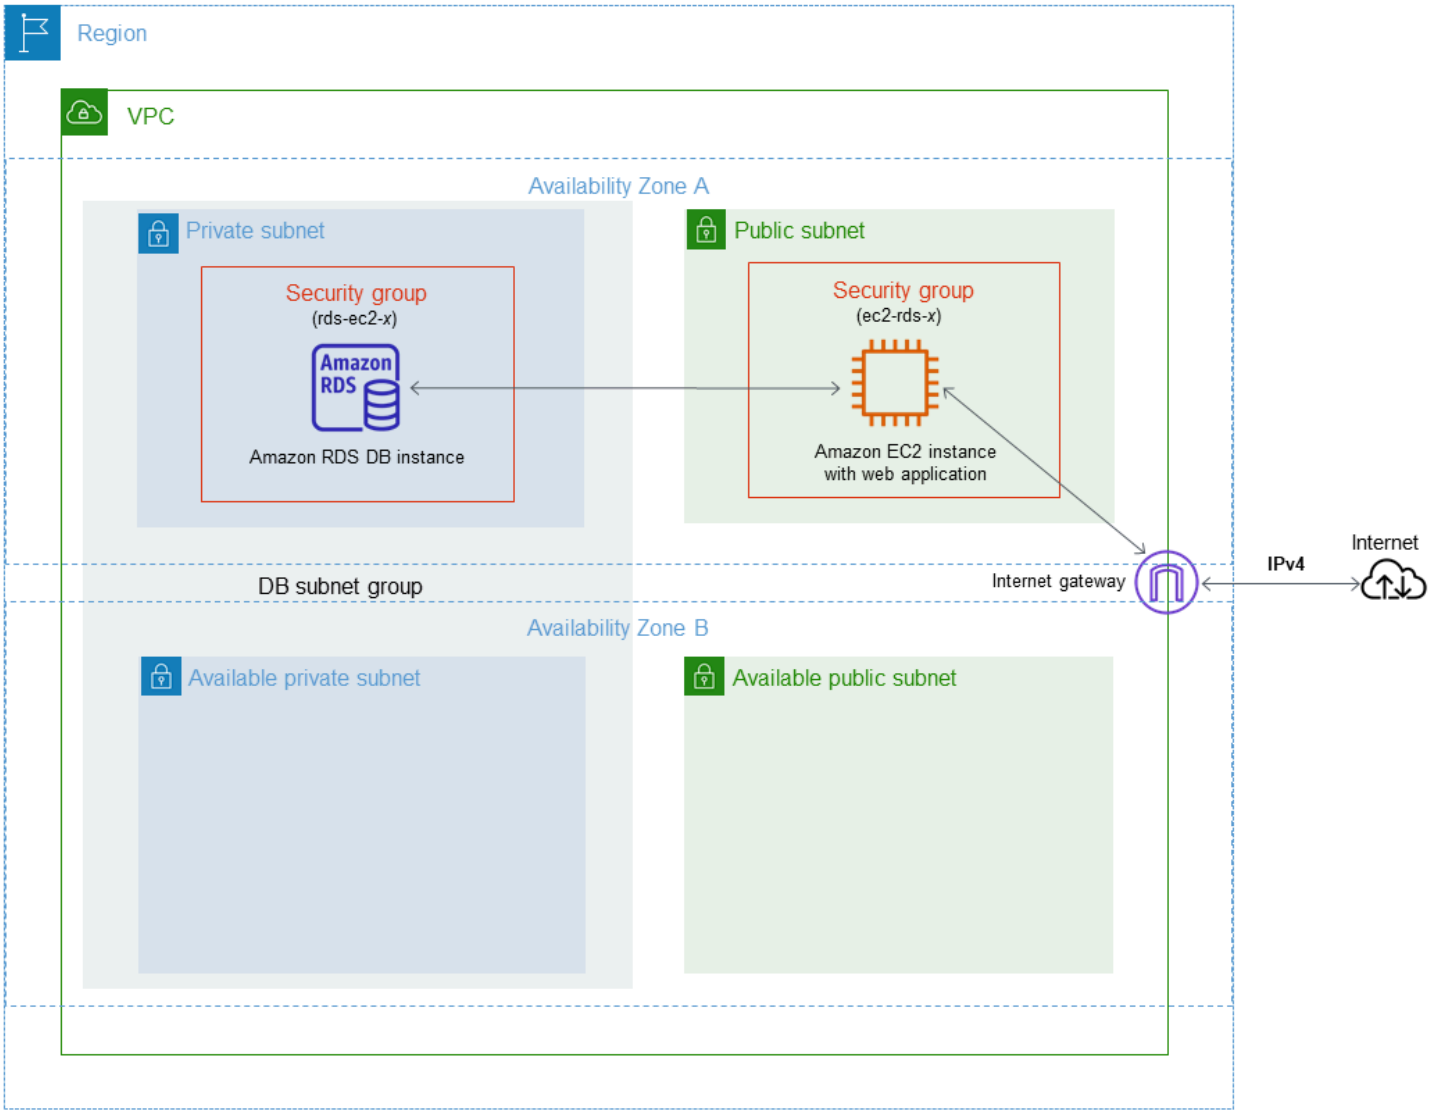
Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB instances . Outbound traffic rules apply only if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the Amazon EC2 API or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see Security groups in the *Amazon Virtual Private Cloud User Guide*.



> **Note**
>
> If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy .

Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, `sg-0123ec2example`) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB instance and add the DB instance to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB instance , use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only) . For more information about using a VPC, see Amazon VPC and Amazon RDS .

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to your DB instance in your VPC by creating a security group and Security groups in the *Amazon Virtual Private Cloud User Guide*.

Associating a security group with a DB instance

You can associate a security group with a DB instance by using **Modify** on the RDS console, the `ModifyDBInstance` Amazon RDS API, or the `modify-db-instance` AWS CLI command.

The following CLI example associates a specific VPC security group and removes DB security groups from the DB instance

```
aws rds modify-db-instance --db-instance-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance . For security group considerations when you restore a DB instance from a DB snapshot, see Security group considerations .

> **Note**
>
> The RDS console displays different security group rule names for your database if the Port value is configured to a non-default value.

For RDS for Oracle DB instances, additional security groups can be associated by populating the security group options setting for the Oracle Enterprise Manager Database Express (OEM), Oracle Management Agent for Enterprise Manager Cloud Control (OEM Agent) and the Oracle Secure Sockets Layer options. In this case, both security groups associated with the DB instance and options settings apply to the DB instance. For more information about these option groups, see Oracle Enterprise Manager ,Oracle Management Agent for Enterprise Manager Cloud Control , and Oracle Secure Sockets Layer .

Master user account privileges

When you create a new DB instance , the default master user that you use gets certain privileges for that DB instance . You can't change the master user name after the DB instance is created.

Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance , see Modifying an Amazon RDS DB instance .

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
RDS for Db2	The master user is assigned to the `masterdba` group and assigned the `master_user_role` . `SYSMON,DBADM with DATAACCESS AND ACCCESSCTRL , BINDADD,CONNECT, CREATETAB ,CREATE_SECURE_OBJECT , EXPLAIN,IMPLICIT_SCHEMA , LOAD,SQLADM,WLMADM`	`DBA,DBA_RESTRICTED , DEVELOPER ,ROLE_NULLID_PACKAGES , ROLE_PROCEDURES ,ROLE_TABLESPACES` For more information, see Amazon RDS for Db2 default roles .
RDS for MariaDB	`SELECT,INSERT,UPDATE,DELETE, CREATE,DROP,RELOAD, PROCESS,REFERENCES ,INDEX, ALTER,SHOW DATABASES ,CREATE TEMPORARY TABLES ,LOCK TABLES, EXECUTE,REPLICATION CLIENT,CREATE VIEW ,SHOW VIEW,CREATE`	—

Database engine	System privilege	Database role
	`ROUTINE, ALTER ROUTINE,CREATE USER, EVENT,TRIGGER,REPLICATION SLAVE` Starting with RDS for MariaDB version 11.4, the master user also gets the `SHOW CREATE ROUTINE` privilege.	
RDS for MySQL 8.0.36 and higher	`SELECT,INSERT,UPDATE, DELETE,CREATE,DROP, RELOAD,PROCESS, REFERENCES ,INDEX,ALTER, SHOW DATABASES ,CREATE TEMPORARY TABLES,LOCK TABLES,EXECUTE, REPLICATI ON SLAVE ,REPLICATION CLIENT , CREATE VIEW,SHOW VIEW,CREATE ROUTINE,ALTER ROUTINE,CREATE USER,EVENT,TRIGGER, CREATE ROLE,DROP ROLE, APPLICATION_PASSWO RD_ADMIN , ROLE_ADMIN ,SET_USER_ID , XA_RECOVER_ADMIN`	`rds_superuser_role` For more information about `rds_superuser_role` , see Role-based privilege model for RDS for MySQL .
RDS for MySQL versions lower than 8.0.36	`SELECT,INSERT,UPDATE, DELETE,CREATE,DROP, RELOAD,PROCESS, REFERENCES ,INDEX,ALTER, SHOW DATABASES ,CREATE TEMPORARY TABLES,LOCK TABLES,EXECUTE, REPLICATI ON CLIENT ,CREATE VIEW, SHOW VIEW,CREATE ROUTINE,ALTER ROUTINE,CREATE USER,EVENT, TRIGGER,REPLICATION SLAVE`	—

Database engine	System privilege	Database role
RDS for PostgreSQL	CREATE ROLE,CREATE DB, PASSWORD VALID UNTIL INFINITY,CREATE EXTENSION ,ALTER EXTENSION ,DROP EXTENSION ,CREATE TABLESPACE ,ALTER <OBJECT> OWNER,CHECKPOINT , PG_CANCEL_BACKEND( ) , PG_TERMINATE_BACKEND() ,SELECT PG_STAT_REPLICATION ,EXECUTE PG_STAT_STATEMENTS_RESET() ,OWN POSTGRES_FDW_HANDLER() ,OWN POSTGRES_FDW_VALIDATOR() ,OWN POSTGRES_FDW , EXECUTE PG_BUFFERCACHE_PAGES() ,SELECT PG_BUFFERCACHE	RDS_SUPERUSER For more information about RDS_SUPERUSER, see Understanding PostgreSQL roles and permissions .
RDS for Oracle	ADMINISTER DATABASE TRIGGER ,ALTER DATABASE LINK,ALTER PUBLIC DATABASE LINK, AUDIT SYSTEM,CHANGE NOTIFICATION , DROP ANY DIRECTORY ,EXEMPT ACCESS POLICY,EXEMPT IDENTITY POLICY,EXEMPT REDACTION POLICY,FLASHBACK ANY TABLE, GRANT ANY OBJECT PRIVILEGE ,RESTRICTED SESSION ,SELECT ANY TABLE,UNLIMITED TABLESPACE	DBA **Note** The DBA role is exempt from the following privileges: ALTER DATABASE,ALTER SYSTEM, CREATE ANY DIRECTORY ,CREATE EXTERNAL JOB,CREATE PLUGGABLE DATABASE, GRANT ANY PRIVILEGE ,GRANT ANY ROLE,READ ANY FILE GROUP

Database engine	System privilege	Database role
Amazon RDS for Microsoft SQL Server	ADMINISTER BULK OPERATIONS ,ALTER ANY CONNECTION ,ALTER ANY CREDENTIAL , ALTER ANY EVENT SESSION,ALTER ANY LINKED SERVER,ALTER ANY LOGIN,ALTER ANY SERVER AUDIT,ALTER ANY SERVER ROLE, ALTER SERVER STATE,ALTER TRACE, CONNECT SQL,CREATE ANY DATABASE, VIEW ANY DATABASE,VIEW ANY DEFINITION ,VIEW SERVER STATE,ALTER ON ROLE SQLAgentOperatorRole	DB_OWNER (database-level role), PROCESSADMIN (server-level role), SETUPADMIN (server-level role), SQLAgentUserRole (database-level role), SQLAgentReaderRole (database-level role), and SQLAgentOperatorRole (database-level role)

Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don't have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account.

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

> **Note**
>
> You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

Important

If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.

Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities

might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the **Summary** page for the chosen role, choose the **Last Accessed** tab.
4. On the **Last Accessed** tab, review recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether Amazon RDS is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete *all* of your DB instances .

Deleting all of your instances

Use one of these procedures to delete each of your instances.

To delete an instance (console)

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. If you are prompted for **Create final Snapshot?**, choose **Yes** or **No**.
6. If you chose **Yes** in the previous step, for **Final snapshot name** enter the name of your final snapshot.
7. Choose **Delete**.

To delete an instance (CLI)

See `delete-db-instance` in the *AWS CLI Command Reference*.

To delete an instance (API)

See `DeleteDBInstance` in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named `AWSServiceRoleForRDSCustom` to allow RDS Custom to call AWS services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSCustom service-linked role trusts the following services to assume the role:

- `custom.rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSCustomServiceRolePolicy` that grants it permissions to operate in your account.

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see AWS managed policy: AmazonRDSCustomServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSCustomServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Service-linked role permissions for Amazon RDS Beta

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDSBeta` to allow Amazon RDS to call AWS services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSBeta service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSBetaServiceRolePolicy` that grants it permissions to operate in your account. For more information, see AWS managed policy: AmazonRDSBetaServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSBetaServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Service-linked role for Amazon RDS Preview

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDSPreview` to allow Amazon RDS to call AWS services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSPreview service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSPreviewServiceRolePolicy` that grants it permissions to operate in your account. For more information, see AWS managed policy: AmazonRDSPreviewServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSPreviewServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Amazon VPC and Amazon RDS

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in a VPC.

Accounts have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise.

- Updating the VPC for a DB instance
- Scenarios for accessing a DB instance in a VPC
- Tutorial: Create a VPC for use with a DB instance (IPv4 only)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode)
- Moving a DB instance not in a VPC into a VPC

Following, you can find a discussion about VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see Scenarios for accessing a DB instance in a VPC.

Topics

- Working with a DB instance in a VPC
- VPC encryption control
- Working with DB subnet groups
- Shared subnets
- Amazon RDS IP addressing
- Hiding a DB instance in a VPC from the internet
- Creating a DB instance in a VPC

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon RDS scenario:

- Tutorial: Create a VPC for use with a DB instance (IPv4 only)
- Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB instances based on your security and operational needs.

  For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone as needed. Make sure to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

  > **Note**
  >
  > The DB subnet group for a Local Zone can have only one subnet.

- If you want your DB instance in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.

- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that subnet group to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB instance.

  For more information, see Scenarios for accessing a DB instance in a VPC.
- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.
- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

  If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the *Amazon Elastic Compute Cloud User Guide*.

  For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the Amazon EC2 pricing page.

  > **Note**
  >
  > When you set the instance tenancy attribute to dedicated for a DB instance, it doesn't guarantee that the DB instance will run on a dedicated host.

- When an option group is assigned to a DB instance, it's associated with the DB instance's VPC. This linkage means that you can't use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC.
- If you restore a DB instance into a different VPC, make sure to either assign the default option group to the DB instance, assign an option group that is linked to that VPC, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

VPC encryption control

VPC encryption controls allow you to enforce encryption-in-transit for all network traffic within your VPCs. Use encryption control to meet regulatory compliance requirements by ensuring that only encryption-capable Nitro-based hardware can be provisioned in designated VPCs. Encryption control also catches compatibility issues at API request time rather than during provisioning. Your existing workloads continue operating and only new incompatible requests are blocked.

Set your VPC encryption controls by setting the VPC control mode to :

- *disabled* (default)
- *monitor*
- *enforced*

To check the current control mode for your VPC, use the AWS Management Console or DescribeVpcs CLI or API command.

If your VPC enforces encryption, you can only provision Nitro-based DB instances that support encryption in transit in that VPC. For more information see, DB instance class types. For information about Nitro instances, see Instances built on the AWS Nitro System in the *Amazon EC2 User Guide*.

> **Note**
>
> If you try to provision incompatible DB instances in an encryption-enforced VPC, Amazon RDS returns a `VpcEncryptionControlViolationException` exception.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you choose a DB subnet group for it. From the DB

subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with the DB instance. The DB uses the Availability Zone that contains the subnet. Amazon RDS always assigns an IP address from a subnet that has free IP address space.

If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and later create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB instance to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB instance changes from public to private, it can affect DB instance availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon RDS IP addressing and Migrating to IPv6 in the *Amazon VPC User Guide.*

> **Note**
>
> The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB instance. We recommend this because the underlying IP address changes during failover.

> **Note**
>
> For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

Shared subnets

You can create a DB instance in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB instance from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB instance.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon RDS IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon RDS supports both IPv4 and IPv6 addressing protocols. By default, Amazon RDS and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB instances in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics

- IPv4 addresses
- IPv6 addresses
- Dual-stack mode

IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB instance can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB instance and other resources, such as Amazon

EC2 instances, in the same VPC. Each DB instance has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB instance and resources on the internet, such as a SQL client. You control whether your DB instance receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the *Amazon VPC User Guide*.

Dual-stack mode

A DB instance runs in dual-stack mode when it can communicate over both IPv4 and IPv6 addressing protocols. Resources can then communicate with the DB instance using either IPv4, IPv6, or both protocols. Private dual-stack mode DB instances have IPv6 endpoints that RDS restricts to VPC access only, ensuring your IPv6 endpoints remain private. Public dual-stack mode DB instances provide both IPv4 and IPv6 endpoints that you can access from the internet.

Topics

- Dual-stack mode and DB subnet groups

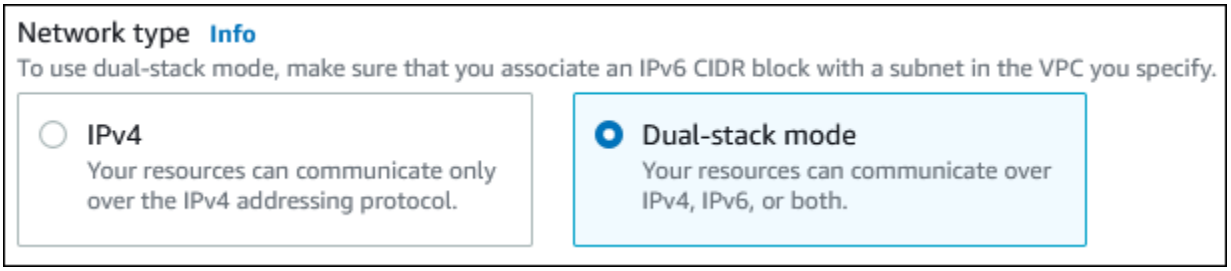
- Working with dual-stack mode DB instances
- Modifying IPv4-only DB instances to use dual-stack mode
- Region and version availability
- Limitations for dual-stack network DB instances

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon RDS scenario, see Tutorial: Create a VPC for use with a DB instance (dual-stack mode).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB instance has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB instance is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB instance detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB instance.



To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, run the describe-db-subnet-groups command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB instance, you can specify dual-stack mode to allow your resources to communicate with your DB instance over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

When you use the AWS CLI to create or modify a DB instance, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB instance, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB instance, see Creating an Amazon RDS DB instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

To determine whether a DB instance is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB instance.

Modifying IPv4-only DB instances to use dual-stack mode

You can modify an IPv4-only DB instance to use dual-stack mode. To do so, change the network type of the DB instance. The modification might result in downtime.

It is recommended that you change the network type of your Amazon RDS DB instances during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-instance` command.

Before modifying a DB instance to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB instance doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB instance. Modifying the DB subnet group of a DB instance can cause downtime.

If you modify the DB subnet group of a DB instance before you change the DB instance to use dual-stack mode, make sure that the DB subnet group is valid for the DB instance before and after the change.

For RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Single-AZ instances, we recommend that you run the modify-db-instance command with only the `--network-type` parameter set to `DUAL` to change the network to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime. To modify multiple parameters, ensure that the network type modification is successfully completed before sending another `modify-db-instance` request with other parameters.

Network type modifications for RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Multi-AZ DB instances cause a brief downtime and trigger a failover if you only use the `--network-type` parameter or if you combine parameters in a modify-db-instance command.

Network type modifications on RDS for SQL Server Single-AZ or Multi-AZ DB instances cause downtime if you only use the `--network-type` parameter or if you combine parameters in a `modify-db-instance` command. Network type modifications cause failover in an SQL Server Multi-AZ instance.

If you can't connect to the DB instance after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

When you modify a DB instance to use dual-stack mode, there can't be a pending change from a Single-AZ deployment to a Multi-AZ deployment, or from a Multi-AZ deployment to a Single-AZ deployment.

To modify an IPv4-only DB instance to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:

   a. Associate an IPv6 CIDR block with your VPC.

      For instructions, see Add an IPv6 CIDR block to your VPC in the *Amazon VPC User Guide*.

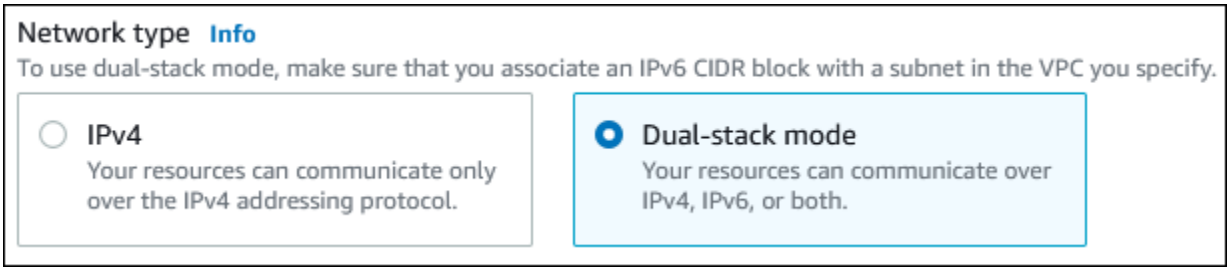
   b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

      For instructions, see Add an IPv6 CIDR block to your subnet in the *Amazon VPC User Guide*.

   c. Confirm that the DB subnet group supports dual-stack mode.

If you are using the AWS Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

If you are using the AWS CLI, run the describe-db-subnet-groups command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual, IPv4`.



2. Modify the security group associated with the DB instance to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

   For instructions, see Security group rules in the *Amazon VPC User Guide*.

3. Modify the DB instance to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

   If you are using the console, make sure that the following settings are correct:

   - **Network type** – **Dual-stack mode**

   - **DB subnet group** – The DB subnet group that you configured in a previous step
   - **Security group** – The security that you configured in a previous step

   If you are using the AWS CLI, make sure that the following settings are correct:

   - `--network-type` – `dual`
   - `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
   - `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

   For example:

```
aws rds modify-db-instance --db-instance-identifier my-instance --network-type
 "DUAL"
```

4. Confirm that the DB instance supports dual-stack mode.

   If you are using the console, choose the **Connectivity & security** tab for the DB instance. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

   If you are using the AWS CLI, run the describe-db-instances command, and make sure that the `NetworkType` value for the DB instance is `dual`.

   Run the `dig` command on the DB instance endpoint to identify the IPv6 address associated with it.

   ```
   dig db-instance-endpoint AAAA
   ```

   Use the DB instance endpoint, not the IPv6 address, to connect to the DB instance.

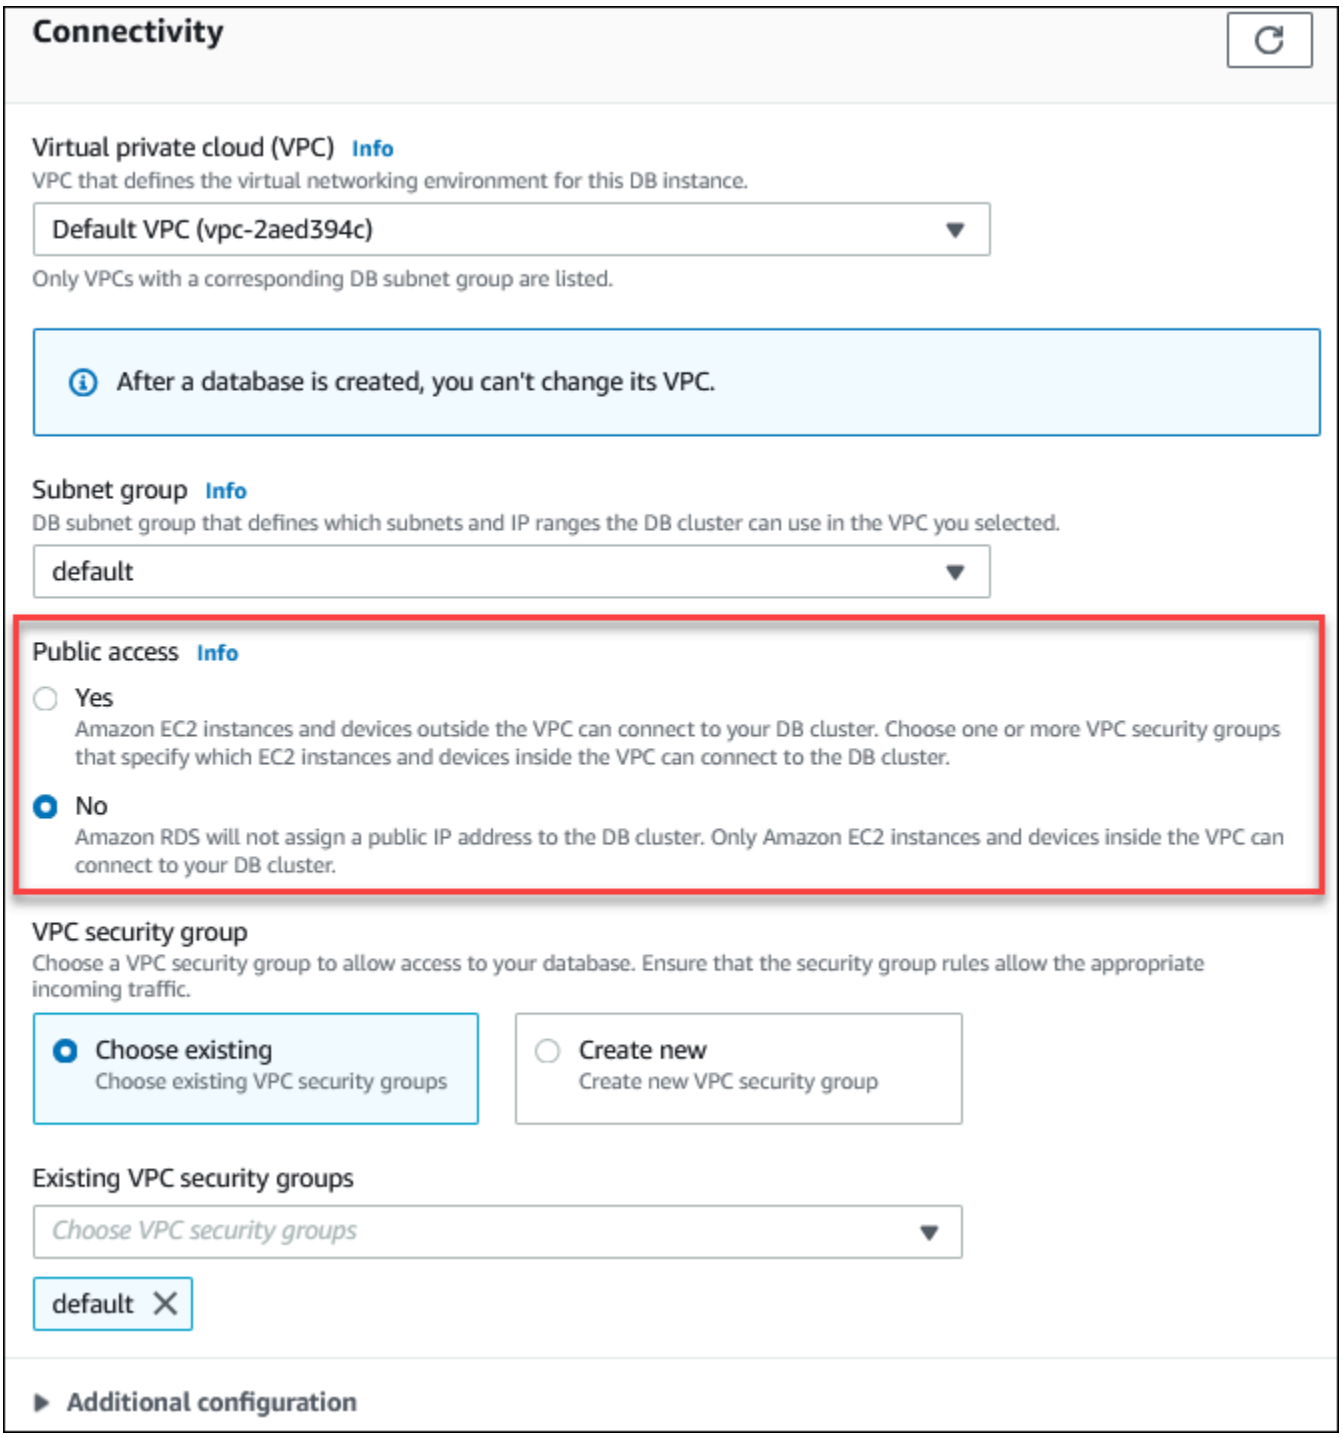
Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with dual-stack mode, see Supported Regions and DB engines for dual-stack mode in Amazon RDS.

Limitations for dual-stack network DB instances

The following limitations apply to dual-stack network DB instances:

- DB instances can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- For RDS for SQL Server, dual-stack mode DB instances that use Always On AGs availability group listener endpoints only present IPv4 addresses.
- You can't use RDS Proxy with dual-stack mode DB instances.
- You can't use dual-stack mode with RDS on AWS Outposts DB instances.
- You can't use dual-stack mode with DB instances in a Local Zone.



Hiding a DB instance in a VPC from the internet

One common Amazon RDS scenario is to have a VPC in which you have an Amazon EC2 instance with a public-facing web application and a DB instance with a database that isn't publicly

accessible. For example, you can create a VPC that has a public subnet and a private subnet. EC2 instances that function as web servers can be deployed in the public subnet. The DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC.

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB instance is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB instance doesn't include inbound rules that permit it. In addition, for a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see Can't connect to Amazon RDS DB instance

You can modify a DB instance to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

For information about modifying a DB instance to set the **Public access** option, see Modifying an Amazon RDS DB instance.

Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

> **Note**
>
> If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:

- Step 1: Create a VPC
- Step 2: Create a DB subnet group
- Step 3: Create a VPC security group
- Step 4: Create a DB instance in the VPC

Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see Create a VPC with private and public subnets, or see Create a VPC in the *Amazon VPC User Guide*.

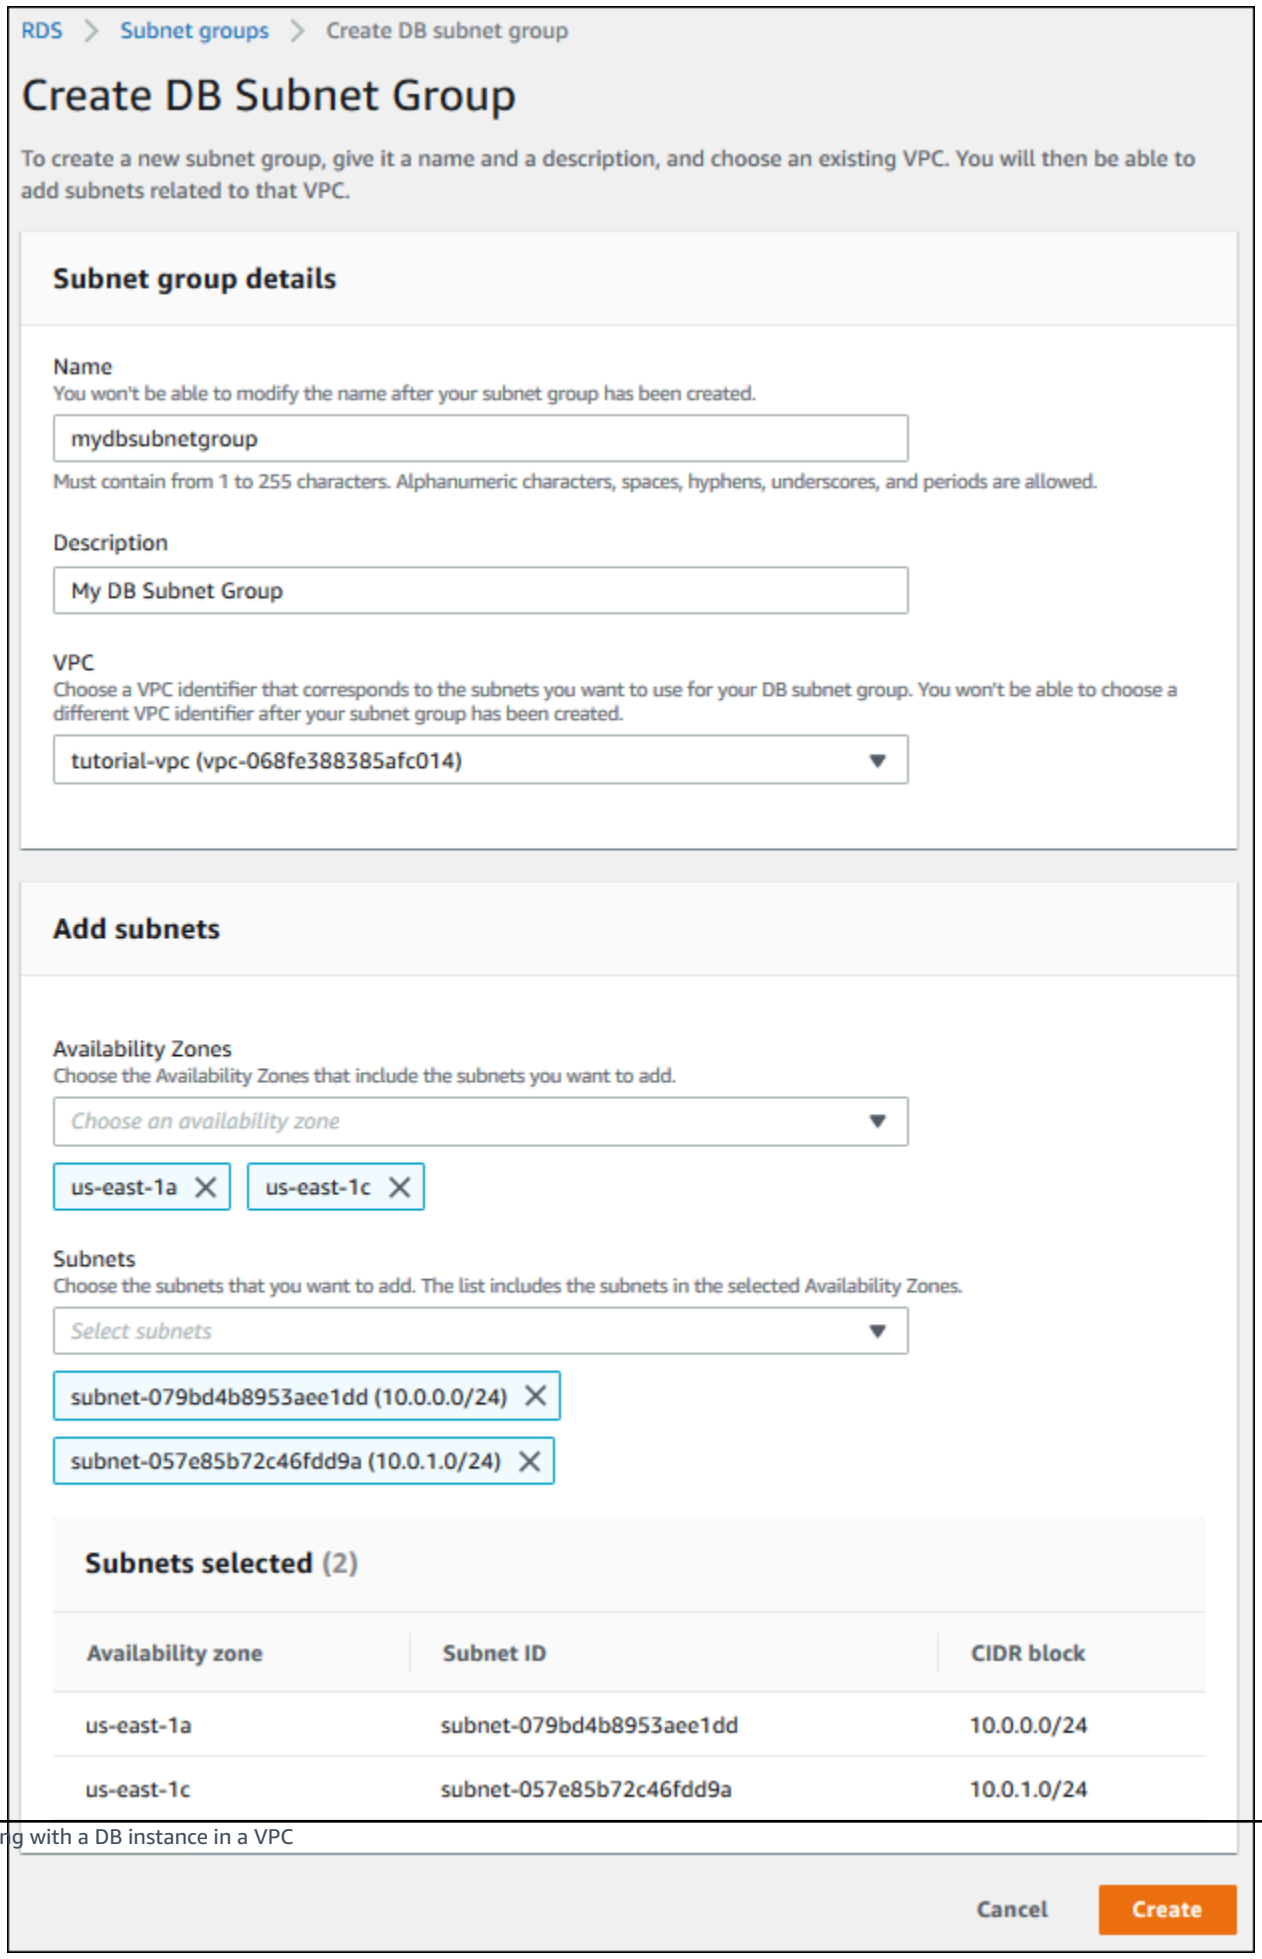
Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the *Amazon VPC User Guide*.

> **Note**
>
> The DB subnet group for a Local Zone can have only one subnet.



When you create a DB instance in a VPC, you can choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. If no DB subnet groups exist, Amazon RDS creates a default subnet group when you create a DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even For Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.

RDS > Subnet groups > Create DB subnet group
Create DB Subnet Group
To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.
Subnet group details
Name
You won't be able to modify the name after your subnet group has been created.
mydbsubnetgroup
Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.
Description
My DB Subnet Group
VPC
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.
tutorial-vpc (vpc-068fe388385afc014)
Add subnets
Availability Zones
Choose the Availability Zones that include the subnets you want to add.
Choose an availability zone
us-east-1a
us-east-1c
Subnets
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.
Select subnets
subnet-079bd4b8953aee1dd (10.0.0.0/24)
subnet-057e85b72c46fdd9a (10.0.1.0/24)
Subnets selected (2)
Availability zone
Subnet ID
CIDR block
us-east-1a
subnet-079bd4b8953aee1dd
10.0.0.0/24
us-east-1c
subnet-057e85b72c46fdd9a
10.0.1.0/24
Cancel
Create

> **Note**
>
> If you have enabled a Local Zone, you can choose an Availability Zone group on the **Create DB subnet group** page. In this case, choose the **Availability Zone group**, **Availability Zones**, and **Subnets**.

8. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

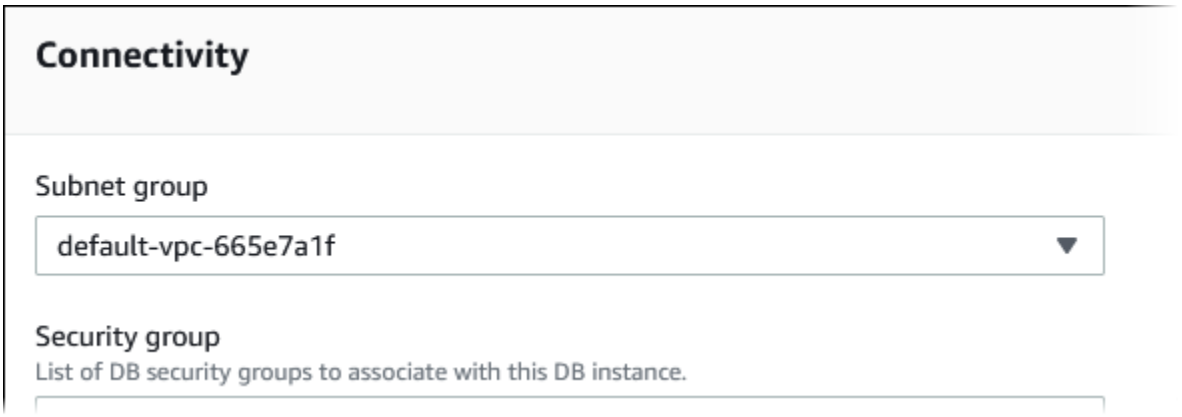
Step 3: Create a VPC security group

Before you create your DB instance, you can create a VPC security group to associate with your DB instance. If you don't create a VPC security group, you can use the default security group when you create a DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance, or see Control traffic to resources using security groups in the *Amazon VPC User Guide*.

Step 4: Create a DB instance in the VPC

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

> **Note**
>
> If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.



For details on how to create a DB instance, see Creating an Amazon RDS DB instance.

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

Updating the VPC for a DB instance

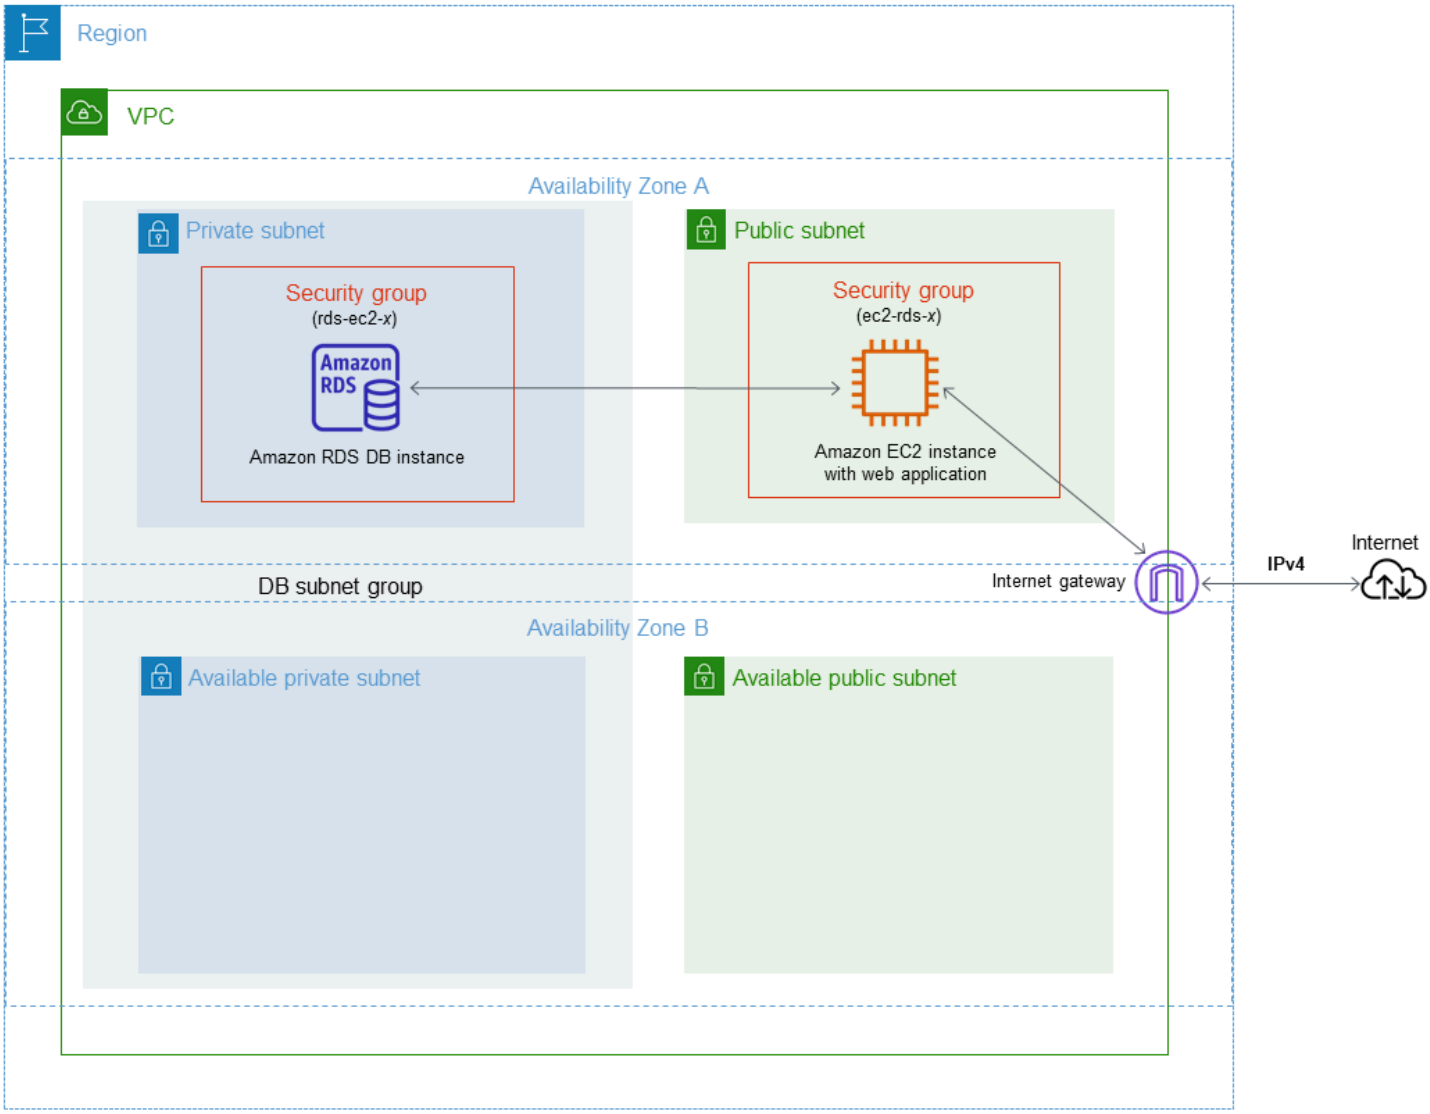
You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance. In the **Connectivity** section of the modify page, shown following, enter the new DB subnet group for **DB subnet group**. The new subnet group must be a subnet group in a new VPC.

You can't change the VPC for a DB instance if the following conditions apply:

- The DB instance is in multiple Availability Zones. You can convert the DB instance to a single Availability Zone, move it to a new VPC, and then convert it back to a Multi-AZ DB instance. For more information, see Configuring and managing a Multi-AZ deployment for Amazon RDS.
- The DB instance has one or more read replicas. You can remove the read replicas, move the DB instance to a new VPC, and then add the read replicas again. For more information, see Working with DB instance read replicas.
- The DB instance is a read replica. You can promote the read replica, and then move the standalone DB instance to a new VPC. For more information, see Promoting a read replica to be a standalone DB instance.
- The subnet group in the target VPC doesn't have subnets in the DB instance's the Availability Zone. You can add subnets in the DB instance's Availability Zone to the DB subnet group, and then move the DB instance to the new VPC. For more information, see Working with DB subnet groups.

Scenarios for accessing a DB instance in a VPC



Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:

- An Amazon EC2 instance in the same VPC
- An EC2 instance in a different VPC
- A client application through the internet
- A private network

A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an Amazon EC2 instance in the same VPC.

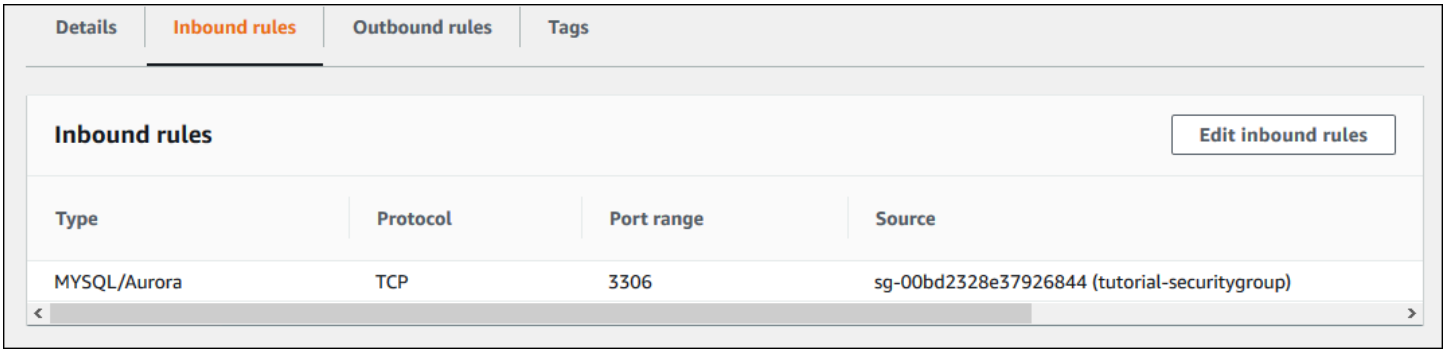
The following diagram shows this scenario.

The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB instances.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB instance (IPv4 only).



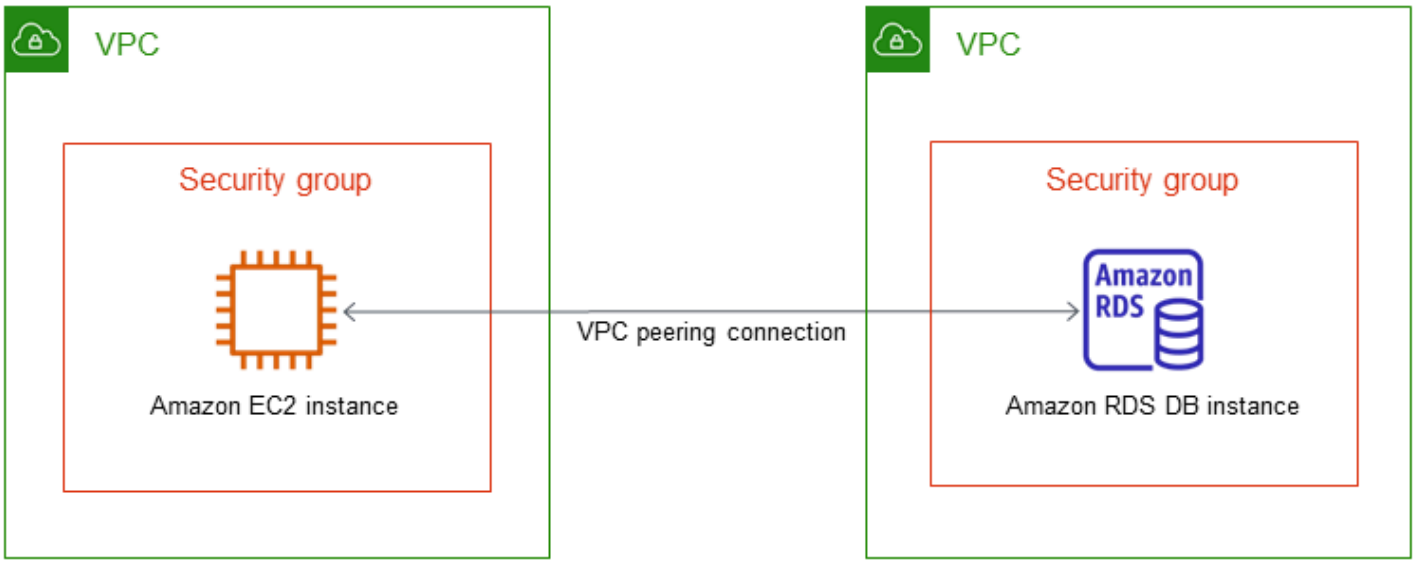
> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see Configure automatic network connectivity with an EC2 instance.

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB instances. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB instance, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

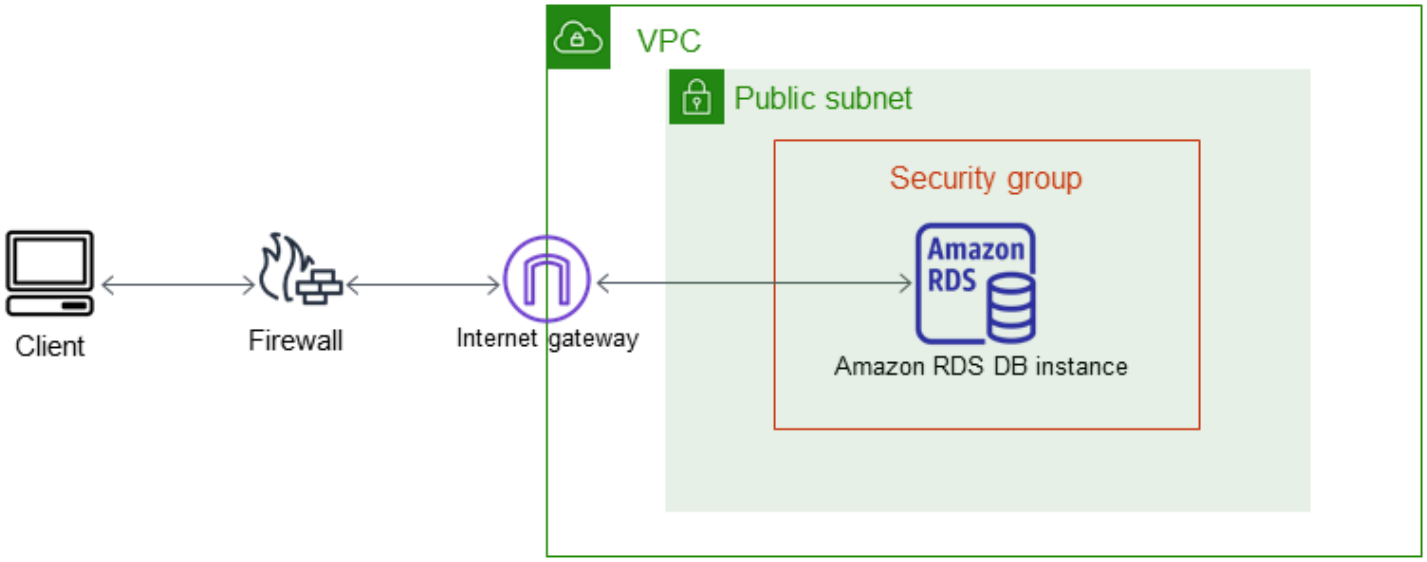


For more information about connecting to the DB instance from your EC2 instance, see Connecting to an Amazon RDS DB instance .

A DB instance in a VPC accessed by an EC2 instance in a different VPC

When your DB instances is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.



A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the *Amazon Virtual Private Cloud User Guide*.

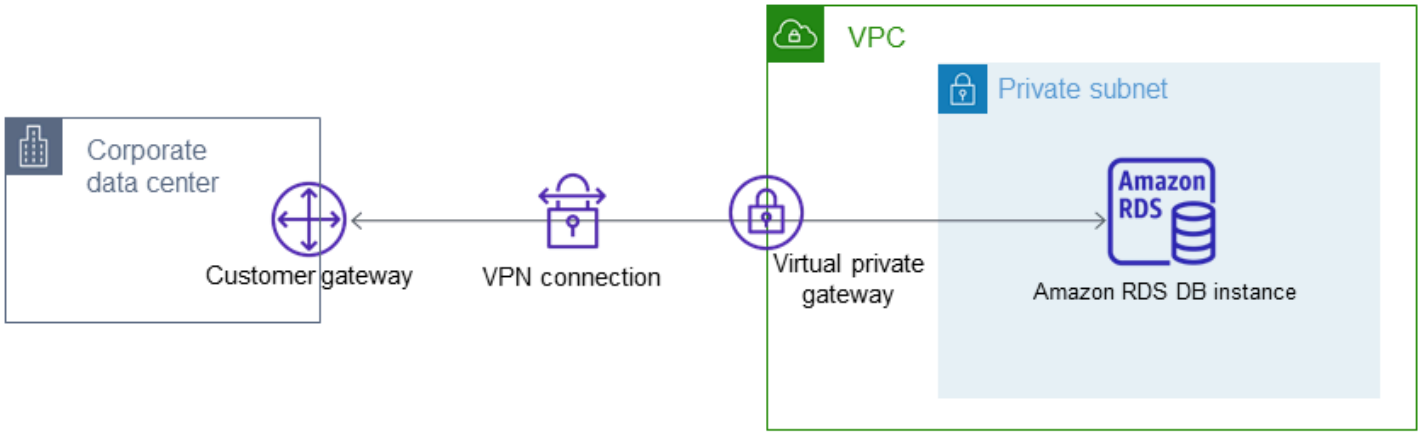
A DB instance in a VPC accessed by a client application through the internet

To access a DB instances in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
- A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.



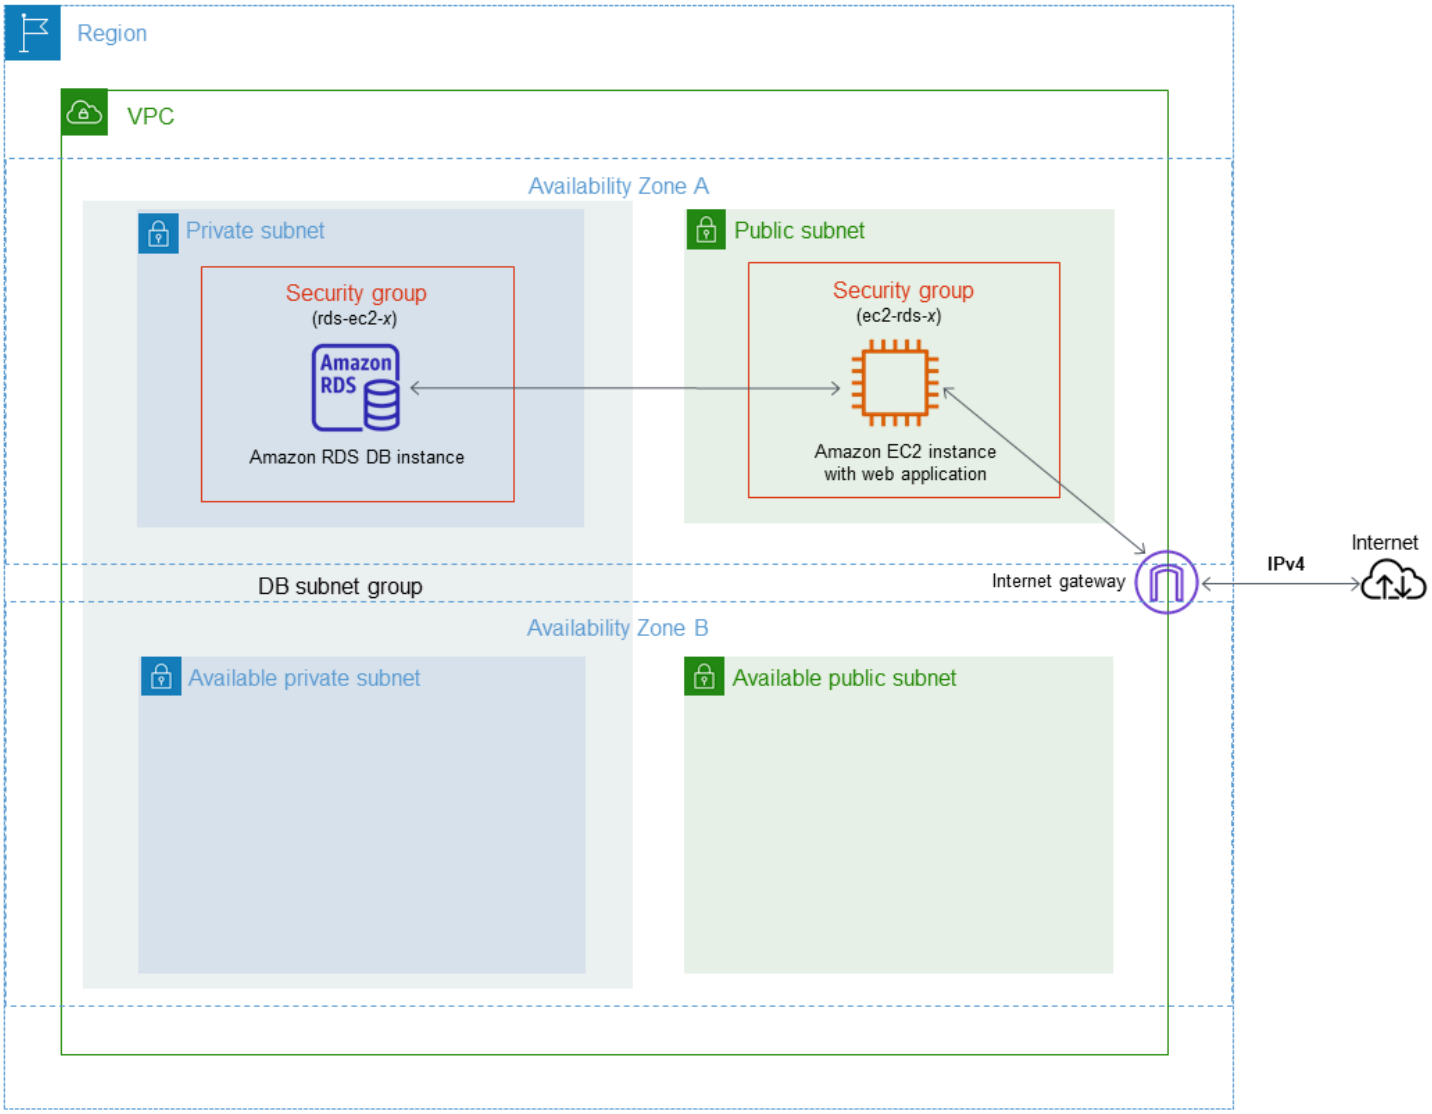
For information about creating a DB instances in a VPC, see Creating a DB instance in a VPC.

A DB instance in a VPC accessed by a private network

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An Direct Connect connection. For more information, see What is Direct Connect?
- An AWS Client VPN connection. For more information, see What is AWS Client VPN?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.



For more information, see Internetwork traffic privacy.

Tutorial: Create a VPC for use with a DB instance (IPv4 only)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC.

Your DB instance needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The web server can connect to the DB instance because it is hosted within the same VPC. But the DB instance isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to switch to a Multi-AZ DB instance deployment in the future.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon RDS DB instance. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:

   - **Name tag auto-generation** – `tutorial`
   - **IPv4 CIDR block** – `10.0.0.0/16`
   - **IPv6 CIDR block** – **No IPv6 CIDR block**
   - **Tenancy** – **Default**
   - **Number of Availability Zones (AZs)** – **2**
   - **Customize AZs** – Keep the default values.

- **Number of public subnet** – **2**
- **Number of private subnets** – **2**
- **Customize subnets CIDR blocks** – Keep the default values.
- **NAT gateways ($)** – **None**
- **VPC endpoints** – **None**
- **DNS options** – Keep the default values.

> **Note**
>
> Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easier to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-securitygroup`**
   - **Description: `Tutorial Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab,

you can use the service at https://checkip.amazonaws.com. An example of an IP address is `203.0.113.25/32`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

- **Type: SSH**
- **Source:** The IP address or range from Step a, for example: **`203.0.113.25/32`**.

d. Choose **Add rule**.

e. Set the following values for your new inbound rule to allow HTTP access to your web server:

- **Type: HTTP**
- **Source: `0.0.0.0/0`**

5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-db-securitygroup`**
   - **Description: `Tutorial DB Instance Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**
4. Add inbound rules to the security group.
   a. In the **Inbound rules** section, choose **Add rule**.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB instance. By doing so, you can store and retrieve data from your web application to your database.
      - **Type: `MySQL/Aurora`**
      - **Source:** The identifier of the **tutorial-securitygroup** security group that you created previously in this tutorial, for example: **sg-9edd5cfb**.
5. Choose **Create security group** to create the security group.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group makes it possible for you to specify a particular VPC when creating DB instances.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **Subnets**.

c. Note the subnet IDs of the subnets named **tutorial-subnet-private1-us-west-2a** and **tutorial-subnet-private2-us-west-2b**.

   You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:

   - **Name: `tutorial-db-subnet-group`**
   - **Description: `Tutorial DB Subnet Group`**
   - **VPC: tutorial-vpc (vpc-*`identifier`*)**

6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

   For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

> **Note**
>
> If you created this VPC to complete Tutorial: Create a web server and an Amazon RDS DB instance, create the DB instance by following the instructions in Create an Amazon RDS DB instance.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

> **Note**
>
> If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB instances. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC that you created, such as **tutorial-vpc**.
   d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.
3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **Security Groups**.
   c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.
   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.

f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the VPC.

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

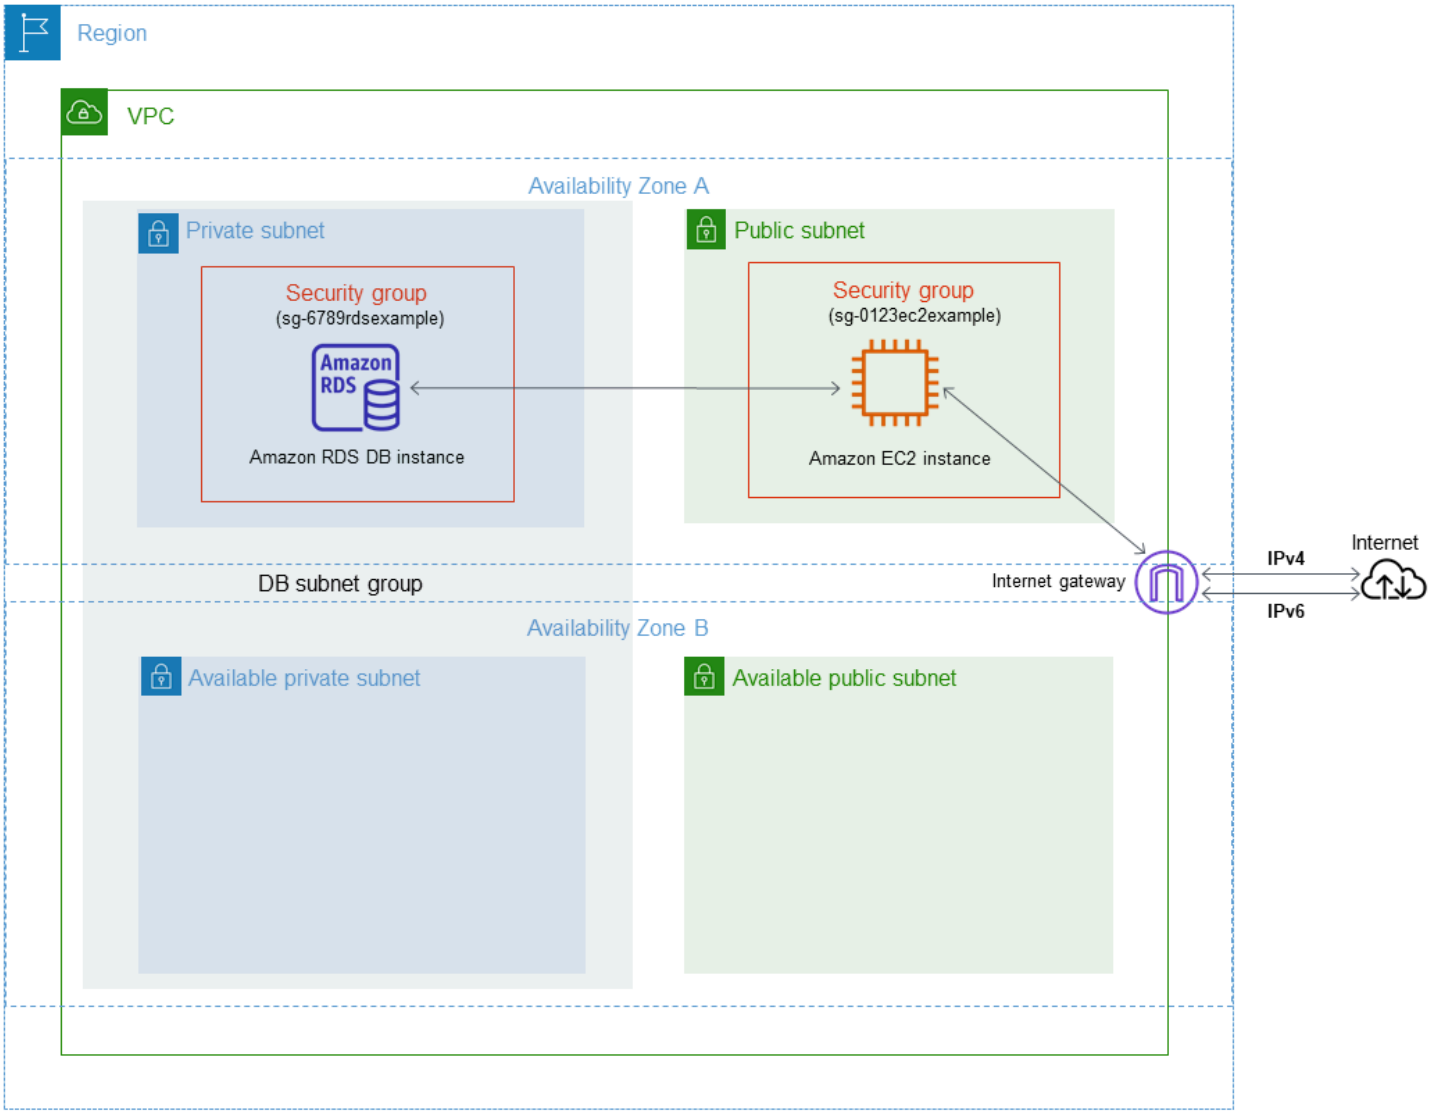
b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. Select the VPC you want to delete, such as **tutorial-vpc**.

d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.



Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see Amazon RDS IP addressing.

Dual-stack network instances are supported in most regions. For more information see Region and version availability. To see the limitations of dual-stack mode, see Limitations for dual-stack network DB instances.

The following diagram shows this scenario.

For information about other scenarios, see Scenarios for accessing a DB instance in a VPC.

Your DB instance needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The Amazon EC2 instance can connect to the DB instance because it's hosted within the same VPC. However, the DB instance is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

To create a DB instance that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB instance with the same setting. For more information, see Creating an Amazon RDS DB instance and Modifying an Amazon RDS DB instance.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC User Guide.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
   - **Name tag auto-generation** – **`tutorial-dual-stack`**
   - **IPv4 CIDR block** – **`10.0.0.0/16`**
   - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
   - **Tenancy** – **Default**
   - **Number of Availability Zones (AZs)** – **2**
   - **Customize AZs** – Keep the default values.
   - **Number of public subnet** – **2**
   - **Number of private subnets** – **2**
   - **Customize subnets CIDR blocks** – Keep the default values.
   - **NAT gateways ($)** – **None**
   - **Egress only internet gateway** – **No**
   - **VPC endpoints** – **None**
   - **DNS options** – Keep the default values.

> **Note**
>
> Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-dual-stack-securitygroup`**
   - **Description: `Tutorial Dual-Stack Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

      An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`.
      An example of an Internet Protocol version 6 (IPv6) address range is `2001:db8:1234:1a00::/64`.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:

- **Type: SSH**
- **Source:** The IP address or range from step a. An example of an IPv4 IP address is **`203.0.113.25/32`**. An example of an IPv6 IP address is **`2001:DB8::/32`**.

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

- **Security group name: `tutorial-dual-stack-db-securitygroup`**
- **Description: `Tutorial Dual-Stack DB Instance Security Group`**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**

4. Add inbound rules to the security group:

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB instance. Doing this means that you can send data from your EC2 instance to your database.

      - **Type: MySQL/Aurora**
      - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.

5. To create the security group, choose **Create security group**.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Subnets**.

   c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

      You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name: `tutorial-dual-stack-db-subnet-group`**
   - **Description: `Tutorial Dual-Stack DB Subnet Group`**
   - **VPC: tutorial-dual-stack-vpc (vpc-*`identifier`*)**
6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

   For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

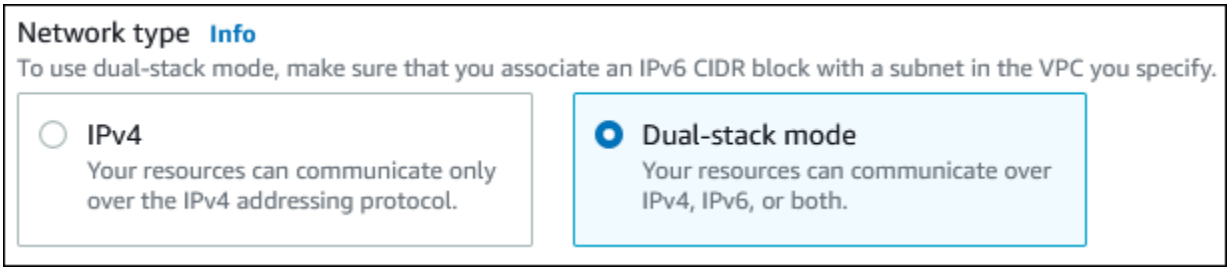
Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in Launch an instance using the new launch instance wizard in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*`identifier`*) created in Create a VPC with private and public subnets.
- **Subnet** – Choose an existing public subnet, such as **subnet-*`identifier`* | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a** created in Create a VPC security group for a public Amazon EC2 instance.
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in Create a VPC security group for a public Amazon EC2 instance. Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.



Create a DB instance in dual-stack mode

In this step, you create a DB instance that runs in dual-stack mode.

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB instance. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the MySQL DB engine type.
6. In the **Connectivity** section, set these values:

   - **Network type** – Choose **Dual-stack mode**.

   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in Create a VPC with private and public subnets.

     The VPC must have subnets in different Availability Zones.

   - **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in Create a DB subnet group.
   - **Public access** – Choose **No**.
   - **VPC security group (firewall)** – Select **Choose existing**.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in Create a VPC security group for a private DB instance.

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB instance settings. For information about each setting, see Settings for DB instances.

Connect to your Amazon EC2 instance and DB instance

After you create your Amazon EC2 instance and DB instance in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in Connect to your Linux instance in the *Amazon EC2 User Guide*.

To connect to your RDS for MySQL DB instance from the Amazon EC2 instance, follow the instructions in Connect to a MySQL DB instance.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB instances. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group:

   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.

d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **Security Groups**.

c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.

d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.

f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.

c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.

d. For **Actions**, choose **Delete NAT gateway**.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

5. Delete the VPC:

a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.

d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

6. Release the Elastic IP addresses:

    a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
    b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.
    c. Select the Elastic IP address that you want to release.
    d. For **Actions**, choose **Release Elastic IP addresses**.
    e. On the confirmation page, choose **Release**.

Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

EC2-Classic was retired on August 15, 2022. If you haven't migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see Migrate from EC2-Classic to a VPC in the *Amazon EC2 User Guide* and the blog EC2-Classic Networking is Retiring – Here's How to Prepare.

Important

If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the *EC2-VPC* platform and have a default VPC. For information about working with DB instances in a VPC, see Working with a DB instance in a VPC.

Follow these steps to create a VPC for your DB instance.

- Step 1: Create a VPC
- Step 2: Create a DB subnet group
- Step 3: Create a VPC security group

After you create the VPC, follow these steps to move your DB instance into the VPC.

- Updating the VPC for a DB instance

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see Backing up, restoring, and exporting data.

The following are some limitations to moving your DB instance into the VPC.

- **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see Amazon RDS instance types.
- **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the **Multi-AZ deployment** setting to **No**. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance.
- **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see Working with DB instance read replicas.
- **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see Working with option groups.

Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

- **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn't propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn't automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see AWS Database Migration Service.

- **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see Restoring to a DB instance and Restoring a DB instance to a specified time for Amazon RDS.

Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

Topics

- Quotas in Amazon RDS
- Naming constraints in Amazon RDS
- Maximum number of database connections
- File size limits in Amazon RDS

Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

Name	Default	Adjustable	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom endpoints per DB cluster	Each supported Region: 5	Yes	The maximum number of custom endpoints that you can create per Aurora DB cluster in this account in the current Region. This value reflects the highest number of custom endpoints in a DB cluster in the account. Other DB

Name	Default	Adjustable	Description
			clusters in the account might have a lower number of custom endpoints.
Custom engine versions	Each supported Region: 40	Yes	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	Yes	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	Yes	The maximum number of Aurora clusters allowed in this account in the current Region
DB instances	ap-south-1: 20 Each of the other supported Regions: 40	Yes	The maximum number of DB instances allowed in this account in the current Region
DB shard groups	Each supported Region: 5	Yes	The maximum number of DB shard groups for Aurora Limitless Database in this account in the current Region
DB subnet groups	ap-south-1: 20 Each of the other supported Regions: 50	Yes	The maximum number of DB subnet groups

Name	Default	Adjustable	Description
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current AWS Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.

Name	Default	Adjustable	Description
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed for this account in the current AWS Region. This quota only applies to Amazon Aurora Serverless v1 clusters.
Event subscriptions	Each supported Region: 20	Yes	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB instance
Integrations	Each supported Region: 100	No	The maximum number of integrations allowed in this account in the current AWS Region
Manual DB cluster snapshots	Each supported Region: 100	Yes	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	Yes	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	Yes	The maximum number of option groups

Name	Default	Adjustable	Description
Parameter groups	ap-south-1: 20 Each of the other supported Regions: 50	Yes	The maximum number of parameter groups
Proxies	Each supported Region: 20	Yes	The maximum number of proxies allowed in this account in the current AWS Region
Read replicas per primary	Each supported Region: 15	Yes	The maximum number of read replicas per primary DB instance. This quota cant be adjusted for Amazon Aurora.
Reserved DB instances	ap-south-1: 20 Each of the other supported Regions: 40	Yes	The maximum number of reserved DB instances allowed in this account in the current AWS Region
Security groups	ap-south-1: 20 Each of the other supported Regions: 25	Yes	The maximum number of DB security groups
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group

Name	Default	Adjustable	Description
Total storage for all DB instances	Each supported Region: 100,000	Yes	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.
The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for Db2 under the "bring-your-own-license" (BYOL) licensing model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose **AWS services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.
For RDS for Oracle, you can create up to 15 read replicas per source DB instance in each Region, but we recommend limiting replicas to 5 to minimize replication lag.

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the manual snapshot quota. For information about AWS Backup, see the *AWS Backup Developer Guide*.

Note that the default quota for cross-Region automated backups is 20 for an AWS account, and the default quota for the number of concurrent snapshot copy requests is 20 for each Region for an AWS account.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API_name* operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher quotas are needed, you can request a quota increase by using one of the following options:

- From the console, open the Service Quotas console.
- From the AWS CLI, use the request-service-quota-increase AWS CLI command.

For more information, see the *Service Quotas User Guide*.

Naming constraints in Amazon RDS

The naming constraints in Amazon RDS are as follows:

- DB instance identifier:
  - Must contain 1–63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Can't end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all DB instances per AWS account, per AWS Region.
- Initial database name:
  - Database name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.
  - SQL Server – Create your databases after creating your DB instance.

- Master username – Master username constraints differ for each database engine. For more information, see the available settings when creating the DB instance.
- Master password:
  - The password for the database master user can include any printable ASCII character except /, ', ", @, or a space.

    For Oracle, & is an additional character limitation.
  - The password can contain the following number of printable ASCII characters depending on the DB engine:
    - Db2: 8–255
    - MariaDB and MySQL: 8–41
    - Oracle: 8–30
    - SQL Server and PostgreSQL: 8–128
- DB parameter group:
  - Must contain 1–255 alphanumeric characters.
  - First character must be a letter.
  - Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
- DB subnet group:
  - Must contain 1–255 characters.
  - Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is generally set in the parameter group associated with the DB instance. The exception is Microsoft SQL Server, where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the **incompatible-parameters** status. For more information, see Diagnosing and resolving incompatible parameters status for a memory limit.

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Amazon RDS Proxy.

Note

For Oracle, you set the maximum number of user processes and user and system sessions. For Db2, you can't set maximum connections. The limit is 64000.

The following table shows information about the maximum database connections for different DB engines.

DB engine	Parameter	Allowed values	Default value	Description
MariaDB	`max_connections`	1–100000	• For MariaDB 10.5 and higher versions, the default is: LEAST({DBInstanceClassMemory/25165760},12000) The formula is effectively equivalent to MB/25. If the default value calculation results in a value greater than 12,000, Amazon RDS sets the limit to 12,000. • For MariaDB version 10.4:	Number of simultaneous client connections allowed

DB engine	Parameter	Allowed values	Default value	Description
			{DBInstanceClassMemory/12582880} The formula is effectively equivalent to MB/12.	
MySQL	`max_connections`	1–100000	{DBInstanceClassMemory/12582880} The formula is effectively equivalent to MB/12.	Number of simultaneous client connections allowed
Oracle	`processes`	80–20000	LEAST({DBInstanceClassMemory/9868951}, 20000)	User processes
Oracle	`sessions`	100–65535	Not applicable	User and system sessions
PostgreSQL	`max_connections`	6–262143	LEAST({DBInstanceClassMemory/9531392}, 5000)	Maximum number of concurrent connections
SQL Server	`user connections`	0–32767	0 (unlimited)	Maximum number of concurrent connections. For more information, see Configure the user connections (server configuration option).

`DBInstanceClassMemory` is in bytes. For details about how this value is calculated, see Specifying DB parameters. Because of memory reserved for the operating system and RDS

management processes, this memory size is smaller than the value in gibibytes (GiB) shown in Hardware specifications for DB instance classes.

For example, some DB instance classes have 8 GiB of memory, which is 8,589,934,592 bytes. For a MySQL DB instance running on a DB instance class with 8 GiB of memory, such as db.m7g.large, the equation that uses the total memory would be `8589934592/12582880=683`. However, the variable `DBInstanceClassMemory` automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the DB instance. The remainder of the subtraction is then divided by 12,582,880. This calculation results in approximately 630 for the value of `max_connections` instead of 683. This value depends on the DB instance class and DB engine.

When a MariaDB or MySQL DB instance is running on a small DB instance class, such as db.t3.micro or db.t3.small, the total memory available is low. For these DB instance classes, RDS reserves a significant portion of the available memory, which affects the value `max_connections`. For example, the default maximum number of connections for a MySQL DB instance running on a db.t3.micro DB instance class is approximately 60. You can determine the `max_connections` value for your DB MariaDB or MySQL DB instance by connecting to it and running the following SQL command:

```
SHOW GLOBAL VARIABLES LIKE 'max_connections';
```

File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- MariaDB file size limits in Amazon RDS
- MySQL file size limits in Amazon RDS
- Oracle file size limits in Amazon RDS

Troubleshooting for Amazon RDS

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics

- Can't connect to Amazon RDS DB instance
- Amazon RDS security issues
- Troubleshooting incompatible-network state
- Resetting the DB instance owner password
- Amazon RDS DB instance outage or reboot
- Amazon RDS DB parameter changes not taking effect
- Amazon RDS DB instance running out of storage
- Amazon RDS insufficient DB instances available
- Freeable memory issues in Amazon RDS
- MySQL and MariaDB issues
- Can't set backup retention period to 0

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Amazon RDS.

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

> **Note**
>
> When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group.

> **Note**
>
> Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see Hiding a DB instance in a VPC from the internet.

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications because of your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.

- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

  To configure an internet gateway for a subnet

  1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
  2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.

3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

   If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-*xxxxxxxx*) to navigate to the route table.

   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

      For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

   c. Choose **Save routes**.

   Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see Working with a DB instance in a VPC.

For engine-specific connection issues, see the following topics:

- Troubleshooting connections to your SQL Server DB instance
- Troubleshooting connections to your Oracle DB instance
- Troubleshooting connections to your RDS for PostgreSQL instance
- Maximum MySQL and MariaDB connections

Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299

  Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/
vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

  Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
 open
  connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

> **Note**
>
> Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Amazon RDS security issues

To avoid security issues, never use your AWS account root user email address and password for a user account. Best practice is to use your root user to create users and assign those to DB user accounts. You can also use your root user to create other user accounts, if necessary.

For information about creating users, see Creating an IAM user in your AWS account. For information about creating users in AWS IAM Identity Center, see Manage identities in IAM Identity Center.

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

Troubleshooting incompatible-network state

The incompatible-network state means that the database might still be accessible at the database level but you can't modify or reboot it.

Causes

The incompatible-network state of your DB instance could be a result of one of the following actions:

- Modifying the DB instance class.
- Modifying the DB instance to use Multi-AZ DB cluster deployment.
- Replacing a host because of a maintenance event.
- Launching a replacement DB instance.
- Restoring from a snapshot backup.

- Starting a DB instance that was stopped.

Resolution

Use start-db-instance command

To fix a database that is in an incompatible-network state, follow these instructions:

1. Open the https://console.aws.amazon.com/rds/ and choose **Databases** from the navigation pane.
2. Choose the DB instance that is in the incompatible-network state and note the DB instance identifier, VPC ID, and subnet IDs from the **Connectivity & Security** tab.
3. Use the AWS CLI to run the `start-db-instance` command. Specify the `--db-instance-identifier` value.

> **Note**
>
> Running this command when your database is in incompatible mode might cause some downtime.
> The `start-db-instance` command does not resolve this issue for RDS for SQL Server DB instances.

Your database status changes to **Available** if the command executes successfully.

If your database restarts, the DB instance might execute the last operation run on the instance before it was moved to incompatible-network state. This might move the instance back to the incompatible-network state.

If the `start-db-instance` command is unsuccessful or the instance moves back to incompatible-network state, open the **Databases** page in the RDS console and select the database. Navigate to the **Logs & events** section. The **Recent events** section displays further resolution steps to follow. The messages are classified as follows:

- **INTERNAL RESOURCE CHECK**: There might be issues with your internal resources.
- **DNS CHECK**: Check DNS resolution and hostnames for the VPC in the VPC console.
- **ENI CHECK**: The elastic network interface (ENI) for your database might not exist.

- **GATEWAY CHECK**: The internet gateway for your publicly available database is not attached to the VPC.
- **IP CHECK**: There are no free IP addresses in your subnets.
- **SECURITY GROUP CHECK**: There are no security groups associated with your database or the security groups are invalid.
- **SUBNET CHECK**: There are no valid subnets in your DB subnet group or there are issues with your subnet.
- **VPC CHECK**: The VPC associated with your database is invalid.

Perform point-in-time recovery

It is best practice to have a backup (snapshot or logical), in case your database enters incompatible-network state. See Introduction to backups. If you turned on automated backups, then temporarily stop any writes to the database and perform a point-in-time recovery.

> **Note**
>
> After an instance enters the incompatible-network state, the DB instance might not be accessible to perform a logical backup.

If you didn't turn on automated backups, create a new DB instance. Then migrate the data using AWS Database Migration Service (AWS DMS), or by using a backup and restore tool.

If this does not resolve the issue, contact Support for further assistance.

Resetting the DB instance owner password

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges.

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.
- You change the storage type from **Magnetic (Standard)** to **General Purpose (SSD**) or **Provisioned IOPS (SSD)**, or from **Provisioned IOPS (SSD)** or **General Purpose (SSD)** to **Magnetic (Standard)**.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.
- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the **Apply Immediately** value has, see Modifying an Amazon RDS DB instance.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter

group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see Modifying parameters in a DB parameter group in Amazon RDS.

Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to `storage-full`. For example, a call to the `DescribeDBInstances` API operation for a DB instance that has used up its storage outputs the following.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance

DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

To recover from this scenario, add more storage space to your instance using the `ModifyDBInstance` API operation or the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --allocated-storage 60 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --allocated-storage 60 ^
    --apply-immediately
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3  60
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

Now, when you describe your DB instance, you see that your DB instance has `modifying` status, which indicates the storage is being scaled.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa
modifying  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com
3306  us-east-1b  3  60
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

After storage scaling is complete, your DB instance status changes to `available`.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  60  sa
available  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306
us-east-1b  3
 SECGROUP  default  active
 PARAMGRP  default.mysql8.0  in-sync
```

You can receive notifications when your storage space is exhausted using the `DescribeEvents` operation. For example, in this scenario, if you make a `DescribeEvents` call after these operations you see the following output.

```
aws rds describe-events --source-type db-instance --source-identifier mydbinstance
```

```
2009-12-22T23:44:14.374Z  mydbinstance  Allocated storage has been exhausted db-
instance
2009-12-23T00:14:02.737Z  mydbinstance  Applying modification to allocated storage db-
instance
2009-12-23T00:31:54.764Z  mydbinstance  Finished applying modification to allocated
 storage
```

Amazon RDS insufficient DB instances available

The `InsufficientDBInstanceCapacity` error can be returned when you try to create, start, or modify a DB instance. It can also be returned when you try to restore a DB instance from a DB snapshot. When this error is returned, a common cause is that the specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:

- Retry the request with a different DB instance class.
- Retry the request with a different Availability Zone.
- Retry the request without specifying an explicit Availability Zone.

For information about troubleshooting instance capacity issues for Amazon EC2, see Insufficient instance capacity in the *Amazon EC2 User Guide*.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance.

Freeable memory issues in Amazon RDS

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Monitoring tools for Amazon RDS.

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see DB instance classes.

You can also change the memory settings. For example, on RDS for MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?

MySQL and MariaDB issues

You can diagnose and correct issues with MySQL and MariaDB DB instances.

Topics

- Maximum MySQL and MariaDB connections
- Diagnosing and resolving incompatible parameters status for a memory limit
- Diagnosing and resolving lag between read replicas
- Diagnosing and resolving a MySQLor MariaDB read replication failure
- Creating triggers with binary logging enabled requires SUPER privilege
- Diagnosing and resolving point-in-time restore failures
- Replication stopped error
- Read replica create fails or replication breaks with fatal error 1236
- Read replica replication fails to initialize metadata structure

Maximum MySQL and MariaDB connections

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see DB instance classes.

The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the `max_connections` parameter in the parameter group for the DB instance. For more information, see Maximum number of database connections and Parameter groups for Amazon RDS.

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```
SELECT @@max_connections;
```

You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.

```
SHOW STATUS WHERE `variable_name` = 'Threads_connected';
```

Diagnosing and resolving incompatible parameters status for a memory limit

A MariaDB or MySQL DB instance can be placed in **incompatible-parameters** status for a memory limit when the following conditions are met:

- The DB instance is restarted at least three times in one hour or at least five times in one day when the DB instance status is **Available**.
- An attempt to restart the DB instance fails because a maintenance action or monitoring process couldn't restart the DB instance.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, it performs a check for memory usage. The check makes a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
  - `innodb_additional_mem_pool_size`
  - `innodb_buffer_pool_size`

    You can modify the value for `innodb_buffer_pool_size`. However, the value won't always match what you input. This mismatch occurs for several reasons. First, if the DB instance is a micro DB instance, then we override the default value and set it to 256 MB. For more information, see Overriding innodb_buffer_pool_size.

    Second, we make sure that 500 MB of memory is reserved on the DB instance for the host manager, the engine, the operating system, and the kernel.

Last, we optimize innodb_buffer_pool_size by dividing it into units. The host manager rounds down to the closest multiple of those units. The units are calculated by multiplying innodb_buffer_pool_chunk_size by innodb_buffer_pool_instances. For more information, see Configuring InnoDB Buffer Pool Size in the MySQL documentation.

The default for innodb_buffer_pool_instances is 8, unless innodb_buffer_pool_size is less than 1 GB. If innodb_buffer_pool_size is less than 1 GB, then the default for innodb_buffer_pool_instances is 1. The default for innodb_buffer_pool_chunk_size is 128 MB.

  - innodb_log_buffer_size
  - key_buffer_size
  - query_cache_size (MySQL version 5.7 only)
  - tmp_table_size
- **Value 2** – The max_connections parameter multiplied by the sum of the following parameters:
  - binlog_cache_size
  - join_buffer_size
  - read_buffer_size
  - read_rnd_buffer_size
  - sort_buffer_size
  - thread_stack
- **Value 3** – If the performance_schema parameter is enabled, then multiply the max_connections parameter by 429498.

  If the performance_schema parameter is disabled, then this value is zero.

So, the value returned by the calculation is the following:

```
Value 1 + Value 2 + Value 3
```

When this value exceeds 1.2 times the memory allocated to the DB instance class used by the DB instance, the DB instance is placed in **incompatible-parameters** status. For information about the memory allocated to DB instance classes, see Hardware specifications for DB instance classes.

The calculation multiplies the value of the max_connections parameter by the sum of several parameters. If the max_connections parameter is set to a large value, it might cause the check to

return an inordinately high value for the potential memory usage of the DB instance. In this case, consider lowering the value of the `max_connections` parameter.

To resolve the problem, complete the following steps:

1. Adjust the memory parameters in the DB parameter group associated with the DB instance. Do so such that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

   For information about setting parameters, see Modifying parameters in a DB parameter group in Amazon RDS.
2. Restart the DB instance.

   For information about setting parameters, see Starting an Amazon RDS DB instance that was previously stopped.

Diagnosing and resolving lag between read replicas

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric.

The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MariaDB or MySQL `SHOW REPLICA STATUS` command. For more information, see SHOW REPLICA STATUS Statement in the MySQL documentation.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQLor MariaDB read replication failure. A `ReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is `NULL`.

> **Note**
>
> Previous versions of MariaDB used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version lower than 10.5, then use `SHOW SLAVE STATUS`.

The `ReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `ReplicaLag` metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `ReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation. For more information about read replicas and MariaDB, see Replication overview in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type parameter` to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
- Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

  For Linux, macOS, or Unix:

```
PROMPT> mysqldump \
```

```
    -h <endpoint> \
    --port=<port> \
    -u=<username> \
    -p <password> \
    database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^
    -h <endpoint> ^
    --port=<port> ^
    -u=<username> ^
    -p <password> ^
    database_name table1 table2 > /dev/null
```

Diagnosing and resolving a MySQLor MariaDB read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `Error` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0057. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, check the error in the MySQL error message documentation. If a MariaDB error message is returned, check the error in the MariaDB error message documentation.

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to *0* to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  ```
  alter table <schema>.<table_name> engine=innodb;
  ```
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error for RDS for MySQL. Your MySQL or MariaDB DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see mysql.rds_skip_repl_error.
- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the mysql.rds_next_source_log (RDS for MySQL major versions 8.4 and higher) or mysql.rds_next_master_log (RDS for MariaDB and RDS for MySQL major versions 8.0 and lower) command.
- You might encounter a temporary performance issue because of high DML load. If so, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. If you do this, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see Troubleshooting a MySQL read replica problem.

Creating triggers with binary logging enabled requires SUPER privilege

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

```
"You do not have the SUPER privilege and binary logging is enabled"
```

To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the `log_bin_trust_function_creators` parameter to true. To set the `log_bin_trust_function_creators` to true, create a new DB parameter group or modify an existing DB parameter group.

You can create a new DB parameter group so you can create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled. To do so, use the following CLI commands. To modify an existing parameter group, start with step 2.

To create a new parameter group to allow triggers with binary logging enabled using the CLI

1. Create a new parameter group.

   For Linux, macOS, or Unix:

   ```
   aws rds create-db-parameter-group \
       --db-parameter-group-name allow-triggers \
       --db-parameter-group-family mysql8.0 \
       --description "parameter group allowing triggers"
   ```

   For Windows:

   ```
   aws rds create-db-parameter-group ^
       --db-parameter-group-name allow-triggers ^
       --db-parameter-group-family mysql8.0 ^
       --description "parameter group allowing triggers"
   ```

2. Modify the DB parameter group to allow triggers.

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-parameter-group \
   ```

```
    --db-parameter-group-name allow-triggers \
    --parameters "ParameterName=log_bin_trust_function_creators,
 ParameterValue=true, ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name allow-triggers ^
    --parameters "ParameterName=log_bin_trust_function_creators,
 ParameterValue=true, ApplyMethod=pending-reboot"
```

3. Modify your DB instance to use the new DB parameter group.

   For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name allow-triggers \
    --apply-immediately
```

   For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name allow-triggers ^
    --apply-immediately
```

4. For the changes to take effect, manually reboot the DB instance.

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

Diagnosing and resolving point-in-time restore failures

Restoring a DB instance that includes temporary tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database
 activity for restore
```

```
functionality. Common examples of incompatible activity include using temporary tables,
 in-memory tables,
or using MyISAM tables. In this case, use of Temporary table was detected.
```

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can decrease the possibility of a PITR failure by performing more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

Restoring a DB instance that includes in-memory tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see Introduction to backups and Restoring a DB instance to a specified time for Amazon RDS.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error because of binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the mysql.rds_set_configuration procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain

binlog files on the DB cluster, up to 720 (30 days). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with `fatal error 1236`.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:

- `sync_binlog = 1`
- `innodb_support_xa = 1`
- `innodb_flush_log_at_trx_commit = 1`

Read replica replication fails to initialize metadata structure

When you attempted to start replication, you received the following error message:

```
Read Replica Replication Error - SQLError: 13124, reason: Replica failed to initialize
 applier metadata structure from the repository
```

This error occurs when there is a problem with the metadata structure of the replica. To fix the metadata structure, you must create a new replica.

To prevent this from happening in the future, perform one of the following actions:

- If possible, disable multi-threading on your replicas. Starting with MySQL 8.0.27, multi-threading is enabled by default.
- If you need to use multi-threading on your replicas, then we recommend that you use GTID-based replication. For more information, see Using GTID-based replication.

Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.

Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics

- Using the Query API
- Troubleshooting applications on Amazon RDS

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the *Amazon EC2 API Reference*.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.`*n* notation. Values of *n* are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

- Retrieving errors
- Troubleshooting tips

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon RDS.

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
    my $xp = XML::XPath->new(xml =>$response);
    if ( $xp->find("//Error") )
    {print "There was an error processing your request:\n", " Error code: ",
    $xp->findvalue("//Error[1]/Code"), "\n", " ",
    $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you're targeting by checking http://status.aws.amazon.com.
- Check the structure of your request.

  Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.
- Check AWS re:Post.

  Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to AWS re:Post.

Document history

Current API version: 2014-10-31

The following table describes important changes in each release of the *Amazon RDS User Guide* after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

> **Note**
>
> You can filter new Amazon RDS features on the What's New with Database? page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **`RDS Proxy`** or **`Oracle 2023`**.

Change	Description	Date
Amazon RDS Extended Support version 5.7.44-RDS.20260212 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20260212 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	February 26, 2026
Amazon RDS supports MariaDB versions 11.8.6, 11.4.10, 10.11.16, and 10.6.25	RDS for MariaDB now supports MariaDB versions 11.8.6, 11.4.10, 10.11.16, and 10.6.25. For more information, see MariaDB on Amazon RDS versions.	February 10, 2026
Amazon RDS supports MySQL 8.4.8 and 8.0.45	You can now create Amazon RDS DB instances running MySQL 8.4.8 and 8.0.45. For more information, see	February 3, 2026

	MySQL on Amazon RDS versions.	
Amazon RDS Extended Support version 5.7.44-RDS.20251212 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20251212 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	December 12, 2025
RDS for SQL Server Developer Edition.	RDS for SQL Server now supports SQL Server Developer Edition. For more information, see Working with SQL Server Developer Edition on RDS for SQL Server.	December 2, 2025
Amazon RDS supports MySQL 9.5 in the Database Preview environment	MySQL 9.5 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 9.5 in the Database Preview environment.	November 21, 2025
Amazon RDS supports MySQL 8.4.7 and 8.0.44	You can now create Amazon RDS DB instances running MySQL 8.4.7 and 8.0.44. For more information, see MySQL on Amazon RDS versions.	November 18, 2025

Amazon RDS supports MariaDB versions 11.4.9, 10.11.15, and 10.6.24	RDS for MariaDB now supports MariaDB versions 11.4.9, 10.11.15, and 10.6.24. For more information, see MariaDB on Amazon RDS versions.	November 18, 2025
Amazon RDS supports additional storage volumes for Oracle and SQL Server	You can add up to three additional storage volumes to an RDS for Oracle or RDS for SQL Server DB instance. Depending on your workload requirements, choose between gp3 or io2 storage for each volume. Scale your total storage up to 256 TiB per DB instance by combining primary and additional storage volumes. For more information, see Additional storage volumes.	November 14, 2025
RDS for Oracle supports db.r7i preconfigured instance classes	RDS for Oracle now supports db.r7i preconfigured instances for Enterprise Edition and Standard Edition 2 with BYOL. These instance classes provide additional memory for Oracle database workloads. For example, db.r7i.xlarge.tpc2.mem2x provides twice as much memory as a standard db.r7i.xlarge instance and enables multithreading. For more information, see DB instance class support.	October 2, 2025

Amazon RDS for Db2 supports backing up a single Db2 database	You can now use the `rdsadmin.backup_database` stored procedure to back up a single Db2 database on an RDS for Db2 DB instance to an Amazon S3 bucket. For more information, see rdsadmin.backup_database.	September 30, 2025
Amazon RDS supports reserved DB instances for Amazon RDS for Db2	You can now purchase reserved DB instances for RDS for Db2. For more information, see Reserved DB instances for Amazon RDS.	September 24, 2025
Amazon RDS for Db2 supports Amazon S3 streaming to restore databases	RDS for Db2 now supports restoring a database directly from multiple database backup files in an Amazon S3 bucket. For more information, see rdsadmin.restore_database.	September 22, 2025
Amazon RDS for Db2 supports Amazon S3 streaming to restore databases	RDS for Db2 now supports restoring a database directly from multiple database backup files in an Amazon S3 bucket. For more information, see rdsadmin.restore_database.	September 22, 2025

Amazon RDS supports MySQL 9.4 in the Database Preview environment	MySQL 9.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 9.4 in the Database Preview environment.	September 19, 2025
Amazon RDS Extended Support version 5.7.44-RDS.20250818 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20250818 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	September 15, 2025
RDS for Oracle supports db.m7i and db.r7i for SE2 LI	RDS for Oracle Standard Edition 2 (SE2) using the License Included (LI) model supports the db.m7i and db.r7i instance classes in the Asia Pacific (Thailand) and Mexico (Central) Region. For more information, see Oracle DB instance classes.	August 28, 2025
Amazon RDS is available in the Asia Pacific (New Zealand) Region	Amazon RDS is now available in the Asia Pacific (New Zealand) Region. For more information, see Regions and Availability Zones.	August 28, 2025

RDS for Oracle and RDS Custom for Oracle support bare metal instance classes	RDS for Oracle and RDS Custom for Oracle now support bare metal instance classes for Enterprise Edition with BYOL. Bare metal instances give your applications direct access to the processor and memory resources of the underlying server. For more information, see DB instance classes and DB instance class support for RDS Custom for Oracle.	August 27, 2025
Amazon RDS supports MariaDB 11.8	You can now create Amazon RDS DB instances running MariaDB version 11.8. For more information, see MariaDB on Amazon RDS versions.	August 25, 2025
Amazon RDS for Oracle supports ECDSA cipher suites and ECC certificates	Amazon RDS for Oracle now supports Elliptic Curve Digital Signature Algorithm (ECDSA) cipher suites for the SSL and OEM Agent options. These cipher suites are compatible with ECC certificates. For more information, see Certificate compatibility with cipher suites for the SSL option and Certificate compatibility with cipher suites for the OEM Agent option.	August 25, 2025

Amazon RDS for Db2 supports cross-Region read-only replicas	You can now create RDS for Db2 cross-Region read-only replicas. For more informati on, see Working with replicas for Amazon RDS for Db2.	August 22, 2025
Amazon RDS supports MariaDB 11.4.8, 10.11.14, and 10.6.23	You can now create Amazon RDS DB instances running MariaDB version 11.4.8, 10.11.14, and 10.6.2. For more information, see MariaDB on Amazon RDS versions.	August 14, 2025
Amazon RDS Custom service-l inked role policy updated	The AmazonRDSCustomSer viceRolePolicy managed policy has been updated to comply with EBS CopySnaps hot authorization behavior. The update removes `ec2:CopySnapshot` from one statement and adds two new statement s for source and destinati on snapshot permissions. For more information, see Updates to AWS managed policies for Amazon RDS.	August 7, 2025

Amazon RDS supports MySQL 8.4.6 and 8.0.43	You can now create Amazon RDS DB instances running MySQL 8.4.6 and 8.0.43. MySQL 8.4.6 includes the addition of the rds_security_audit database plugin, an internal RDS MySQL plugin that collects security-related metrics. For more information, see MySQL on Amazon RDS versions.	August 1, 2025
RDS for Oracle supports the db.m6in and db.r6in DB instance classes	You can use the db.m6in and db.r6in DB instance classes with RDS for Oracle with the Bring Your Own License (BYOL) model. For more information, see RDS for Oracle DB instance classes.	July 29, 2025
Zero-ETL integrations from RDS for PostgreSQL and RDS for Oracle are now available	You can now create Zero-ETL integrations with RDS for PostgreSQL and RDS for Oracle as the source. For more information, see Amazon RDS zero-ETL integrations.	July 23, 2025
Amazon RDS for Db2 supports group authorization using Kerberos	You can now perform group authorization using Kerberos with your self-managed Active Directory. For more information, see Setting up Kerberos authentication for RDS for Db2 DB instances.	July 21, 2025

Zero-ETL integrations with Amazon SageMaker AI is generally available	Zero-ETL integrations make transactional data availabl e in an Amazon SageMaker lakehouse within seconds of it being written to an RDS for MySQL DB instance. For more information, see Working with Amazon RDS zero-ETL integrations.	June 30, 2025
Amazon RDS supports MySQL 9.3 in the Database Preview environment	MySQL 9.3 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 9.3 in the Database Preview environment.	June 16, 2025
Amazon RDS for Db2 supports cross-Region replicas in standby mode	You can now create RDS for Db2 cross-Region replicas in standby mode for disaster recovery. For more informati on, see Working with replicas for RDS for Db2.	June 11, 2025
Amazon RDS is available in the Asia Pacific (Taipei) Region	Amazon RDS is now available in the Asia Pacific (Taipei) Region. For more information, see Regions and Availability Zones.	June 5, 2025
Amazon RDS supports MariaDB 10.11.13 and 11.4.7	You can now create Amazon RDS DB instances running MariaDB version 10.11.13 and 11.4.7. For more information, see MariaDB on Amazon RDS versions.	June 4, 2025

End-of-life information for Performance Insights	AWS has announced the end-of-life date for Performance Insights: November 30, 2025. After this date, Amazon RDS will no longer support the Performance Insights console experience, flexible retention periods (1-24 months), and their associated pricing. We recommend upgrading your DB instances to Database Insights before this date. For more information, see Monitoring DB load with Performance Insights on Amazon RDS.	May 30, 2025
Amazon RDS Extended Support version 5.7.44-RDS.20250508 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20250508 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	May 27, 2025
RDS Custom for Oracle supports the db.m7i and db.r7i instance classes	You can now use the db.m7i and db.r7i instance classes for RDS Custom for Oracle. For more information, see DB instance class support for RDS Custom for Oracle.	May 22, 2025

Viewing support dates for open source engine major versions	You can now view information about the start and end dates for open source engine major versions in RDS standard support and RDS Extended Support by using the AWS CLI and the RDS API. For more information, see Viewing support dates for engine versions in Amazon RDS Extended Support.	May 20, 2025
Amazon RDS supports MariaDB 10.5.29 and 10.6.22	You can now create Amazon RDS DB instances running MariaDB version 10.5.29 and 10.6.22. For more informati on, see MariaDB on Amazon RDS versions.	May 20, 2025
Amazon RDS supports MySQL 8.0.42	You can now create Amazon RDS DB instances running MySQL 8.0.42. For more information, see MySQL on Amazon RDS versions.	May 12, 2025
Amazon RDS supports MySQL 8.4.5	You can now create Amazon RDS DB instances running MySQL 8.4.5. For more information, see MySQL on Amazon RDS versions.	May 1, 2025

Amazon RDS supports backup replication for Asia Pacific (Hong Kong), Asia Pacific (Melbourne), Asia Pacific (Malaysia), Canada West (Calgary), and Europe (Zurich)	Backup replication is now available for databases in the Asia Pacific (Hong Kong), Asia Pacific (Melbourne), Asia Pacific (Malaysia), Canada West (Calgary), and Europe (Zurich) Regions. For more information about available Regions, see Replicating automated backups to another AWS Region.	April 30, 2025
Amazon RDS supports managed master user passwords in the Oracle multitenant architecture	You can use AWS Secrets Manager to manage master user passwords for RDS for Oracle container databases (CDBs) and pluggable databases (PDBs). The single-tenant and multi-tenant configurations of the CDB architecture both support managed passwords. For more information, see User accounts and privileges in a CDB.	April 24, 2025
Amazon RDS for Oracle supports m6id and r6id instance classes for BYOL	You can now create RDS for Oracle DB instances using the m6id and r6id instance classes on the BYOL model. Enterprise and Standard Edition 2 are both supported. For more information, see Supported edition, instance class, and licensing combinations in RDS for Oracle.	April 9, 2025

Amazon RDS supports MariaDB 11.8 in the Database Preview environment	MariaDB 11.8 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MariaDB version 11.8 in the Database Preview environment.	April 2, 2025
Update to IAM service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` policy now grants additional permissions to manage EC2 key-pair and integrate with Amazon SQS. For more information, see Amazon RDS updates to AWS managed policies.	March 25, 2025
Amazon RDS supports MySQL 9.2 in the Database Preview environment	MySQL 9.2 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 9.2 in the Database Preview environment.	March 24, 2025

Update to existing policy	Amazon RDS added new permissions to the managed policy `AmazonRDSCustomInstanceProfileRolePolicy` to allow the usage of RDS Custom managed secrets on an RDS Custom instance. For more information, see AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy.	March 20, 2025
Amazon RDS Extended Support version 5.7.44-RDS.20250213 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20250213 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	March 12, 2025
Update to IAM service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` policy now grants additional permissions to list and restore Secrets Manager secrets. For more information, see Amazon RDS updates to AWS managed policies.	March 6, 2025
Amazon RDS for Db2 supports the db.m7i and db.r7i instance classes	You can now use the db.m7i and db.r7i instance classes for RDS for Db2. For more information, see DB instance class types.	February 27, 2025

Amazon RDS for Oracle supports Spatial Patch Bundles (SPBs)	RDS for Oracle now publishes Spatial Patch Bundles (SPB) engine versions for Oracle Database 19c. An SPB engine version contains Release Update (RU) patches plus patches specific to Oracle Spatial. Typically, an SPB is released 2-3 weeks after its corresponding RU. You can upgrade your DB instance from a standard RU to an SPB on the same DB engine version or higher. For more information, see Oracle minor version upgrades.	February 25, 2025
Amazon RDS supports MariaDB 11.4.5, 10.11.11, 10.6.21, and 10.5.28	You can now create Amazon RDS DB instances running MariaDB version 11.4.5, 10.11.11, 10.6.21, and 10.5.28. For more informati on, see MariaDB on Amazon RDS versions.	February 24, 2025
Amazon RDS supports CloudWatch Database Insights	You can now use Database Insights to monitor Amazon RDS databases. For more information, see Monitorin g Amazon RDS databases with CloudWatch Database Insights.	February 20, 2025

Amazon RDS supports MySQL 8.4.4 and MySQL 8.0.41	You can now create Amazon RDS DB instances running MySQL 8.4.4 and 8.0.41. For more information, see MySQL on Amazon RDS versions.	February 19, 2025
Amazon RDS Extended Support version 5.7.44-RDS.20250103 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20250103 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	February 13, 2025
Amazon RDS is available in the Mexico (Central) Region	Amazon RDS is now available in the Mexico (Central) Region. For more information, see Regions and Availability Zones.	January 14, 2025
Amazon RDS supports MariaDB 11.7 in the Database Preview environment	MariaDB 11.7 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MariaDB version 11.7 in the Database Preview environment.	January 9, 2025
Amazon RDS is available in the Asia Pacific (Thailand) Region	Amazon RDS is now available in the Asia Pacific (Thailand) Region. For more information, see Regions and Availability Zones.	January 7, 2025

Amazon RDS supports MariaDB 11.4.4, 10.11.10, 10.6.20, and 10.5.27	You can now create Amazon RDS DB instances running MariaDB version 11.4.4, 10.11.10, 10.6.20, and 10.5.27. For more informati on, see MariaDB on Amazon RDS versions.	December 20, 2024
Amazon RDS for Db2 supports multiple databases	You can add up to 50 Db2 databases to an RDS for Db2 DB instance. For more information, see Multiple databases on an Amazon RDS for Db2 DB instance.	December 20, 2024
Amazon RDS supports MySQL 9.1 in the Database Preview environment	MySQL 9.1 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 9.1 in the Database Preview environment.	December 19, 2024
Amazon RDS supports the db.m8g and db.r8g instance classes	You can now use the db.m8g and db.r8g instance classes for RDS for MySQL, RDS for PostgreSQL, and RDS for MariaDB. For more informati on, see DB instance class types.	November 21, 2024
Amazon RDS supports MySQL 8.4	You can now create Amazon RDS DB instances running MySQL version 8.4. For more information, see MySQL on Amazon RDS versions.	November 21, 2024

Amazon Relational Database Service supports auto-migrating EC2 databases	You can use the RDS console to migrate an EC2 database to Amazon RDS. Amazon RDS uses AWS Database Migration Service (AWS DMS) to migrate your source EC2 database. AWS DMS allows you to migrate relational databases into your AWS Cloud. For more information, see Auto migrating EC2 databases to Amazon Relational Database Service using AWS Database Migration Service.	November 20, 2024
Amazon RDS supports MariaDB version 11.8.5	RDS for MariaDB now supports MariaDB version 11.8.5. For more information, see MariaDB on Amazon RDS versions.	November 20, 2024
Amazon RDS blue/green deployments support scaling storage	You can now use Amazon RDS blue/green deployments to adjust storage settings in the green environment in order to optimize resource allocation. For more information, see Specifying changes when creating a blue/green deployment.	November 20, 2024

Amazon RDS blue/green deployments add storage initialization	Amazon RDS now supports storage initialization in green environments for blue/green deployments, improving volume performance from first use without affecting availability. For more information, see Lazy loading and storage initialization for blue/green deployments.	November 20, 2024
Amazon RDS for Oracle supports the db.m7i and db.r7i instance classes for BYOL	You can use the db.m7i and db.r7i instance classes for RDS for Oracle on the BYOL licensing model. All editions of Oracle Database are supported. For more information, see DB instance class types and Supported RDS for Oracle DB instance classes.	November 18, 2024
Amazon RDS Proxy supports RDS for PostgreSQL 17	You can now create proxies using RDS Proxy for RDS for PostgreSQL 17 DB instances. For more information, see Using Amazon RDS Proxy.	November 15, 2024
Amazon RDS supports MySQL 8.0.40	You can now create Amazon RDS DB instances running MySQL version 8.0.40. For more information, see MySQL on Amazon RDS versions.	November 13, 2024

Amazon RDS supports backup replication for Africa (Cape Town) and Asia Pacific (Hyderabad)	Backup replication is now available for databases in the Africa (Cape Town) and Asia Pacific (Hyderabad) Regions. For more information about available Regions, see Replicating automated backups to another AWS Region.	November 1, 2024
Amazon RDS supports the db.m7i and db.r7i instance classes	You can now use the db.m7i and db.r7i instance classes for RDS for MySQL, RDS for PostgreSQL, and RDS for MariaDB. For more information, see DB instance class types.	October 29, 2024
Amazon RDS for Oracle supports Oracle APEX version 24.1.v1	You can use Oracle APEX 24.1.v1 with Oracle Database 19c and higher. For more information, see Oracle Application Express.	October 22, 2024
Multi-AZ DB clusters support IAM database authentication	You can now authenticate to your Multi-AZ DB cluster using AWS Identity and Access Management (IAM) database authentication. For more information, see Settings for creating Multi-AZ DB clusters.	October 17, 2024
Amazon RDS supports MariaDB 11.4	You can now create Amazon RDS DB instances running MariaDB version 11.4. For more information, see MariaDB on Amazon RDS versions.	October 15, 2024

Amazon RDS supports Console-to-Code	You can now use Console-to-Code to generate code from actions that you perform in the RDS console. The generated code can help you write code to automate your use of other AWS services. For more information, see Use Console-to-Code to generate code for your Amazon RDS console actions.	October 3, 2024
Amazon RDS for Oracle supports Oracle Management Agent 13.5.0.0.v2	RDS supports Oracle Management Agent 13.5.0.0.v2, which requires Oracle Management Service (OMS) 13.5.0.23. For more information, see Requirements for Management Agent.	September 25, 2024
Zero-ETL integrations with Amazon Redshift generally available	Zero-ETL integrations make transactional data availabl e in Amazon Redshift within seconds of it being written to an RDS for MySQL DB instance. The feature is now generally available. For more information, see Working with Amazon RDS zero-ETL integrations with Amazon Redshift.	September 12, 2024

Amazon RDS supports MariaDB 10.11.9, 10.6.19, and 10.5.26	You can now create Amazon RDS DB instances running MariaDB version 10.11.9, 10.6.19, and 10.5.26. For more information, see Requirements for Management Agent.	September 4, 2024
Amazon RDS for Oracle supports the OEM, OEMAGENT, and OLS options for the CDB architecture	You can now use Oracle Enterprise Manager and Oracle Label Security with RDS for Oracle CDB instances . For more information, see Oracle Enterprise Manager and Oracle Label Security.	September 4, 2024
RDS Custom for SQL Server is available in additional Regions	RDS Custom for SQL Server is now available in the US West (N. California) Region, Asia Pacific (Osaka) Region, and Europe (Paris) Region. For more information, see Supported Regions and DB engines for RDS Custom .	August 29, 2024
Amazon RDS Extended Support version 5.7.44-RDS.20240808 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20240808 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	August 29, 2024

Amazon RDS is available in the Asia Pacific (Malaysia) Region	Amazon RDS is now available in the Asia Pacific (Malaysia) Region. For more information, see Regions and Availability Zones.	August 22, 2024
Amazon RDS supports MySQL 8.0.39	You can now create Amazon RDS DB instances running MySQL version 8.0.39. For more information, see MySQL on Amazon RDS versions.	August 12, 2024
Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see Amazon RDS updates to AWS managed policies.	August 7, 2024
Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSBetaServiceRolePolicy` of the `AWSServiceRoleForRDSBeta` service-linked role. For more information, see Amazon RDS updates to AWS managed policies.	August 7, 2024

Amazon RDS supports MySQL 8.4 in the Database Preview environment	MySQL 8.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.4 in the Database Preview environment.	August 1, 2024
Update to IAM service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` policy now grants additional permissions to communicate with Amazon RDS services in another AWS Region and copy EC2 images. For more information, see Amazon RDS updates to AWS managed policies.	July 18, 2024
Amazon RDS supports MariaDB 11.4 in the Database Preview environment	MariaDB 11.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MariaDB version 11.4 in the Database Preview environment.	July 18, 2024
AWS ODBC Driver for MySQL generally available	The Amazon Web Services (AWS) ODBC Driver for MySQL is a client driver designed for the high availability of RDS for MySQL. For more information, see Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL.	July 18, 2024

Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see AWS managed policy: Amazon RDSServiceRolePolicy.	July 2, 2024
AWS Marketplace private offer for Db2	AWS Marketplace now supports private offers for a Db2 license through AWS Marketplace for Amazon RDS for Db2. For more information, see Obtaining a private offer.	July 1, 2024
Export Multi-AZ DB cluster snapshot data to Amazon S3	You can now export Multi-AZ DB cluster snapshot data to Amazon S3. For more information, see Exporting DB snapshot data to Amazon S3.	June 27, 2024
Amazon RDS for Oracle supports preconfigured r6i memory optimized instance classes	The db.r6i Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For example, db.r6i.8xlarge.tpc2.mem4x has multithreading turned on and provides 4 times as much memory as db.r6i.8xlarge. For more information, see RDS for Oracle instance classes.	June 21, 2024

Amazon RDS Extended Support version 5.7.44-RDS.20240529 for RDS for MySQL	The RDS Extended Support version 5.7.44-RDS.20240529 is now available for RDS for MySQL. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	June 20, 2024
Amazon RDS supports MySQL 8.0.37	You can now create Amazon RDS DB instances running MySQL version 8.0.37. For more information, see MySQL on Amazon RDS versions.	June 18, 2024
Amazon RDS supports MariaDB 10.11.8, 10.6.18, 10.5.25, and 10.4.34	You can now create Amazon RDS DB instances running MariaDB version 10.11.8, 10.6.18, 10.5.25, and 10.4.34. For more information, see MariaDB on Amazon RDS versions.	June 14, 2024
Amazon RDS is ending support for the db.m4, db.r4, and db.t2 DB instance classes	For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, you can no longer create DB instances that use the db.m4, db.r4, and db.t2 instance classes. RDS is automatically upgrading existing DB instances that use these classes to a newer generation. For more information, see DB instance class types.	June 4, 2024

Multi-AZ DB clusters are available in additional AWS Regions	You can create Multi-AZ DB clusters in more AWS Regions. For a table that shows all supported Regions, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.	May 29, 2024
AWS Python Driver generally available	The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more informati on, see Connecting to DB instances with the AWS drivers.	May 23, 2024
RDS Proxy is available in more Regions	RDS Proxy is now available in the Asia Pacific (Hyderaba d), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary) , and Europe (Zurich) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	May 21, 2024
Db2 license through AWS Marketplace	With Db2 license through AWS Marketplace, you can now pay an hourly rate to subscribe to Db2 licenses for Amazon RDS for Db2. For more information, Amazon RDS for Db2 licensing options.	May 21, 2024

Amazon RDS supports fine-grained access for Performance Insights	You can now allow or deny access to individual dimensions in Performance Insights. This fine-grained access can be used for `GetResourceMetrics`, `DescribeDimensionKeys`, and `GetDimensionKeyDetails` actions. For more information, see Granting fine-grained access for Performance Insights.	May 21, 2024
Amazon RDS Extended Support versions for RDS for MySQL	You can view all releases of RDS Extended Support for RDS for MySQL versions. For more information, see Amazon RDS Extended Support versions for RDS for MySQL.	May 16, 2024
Amazon RDS supports MySQL 8.3 in the Database Preview environment	MySQL 8.3 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.3 in the Database Preview environment.	April 30, 2024
Amazon RDS for Db2 supports time zones	RDS for Db2 now supports setting local time zones for new RDS for Db2 DB instances. For more information, see Local time zones for Amazon RDS for Db2 DB instances.	April 25, 2024

Update to IAM service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` policy now grants additional permissions to associate a service role as an instance profile to a RDS Custom instance. For more information, see Amazon RDS updates to AWS managed policies.	April 19, 2024
Amazon RDS for Oracle supports Oracle Data Guard switchover in all AWS Regions	You can now use Oracle Data Guard switchover in all supported Regions. For more information, see Overview of Oracle Data Guard switchover.	April 16, 2024
RDS Custom for Oracle supports Oracle Standard Edition 2	You can now create DB instances using Standard Edition 2 on Oracle Database 12c Release 1 (12.1), 12c Release 2 (12.2), 18c, and 19c. You can create both CDBs and non-CDBs. For more information, see Edition and licensing support for RDS Custom for Oracle.	April 11, 2024
Amazon RDS for Oracle supports Oracle APEX version 23.2.v1	You can use Oracle APEX 23.2.v1 with Oracle Database 19c and higher. For more information, see Oracle Application Express.	April 11, 2024

Update to RDS Custom service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` now grants additional permissions to allow RDS Custom for SQL Server to get EC2 instance type information and modify DB host instance type. For more information, Updates to AWS managed policies.	April 8, 2024
Amazon RDS Custom for Oracle supports the db.x2iezn DB instance class	You can now use the db.x2iezn instance class for RDS Custom for Oracle DB instances. For more information, see DB instance class support for RDS Custom for Oracle.	March 26, 2024
Amazon RDS supports the db.c6gd instance classes for Multi-AZ DB clusters	You can now use the db.c6gd instance classes for Multi-AZ DB cluster deployments. For more information, see Instance class availability for Multi-AZ DB clusters.	March 21, 2024

Amazon RDS Extended Support	Creating or restoring an RDS for MySQL 5.7 or RDS for PostgreSQL 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the RDS end of standard support date for your database engine. For more information, see Using Amazon RDS Extended Support.	March 21, 2024
RDS for Db2 integration with AWS License Manager	RDS for Db2 is now integrated with AWS License Manager. If you use the bring your own license (BYOL) model, the AWS License Manager integration aids in monitoring your Db2 license usage within your organization. For more information, see Integrating with AWS License Manager.	March 20, 2024

CA certificate rotation for Multi-AZ DB clusters	You can now rotate the CA certificates for your Multi-AZ DB clusters. Consider using one of the new CA certificates rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1. For more information, see Rotating your SSL/TLS certificate.	March 6, 2024
Amazon RDS supports io2 Block Express storage	You can now create RDS DB instances that use the io2 Block Express storage type. For more information, see io2 Block Express storage.	March 6, 2024
RDS Custom for SQL Server supports the db.r5b and db.x2iedn DB instance classes	You can now use the db.r5b and db.x2iedn instance classes for RDS Custom for SQL Server DB instances. For more information, see DB instance class support for RDS Custom for SQL Server.	March 4, 2024
RDS Custom for Oracle is available in the Middle East (UAE) Region	You can create RDS Custom for Oracle DB instances in the Middle East (UAE) Region. For a table that shows all supported AWS Regions, see Supported Regions and DB engines for RDS Custom for Oracle.	March 4, 2024

New AWS managed policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see Amazon RDS updates to AWS managed policies.	February 27, 2024
Amazon RDS supports MariaDB 10.11.7, 10.6.17, 10.5.24, and 10.4.33	You can now create Amazon RDS DB instances running MariaDB version 10.11.7, 10.6.17, 10.5.24, and 10.4.33. For more information, see MariaDB on Amazon RDS versions.	February 26, 2024
Amazon RDS Multi-AZ DB clusters support the Amazon EBS gp3 storage volume	Multi-AZ DB clusters now support gp3 SSD-based EBS volumes. For more information, see gp3 storage.	February 26, 2024
Amazon RDS support for AWS Secrets Manager in the Israel (Tel Aviv) Region	Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	February 21, 2024

Amazon RDS for Db2 supports audit logging	RDS for Db2 now supports database-level audit logging. When you enable audit logging for an RDS for Db2 database, Amazon RDS records the database activity and stores the audit logs in Amazon S3. For more information, see Db2 audit logging.	February 15, 2024
Amazon RDS Extended Support	Amazon RDS now automatically enables Amazon RDS Extended Support when RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances and Multi-AZ DB clusters reach the RDS end of standard support date. For more information, see Using Amazon RDS Extended Support.	February 15, 2024
Amazon RDS supports MySQL 8.0.36	You can now create Amazon RDS DB instances running MySQL version 8.0.36. For more information, see MySQL on Amazon RDS versions.	February 12, 2024

Amazon RDS supports EBCDIC collation for RDS for Db2	You can now create Db2 databases that use EBCDIC collation sequences to sort content in the databases. For more information, see EBCDIC collation for Db2 databases on Amazon RDS.	January 29, 2024
Update to default CA Certificate	The default CA certificate is set to `rds-ca-rsa2048-g1`. For more information, see Using SSL/TLS to encrypt a connection to a DB instance.	January 26, 2024
Amazon RDS for PostgreSQL supports two new crates for PL/Rust, croaring-rs and num-bigint	You can use two new crates in Amazon RDS for PostgreSQL. For more information, see Using crates with PL/Rust.	January 24, 2024
Amazon RDS for PostgreSQL supports TLS version 1.3	You can use Transport Layer Security (TLS) version 1.3 in RDS for PostgreSQL. For more information, see Using SSL with a PostgreSQL DB instance.	January 24, 2024
RDS Custom for SQL Server supports Microsoft SQL Server 2022	You can now create RDS Custom for SQL Server DB instances that use SQL Server 2022. For more information, see Working with RDS Custom for SQL Server.	January 22, 2024

Update to AWS managed policy permissions	The `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role has new statement IDs. For more information, see Amazon RDS updates to AWS managed policies.	January 19, 2024
RDS Custom for Oracle supports the Europe (Paris) Region	You can create RDS Custom for Oracle DB instances in the Europe (Paris) Region. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	January 18, 2024
Amazon RDS for MySQL supports multi-source replication	You can now use multi-source replication on RDS for MySQL DB instances. For more information, see Configuring multi-source replication on RDS for MySQL.	January 16, 2024
Amazon RDS supports MySQL 8.2 in the Database Preview environment	MySQL 8.2 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.2 in the Database Preview environment.	January 11, 2024
RDS Proxy is available in the Europe (Spain) Region	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 8, 2024

Amazon RDS is available in the Canada West (Calgary) Region	Amazon RDS is now available in the Canada West (Calgary) Region. For more information, see Regions and Availability Zones.	December 20, 2023
Amazon RDS for Db2 supports 5,000 local users	You can now add up to 5,000 local users to an authorization list. For more information, see rdsadmin.add_user.	December 20, 2023
Amazon RDS supports viewing and responding to recommendations	Amazon RDS recommend ations now includes threshold based proactive and machine learning based reactive recommendations for RDS for PostgreSQL. For more information, see Recommend ations from Amazon RDS.	December 19, 2023
Amazon RDS supports MariaDB 10.11.6, 10.6.16, 10.5.23, and 10.4.32	You can now create Amazon RDS DB instances running MariaDB version 10.11.6, 10.6.16, 10.5.23, and 10.4.32. For more information, see MariaDB on Amazon RDS versions.	December 12, 2023

Amazon RDS introduces zero-ETL integrations with Amazon Redshift (preview)	Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an RDS for MySQL DB instance. For more information, see Working with Amazon RDS zero-ETL integrations with Amazon Redshift (preview).	November 28, 2023
Amazon RDS supports IBM Db2 database engines	You can now run IBM Db2 database engines in Amazon RDS. For more information, see Amazon RDS for Db2.	November 27, 2023
RDS for PostgreSQL supports major version upgrades to PostgreSQL 16.1 and minor version upgrades to 15.5, 14.10, 13.13, 12.17, and 11.22	With RDS for PostgreSQL, you can now upgrade the DB engine to major version 16.1 and minor version upgrades to 15.5, 14.10, 13.13, 12.17, and 11.22. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS.	November 17, 2023
RDS Custom for Oracle supports option groups	You can create or modify an option group and associate it with an RDS Custom for Oracle DB instance. The `Timezone` option is now supported. For more information, see Working with option groups in RDS Custom for Oracle.	November 17, 2023

Amazon RDS for MySQL supports the Group Replication plugin	You can now set up an active-active cluster with RDS for MySQL version 8.0.35 or higher DB instances by using the Group Replication plugin developed and maintained by the MySQL community. For more information, see Configuring active-active clusters for RDS for MySQL.	November 17, 2023
Amazon RDS Proxy supports RDS for PostgreSQL 16.1	You can now create proxies using RDS Proxy for RDS for PostgreSQL 16.1 DB instances. For more information, see Using Amazon RDS Proxy.	November 17, 2023
RDS Custom for SQL Server supports Microsoft SQL Server 2019 Developer edition	You can create RDS Custom for SQL Server DB instances that use SQL Server 2019 Developer edition. For more information, see Bring Your Own Media with RDS Custom for SQL Server.	November 16, 2023

Minor version upgrades of Multi-AZ DB clusters with minimal downtime	When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS now upgrades the reader DB instances before the writer instance, thereby significantly reducing downtime. You can further reduce downtime to one second or less by using RDS Proxy. For more information, see Upgrading the engine version of a Multi-AZ DB cluster.	November 16, 2023
RDS for SQL Server supports Microsoft SQL Server 2022	You can now create RDS DB instances that use SQL Server 2022. For more information, see Microsoft SQL Server versions on Amazon RDS.	November 15, 2023
RDS for MySQL supports upgrading snapshots from version 5.7 to 8.0	You can now upgrade the engine version of an RDS for MySQL snapshot from version 5.7 to version 8.0. You can do so by using the AWS Management Console, or the `ModifyDBSnapshot` operation of the RDS API or AWS CLI. For more information, see Upgrading a MySQL DB snapshot engine version.	November 15, 2023

RDS Custom for SQL Server supports point in time recovery of 1,0000 databases	You can now make up to 1,000 databases eligible for full backup and point in time recovery on your RDS Custom for SQL Server DB instance. For more information, see Restoring an RDS Custom for SQL Server instance to a point in time.	November 15, 2023
RDS Custom for SQL Server supports a using a Service Master Key	RDS Custom for SQL Server now supports using a Service Master Key (SMK). An SMK allows you to encrypt objects such as credentials, and use SQL Server features like TDE and column-encryption. For more information, see Using a Service Master Key with RDS Custom for SQL Server.	November 13, 2023
Amazon RDS supports MySQL 8.1 in the Database Preview environment	MySQL 8.1 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see MySQL version 8.1 in the Database Preview environment.	November 10, 2023
RDS supports MySQL 8.0.35 and MySQL 5.7.44	You can now create Amazon RDS DB instances running MySQL version 8.0.35 and 5.7.44. For more information, see MySQL on Amazon RDS versions.	November 9, 2023

RDS Proxy supports Multi-AZ DB clusters	RDS Proxy now supports connecting to Multi-AZ DB clusters. For more informati on, see Working with Amazon RDS Proxy endpoints.	November 9, 2023
RDS Custom for Oracle is available in the AWS GovCloud (US) Regions	Amazon RDS is now available in the AWS GovCloud (US) Regions. For more informati on, see Supported Regions and DB engines for RDS Custom for Oracle.	November 9, 2023
Amazon RDS Optimized Writes supports the db.m5 DB instance class	Amazon RDS Optimized Writes now supports the db.m5 DB instance class. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.	November 9, 2023

Amazon RDS for Oracle supports the multi-tenant configuration of the CDB architecture	With the RDS for Oracle multi-tenant feature, RDS delivers a fully managed Oracle multitenant architecture and experience for your Oracle databases. You can use RDS APIs to create multiple PDBs, called *tenant databases*, in a CDB. RDS offers the multi-tenant configuration of the CDB architecture as an alternative to the legacy single-tenant configuration. For more information, see Multi-tenant configuration of the CDB architecture.	November 8, 2023
Amazon RDS exports Performance Insights metrics to Amazon CloudWatch	Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see Exporting Performance Insights metrics to CloudWatch.	November 8, 2023

Amazon RDS Custom for Oracle allows you to upgrade the operating system on a DB instance	You can now upgrade the database or operating system (OS) for an RDS Custom for Oracle DB instance using the CLI command `modify-db-instance` . For more information, see Upgrading a DB instance for Amazon RDS Custom for Oracle.	November 7, 2023
RDS Proxy supports Extended Protocol for RDS for PostgreSQL	You can now execute extended query protocols on an RDS for PostgreSQL DB instance. For more information, see Using Amazon RDS Proxy.	November 6, 2023
RDS for PostgreSQL support for RDS Blue/Green Deployments	You can now create a blue/green deployment from an RDS for PostgreSQL DB instance. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	October 26, 2023
Update to AWS managed policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see Amazon RDS updates to AWS managed policies.	October 23, 2023

RDS Custom for Oracle supports the Europe (Milan) Region	For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	October 23, 2023
Enable RDS Optimized Writes on existing databases	You can now enable RDS Optimized Writes on an existing DB instance even if it was created with an engine version, DB instance class, or file system config uration that doesn't support the feature. For more information, see Enabling RDS Optimized Writes on an existing database for RDS for MySQL, and Enabling RDS Optimized Writes on an existing database for RDS for MariaDB.	October 19, 2023
Amazon RDS supports using a dedicated log volume (DLV).	You can now use a dedicated log volume (DLV) with RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL. DLVs are ideal for databases with large allocated storage, high I/O per second (IOPS) requirements, or latency-s ensitive workloads. For more information, see Using a dedicated log volume (DLV).	October 17, 2023

Amazon RDS for PostgreSQL, MySQL, and MariaDB support new DB instance classes	You can create Amazon RDS DB instances running PostgreSQL, MySQL, and MariaDB that use the db.m6.in, db.m6idn, db.r6.in, and db.r6.idn DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	October 12, 2023
Amazon RDS for PostgreSQL supports pgactive	The pgactive extension is available in Amazon RDS for PostgreSQL. For more information, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.	October 9, 2023
RDS Custom for Oracle is available in the Asia Pacific (Jakarta) Region	You can create RDS Custom for Oracle DB instances in the Asia Pacific (Jakarta) Region. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	October 5, 2023
RDS Custom for SQL Server supports new server-level collations	RDS Custom for SQL Server now supports a wide range of server collations, both in traditional and UTF-8 encoding, for the SQL_Latin, Japanese, German, and Arabic locales. For more information, see Collation and character support for RDS Custom for SQL Server DB instances.	September 26, 2023

Update to AWS managed policy permissions	The `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role has new permissions that allow RDS Custom to create, modify, and delete EventBridge Managed Rules. For more information, see Amazon RDS updates to AWS managed policies.	September 20, 2023
Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch	The **DB_PERF_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see Creating CloudWatch alarms to monitor Amazon RDS.	September 20, 2023
Performance Insights supports digest-level statistics for SQL Server	When you use Performance Insights, you can view SQL statistics both at the statement and digest level for Amazon RDS for SQL Server. For more information, see Analyzing running queries in SQL Server.	September 18, 2023

Amazon RDS for PostgreSQL, MySQL, and MariaDB support the db.m6.id and db.r6.id DB instance class types	You can now create Amazon RDS DB instances running PostgreSQL, MySQL, and MariaDB that use the memory-optimized db.m6.id and db.r6.id DB instance class types. These types offer local NVMe-based SSD storage. For more information, see Supported DB engines for all available DB instance classes.	September 11, 2023
Major version upgrade support for RDS for PostgreSQL Multi-AZ DB clusters	You can now perform major version upgrades of your RDS for PostgreSQL Multi-AZ DB clusters. For more informati on, see Upgrading the engine version of a Multi-AZ DB cluster.	September 7, 2023
Amazon RDS supports MariaDB 10.11.5, 10.6.15, 10.5.22, and 10.4.31	You can now create Amazon RDS DB instances running MariaDB version 10.11.5, 10.6.15, 10.5.22, and 10.4.31. For more information, see MariaDB on Amazon RDS versions.	September 7, 2023

Amazon RDS Extended Support	Amazon RDS announces the upcoming ability to continue running RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances past the RDS end of standard support date. For more information, see Using Amazon RDS Extended Support.	September 1, 2023
RDS Custom supports starting and stopping an RDS Custom for SQL Server DB instance	RDS Custom now supports starting and stopping an RDS Custom for SQL Server DB instance. For more information, see Starting and stopping an RDS Custom for SQL Server DB instance.	August 31, 2023
Amazon RDS Optimized Writes supports the db.r5 DB instance class	Amazon RDS Optimized Writes now supports the db.r5 DB instance class. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.	August 31, 2023

Amazon RDS for Oracle supports timezone file autoupgrade for CDBs	With the `TIMEZONE_FILE_AUTOUPGRADE` option, you can upgrade the current time zone file to the latest version on your RDS for Oracle container database (CDB). For more informati on, see Oracle time zone file autoupgrade.	August 29, 2023
Amazon RDS Optimized Writes supports the db.m6g and db.m6i DB instance classes	Amazon RDS Optimized Writes now supports the db.m6g and db.m6i DB instance classes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL.	August 28, 2023
Amazon RDS supports MariaDB 10.11	You can now create Amazon RDS DB instances running MariaDB version 10.11. For more information, see MariaDB on Amazon RDS versions.	August 21, 2023

Update to AWS managed policy permissions	The `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role has new permissions that allow RDS Custom to create network interfaces. For more information, see Amazon RDS updates to AWS managed policies.	August 18, 2023
Update to AWS managed policy permissions	The `AmazonRDSFullAccess` managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.	August 17, 2023
Update to AWS managed policy permissions	The addition of new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and addition of new managed policy `AmazonRDSPerformanceInsightsFullAccess` allows you generate a DB load analysis report for a time period. For more information, see Amazon RDS updates to AWS managed policies.	August 16, 2023

Amazon RDS supports performance analysis for a period of time	Performance Insights allows you to create and view performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see Analyzing DB load for a period of time.	August 16, 2023
Amazon RDS Custom for Oracle supports the db.r5b and db.x2iedn DB instance classes	You can now use the db.r5b and db.x2iedn instance classes for RDS Custom for Oracle DB instances. For more information, see DB instance class support for RDS Custom for Oracle.	August 16, 2023
Amazon RDS Custom for Oracle supports the db.m6i, db.r6i, and db.t3 DB instance classes	You can now use the db.m6i, db.r6i, and db.t3 instance classes for RDS Custom for Oracle DB instances. For more information, see DB instance class support for RDS Custom for Oracle.	August 15, 2023
Amazon RDS for PostgreSQL now supports PostgreSQL version 16 Beta 3 in the database preview environment	PostgreSQL version 16 Beta 3 is now available in the database preview envir onment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	August 11, 2023

Amazon RDS supports MySQL 8.0.34 and 5.7.43	You can now create Amazon RDS DB instances running MySQL version 8.0.34 and 5.7.43. For more information, see MySQL on Amazon RDS versions.	August 9, 2023
RDS for SQL Server supports OS metrics view for the standby replica	You can now view OS metrics for standby replica for RDS for SQL Server. For more information, see Viewing OS metrics in the RDS console.	August 3, 2023
RDS for Oracle supports Oracle Data Guard for CDBs	RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c container databases (CDBs). You can create, manage, and promote read replicas in a CDB, just as you can in a non-CDB, using the existing RDS APIs. For more information, see Multitenant read replicas.	August 1, 2023
Amazon RDS is available in the Israel (Tel Aviv) Region	Amazon RDS is now available in the Israel (Tel Aviv) Region. For more information, see Regions and Availability Zones.	August 1, 2023
Amazon RDS supports Oracle APEX version 23.1.v1	You can use Oracle APEX 23.1.v1 with Oracle Database 19c and higher. For more information, see Oracle Application Express.	July 26, 2023

Amazon RDS Custom for Oracle supports a nondefault Oracle SID	When you create an RDS Custom for Oracle DB instance using Oracle Database 19c, you can specify a nondefault Oracle system identifier (Oracle SID). This value is also the name of the CDB. For more informati on, see Multitenant architect ure considerations .	July 21, 2023
RDS for SQL Server supports Self Managed Active Directory	You can now use Self Managed Active Directory to directly join your RDS for SQL Server DB instances to your Microsoft Active Directory (AD) domains. Self-mana ged AD domains can be on-premises or in the cloud. For more information, see Working with Self Managed Active Directory.	July 7, 2023
PostgreSQL logical replicati on support for Multi-AZ DB clusters	You can now use PostgreSQ L logical replication with your Multi-AZ DB cluster to replicate and synchronize individual tables rather than an entire database instance. For more information, see Setting up PostgreSQL logical replication with Multi-AZ DB clusters for Amazon RDS.	July 6, 2023

Amazon RDS for PostgreSQL now supports PostgreSQL version 16 Beta 2 in the database preview environment	PostgreSQL version 16 Beta 2 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	July 6, 2023
Update to AWS managed policy permissions	The `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role has new permissions that allow RDS Custom for Oracle to use snapshots. For more information, see Amazon RDS updates to AWS managed policies.	June 23, 2023
RDS supports MariaDB 10.6.14, 10.5.21, and 10.4.30	You can now create Amazon RDS DB instances running MariaDB version 10.6.14, 10.5.21, and 10.4.30. For more information, see MariaDB on Amazon RDS versions.	June 22, 2023
RDS supports MySQL 8.0.33 and 5.7.42	You can now create Amazon RDS DB instances running MySQL version 8.0.33 and 5.7.42. For more information, see MySQL on Amazon RDS versions.	June 15, 2023

RDS supports MariaDB 10.6.13, 10.5.20, 10.4.29, and 10.3.39	You can now create Amazon RDS DB instances running MariaDB version 10.6.13, 10.5.20, 10.4.29, and 10.3.39. For more information, see MariaDB on Amazon RDS versions.	June 15, 2023
RDS for Oracle supports transportable tablespaces	You can migrate data from an on-premises Oracle database into an RDS for Oracle DB instance using transportable tablespaces. This technique doesn't require additional licensing and is the migration technique with the least downtime. For more information, see Migrating using Oracle transportable tablespaces.	June 15, 2023
Amazon RDS supports RDS Proxy with RDS for MariaDB version 10.6	You can now create an RDS Proxy with an RDS for MariaDB version 10.6 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	June 15, 2023
RDS Custom for SQL Server supports Bring Your Own Media (BYOM)	You can now create a Custom Engine Version (CEV) using your own SQL Server media. For more information, see Bring Your Own Media with RDS Custom for SQL Server.	June 8, 2023

RDS for Oracle can convert an Oracle Database 19c non-CDB to a CDB	If your DB instance runs Oracle Database 19c with the April 2021 or higher RU, you can convert a non-CDB to a CDB (container database) . After you convert the architecture, you can upgrade your 19c CDB to a 21c CDB. This step is necessary bec ause you can't upgrade your database and convert the architecture using a single command. For more informati on, see Converting an RDS for Oracle non-CDB into a CDB.	May 31, 2023
Multi-AZ DB clusters available in the China Regions	Multi-AZ DB clusters are now available in the AWS Regions China (Beijing) and China (Ningxia). For more informati on, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.	May 30, 2023
Amazon RDS Optimized Reads support for Multi-AZ DB clusters	Amazon RDS Optimized Reads now supports Multi-AZ DB clusters. For more information, see Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads and Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Re ads.	May 30, 2023

RDS Custom for Oracle supports the Asia Pacific (Jakarta) Region	For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	May 29, 2023
Create a DB instance read replica with a source RDS for PostgreSQL Multi-AZ DB cluster	You can now create a DB instance read replica with an RDS for PostgreSQL Multi-AZ DB cluster as the source. Previously, only RDS for MySQL was supported. For more information, see Creating a DB instance read replica from a Multi-AZ DB cluster.	May 24, 2023
Amazon RDS provides combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard	Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dash board. For more informati on, see Viewing combined metrics with the Performance Insights dashboard.	May 24, 2023

Amazon RDS Optimized Reads available in the China Regions	Amazon RDS Optimized Reads is now available in the AWS Regions China (Beijing) and China (Ningxia). For more information, see Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads and Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads.	April 24, 2023
Amazon RDS support for AWS Secrets Manager in the China Regions	Amazon RDS supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	April 20, 2023
RDS Custom for Oracle supports reuse of AMI IDs for new CEVs	When you create a custom engine version (CEV), RDS Custom for Oracle defaults to the most recent Amazon Machine Image (AMI) available. Now you can specify an AMI ID that was used in a previous CEV. For more information, see Creating a CEV.	April 19, 2023

Amazon RDS supports publishing events with tags to topic subscribers	Amazon RDS event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see Amazon RDS event notification tags and attributes.	April 17, 2023
Purchase reserved instances for a Multi-AZ DB cluster	You can now purchase reserved DB instances for a Multi-AZ DB cluster. For more information, see Reserved DB instances for a Multi-AZ DB cluster.	April 12, 2023
Amazon RDS supports the db.m7g and db.r7g instance classes	You can now use the db.m7g and db.r7g instance classes for RDS for MySQL, RDS for MariaDB, and RDS for PostgreSQL DB instances. For more information, see Supported DB engines for DB instance classes.	April 12, 2023

Update to Amazon RDS Custom service-linked role permissions	The `AmazonRDSCustomServiceRolePolicy` now grants additional permissions to allow RDS Custom for SQL Server to use Amazon SQS and create snapshots. For more information, see Updates to AWS managed policies.	April 6, 2023
Migrate to an RDS for MySQL Multi-AZ DB cluster using a read replica	You can now use a read replica to migrate an RDS for MySQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for MySQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see Migrating to a Multi-AZ DB cluster using a read replica.	April 6, 2023
Create a DB instance read replica from a Multi-AZ DB cluster	You can now create a DB instance read replica from a Multi-AZ DB cluster in order to scale beyond the compute capacity of the source cluster. For more information, see Creating a DB instance read replica from a Multi-AZ DB cluster.	April 6, 2023

Amazon RDS Custom for SQL Server supports Multi-AZ	You can create a Multi-AZ deployment with RDS Custom for SQL Server. For more information, see Managing a Multi-AZ deployment for RDS Custom for SQL Server.	April 6, 2023
Update to AWS managed policy permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see Amazon RDS updates to AWS managed policies.	March 30, 2023
Amazon RDS supports Oracle APEX version 22.2.v1	You can use Oracle APEX 22.2.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	March 30, 2023

Amazon DevOps Guru available for RDS for PostgreSQL	RDS for PostgreSQL alerts you to recent anomalies detected by Amazon DevOps Guru. The database details page of the console alerts you to current and anomalies that occurred in the past 24 hours. DevOps Guru publishes proactive insights with recommendations to help address issues in your RDS for PostgreSQL databases before they are predicted to happen. For more information, see How DevOps Guru for RDS works.	March 30, 2023
RDS Custom supports the Amazon EBS gp3 storage volume	RDS Custom for Oracle and RDS Custom for SQL Server both support the io1, gp2, and gp3 SSD-based EBS volumes. For more informati on, see General requirements for RDS Custom for Oracle and General requirements for RDS Custom for SQL Server.	March 29, 2023

Update to AWS managed policy permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to Amazon CloudWatch. For more information, see Amazon RDS updates to AWS managed policies.	March 16, 2023
RDS Proxy is available in the China Regions	RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 15, 2023
RDS Proxy is available in the Asia Pacific (Jakarta) Region	RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 8, 2023
Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MariaDB	You can improve the performance of write transactions for RDS for MariaDB DB instances with Amazon RDS Optimized Writes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MariaDB.	March 7, 2023

Amazon RDS for PostgreSQL versions 15.2	New features in Amazon RDS for PostgreSQL 15.2 include the SQL standard "MERGE" command for conditional SQL queries, performance improvements for both in-memory and disk-based sorting, and support for two-phase commit and row/column filtering for logical replication.	February 27, 2023
RDS Custom for Oracle is available in the Canada (Central) Region and South America (São Paulo) Regions	For a table that shows all supported AWS Regions, see Supported Regions and DB engines for RDS Custom for Oracle.	February 22, 2023
Amazon RDS supports cross-Region automated backups for RDS for MariaDB and RDS for MySQL	You can now replicate DB snapshots and transaction logs between AWS Regions for RDS for MariaDB and RDS for MySQL DB instances. For more information, see Replicating automated backups to another AWS Region.	February 22, 2023

Amazon RDS for Oracle supports advance notice of automatic minor version upgrades	RDS notifies you in advance of the date when a new minor version of the RDS for Oracle engine will become available . RDS begins scheduling automatic minor version upgrades of your RDS for Oracle DB instances on the availability date. For more information, see Before an automatic minor version upgrade is scheduled.	February 21, 2023
Amazon RDS for SQL Server supports Database Activity Streams	You can now monitor a SQL Server DB instance using Database Activity Streams. A SQL Server database instance has the server audit which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification. You can create a database audit specification and define the policies to record databa se events. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream for further analysis. For more information, see Monitoring Amazon RDS with Database Activity Streams.	February 15, 2023

RDS supports MySQL 8.0.32 and 5.7.41	You can now create Amazon RDS DB instances running MySQL version 8.0.32 and 5.7.41. For more information, see MySQL on Amazon RDS versions.	February 7, 2023
Amazon RDS for Oracle supports new cipher suites for SSL	If you run Oracle Database 19c or 21c, you can specify six new cipher suites in the SSL option for RDS for Oracle. These suites support FIPS and are FedRAMP-complaint. For more information, see Oracle Secure Sockets Layer.	February 3, 2023
Amazon RDS for Oracle supports new cipher suites for Oracle Enterprise Manager	You can use four new FedRAMP-compliant cipher suites for the OEM option. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	February 3, 2023
RDS for Oracle supports Database Activity Streams in the Asia Pacific (Hyderabad), Europe (Spain), and Middle East (UAE) Regions	For more information, see Supported Regions and DB engines for database activity streams in Amazon RDS.	January 27, 2023

Migrate to an RDS for PostgreSQL Multi-AZ DB cluster using a read replica	By using a read replica, you can migrate an RDS for PostgreSQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for PostgreSQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see Migrating to a Multi-AZ DB cluster using a read replica.	January 23, 2023
Amazon RDS is available in the Asia Pacific (Melbourne) Region	Amazon RDS is now available in the Asia Pacific (Melbourne) Region. For more information, see Regions and Availability Zones.	January 23, 2023
RDS for MariaDB supports enforcing SSL/TLS connections	RDS for MariaDB now supports enforcing SSL/TLS connections by setting the `require_secure_transport` parameter to `ON`. For more information, see Requiring SSL/TLS for all connections to a MariaDB DB instance.	January 19, 2023
Amazon RDS Optimized Reads improves query performance for RDS for MariaDB	You can achieve faster query processing for RDS for MariaDB DB instances with Amazon RDS Optimized Reads. For more information, see Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads.	January 11, 2023

Restore a Multi-AZ DB cluster snapshot to a DB instance	You can now restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment. For more information, see Restoring from a Multi-AZ DB cluster snapshot to a DB instance.	January 10, 2023
Specify certificate authority (CA) during DB instance creation	You can now specify which CA to use for a DB instance's server certificate during DB instance creation. For more information, see Certificate authorities.	January 5, 2023
RDS Custom for SQL Server supports custom engine versions	A custom engine version (CEV) for RDS Custom for SQL Server is an Amazon Machine Image (AMI) with Microsoft SQL Server pre-installed. You choose an Amazon EC2 Windows AMI to use as a base image and can install other software on the operating system (OS). You can customize the configuration of the OS and SQL Server to meet your enterprise needs. For more information, see Working with custom engine versions for RDS Custom for SQL Server.	December 28, 2022

Use Amazon RDS Blue/Green Deployments available in additional AWS Regions	The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	December 22, 2022
Update to IAM service-linked role permissions	The AmazonRDSServiceRolePolicy policy now grants additional permissions to AWS Secrets Manager. For more information, see Amazon RDS updates to AWS managed policies.	December 22, 2022
Amazon RDS supports renaming a Multi-AZ DB cluster	You can now rename a Multi-AZ DB cluster. For more information, see Renaming a Multi-AZ DB cluster.	December 22, 2022
Amazon RDS integrates with AWS Secrets Manager for password management	Amazon RDS can manage the master user password for a DB instance or Multi-AZ DB cluster in Secrets Manager. For more information, see Password management with Amazon RDS and AWS Secrets Manager.	December 22, 2022

Amazon RDS Optimized Writes supports the db.r6g and db.r6gd DB instance classes	Amazon RDS Optimized Writes now supports the db.r6g and db.r6gd DB instance classes. For more information, see Improving write performance with Amazon RDS Optimized Writes.	December 22, 2022
Amazon RDS Custom for Oracle supports new AWS Regions	You can create RDS Custom for Oracle DB instances in the Asia Pacific (Seoul) and Asia Pacific (Osaka) Regions. For more information, see Supported Regions and DB engines for RDS Custom for Oracle.	December 21, 2022
Amazon RDS on AWS Outposts supports read replicas	You can now create a read replica from an RDS on Outposts MySQL or PostgreSQL DB instance. For more information, see Creating read replicas for Amazon RDS on AWS Outposts.	December 19, 2022
RDS Custom for Oracle supports modifying the DB instance class	You can now change the instance class of your RDS Custom for Oracle DB instance. For more information, see Modifying your RDS Custom for Oracle DB instance.	December 16, 2022

RDS for MySQL and RDS for PostgreSQL support db.x2iedn DB instance classes	You can now use the db.x2iedn DB instance classes for RDS for MySQL and RDS for PostgreSQL DB instances . For more information, see Supported DB engines for DB instance classes.	December 14, 2022
Amazon RDS Optimized Writes supports db.x2iedn DB instance classes	Amazon RDS Optimized Writes now supports db.x2iedn DB instance classes. For more information, see Improving write performance with Amazon RDS Optimized Writes.	December 14, 2022
Amazon RDS supports copying DB option groups when copying DB snapshots	You can now copy an option group across AWS accounts as part of a snapshot copy request on RDS for Oracle databases. For more information, see Option group considerations.	December 13, 2022
Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 14	You can now create an RDS Proxy with an RDS for PostgreSQL version 14 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	December 13, 2022

Amazon RDS for Oracle supports db.x2idn, db.x2iedn, and db.x2iezn instance classes	You can now use the db.x2idn, db.x2iedn, and db.x2iezn instance classes for Amazon RDS for Oracle DB instances . For more information, see Supported DB engines for DB instance classes and Supported RDS for Oracle instance classes.	December 12, 2022
RDS for PostgreSQL DB instances support Trusted Language Extensions for PostgreSQL	Trusted Language Extension s for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQ L extensions and safely run them on your RDS for PostgreSQL DB instance. For more information, see Working with Trusted Language Extensions for PostgreSQL.	November 30, 2022

Use Amazon RDS Blue/Green Deployments for database updates	You can make changes to a DB instance in a staging environment and test the changes without affecting your production DB instance. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	November 27, 2022
Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MySQL	You can improve the performance of write transactions for RDS for MySQL DB instances with Amazon RDS Optimized Writes. For more information, see Improving write performance with Amazon RDS Optimized Writes for MySQL.	November 27, 2022
Amazon RDS Optimized Reads improves query performance for RDS for MySQL	You can achieve faster query processing for RDS for MySQL DB instances with Amazon RDS Optimized Reads. For more information, see Improving query performance with Amazon RDS Optimized Reads.	November 27, 2022

Amazon RDS is available in the Asia Pacific (Hyderabad) Region	Amazon RDS is now available in the Asia Pacific (Hyderabad) Region. For more information, see Regions and Availability Zones.	November 22, 2022
RDS supports MariaDB 10.6.11, 10.5.18, 10.4.27, and 10.3.37	You can now create Amazon RDS DB instances running MariaDB versions 10.6.11, 10.5.18, 10.4.27, and 10.3.37. For more informati on, see MariaDB on Amazon RDS versions.	November 18, 2022
RDS Custom for Oracle supports setting nondefault installation parameters in a custom engine version (CEV)	When you create a CEV, you can set nondefault values for the Oracle base, Oracle home, UNIX user name and ID, and UNIX group name and ID. In this way, you gain more control over the database installation on your RDS Custom for Oracle DB instance. For more informati on, see Preparing the CEV manifest.	November 18, 2022
Amazon RDS supports Oracle APEX version 22.1.v1	You can use Oracle APEX 22.1.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	November 18, 2022

RDS for SQL Server supports cross-Region read replicas	You can now create a cross-Region read replica to enhance disaster recovery capability, reduce application read latency, and offload read workloads from the primary DB instance. For more information, see Creating a read replica in a different AWS Region.	November 16, 2022
Amazon RDS is available in the Europe (Spain) Region	Amazon RDS is now available in the Europe (Spain) Region. For more information, see Regions and Availability Zones.	November 16, 2022
RDS for SQL Server supports linked servers for Oracle database	You can now create a linked server to access external Oracle databases to read data and execute SQL commands. For more information, see Linked Servers with Oracle OLEDB with RDS for SQL Server.	November 15, 2022

RDS Custom for Oracle supports Oracle Multitenant	You can create an RDS Custom for Oracle DB instance as a container database (CDB). After creation, the CDB contains the CDB root, PDB seed, and one PDB. You can add more PDBs manually using Oracle SQL. For more information, see Overview of Amazon RDS Custom for Oracle architecture.	November 15, 2022
Amazon RDS for Oracle supports Amazon EFS integration	If you add the `EFS_INTEGRATION` option to your option group, you can transfer files between your RDS for Oracle DB instance and an Amazon EFS file system. For more information, see Amazon EFS.	November 15, 2022
RDS supports MySQL 8.0.31 and 5.7.40	You can now create Amazon RDS DB instances running MySQL version 8.0.31 and 5.7.40. For more information, see MySQL on Amazon RDS versions.	November 10, 2022
Amazon RDS is available in the Europe (Zurich) Region	Amazon RDS is now available in the Europe (Zurich) Region. For more information, see Regions and Availability Zones.	November 9, 2022

Access to transaction log backups is now available for RDS for SQL Server	You can now view and copy database transaction log backups to an Amazon S3 bucket. For more informati on, see Access to transaction log backups.	November 7, 2022
Multi-AZ DB clusters supported in additional AWS Regions	Multi-AZ DB clusters are now available in additional AWS Regions. For more information, see Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS.	November 4, 2022
Amazon RDS supports gp3 storage	You can now create Amazon RDS DB instances that use Amazon EBS General Purpose SSD (gp3) storage volumes, which let you customize storage performan ce independently of storage capacity. For more informati on, see General Purpose SSD storage.	November 4, 2022
Amazon RDS supports a new event for operating system updates	Amazon RDS now supports a new DB instance event, RDS-EVENT-0230, under the event category of security patching. This new event alerts you when an operating system update is available for your DB instance. For more information, see Monitorin g Amazon RDS events and Working with operating system updates.	October 28, 2022

Amazon RDS for Oracle supports preconfigured r5b memory optimized instance classes	The db.r5b Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For example, db.r5b.4xlarge.tpc2.mem2x has multithreading turned on and provides twice as much memory as db.r5b.4xlarge. For more information, see RDS for Oracle instance classes.	October 27, 2022
Amazon RDS supports 15 read replicas for RDS for MariaDB, MySQL, and PostgreSQL DB instances	You can now create up to 15 read replicas for RDS for MariaDB, MySQL, and PostgreSQL DB instances. For more information about read replicas, see Working with read replicas.	October 20, 2022
Amazon RDS for PostgreSQL now supports PostgreSQL version 15 RC 3 in the database preview environment	PostgreSQL version 15 Beta 3 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	October 18, 2022

Amazon RDS supports automatically setting up connectivity between an RDS database and an EC2 instance	You can use the AWS Management Console to set up connectivity between an existing RDS DB instance or Multi-AZ DB cluster and an EC2 instance. For more information, see Connecting an EC2 instance and an RDS database automatically.	October 14, 2022
AWS JDBC Driver for PostgreSQL generally available	The AWS JDBC Driver for PostgreSQL is a client driver designed for RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL is now generally available. For more information, see Connecting with the AWS JDBC Driver for PostgreSQL.	October 6, 2022
Amazon RDS for Oracle supports Oracle APEX version 21.2.v1	Oracle APEX 21.2 includes patch 33420059. For more information, see Oracle APEX version requirements.	October 3, 2022
RDS supports MySQL 5.7.39	You can now create Amazon RDS DB instances running MySQL versions 5.7.39. For more information, see MySQL on Amazon RDS versions.	September 29, 2022

RDS supports MariaDB 10.6.10	You can now create Amazon RDS DB instances running MariaDB versions 10.6.10. For more information, see MariaDB on Amazon RDS versions.	September 29, 2022
RDS Proxy supports RDS for SQL Server	You can now create an RDS Proxy for an RDS DB instance that runs Microsoft SQL Server version 2014 or higher. For more information about RDS Proxy, see Using Amazon RDS Proxy.	September 19, 2022
RDS supports MariaDB 10.5.17, 10.4.26, and 10.3.36	You can now create Amazon RDS DB instances running MariaDB versions 10.5.17, 10.4.26, and 10.3.36. For more information, see MariaDB on Amazon RDS versions.	September 15, 2022

Amazon RDS for Oracle supports local instance storage for temporary data	You can now launch Amazon RDS for Oracle on Amazon EC2 db.r5d and db.m5d instance types with the temporary tablespace and Database Smart Flash Cache (the flash cache) configured to use an instance store. By storing temporary data locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Storing temporary Oracle data in the instance store.	September 14, 2022
Performance Insights shows the top 25 SQL queries	In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see Overview of the Top SQL tab.	September 13, 2022
RDS supports MySQL 8.0.30	You can now create Amazon RDS DB instances running MySQL version 8.0.30. For more information, see MySQL on Amazon RDS versions.	September 9, 2022
Amazon RDS is available in the Middle East (UAE) Region	Amazon RDS is now available in the Middle East (UAE) Region. For more information, see Regions and Availability Zones.	August 30, 2022

Amazon RDS for SQL Server supports SSRS Email subscriptions	You can now use the SQL Server Reporting Services (SSRS) Email extension to send reports to users and subscribe to reports on the report server. For more information, see Support for SQL Server Reporting Services in RDS for SQL Server.	August 26, 2022
RDS for Oracle supports read replica backups	You can turn on automatic backups and create manual snapshots of RDS for Oracle replicas. For more information, see Working with RDS for Oracle replica backups.	August 23, 2022
RDS for Oracle supports Oracle Data Guard switchover	A switchover is a role reversal between a primary database and a mounted or open Oracle replica. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role. For more information, see Performing an Oracle Data Guard switchover.	August 23, 2022

Amazon RDS supports automatically setting up connectivity with an EC2 instance	When you create a DB instance or Multi-AZ DB cluster, you can use the AWS Management Console to s et up connectivity between an Amazon Elastic Compute Cloud instance and the new DB instance or DB c luster. For more informati on, see Configure automatic network connectivity with an EC2 instance for a new DB instance and Configure automatic network connectiv ity with an EC2 instance for a new DB cluster.	August 22, 2022
RDS Custom for Oracle supports promotion of Oracle replicas	If you use RDS Custom for Oracle, you can promote your managed Oracle replicas by using the `promote-read-replica` CLI command. Also, you can delete your primary DB instance, which causes RDS Custom for Oracle to promote your managed Oracle replicas to standalone instances. For more informati on, see Working with Oracle replicas for RDS Custom for Oracle.	August 5, 2022

RDS for MySQL supports enforcing SSL/TLS connections	RDS for MySQL now supports enforcing SSL/TLS connections by setting the `require_secure_transport` parameter to ON. For more information, see Requiring an SSL/TLS connection to a MySQL DB instance.	August 1, 2022
Amazon RDS has deprecated support for Oracle Database 12c Release 1 (12.1.0.2)	Support for version 12.1.0.2 is deprecated for both the BYOL and LI licensing models. On August 1, 2022, RDS for Oracle begins automatic upgrades of 12c Release 1 (12.1.0.2) DB instances and restored 12.1.0.2 snapshots to Oracle Database 19c. For more information, see the end of support timeline on AWS re:Post.	August 1, 2022
RDS Proxy supports RDS for MariaDB	You can now create an RDS Proxy for an RDS DB instance that runs MariaDB version 10.2, 10.3, 10.4, or 10.5. The MariaDB support is included under the MySQL engine family. For more information about RDS Proxy, see Using Amazon RDS Proxy.	July 26, 2022

RDS for MariaDB supports the db.r5b DB instance classes	You can now create RDS for MariaDB DB instances that use the db.r5b DB instance classes. For more information, Supported DB engines for DB instance classes.	July 25, 2022
RDS for Oracle supports modifying database activity streams	If you use RDS for Oracle, you can change the audit policy state of a database acti vity stream to either locked (default) or unlocked. Instead of stopping an activity stream, you can unlock its policy state, customize your audit policy, and then relock the policy state. For more information, see Modifying a database activity stream.	July 22, 2022
Performance Insights supports the Asia Pacific (Jakarta) Region	Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Reg ion. This restriction has been removed. For more informati on, see Supported Regions and DB engines for Performan ce Insights in Amazon RDS.	July 21, 2022

Microsoft SQL Server 2012 has reached its end of support on Amazon RDS	Microsoft SQL Server 2012 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 12, 2022. Any existing Microsoft SQL Server 2012 instances are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2014 starting on June 1, 2022. For more information, see Microsoft SQL Server 2012 support on Amazon RDS.	July 12, 2022
RDS supports MariaDB 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44	You can now create Amazon RDS DB instances running MariaDB versions 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44. For more information, see Supported MariaDB versions on Amazon RDS.	July 8, 2022

RDS Performance Insights supports additional retention periods	Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance d ata for longer than 7 days, you can specify from 1–24 months. For more informat ion, see Pricing and data retention for Performance Insights.	July 1, 2022
RDS Custom supports the Asia Pacific (Mumbai) and Europe (London) Regions	You can create RDS Custom for Oracle and RDS Custom for SQL Server DB instances in two new AWS Regions: Asia Pacific (Mumbai) and Europe (London). For more informati on, see AWS Region support for RDS Custom for Oracle and AWS Region support for RDS Custom for SQL Server.	June 21, 2022
RDS Custom for Oracle supports Oracle Database 18c and 12c Release 2 (12.2)	You can now create a CEV for RDS Custom for Oracle using installation files for Oracle Database 18c and 12c Release 2 (12.2). You can use this these CEVs to create an RDS Custom for Oracle DB instance. For more informati on, see Working with custom engine versions for Amazon RDS Custom for Oracle.	June 21, 2022

Multi-AZ DB clusters support the db.m5d and db.r5d DB instance classes	You can now create Multi-AZ DB clusters that use the db.m5d and db.r5d DB instance classes. For more information, see Multi-AZ DB cluster deployments and DB instance class types.	June 21, 2022
Multi-AZ DB clusters available in additional AWS Regions	You can now create Multi-AZ DB clusters in the following Regions: Europe (Frankfurt) and Europe (Stockholm). For more information, see Multi-AZ DB cluster deployments.	June 21, 2022
RDS for Microsoft SQL Server supports migration of databases that use Transparent Data Encryption (TDE)	RDS for SQL Server now supports migrating Microsoft SQL Server databases with TDE turned on, using native backup and restore. For more information, see Support for Transparent Data Encryption in SQL Server.	June 14, 2022
Amazon RDS supports publishing events to encrypted Amazon SNS topics	Amazon RDS can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see Subscribing to Amazon RDS event notification.	June 1, 2022

RDS supports MySQL 5.7.38	You can now create Amazon RDS DB instances running MySQL version 5.7.38. For more information, see MySQL on Amazon RDS versions.	May 31, 2022
RDS for PostgreSQL supports cascading read replicas	You can now use cascading read replicas with RDS for PostgreSQL version 14.1 and higher releases. For more information, see Working with PostgreSQL read replicas in Amazon RDS.	May 4, 2022
Amazon RDS on AWS Outposts supports scale storage and autoscaling operations	You can now change the storage sizes of DB instances on your Outpost and use storage autoscaling. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	May 2, 2022
Multi-AZ DB clusters available in additional AWS Regions	You can now create Multi-AZ DB clusters in the following Regions: Asia Pacific (Singapore) and Asia Pacific (Sydney). For more informati on, see Multi-AZ DB cluster deployments.	April 29, 2022

Amazon RDS supports dual-stack mode	DB instances can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB instance over IPv4, IPv6, or both. For more informati on, see Amazon RDS IP addressing.	April 29, 2022
Amazon RDS publishes usage metrics to Amazon CloudWatc h	The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see Amazon CloudWatch usage metrics for Amazon RDS.	April 28, 2022
Amazon RDS for MySQL supports the db.m6i and db.r6i DB instance classes	You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MySQL. For more information, see Supported DB engines for DB instance classes.	April 28, 2022
Amazon RDS for PostgreSQ L supports the db.m6i and db.r6i DB instance classes	You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running Postg reSQL. For more information, see Supported DB engines for DB instance classes.	April 27, 2022

Amazon RDS for MariaDB supports the db.m6i and db.r6i DB instance classes	You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MariaDB. For more information, see Supported DB engines for DB instance classes.	April 26, 2022
Amazon RDS on AWS Outposts supports Multi-AZ deployments	You can now create a standby DB instance on a different Outpost. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	April 19, 2022
Amazon RDS for Oracle supports the db.m6i and db.r6i instance classes	If you run Oracle Database 19c, you can use the db.m6i and db.r6i instance classes. The db.m6i classes are general-purpose instance classes that are well suited for a broad range of workloads. For more information, see RDS for Oracle instance classes.	April 8, 2022
Amazon RDS for SQL Server supports SQL Server Agent job replication	When you turn on this feature, SQL Server Agent jobs created, modified, or deleted on the primary host are automatically synchronized to the secondary host in a Multi-AZ configuration. For more information, see Using SQL Server Agent.	April 7, 2022

Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 13	You can now create an RDS Proxy with an RDS for PostgreSQL version 13 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	April 4, 2022
Amazon RDS plans to deprecate Oracle Database 12c	Oracle Database 12c is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 12c releases after the end-of-support dates. Amazon RDS plans to begin automatically upgrading Oracle Database 12c DB instances to Oracle Database 19c.	March 22, 2022
Amazon RDS for PostgreSQL Release Notes	There is now a separate guide for the Amazon RDS for PostgreSQL release notes. For more information, see *Amazon RDS for PostgreSQL Release Notes*.	March 22, 2022
Amazon RDS for Oracle Release Notes	There is now a separate guide for the Amazon RDS for Oracle release notes. For more information, see *Amazon RDS for Oracle Release Notes*.	March 22, 2022

Multi-AZ DB clusters available in additional AWS Regions	You can now create Multi-AZ DB clusters in the following Regions: US East (Ohio) and Asia Pacific (Tokyo). For more information, see Multi-AZ DB cluster deployments.	March 15, 2022
Amazon RDS for PostgreSQL versions 14.2, 13.6, 12.10, 11.15, and 10.20	RDS for PostgreSQL now supports versions 14.2, 13.6, 12.10, 11.15, and 10.20. Version 14.2 and 13.6 add support for two new foreign data wrappers. The `mysql_fdw` extension lets PostgreSQL work with data stored in MySQL, MariaDB, and Aurora MySQL databases. The `tds_fdw` extension lets PostgreSQL work with data stored in SQL Server databases. For more information, see Supported PostgreSQL database versions.	March 12, 2022
RDS supports MySQL 5.7.37	You can now create Amazon RDS DB instances running MySQL version 5.7.37. For more information, see MySQL on Amazon RDS versions.	March 11, 2022

Amazon RDS for SQL Server supports new DB instance classes	You can now create Amazon RDS DB instances running Microsoft SQL Server that use the db.m6i and db.r6i DB instance classes. For more information, see DB instance class support for Microsoft SQL Server.	March 9, 2022
Amazon RDS for Oracle supports Oracle Database 21c	You can now create Amazon RDS DB instances running Oracle Database 21c (21.0.0.0). This is the first Oracle Database release that supports only the multitena nt (CDB) architecture. For more information, see Oracle Database 21c with Amazon RDS.	March 7, 2022
RDS supports MariaDB 10.6.7, 10.5.15, 10.4.24, 10.3.34, and 10.2.43	You can now create Amazon RDS DB instances running MariaDB versions 10.6.7, 10.5.15, 10.4.24, 10.3.34, and 10.2.43. For more information, see MariaDB on Amazon RDS versions.	March 3, 2022
AWS JDBC Driver for MySQL generally available	The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. The AWS JDBC Driver for MySQL is now generally available. For more informat ion, see Connecting with the Amazon Web Services JDBC Driver for MySQL.	March 2, 2022

Multi-AZ DB clusters generally available	A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. Multi-AZ DB clusters are now generally available. For more information, see Multi-AZ DB cluster deployments.	March 1, 2022
RDS supports MySQL 8.0.28	You can now create Amazon RDS DB instances running MySQL version 8.0.28. For more information, see MySQL on Amazon RDS versions.	February 28, 2022
Amazon RDS for Oracle supports new settings for native network encryption (NNE)	To control whether clients can connect with non-secure encryption and checksumming methods, set `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS` and `SQLNET.ALLOW_WEAK_CRYPTO` in the NNE option. Examples of insecure methods include DES, 3DES, RC4, and MD5. For more information, see NNE option settings.	February 25, 2022

Amazon RDS for SQL Server supports Always On Availability Groups for Microsoft SQL Server 2017 Standard Edition	When you create a DB instance using the Multi-AZ configuration on SQL Server 2017 Standard Edition 14.00.3401.7 and higher versions, RDS automatically uses Availability Groups. For more information, see Multi-AZ deployments for Microsoft SQL Server.	February 18, 2022
RDS for Oracle supports Database Activity Streams in the Asia Pacific (Jakarta) Region	For more information, see Support for AWS Regions for database activity streams.	February 16, 2022
Amazon RDS Custom for Oracle support for Oracle Database 12.1	You can now create custom engine versions for RDS Custom for Oracle that use Oracle Database 12.1 Enterprise Edition. For more information, see Working with custom engine versions for Amazon RDS Custom for Oracle.	February 4, 2022
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.6. For more information, see MariaDB 10.6 support on Amazon RDS.	February 3, 2022

Performance Insights supports plan capture for Oracle queries	The Performance Insights console supports a new plan dimension for top SQL. When you slice by plan, you can see which plans your top Oracle queries are using. If a query uses multiple plans, you can compare the plans side by side in the console and determine which plan is most efficient. You can also drill down to see which steps in a plan have the highest cost. For more information, see Analyzing Oracle execution plans using the Performance Insights dashboard.	January 27, 2022
Performance Insights supports new APIs	Performance Insights supports the following APIs: `GetResourceMetadata`, `ListAvailableResourceDimensions`, and `ListAvailableResourceMetrics`. For more information, see Retrieving metrics with the Performance Insights API in this manual and the *Amazon RDS Performance Insights API Reference*.	January 12, 2022

RDS Proxy supports events	RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see Working with RDS Proxy events.	January 11, 2022
Amazon RDS for SQL Server supports SSAS Multidimensional mode	RDS for SQL Server supports running SQL Server Analysis Services (SSAS) in Tabular or Multidimensional mode. For more information, see Support for SQL Server Analysis Services in RDS for SQL Server.	January 7, 2022
RDS Proxy available in additional AWS Regions	RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 5, 2022
RDS supports MySQL 8.0.27	You can now create Amazon RDS DB instances running MySQL version 8.0.27. For more information, see MySQL on Amazon RDS versions.	December 21, 2021

Amazon RDS is available in the Asia Pacific (Jakarta) Region	Amazon RDS is now available in the Asia Pacific (Jakarta) Region. For more information, see Regions and Availability Zones.	December 13, 2021
Amazon RDS supports MariaDB 10.5.13, 10.4.22, 10.3.32, and 10.2.41	You can now create Amazon RDS DB instances running MariaDB versions 10.5.13, 10.4.22, 10.3.32, and 10.2.41. For more informati on, see MariaDB on Amazon RDS versions.	December 8, 2021
Amazon RDS Custom for SQL Server	Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibili ty of Amazon EC2. For more information, see Working with Amazon RDS Custom.	December 1, 2021

Multi-AZ DB clusters (preview)	You can now create Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL. A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. Multi-AZ DB clusters are in preview. For more information, see Multi-AZ DB cluster deployments (preview).	November 23, 2021
Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 12	You can now create an RDS Proxy with an RDS for PostgreSQL version 12 database. For more information about RDS Proxy, see Using Amazon RDS Proxy.	November 22, 2021
Amazon RDS on AWS Outposts supports local backups	You can store automated backups and manual snapshots in your AWS Region or locally on your Outpost. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	November 22, 2021
Amazon RDS support for cross-account AWS KMS keys	You can use a KMS key from a different AWS account for encryption when exporting DB snapshots to Amazon S3. For more information, see Exporting DB snapshot data to Amazon S3.	November 3, 2021

Amazon RDS on AWS Outposts supports publishing database engine logs to CloudWatch Logs	RDS on Outposts now supports publishing database engine logs to CloudWatch Logs. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	November 2, 2021
Amazon RDS Custom for Oracle	Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibility of Amazon EC2. For more information, see Working with Amazon RDS Custom.	October 26, 2021
Support for delayed replication for RDS for MySQL version 8.0	Starting with RDS for MySQL version 8.0.26, you can configure delayed replication for RDS for MySQL version 8.0 DB instances. For more information, see Configuring delayed replication with MySQL.	October 25, 2021
Support for MySQL 8.0.26	You can now create Amazon RDS DB instances running MySQL version 8.0.26. For more information, see MySQL on Amazon RDS versions.	October 25, 2021

Support for GTID-based replication for RDS for MySQL version 8.0	Starting with RDS for MySQL version 8.0.26, you can configure GTID-based re plication for RDS for MySQL version 8.0 DB instances. For more information, see Using GTID-based replication for RDS for MySQL.	October 25, 2021
Amazon RDS supports RDS Proxy with RDS for MySQL 8.0	You can now create an RDS Proxy for an RDS for MySQL 8.0 database instance. For more information, see Using Amazon RDS Proxy.	October 21, 2021
Amazon RDS on AWS Outposts supports additional RDS for MySQL versions	RDS on Outposts now supports RDS for MySQL versions 8.0.23 and 8.0.25. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	October 20, 2021
Amazon RDS for PostgreSQ L now supports PostgreSQ L version 14 RC 1 in the database preview environme nt	PostgreSQL version 14 RC 1 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see Working with the database preview environment.	October 19, 2021

Amazon RDS supports Performance Insights in additional AWS Regions	Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see Supported Regions and DB engines for Performance Insights in Amazon RDS.	October 5, 2021
Performance Insights supports digest-level statistics for Oracle	When you use Performance Insights, you can view SQL statistics both at the statement and digest level for Amazon RDS for Oracle. For more information, see Analyzing running queries in Oracle.	October 4, 2021
Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions	RDS on Outposts now supports RDS for PostgreSQL versions 12.8 and 13.4. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	October 1, 2021
Amazon RDS supports Oracle APEX version 21.1.v1	You can use Oracle APEX 21.1.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	September 24, 2021

Amazon RDS for Oracle supports client-side encryption for NNE	When you configure NNE, you might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the `SQLNET.*CLIENT` options. For more information, see Oracle native network encryption.	September 24, 2021
Amazon RDS for MySQL and RDS for PostgreSQL support new DB instance classes	You can now use the db.r5b, db.t4g, and db.x2g instance classes to create Amazon RDS DB instances running MySQL or PostgreSQL. For more information, see Supported DB engines for DB instance classes.	September 15, 2021
Amazon RDS for Microsoft SQL Server supports Java Database Connectivity (JDBC) with Microsoft Distributed Transaction Coordinator (MSDTC)	JDBC XA transactions are now supported with MSDTC for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019. For more information, see Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server.	September 7, 2021

Amazon RDS supports MariaDB 10.5.12, 10.4.21, 10.3.31, and 10.2.40	You can now create Amazon RDS DB instances running MariaDB versions 10.5.12, 10.4.21, 10.3.31, and 10.2.40. For more informati on, see MariaDB on Amazon RDS versions.	September 2, 2021
Amazon RDS has ended support for Oracle Database 18c	You can create DB instances only for Oracle Database 12c and Oracle Database 19c. If you have Oracle Database 18c snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.	August 17, 2021
Amazon RDS for PostgreSQ L now supports PostgreSQ L version 14 beta 2 in the database preview environme nt	For more about PostgreSQ L version 14 beta 1, see PostgreSQL 14 beta 1 release notes. For more about PostgreSQL version 14 beta 2, see PostgreSQL 14 beta 2 release notes. For informati on on the Database Preview Environment, see Working with the database preview environment.	August 9, 2021
Amazon RDS supports RDS Proxy in a shared VPC	You can now create an RDS Proxy in a shared VPC. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora User Guide.	August 6, 2021

Amazon RDS supports MariaDB 10.2.39	You can now create Amazon RDS DB instances running MariaDB versions 10.2.39. For more information, see MariaDB on Amazon RDS versions.	August 4, 2021
Amazon RDS for Oracle adds the `TIMEZONE_FILE_AUTOUPGRADE` option	With this option, you can upgrade the current time zone file to the latest version on your Oracle DB instance. For more information, see Oracle time zone file autoupgrade.	July 30, 2021
Amazon RDS extends support for cross-Region automated backups	You can now replicate DB snapshots and transaction logs between more AWS Regions. For more information, see Replicating automated backups to another AWS Region.	July 19, 2021
Support for MySQL 5.7.34	You can now create Amazon RDS DB instances running MySQL version 5.7.34. For more information, see MySQL on Amazon RDS versions.	July 8, 2021
Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions	RDS on Outposts now supports RDS for PostgreSQL versions 12.7 and 13.3. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	July 8, 2021

Amazon RDS for PostgreSQL supports oracle_fdw	You can now use the oracle_fdw extension to provide a foreign data wrapper for access to Oracle databases. For more informati on, see Accessing external data with the oracle_fdw extension.	July 8, 2021
Amazon RDS supports Oracle Management Agent (OMA) version 13.5	You can use Oracle Management Agent (OMA) version 13.5 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 5 and higher. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitorin g information. If you run OMS 13.5, you can manage databases by installing OMA 13.5. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	July 7, 2021

Amazon RDS for Oracle supports downloading logs from Amazon S3	If archived redo logs aren't on your instance but are protected by your backup retention period, you can use `rdsadmin.rdsadmin_archive_log_download` to download them from Amazon S3. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance. For more information, see Downloading archived redo logs from Amazon S3.	July 2, 2021
Amazon RDS supports MariaDB 10.4.18 and 10.5.9	You can now create Amazon RDS DB instances running MariaDB versions 10.4.18 and 10.5.9. For more information, see MariaDB on Amazon RDS versions.	June 30, 2021

Amazon RDS for Oracle supports Database Activity Streams	You can now monitor an Oracle DB instance using Database Activity Streams. An Oracle database writes audit records to the unified audit trail. When you start a database activity stream on an Oracle DB instance, Amazon Kinesis streams all activities that match the Oracle Database audit policies. For more information, see Monitoring Amazon RDS with Database Activity Streams.	June 23, 2021
Amazon RDS for Oracle introduces memory optimized instance classes	New Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For more information, see RDS for Oracle instance classes.	June 23, 2021
Support for MySQL 8.0.25	You can now create Amazon RDS DB instances running MySQL version 8.0.25. For more information, see MySQL on Amazon RDS versions.	June 18, 2021

Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions	RDS on Outposts now supports RDS for PostgreSQL versions 12.5, 12.6, 13.1, and 13.2. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	May 28, 2021
Amazon RDS supports MariaDB 10.2.37 and 10.3.28	You can now create Amazon RDS DB instances running MariaDB versions 10.2.37 and 10.3.28. For more information, see MariaDB on Amazon RDS versions.	May 27, 2021
Amazon RDS for Oracle supports multitenant container database (CDB)	A multitenant architecture enables an Oracle database to be a CDB. In Oracle Database 19c, your CDB can include a single PDB. The user experience with a PDB is mostly identical to the user experience with a non-CDB. For more information, see RDS for Oracle architecture.	May 25, 2021
Amazon RDS on AWS Outposts supports Amazon RDS for SQL Server	RDS on Outposts now supports Amazon RDS for SQL Server. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	May 11, 2021

Amazon RDS extends support for cross-Region automated backups	You can now configure Amazon RDS database instances running Microsoft SQL Server to replicate DB snapshots and transacti on logs to a different AWS Region. For more informati on, see Replicating automated backups to another AWS Region.	May 7, 2021
Amazon RDS supports cross-Region automated backups for encrypted DB instances	You can now replicate DB snapshots and transacti on logs to a different AWS Region for encrypted Amazon RDS database instances running Oracle or PostgreSQ L. For more information, see Replicating automated backups to another AWS Region.	May 3, 2021
Amazon RDS on AWS Outposts supports Amazon CloudWatch monitoring	RDS on Outposts now supports Amazon CloudWatc h monitoring. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	April 21, 2021
RDS for PostgreSQL supports AWS Lambda functions	You can now invoke AWS Lambda functions for your RDS for PostgreSQL DB instances. For more informati on, see Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance.	April 13, 2021

RDS for SQL Server supports extended events	You can use SQL Server extended events to capture debugging and troublesh ooting information. For more information, see Using extended events with Amazon RDS for Microsoft SQL Server.	April 8, 2021
Support for MySQL 8.0.23, 5.7.33, and 5.6.51	You can now create Amazon RDS DB instances running MySQL version 8.0.23, 5.7.33, and 5.6.51. For more information, see MySQL on Amazon RDS versions.	March 31, 2021
Automatic rollback on failed Amazon RDS for MySQL upgrade	If a DB instance upgrade from MySQL version 5.7 to MySQL version 8.0 fails, Amazon RDS rolls back the changes performed for the upgrade automatic ally. After the rollback, the MySQL DB instance is running MySQL version 5.7. For more information, see Rollback after failure to upgrade from MySQL 5.7 to 8.0.	March 18, 2021
Amazon RDS supports cross-Region read replicas in opt-in Regions	You can now replicate DB instances to opt-in Regions. For more information, see Creating a read replica in a different AWS Region.	March 18, 2021

Amazon RDS plans to deprecate Oracle Database 18c	Oracle Database 18c (18.0.0.0) is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 18c after the end-of-support date. On July 1, 2021, Amazon RDS plans to begin automatically upgrading Oracle Database 18c instances to Oracle Database 19c. Before the automatic upgrades begin, we highly recommend that you manually upgrade your existing Oracle Database 18c instances to Oracle Database 19c. For more information, see Preparing for the automatic upgrade of Oracle Database 18c.	March 11, 2021
Amazon RDS has ended support for Oracle Database 11g	You can only create DB instances for Oracle Database 12c Release 1 (12.1.0.2) and later. If you have Oracle Database 11g snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.	March 11, 2021

Amazon RDS supports continuous backups of DB instances in AWS Backup	You can now create automated backups in AWS Backup and restore DB instances from these backups to a specified time. For more information, see Using AWS Backup to manage automated backups.	March 10, 2021
Amazon RDS supports Oracle Management Agent (OMA) version 13.4	You can use Oracle Management Agent (OMA) version 13.4 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 4 Update 9. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.4, you can manage databases by installing OMA 13.4. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	March 10, 2021

RDS Proxy endpoint enhancements	You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.	March 8, 2021
Amazon RDS extends supports for cross-Region automated backups	You can now configure Amazon RDS database instances running PostgreSQL to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see Replicating automated backups to another AWS Region.	March 8, 2021

Replication filters for Amazon RDS for MariaDB and MySQL supported in the China (Beijing) Region and China (Ningxia) Region	Replication filtering is now supported in the China (Beijing) Region and China (Ningxia) Region. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.	March 5, 2021
Amazon RDS supports cross-Region DB snapshot copy in opt-in Regions	You can now copy DB snapshots to and from opt-in AWS Regions. For more information, see Copying snapshots across AWS Regions.	March 4, 2021
Amazon RDS for SQL Server supports Always On Availability Groups for Standard Edition	When you create a DB instance using the Multi-AZ configuration on SQL Server 2019 for the Standard Edition database engine, RDS automatically uses Availability Groups. For more information, see Multi-AZ deployments for Microsoft SQL Server.	February 23, 2021

Amazon RDS for Oracle introduces advisor-related procedures	The `rdsadmin_util` package includes the procedures `advisor_task_set_parameter` , `advisor_task_drop` , and `dbms_stats_init` . You can use these procedures to modify, stop, and re-enable advisor tasks such as `AUTO_STATS_ADVISOR_TASK` . For more information, see Setting parameters for advisor tasks.	February 23, 2021
Amazon RDS provides failover reasons for Multi-AZ DB instances	You can now see more detailed explanations when a Multi-AZ DB instance fails over to a standby replica. For more information, see Failover process for Amazon RDS.	February 18, 2021
Amazon RDS extends support for exporting snapshots to Amazon S3	You can now export DB snapshot data to Amazon S3 in China. For more information, see Exporting DB snapshot data to Amazon S3.	February 17, 2021

Replication filters for Amazon RDS for MariaDB and MySQL	You can configure replication filters for MySQL and MariaDB instances. Replication filters specify which databases and tables are replicated in a read replica. You can create lists of databases and tables to include or exclude for each read replica. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.	February 12, 2021
RDS for Oracle supports Oracle APEX 20.2v1	You can use Oracle APEX 20.2.v1 with all supported versions of Oracle Database. For more information, see Oracle Application Express.	February 2, 2021
Amazon RDS for SQL Server supports local instance storage for the tempdb database	You can now launch Amazon RDS for SQL Server on Amazon EC2 db.r5d and db.m5d instance types with the tempdb database configured to use an instance store. By placing tempdb data files and log files locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Instance store support for the tempdb database on Amazon RDS for SQL Server.	January 27, 2021

Amazon RDS for PostgreSQL supports pg_partman and pg_cron	Amazon RDS for PostgreSQL now supports the pg_partman and pg_cron extensions. For more information on the pg_partman extension, see Managing PostgreSQL partitions with the pg_partman extension. For more information on the pg_cron extension, see Scheduling maintenance with the PostgreSQL pg_cron extension.	January 12, 2021
Amazon RDS supports publishing the Oracle Management Agent log to Amazon CloudWatch Logs	The Oracle Management Agent log consists of emctl.log, emdctlj.log, gcagent.log, gcagent_errors.log, emagent.nohup, and secure.log. Amazon RDS publishes each of these logs as a separate CloudWatch log stream. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.	December 28, 2020
Amazon RDS on AWS Outposts supports additional database versions	RDS on Outposts now supports additional MySQL and PostgreSQL versions. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.	December 23, 2020

Amazon RDS on AWS Outposts supports CoIPs	RDS on Outposts now supports customer-owned IP addresses (CoIPs). CoIPs provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information, see Customer-owned IP addresses for RDS on Outposts.	December 22, 2020
Amazon RDS for Oracle plans upgrade of 11g BYOL instances to 19c	On January 4, 2021, we plan to begin automatically upgrading all editions of Oracle Database 11g instances on the Bring Your Own License (BYOL) model to Oracle Database 19c. All Oracle Database 11g instances, including reserved instances, will move to the latest available Release Update (RU). For more information, see Preparing for the automatic upgrade of Oracle Database 11g BYOL.	December 11, 2020

Amazon RDS supports replicating automated backups to another AWS Region	You can now configure your Amazon RDS database instances to replicate snapshots and transacti on logs to a destination AWS Region of your choice. For more information, see Replicating automated backups to another AWS Region.	December 4, 2020
Amazon RDS for Oracle and Microsoft SQL Server support a new DB instance class	You can now use the db.r5b instance class to create Amazon RDS DB instances running Oracle or SQL Server. For more information, see Supported DB engines for DB instance classes.	December 4, 2020
Support for MariaDB 10.2.32	You can now create Amazon RDS DB instances running MariaDB version 10.2.32. For more information, see MariaDB on Amazon RDS versions.	November 25, 2020
Amazon RDS for SQL Server supports the Microsoft Business Intelligence Suite on SQL Server 2019	You can now run SQL Server Analysis Services, SQL Server Integration Services, and SQL Server Reporting Services on DB instances using the latest major version. For more information, see Options for the Microsoft SQL Server database engine.	November 24, 2020

Amazon RDS for PostgreSQL version 13 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL version 13 in the database preview environment. For more information, see PostgreSQL 13 versions.	November 24, 2020
Amazon RDS Performance Insights introduces new dimensions	You can group database load according to the dimension groups for database (PostgreSQL, MySQL, and MariaDB), application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name (PostgreSQL, MySQL, and MariaDB), db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see Top load table.	November 24, 2020
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.5. For more information, see MariaDB on Amazon RDS versions.	November 23, 2020
Support for MySQL 5.6.49	You can now create Amazon RDS DB instances running MySQL version 5.6.49. For more information, see MySQL on Amazon RDS versions.	November 20, 2020

Support for MySQL 5.5.62	You can now create Amazon RDS DB instances running MySQL version 5.5.62. For more information, see MySQL on Amazon RDS versions.	November 20, 2020
Performance Insights supports analyzing statistics for running PostgreSQL queries	You can now analyze statistics for running queries with Performance Insights for PostgreSQL DB instances. For more information, see Statistics for PostgreSQL.	November 18, 2020
Amazon RDS extends support for storage autoscaling	You can now enable storage autoscaling when creating a read replica, restoring a DB instance to a specified time, or restoring a MySQL DB instance from an Amazon S3 backup. For more information, see Managing capacity automatically with Amazon RDS storage autoscaling.	November 18, 2020
Amazon RDS for SQL Server supports Database Mail	With Database Mail you can send email messages from your Amazon RDS for SQL Server database instance. After specifying the email recipients, you can add files or query results to the message you send. For more information, see Using Database Mail on Amazon RDS for SQL Server.	November 4, 2020

Support for MySQL 8.0.21	You can now create Amazon RDS DB instances running MySQL version 8.0.21. For more information, see MySQL on Amazon RDS versions.	October 22, 2020
Amazon RDS extends support for exporting snapshots to Amazon S3	You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see Exporting DB snapshot data to Amazon S3.	October 22, 2020
Amazon RDS for PostgreSQL supports read replica upgrades	With Amazon RDS for PostgreSQL, when you do a major version upgrade of the primary DB instance, read replicas are also automatically upgraded. For more information, see Upgrading the PostgreSQL DB engine.	October 15, 2020
Amazon RDS for MariaDB, MySQL and PostgreSQL support the Graviton2 DB instance classes	You can now use the Graviton2 DB instance classes db.m6g.x and db.r6g.x to create Amazon RDS DB instances running MariaDB, MySQL or PostgreSQL. For more information, see Supported DB Engines for All Available DB instance Classes.	October 15, 2020

Amazon RDS for SQL Server supports upgrades to SQL Server 2019	You can upgrade your SQL Server DB instances to SQL Server 2019. For more information, see Upgrading the Microsoft SQL Server DB Engine.	October 6, 2020
Amazon RDS for Oracle supports specifying the national character set	The national character set, also called the NCHAR character set, is used in the NCHAR, NVARCHAR2 , and NCLOB data types. When you create a database, you can specify either AL16UTF16 (default) or UTF8 as the NCHAR character set. For more information, see Oracle character sets supported in Amazon RDS.	October 2, 2020
Support for MySQL 5.7.31	You can now create Amazon RDS DB instances running MySQL version 5.7.31. For more information, see MySQL on Amazon RDS versions.	October 1, 2020
Amazon RDS for PostgreSQL supports exporting data to Amazon S3	You can query data from a PostgreSQL DB instance and export it directly into files stored in an Amazon S3bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3.	September 24, 2020

Amazon RDS for MySQL 8.0 supports Percona XtraBackup	You can now use Percona XtraBackup to restore a backup into an Amazon RDS for MySQL 8.0 DB instance. For more information, see Restoring a backup into a MySQL DB instance.	September 17, 2020
Amazon RDS for SQL Server supports native backup and restore on DB instances with read replicas	You can restore a SQL Server native backup onto a DB instance that has read replicas configured. For more information, see Importing and exporting SQL Server databases.	September 16, 2020
Amazon RDS for SQL Server supports additional time zones	You can match your DB instance time zone with your chosen time zone. For more information, see Local time zone for Microsoft SQL Server DB instances.	September 11, 2020
Amazon RDS for PostgreSQL version 13 beta 3 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 3 in the Database Preview Environment. For more information, see PostgreSQL 13 versions.	September 9, 2020

Amazon RDS for SQL Server supports trace flag 692	You can now use trace flag 692 as a startup parameter using DB parameter gro ups. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes. For more information, see Disabling fast inserts during bulk loading.	August 27, 2020
Amazon RDS for SQL Server supports Microsoft SQL Server 2019	You can now create RDS DB instances that use SQL Server 2019. For more informati on, see Microsoft SQL Server versions on Amazon RDS.	August 26, 2020
RDS for Oracle supports mounted replica database	When creating or modifying an Oracle replica, you can place it in mounted mode. Because the replica database doesn't accept user connectio ns, it can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see Overview of Oracle replicas.	August 13, 2020

RDS for Oracle plans upgrade of 11g SE1 LI instances	On November 1, 2020, we plan to begin automatically upgrading Oracle Database 11g SE1 License Included (LI) instances to Oracle Database 19c for Amazon RDS for Oracle. All 11g instances, including reserved instances, will move to the latest available Oracle Release Update (RU). For more information, see Preparing for the automatic upgrade of Oracle Database 11g SE1.	July 31, 2020
Amazon RDS supports new Graviton2 DB instance classes in preview release for PostgreSQL and MySQL	You can now create Amazon RDS DB instances running PostgreSQL or MySQL that use the db.m6g.x and db.r6g.x DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	July 30, 2020
RDS for Oracle supports Oracle APEX 20.1v1	You can use Oracle APEX 20.1v1 with all supported versions of Oracle Database. For more information, see Oracle application Express.	July 28, 2020
Support for MySQL 8.0.20	You can now create Amazon RDS DB instances running MySQL version 8.0.20. For more information, see MySQL on Amazon RDS versions.	July 23, 2020

Amazon RDS for MariaDB and MySQL support new DB instance classes	You can now create Amazon RDS DB instances running MariaDB and MySQL that use the db.m5.16xlarge, db.m5.8xlarge, db.r5.16x large, and db.r5.8xlarge DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	July 23, 2020
RDS for SQL Server supports disabling old versions of TLS and ciphers	You can turn certain security protocols and ciphers on and off. For more information, see Configuring security protocols and ciphers.	July 21, 2020
RDS supports Oracle Spatial on SE2	You can use Oracle Spatial in Standard Edition 2 (SE2) for all versions of 12.2, 18c, and 19c. For more information, see Oracle Spatial.	July 9, 2020
Amazon RDS supports AWS PrivateLink	Amazon RDS now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Amazon RDS in the AWS network. For more informat ion, see Amazon RDS and interface VPC endpoints (AWS PrivateLink).	July 9, 2020

Amazon RDS for PostgreSQL versions 9.4.x has reached its end of support.	Amazon RDS for PostgreSQL no longer supports versions 9.4.x. For supported versions, see Supported PostgreSQL database versions.	July 8, 2020
Support for MariaDB 10.3.23 and 10.4.13	You can now create Amazon RDS DB instances running MariaDB version 10.3.23 and 10.4.13. For more informati on, see MariaDB on Amazon RDS versions.	July 6, 2020
Amazon RDS on AWS Outposts	You can create Amazon RDS DB instances on AWS Outposts. For more informati on, see Working with Amazon RDS on AWS Outposts.	July 6, 2020
Amazon RDS for Oracle creates inventory files automatically	To open service requests for BYOL customers, Oracle Support requests inventory files generated by Opatch. Amazon RDS for Oracle automatically creates inventory files every hour in the BDUMP directory. For more information, see Accessing Opatch files.	July 6, 2020
Support for MySQL 5.7.30 and 5.6.48	You can now create Amazon RDS DB instances running MySQL version 5.7.30 and 5.6.48. For more information, see MySQL on Amazon RDS versions.	June 25, 2020

Amazon RDS for Oracle supports ADRCI	The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. By using the functions in the Amazon RDS package `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. For more information, see Common DBA diagnostic tasks for Oracle DB instances.	June 17, 2020
Support for MySQL 8.0.19	You can now create Amazon RDS DB instances running MySQL version 8.0.19. For more information, see MySQL on Amazon RDS versions.	June 2, 2020
MySQL 8.0 supports lower case table names	You can now set the `lower_case_table_names` parameter to 1 for Amazon RDS DB instances running MySQL version 8.0.19 and higher 8.0 versions. For more information, see MySQL parameter exceptions for Amazon RDS DB instances.	June 2, 2020

Amazon RDS for Microsoft SQL Server supports SQL Server Integration Services (SSIS)	SSIS is a platform for data integration and workflow applications. You can enable SSIS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see Support for SQL Server Integration Services in SQL Server.	May 19, 2020
Amazon RDS for Microsoft SQL Server supports SQL Server Reporting Services (SSRS)	SSRS is a server-based application used for report generation and distribut ion. You can enable SSRS on existing or new DB instances . It's installed on the same DB instance as your database engine. For more information, see Support for SQL Server Reporting Services in SQL Server.	May 15, 2020
Amazon RDS for Microsoft SQL Server supports S3 integration on Multi-AZ instances	You can now use Amazon S3 with SQL Server features such as bulk insert on Multi-AZ DB instances. For more information, see Integrati ng an Amazon RDS for SQL Server DB instance with Amazon S3.	May 15, 2020

Amazon RDS for Oracle supports purging the recycle bin	The `rdsadmin.rdsadmin_util.purge_dba_recyclebin` procedure purges the recycle bin. For more information, see Purging the recycle bin.	May 13, 2020
Amazon RDS for Oracle improves manageability of Automatic Workload Repository (AWR)	The `rdsadmin.rdsadmin_diagnostic_util` procedures generate AWR reports and extract AWR data into dump files. For more information, see Generating performance reports with Automatic Workload Repository (AWR).	May 13, 2020
Amazon RDS for Microsoft SQL Server supports Microsoft Distributed Transaction Coordinator (MSDTC)	Amazon RDS for SQL Server supports distributed transactions between hosts. For more information, see Support for Microsoft Distributed Transaction Coordinator in SQL Server.	May 4, 2020
Amazon RDS for Microsoft SQL Server supports new versions	You can now create Amazon RDS DB instances running SQL Server versions 2017 CU19 14.00.3281.6, 2016 SP2 CU11 13.00.5598.27, 2014 SP3 CU4 12.00.6329.1, and 2012 SP4 GDR 11.0.7493.4 for all editions. For more information, see Microsoft SQL Server versions on Amazon RDS.	April 28, 2020

Amazon RDS available in the Europe (Milan) Region	Amazon RDS is now available in the Europe (Milan) Region. For more information, see Regions and Availability Zones.	April 28, 2020
Amazon RDS support for Local Zones	You can now launch DB instances into a Local Zone subnet. For more information, see Regions, Availability Zones, and Local Zones.	April 23, 2020
Amazon RDS available in the Africa (Cape Town) Region	Amazon RDS is now available in the Africa (Cape Town) Region. For more information, see Regions and Availability Zones.	April 22, 2020
Amazon RDS for Microsoft SQL Server supports SQL Server Analysis Services (SSAS)	SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You can enable SSAS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see Support for SQL Server Analysis Services in SQL Server.	April 17, 2020

Amazon RDS proxy for PostgreSQL	Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your DB instance and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see Managing connections with Amazon RDS proxy (preview).	April 8, 2020
Amazon RDS for Oracle supports Oracle APEX version 19.2.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.2.v1. For more information, see Oracle application Express.	April 8, 2020
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.4. For more information, see MariaDB on Amazon RDS versions.	April 6, 2020
Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.4	Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.4. For more information, see Using Amazon RDS performance insights.	April 6, 2020

Amazon RDS for PostgreSQL versions 9.3.x has reached its end of support	Amazon RDS for PostgreSQL no longer supports versions 9.3.x. For supported versions, see Supported PostgreSQL database versions.	April 3, 2020
Amazon RDS for Microsoft SQL Server supports read replicas	You can now create read replicas for SQL Server DB instances. For more informati on, see Working with read replicas.	April 3, 2020
Amazon RDS for Microsoft SQL Server supports multifile backups	You can now back up databases to multiple files using SQL Server native backup and restore. For more information, see Backing up a database.	April 2, 2020
Amazon RDS for Oracle integration with AWS License Manager	Amazon RDS for Oracle is now integrated with AWS License Manager. If you use the Bring Your Own License model, AWS License Manager integration makes it easier to monitor your Oracle license usage within your organizat ion. For more information, see Integrating with AWS License Manager.	March 23, 2020

Support for 64 TiB on db.r5 instances in Amazon RDS for MariaDB and MySQL	You can now create Amazon RDS DB instances for MariaDB and MySQL that use the db.r5 DB instance class with up to 64 TiB of storage. For more information, see Factors that affect storage performance.	March 18, 2020
Support for MySQL 8.0.17	You can now create Amazon RDS DB instances running MySQL version 8.0.17. For more information, see MySQL on Amazon RDS versions.	March 10, 2020
Amazon RDS Performance Insights is available for Amazon RDS for MySQL 8.0	Amazon RDS Performance Insights is now available for Amazon RDS for MySQL version 8.0.17 and higher 8.0 versions. For more information, see Using Amazon RDS performance insights.	March 10, 2020
Support for MySQL 5.6.46	You can now create Amazon RDS DB instances running MySQL version 5.6.46. For more information, see MySQL on Amazon RDS versions.	February 28, 2020

Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.3	Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.3.13 and higher 10.3 versions. For more information, see Using Amazon RDS performance insights.	February 26, 2020
Support for MySQL 5.7.28	You can now create Amazon RDS DB instances running MySQL version 5.7.28. For more information, see MySQL on Amazon RDS versions.	February 20, 2020
Support for MariaDB 10.3.20	You can now create Amazon RDS DB instances running MariaDB version 10.3.20. For more information, see MariaDB on Amazon RDS versions.	February 20, 2020
Amazon RDS for Microsoft SQL Server supports a new DB instance class	You can now create Amazon RDS DB instances running SQL Server that use the db.z1d DB instance class. For more information, see DB instance class support for Microsoft SQL Server.	February 19, 2020

Support for cross-account, cross-VPC Active Directory domains in Amazon RDS for SQL Server	Amazon RDS for Microsoft SQL Server now supports associating DB instances with Active Directory domains owned by different accounts and VPCs. For more information, see Using Windows authentication with a Microsoft SQL Server DB instance.	February 13, 2020
Oracle OLAP option	Amazon RDS for Oracle now supports the On-line Analytical Processing (OLAP) option for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see Oracle OLAP.	February 13, 2020
FIPS 140-2 support for Oracle	Amazon RDS for Oracle supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see FIPS support.	February 11, 2020

Amazon RDS for PostgreSQL supports new DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.m5.16xlarge, db.m5.8xlarge, db.r5.16xlarge, and db.r5.8xlarge DB instance classes. For more information, see Supported DB engines for all available DB instance classes.	February 11, 2020
Performance Insights supports analyzing statistics of running MariaDB and MySQL queries	You can now analyze statistics of running queries with Performance Insights for MariaDB and MySQL DB instances. For more information, see Analyzing statistics of running queries.	February 4, 2020
Support for exporting DB snapshot data to Amazon S3 for MariaDB, MySQL, and PostgreSQL	Amazon RDS supports exporting DB snapshot data to Amazon S3 for MariaDB, MySQL, and PostgreSQL. For more information, see Exporting DB snapshot data to Amazon S3.	January 23, 2020
Amazon RDS for MySQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS for MySQL DB instances. For more information, see Using Kerberos authentication for MySQL.	January 21, 2020

Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS for Microsoft SQL Server	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS for Microsoft SQL Server DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	December 17, 2019
Amazon RDS proxy	You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the RDS for MySQL database engine. For more information, see Managing connections with Amazon RDS proxy (preview).	December 3, 2019

Amazon RDS on AWS Outposts (preview)	With Amazon RDS on AWS Outposts, you can create AWS-managed relational databases in your on-premises data centers. RDS on Outposts enables you to run RDS databases on AWS Outposts. For more information, see Amazon RDS on AWS Outposts (preview).	December 3, 2019
Amazon RDS for Oracle supports cross-region read replicas	Amazon RDS for Oracle now supports cross-region read replicas with Active Data Guard. For more information, see Working with read replicas and Working with Oracle read replicas.	November 26, 2019
Performance Insights supports analyzing statistics of running Oracle queries	You can now analyze statistics of running queries with Performance Insights for Oracle DB instances. For more information, see Analyzing statistics of running queries.	November 25, 2019
Amazon RDS for Microsoft SQL Server supports publishing logs to CloudWatch Logs	You can configure your Amazon RDS for SQL Server DB instance to publish log events directly to Amazon CloudWatch Logs. For more information, see Publishing SQL Server logs to Amazon CloudWatch Logs.	November 25, 2019

Amazon RDS for Microsoft SQL Server supports new DB instance classes	You can now create Amazon RDS DB instances running SQL Server that use the db.x1e and db.x1 DB instance classes. For more information, see DB instance class support for Microsoft SQL Server.	November 25, 2019
Amazon RDS for Microsoft SQL Server supports differential and log restores	You can restore differential backups and logs using SQL Server native backup and restore. For more information, see Using native backup and restore.	November 25, 2019
Multi-AZ supported on Amazon RDS for Microsoft SQL Server in new regions	Multi-AZ on SQL Server is now available in China, Middle East (Bahrain), and Europe (Stockholm). For more information, see Multi-AZ deployments for Microsoft SQL Server.	November 22, 2019
Amazon RDS for Microsoft SQL Server now supports bulk insert and S3 integration	You can transfer files between a SQL Server DB instance and an Amazon S3 bucket. Then you can use Amazon S3 with SQL Server features such as bulk insert. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3.	November 21, 2019

Performance Insights counters for Amazon RDS for Microsoft SQL Server	You can now add performance counters to your Performance Insights charts for Microsoft SQL Server DB instances. For more information, see Performance Insights counters for Amazon RDS for Microsoft SQL Server.	November 12, 2019
Amazon RDS for Microsoft SQL Server supports new DB instance class sizes	You can now create Amazon RDS DB instances running SQL Server that use the 8xlarge and 16xlarge instance sizes for the db.m5 and db.r5 DB instance classes. Instance sizes ranging from small to 2xlarge are now available for the db.t3 instance class. For more information, see DB instance class support for Microsoft SQL Server.	November 11, 2019
Support for PostgreSQL snapshot upgrades	If you have existing manual DB snapshots of your Amazon RDS PostgreSQL DB instances, you can now upgrade them to a later version of the PostgreSQL database engine. For more information, see Upgrading a PostgreSQL DB snapshot.	November 7, 2019

Amazon RDS for Oracle supports a new major version	You can now create Amazon RDS DB instances running Oracle Database 19c (19.0). For more information, see Oracle Database 19c with Amazon RDS.	November 7, 2019
Amazon RDS for PostgreSQL version 12.0 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 12.0 in the Database Preview Environment. For more information, see PostgreSQL version 12.0 in the database preview environment.	November 1, 2019
Amazon RDS for PostgreSQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running PostgreSQL. For more information, see Using Kerberos authentication with Amazon RDS for PostgreSQL.	October 28, 2019
OEM Management Agent database tasks for Oracle DB instances	Amazon RDS for Oracle DB instances now support procedures to invoke certain EMCTL commands on the Management Agent. For more information, see OEM agent database tasks.	October 24, 2019

Amazon RDS for PostgreSQL supports PostgreSQL transportable databases	PostgreSQL Transportable Databases provide an extremely fast method of migrating an RDS PostgreSQL database between two DB instances. For more information, see Transporting PostgreSQL databases between DB instances.	October 8, 2019
Amazon RDS for Oracle supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running Oracle. For more information, see Using Kerberos authentication with Amazon RDS for Oracle.	September 30, 2019
Amazon RDS for PostgreSQL version 12 beta 3 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 12 Beta 3 in the Database Preview Environment. For more information, see PostgreSQL version 12 beta 3 on Amazon RDS in the database preview environment.	August 28, 2019
Support for MySQL 8.0.16	You can now create Amazon RDS DB instances running MySQL version 8.0.16. For more information, see MySQL on Amazon RDS versions.	August 19, 2019

Amazon RDS for Oracle supports a new major version	You can now create Amazon RDS DB instances running Oracle Database 18c (18.0). For more information, see Oracle Database 18c with Amazon RDS.	August 15, 2019
Management Agent for OEM 13c release 3	Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c Release 3. For more information, see Oracle Management Agent for Enterprise Manager cloud control.	August 7, 2019
Amazon RDS for PostgreSQL version 12 beta 2 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 12 Beta 2 in the Database Preview Environment. For more information, see PostgreSQL version 12 beta 2 on Amazon RDS in the database preview environment.	August 6, 2019
Amazon RDS supports server collations for SQL Server	Amazon RDS for SQL Server supports a selection of collations for new DB instances. For more information, see Collations and character sets for Microsoft SQL Server.	July 29, 2019

Amazon RDS for Oracle supports Oracle APEX version 19.1.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.1.v1. For more information, see Oracle application Express.	June 28, 2019
Amazon RDS for PostgreSQL version 13 beta 1 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 1 in the Database Preview Environment. For more information, see PostgreSQL 13 versions.	June 22, 2019
Amazon RDS storage autoscaling	Storage autoscaling for Amazon RDS DB instances enables Amazon RDS to automatically expand the storage associated with a DB instance to reduce the chance of out-of-space conditions. For information about storage autoscaling, see Working with storage for Amazon RDS DB instances.	June 20, 2019
Amazon RDS for Oracle supports db.z1d DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.z1d DB instance classes. For more information, see DB instance class.	June 13, 2019

Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS for Oracle	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS for Oracle DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	June 10, 2019
Amazon RDS adds support native restores of SQL Server databases up to 16 TB	You can now do native restores of up to 16 TB from SQL Server to Amazon RDS. For more information, see Amazon RDS for SQL Server: Limitations and recommendations.	June 4, 2019
Amazon RDS adds support for Microsoft SQL Server audit	Using Amazon RDS for Microsoft SQL Server, you can audit server and database level events using SQL Server Audit, and view the results on your DB instance or send the audit log files directly to Amazon S3. For more information, see SQL Server Audit.	May 23, 2019

Improvements to Amazon RDS recommendations	Amazon RDS has improved its automated recommendations for database resources. For example, Amazon RDS now provides recommendations for database parameters. For more information, see Using Amazon RDS recommendations.	May 22, 2019
Support for more databases per DB instance for Amazon RDS for SQL Server	You can create up to 30 databases on each of your DB instances running Microsoft SQL Server. For more information, see Limits for Microsoft SQL Server DB instances.	May 21, 2019
Support for 64 TiB and 80k IOPS of storage for Amazon RDS for MariaDB, MySQL and PostgreSQL	You can now create Amazon RDS DB instances for MariaDB, MySQL and PostgreSQL with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see DB instance storage.	May 20, 2019
Amazon RDS for MySQL supports upgrade prechecks	When you upgrade a DB instance from MySQL 5.7 to MySQL 8.0, Amazon RDS performs prechecks for incompatibilities. For more information, see Prechecks for upgrades from MySQL 5.7 to 8.0.	May 17, 2019

Support for the MySQL password validation plugin	You can now use the MySQL `validate_password` plugin for improved security of Amazon RDS for MySQL DB instances. For more information, see Using the Password Validation Plugin.	May 16, 2019
Performance Insights counters for Amazon RDS for Oracle	You can now add performance counters to your Performance Insights charts for Oracle DB instances. For more information, see Performance Insights counters for Amazon RDS for Oracle.	May 8, 2019
Support for per-second billing	Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see DB instance billing for Amazon RDS.	April 25, 2019
Support for importing data from Amazon S3 for Amazon RDS for PostgreSQL	You can now import data from Amazon S3 file into a table in an RDS PostgreSQL DB instance. For more information, see Importing Amazon S3 data into an RDS PostgreSQL DB instance.	April 24, 2019

Support for restoring 5.7 backups from Amazon S3	You can now create a backup of your MySQL version 5.7 database, store it on A mazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see Restoring a backup into a MySQL DB instance.	April 17, 2019
Support for multiple major version upgrades for Amazon RDS for PostgreSQL	With Amazon RDS for PostgreSQL, you can now choose from multiple major versions when you upgrade the DB engine. This feature enables you to skip ahead to a newer major version when you upgrade select PostgreSQ L engine versions. For more information, see Upgrading the PostgreSQL DB engine.	April 16, 2019
Support for 64 TiB of storage for Amazon RDS for Oracle	You can now create Amazon RDS DB instances for Oracle with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see DB instance storage.	April 4, 2019
Support for MySQL 8.0.15	You can now create Amazon RDS DB instances running MySQL version 8.0.15. For more information, see MySQL on Amazon RDS versions.	April 3, 2019

Support for MariaDB 10.3.13	You can now create Amazon RDS DB instances running MariaDB version 10.3.13. For more information, see MariaDB on Amazon RDS versions.	April 3, 2019
Microsoft SQL Server 2008 R2 has reached its end of support on Amazon RDS	Microsoft SQL Server 2008 R2 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 9, 2019. Any existing Microsoft SQL Server 2008 R2 snapshots are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2012 starting on June 1, 2019. For more information, see Microsoft SQL Server 2008 R2 support on Amazon RDS .	April 2, 2019
Always On availability groups supported in Microsoft SQL Server 2017	You can now use Always On Availability Groups in SQL Server 2017 Enterprise Edition 14.00.3049.1 or later. For more information, see Multi-AZ deployments for Microsoft SQL Server.	March 29, 2019

View volume metrics	You can now view metrics for the Amazon Elastic Block Store (Amazon EBS) volumes, which are the physical devices used for database and log storage. For more informati on, see Viewing Enhanced Monitoring.	March 20, 2019
Support for MySQL 5.7.25	You can now create Amazon RDS DB instances running MySQL version 5.7.25. For more information, see MySQL on Amazon RDS versions.	March 19, 2019
Amazon RDS for Oracle supports RMAN DBA tasks	Amazon RDS for Oracle now supports Oracle Recovery Manager (RMAN) DBA tasks, including RMAN backups. For more information, see Common DBA Recovery Manager (RMAN) tasks for Oracle DB instances.	March 14, 2019
Amazon RDS for PostgreSQL supports version 11.1	You can now create Amazon RDS DB instances running PostgreSQL version 11.1. For more information, see PostgreSQL version 11.1 on Amazon RDS.	March 12, 2019
Multiple-file restore is available in Amazon RDS for SQL Server	You can now restore from multiple files with Amazon RDS for SQL Server. For more information, see Restoring a database.	March 11, 2019

MariaDB 10.2.21	You can now create Amazon RDS DB instances running MariaDB version 10.2.21. For more information, see MariaDB on Amazon RDS versions.	March 11, 2019
Amazon RDS for Oracle supports read replicas	Amazon RDS for Oracle now supports read replicas with Active Data Guard. For more information, see Working with read replicas and Working with Oracle read replicas.	March 11, 2019
Amazon RDS Performance Insights is available for Amazon RDS for MariaDB	Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB. For more information, see Using Amazon RDS Performance Insights.	March 11, 2019
MySQL 8.0.13 and 5.7.24	You can now create Amazon RDS DB instances running MySQL versions 8.0.13 and 5.7.24. For more information, see MySQL on Amazon RDS versions.	March 8, 2019
Amazon RDS Performance Insights is available for Amazon RDS for SQL Server	Amazon RDS Performance Insights is now available for Amazon RDS for SQL Server. For more information, see Using Amazon RDS Performance Insights.	March 4, 2019

Amazon RDS for Oracle supports Amazon S3 integration	You can now transfer files between an Amazon RDS for Oracle DB instance and an Amazon S3 bucket. For more information, see Integrating Amazon RDS for Oracle and Amazon S3.	February 26, 2019
Amazon RDS for MySQL and Amazon RDS for MariaDB support db.t3 DB instance classes	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.t3 DB instance classes. For more information, see DB instance class.	February 20, 2019
Amazon RDS for MySQL and Amazon RDS for MariaDB support db.r5 DB instance classes	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.r5 DB instance classes. For more information, see DB instance class.	February 20, 2019
Performance Insights counters for RDS for MySQL and PostgreSQL	You can now add performance counters to your Performance Insights charts for MySQL and PostgreSQL DB instances. For more information, see Performance Insights dashboard components.	February 19, 2019

Amazon RDS for PostgreSQL now supports adaptive autovacuum parameter tuning	Adaptive autovacuum parameter tuning with Amazon RDS for PostgreSQL helps prevent transaction ID wraparound by adjusting autovacuum parameter values automatically. For more information, see Reducing the likelihood of transaction ID wraparound.	February 12, 2019
Amazon RDS for Oracle supports Oracle APEX versions 18.1.v1 and 18.2.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) versions 18.1.v1 and 18.2.v1. For more information, see Oracle application Express.	February 11, 2019
Amazon RDS Performance Insights supports viewing more SQL text for RDS for MySQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for MySQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	February 6, 2019
Amazon RDS for PostgreSQL supports db.t3 DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.t3 DB instance classes. For more information, see DB instance class.	January 25, 2019

Amazon RDS for Oracle supports db.t3 DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.t3 DB instance classes. For more information, see DB instance class.	January 25, 2019
Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS PostgreSQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS PostgreSQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	January 24, 2019
Amazon RDS for Oracle supports a new version of SQLT	Amazon RDS for Oracle now supports SQLT version 12.2.180725. For more information, see Oracle SQLT.	January 22, 2019
Amazon RDS for PostgreSQL supports db.r5 DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.r5 DB instance classes. For more information, see DB instance class.	December 19, 2018

Amazon RDS for PostgreSQL now supports restricted password management	Amazon RDS for PostgreSQL enables you to restrict who can manage user passwords and password expiration changes by using the parameter `rds.restrict_password_commands` and the role `rds_password`. For more information, see Restricting password management.	December 19, 2018
Amazon RDS for PostgreSQL supports uploading database logs to Amazon CloudWatch Logs	Amazon RDS for PostgreSQL supports uploading database logs to CloudWatch Logs. For more information, see Publishing PostgreSQL logs to CloudWatch Logs.	December 10, 2018
Amazon RDS for Oracle supports db.r5 DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.r5 DB instance classes. For more information, see DB instance class.	November 20, 2018
Retain backups when deleting a DB instance	Amazon RDS supports retaining automated backups when you delete a DB instance. For more information, see Working with backups.	November 15, 2018

Amazon RDS for PostgreSQL supports db.m5 DB instance classes	You can now create Amazon RDS DB instances running PostgreSQL that use the db.m5 DB instance classes. For more information, see DB instance class.	November 15, 2018
Amazon RDS for Oracle supports a new major version	You can now create Amazon RDS DB instances running Oracle version 12.2.	November 13, 2018
Amazon RDS for SQL Server supports Always On	Amazon RDS for SQL Server supports Always On Availability Groups. For more information, see Multi-AZ deployments for Microsoft SQL Server.	November 8, 2018
Amazon RDS for PostgreSQL supports outbound network access using custom DNS servers	Amazon RDS for PostgreSQL supports outbound network access using custom DNS servers. For more informati on, see Using a custom DNS server for outbound network access.	November 8, 2018
Amazon RDS for MariaDB, MySQL, and PostgreSQL supports 32 TiB of storage	You can now create Amazon RDS DB instances with up to 32 TiB of storage for MySQL, MariaDB, and PostgreSQL. For more information, see DB instance storage.	November 7, 2018

Amazon RDS for Oracle supports extended data types	You can now enable extended data types on Amazon RDS DB instances running Oracle. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. For more information, see Using extended data types.	November 6, 2018
Amazon RDS for Oracle supports db.m5 DB instance classes	You can now create Amazon RDS DB instances running Oracle that use the db.m5 DB instance classes. For more information, see DB instance class.	November 2, 2018
Amazon RDS for Oracle migration from SE, SE1, or SE2 to EE	You can now migrate from any Oracle Database Standard Edition (SE, SE1, or SE2) to Oracle Database Enterprise Edition (EE). For more information, see Migrating between Oracle editions.	October 31, 2018
Amazon RDS can now stop Multi-AZ instances	Amazon RDS can now stop a DB instance that is part of a Multi-AZ deployment. Formerly, the stop instance feature had a limitation for multi-AZ instances. For more information, see Stopping an Amazon RDS DB instance temporarily.	October 29, 2018

Amazon RDS Performance Insights is available for Amazon RDS for Oracle	Amazon RDS Performance Insights is now available for Amazon RDS for Oracle. For more information, see Using Amazon RDS Performance Insights.	October 29, 2018
Amazon RDS for PostgreSQL supports PostgreSQL version 11 in the database preview environment	Amazon RDS for PostgreSQL now supports PostgreSQL version 11 in the Database Preview Environment. For more information, see PostgreSQL version 11 on Amazon RDS in the database preview environment.	October 25, 2018
MySQL supports a new major version	You can now create Amazon RDS DB instances running MySQL version 8.0. For more information, see MySQL on Amazon RDS versions.	October 23, 2018
MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.3. For more information, see MariaDB on Amazon RDS versions.	October 23, 2018
Amazon RDS for Oracle supports Oracle JVM	Amazon RDS for Oracle now supports the Oracle Java Virtual Machine (JVM) option. For more information, see Oracle Java virtual machine.	October 16, 2018

Custom parameter group for restore and point in time recovery	You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see Restoring from a DB snapshot and Restoring a DB instance to a specified time.	October 15, 2018
Amazon RDS for Oracle supports 32 TiB storage	You can now create Oracle RDS DB instances with up to 32 TiB of storage. For more information, see DB instance storage.	October 15, 2018
Amazon RDS for MySQL supports GTIDs	Amazon RDS for MySQL now supports global transaction identifiers (GTIDs), which are unique across all DB instances and in a replication configuration. For more information, see Using GTID-based replication for RDS for MySQL.	October 10, 2018
MySQL 5.7.23, 5.6.41, and 5.5.61	You can now create Amazon RDS DB instances running MySQL versions 5.7.23, 5.6.41, and 5.5.61. For more information, see MySQL on Amazon RDS versions.	October 8, 2018
Amazon RDS for Oracle supports a new version of SQLT	Amazon RDS for Oracle now supports SQLT version 12.2.180331. For more information, see Oracle SQLT.	October 4, 2018

Amazon RDS for PostgreSQL now supports IAM authentication	Amazon RDS for PostgreSQL now supports IAM authentication. For more information see IAM database authentication for MySQL and PostgreSQL.	September 27, 2018
You can enable deletion protection for your Amazon RDS DB instances	When you enable deletion protection for a DB instance, the database cannot be deleted by any user. For more information, see Deleting a DB instance.	September 26, 2018
Amazon RDS for MySQL and Amazon RDS for MariaDB support db.m5 DB instance classes	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.m5 DB instance classes. For more information, see DB instance class.	September 18, 2018
Amazon RDS now supports upgrades to SQL Server 2017	You can upgrade your existing DB instance to SQL Server 2017 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions first. For information, see Upgrading the Microsoft SQL Server DB engine.	September 11, 2018

Amazon RDS for PostgreSQL now supports PostgreSQL version 11 beta 3 in the database preview environment	In this release, the Write-Ahead Log (WAL) segment size (wal_segment_size) is now set to 64MB. For more about PostgreSQL version 11 Beta 3, see PostgreSQL 11 beta 3 released. For information on the Database Preview Environment, see Working with the database preview environment.	September 7, 2018
Amazon Aurora User Guide	The *Amazon Aurora User Guide* describes all Amazon Aurora concepts and provides instructions on using the various features with both the console and the command line interface. The *Amazon RDS User Guide* now covers non-Aurora database engines.	August 31, 2018
Amazon RDS Performance Insights is available for RDS for MySQL	Amazon RDS Performance Insights is now available for RDS for MySQL. For more information, see Using Amazon RDS Performance Insights.	August 28, 2018
Aurora PostgreSQL-Compatible Edition now supports Aurora Auto Scaling	Auto Scaling of Aurora replicas is now available for Aurora PostgreSQL-Compatible Edition. For more information, see Amazon Aurora auto scaling with Aurora replicas.	August 16, 2018

Aurora Serverless for Aurora MySQL	Aurora Serverless is an on-demand, autoscaling configuration for Amazon Aurora. For more information, see Using Amazon Aurora Serverless.	August 9, 2018
MySQL 5.7.22 and 5.6.40	You can now create Amazon RDS DB instances running MySQL versions 5.7.22 and 5.6.40. For more information, see MySQL on Amazon RDS versions.	August 6, 2018
Aurora is now available in the China (Ningxia) region	Aurora MySQL and Aurora PostgreSQL are now available in the China (Ningxia) region. For more information, see Availability for Amazon Aurora MySQL and Availability for Amazon Aurora PostgreSQL.	August 6, 2018
Amazon RDS for MySQL supports delayed replication	Amazon RDS for MySQL now supports delayed replication as a strategy for disaster recovery. For more information, see Configuring delayed replication with MySQL.	August 6, 2018
Amazon RDS Performance Insights is available for Aurora MySQL	Amazon RDS Performance Insights is now available for Aurora MySQL. For more information, see Using Amazon RDS Performance Insights.	August 6, 2018

Amazon RDS Performance Insights integration with Amazon CloudWatch	Amazon RDS Performance Insights automatically publishes metrics to Amazon CloudWatch. For more information, see Performance Insights metrics published to CloudWatch.	August 6, 2018
Amazon RDS recommendations	Amazon RDS now provides automated recommendations for database resources. For more information, see Using Amazon RDS recommendations.	July 25, 2018
Incremental snapshot copies across AWS Regions	Amazon RDS supports incremental snapshot copies across AWS Regions for both unencrypted and encrypted instances. For more information, see Copying snapshots across AWS Regions.	July 24, 2018
Amazon RDS Performance Insights is available for Amazon RDS for PostgreSQL	Amazon RDS Performance Insights is now available for Amazon RDS for PostgreSQL. For more information, see Using Amazon RDS Performance Insights.	July 18, 2018
Amazon RDS for Oracle supports Oracle APEX version 5.1.4.v1	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 5.1.4.v1. For more information, see Oracle application Express.	July 10, 2018

Amazon RDS for Oracle supports publishing logs to Amazon CloudWatch Logs	Amazon RDS for Oracle now supports publishing alert, audit, trace, and listener log data to a log group in CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.	July 9, 2018
MariaDB 10.2.15, 10.1.34, and 10.0.35	You can now create Amazon RDS DB instances running MariaDB versions 10.2.15, 10.1.34, and 10.0.35. For more information, see MariaDB on Amazon RDS versions.	July 5, 2018
Aurora PostgreSQL 1.2 is available and compatible with PostgreSQL 9.6.8	Aurora PostgreSQL 1.2 is now available and is compatible with PostgreSQL 9.6.8. For more information, see Version 1.2.	June 27, 2018
Read replicas for Amazon RDS PostgreSQL support Multi-AZ deployments	RDS read replicas in Amazon RDS PostgreSQL now support multiple Availability Zones. For more information, see Working with PostgreSQL read replicas.	June 25, 2018

Performance Insights available for Aurora PostgreSQL	Performance Insights is generally available for Aurora PostgreSQL, with support for extended retention of performance data. For more information, see Using Amazon RDS performance insights.	June 21, 2018
Aurora PostgreSQL available in western US (northern California) region	Aurora PostgreSQL is now available in the western United States (Northern Cal ifornia) region. For more information, see Availability for Amazon Aurora PostgreSQ L.	June 11, 2018
Amazon RDS for Oracle now supports CPU configuration	Amazon RDS for Oracle supports configuring the number of CPU cores and the number of threads for each core for the processor of a DB instance class. For more information, see Configuri ng the processor of the DB instance class.	June 5, 2018

Earlier updates

The following table describes the important changes in each release of the *Amazon RDS User Guide* before June 2018.

Change	Description	Date changed
Amazon RDS for PostgreSQL now supports PostgreSQL Version 11 Beta 1 in the Database Preview Environment	PostgreSQL version 11 Beta 1 contains several improvements that are described in PostgreSQL 11 beta 1 released! For information on the Database Preview Environment, see Working with the Database Preview environment.	May 31, 2018
Amazon RDS for Oracle now supports TLS versions 1.0 and 1.2	Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. For more information, see TLS versions for the Oracle SSL option.	May 30, 2018
Aurora MySQL supports publishing logs to Amazon CloudWatch Logs	Aurora MySQL now supports publishing general, slow, audit, and error log data to a log group in CloudWatch Logs. For more information, see Publishing Aurora MySQL to CloudWatch Logs.	May 23, 2018
Database Preview Environment for Amazon RDS PostgreSQL	You can now launch a new instance of Amazon RDS PostgreSQL in a preview mode. For more information about the Database Preview Environment see, Working with the Database Preview environment.	May 22, 2018
Amazon RDS for Oracle DB instances support new DB instance classes	Oracle DB instances now support the db.x1e and db.x1 DB instance classes. For more information, see DB instance classes and RDS for Oracle DB instance classes.	May 22, 2018
Amazon RDS PostgreSQL now supports	You can now use postgres_fdw to connect to a remote server from a read replica. For more information see, Using the postgres_fdw extension to access external data.	May 17, 2018

Change	Description	Date changed
postgres_fdw on a read replica.		
Amazon RDS for Oracle now supports setting sqlnet.ora parameters	You can now set sqlnet.ora parameters with Amazon RDS for Oracle. For more information, see Modifying connection properties using sqlnet.ora parameters.	May 10, 2018
Aurora PostgreSQL available in Asia Pacific (Seoul) region.	Aurora PostgreSQL is now available in the Asia Pacific (Seoul) region. For more information, see Availability for Amazon Aurora PostgreSQL.	May 9, 2018
Aurora MySQL supports backtracking	Aurora MySQL now supports "rewinding" a DB cluster to a specific time, without restoring data from a backup. For more information, see Backtracking an Aurora DB cluster.	May 9, 2018
Aurora MySQL supports encrypted migration and replication from external MySQL	Aurora MySQL now supports encrypted migration and replication from an external MySQL database. For more information, see Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster and Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster.	April 25, 2018
Aurora PostgreSQL-Compatible Edition support for the Copy-on-Write protocol.	You can now clone databases in an Aurora PostgreSQL database cluster. For more information see, Cloning databases in an Aurora DB cluster.	April 10, 2018

Change	Description	Date changed
MariaDB 10.2.12, 10.1.31, and 10.0.34	You can now create Amazon RDS DB instances running MariaDB versions 10.2.12, 10.1.31, and 10.0.34. For more information, see MariaDB on Amazon RDS versions.	March 21, 2018
Aurora PostgreSQL Support for new regions	Aurora PostgreSQL is now available in the EU (London) and Asia Pacific (Singapore) regions. For more information, see Availability for Amazon Aurora PostgreSQL.	March 13, 2018
MySQL 5.7.21, 5.6.39, and 5.5.59	You can now create Amazon RDS DB instances running MySQL versions 5.7.21, 5.6.39, and 5.5.59. For more information, see MySQL on Amazon RDS versions.	March 9, 2018
Amazon RDS for Oracle now supports Oracle REST Data Services	Amazon RDS for Oracle supports Oracle REST Data Services as part of the APEX option. For more information, see Oracle Application Express (APEX).	March 9, 2018
Amazon Aurora MySQL-Compatible Edition available in new AWS Region	Aurora MySQL is now available in the Asia Pacific (Singapore) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.	March 6, 2018
Amazon RDS DB instances running Microsoft SQL Server support change data capture (CDC)	DB instances running Amazon RDS for Microsoft SQL Server now support change data capture (CDC). For more information, see Change data capture support for Microsoft SQL Server DB instances.	February 6, 2018

Change	Description	Date changed
Aurora MySQL supports a new major version	You can now create Aurora MySQL DB clusters running MySQL version 5.7. For more information, see Amazon Aurora MySQL database engine updates 2018-02-06.	February 6, 2018
Publish MySQL and MariaDB logs to Amazon CloudWatch Logs	You can now publish MySQL and MariaDB log data to CloudWatch Logs. For more information, see Publishing MySQL logs to Amazon CloudWatch Logs and Publishing MariaDB logs to Amazon CloudWatch Logs.	January 17, 2018
Multi-AZ support for read replicas	You can now create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance. For more information, see Working with DB instance read replicas.	January 11, 2018
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.2. For more information, see MariaDB 10.2 support on Amazon RDS.	January 3, 2018
Amazon Aurora PostgreSQL-Compatible Edition available in new AWS Region	Aurora PostgreSQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora PostgreSQL, see Availability for Amazon Aurora PostgreSQL.	December 22, 2017
Aurora PostgreSQL supports new instance types	Aurora PostgreSQL now supports new instance types. For the complete list of instance types, see Choosing the DB instance class.	December 20, 2017

Change	Description	Date changed
Amazon Aurora MySQL-Com patible Edition available in new AWS Region	Aurora MySQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.	December 18, 2017
Aurora MySQL supports hash joins	This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information, see Working with hash joins in Aurora MySQL.	December 11, 2017
Aurora MySQL supports native functions to invoke AWS Lambda fun ctions	You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster.	December 11, 2017
Added Aurora PostgreSQL HIPAA eligibility	Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see Working with Amazon Aurora PostgreSQL.	December 6, 2017
Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility	Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see Availability for Amazon Aurora PostgreSQL.	November 22, 2017
Modify storage for Amazon RDS DB instances running Microsoft SQL Server	You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more informati on, see Modifying an Amazon RDS DB instance.	November 21, 2017

Change	Description	Date changed
Amazon RDS supports 16 TiB storage for Linux-based engines	You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see Amazon RDS DB instance storage.	November 21, 2017
Amazon RDS supports fast scale up of storage	You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see Amazon RDS DB instance storage.	November 21, 2017
Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32	You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see MariaDB on Amazon RDS versions.	November 20, 2017
Amazon RDS for Microsoft SQL Server now supports new DB instance classes	You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see DB instance class support for Microsoft SQL Server.	November 20, 2017
Amazon RDS for MySQL and MariaDB now supports new DB instance classes	You can now create Amazon RDS DB instances running MySQL and MariaDB that use the db.r4, db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge DB instance classes. For more information, see DB instance classes.	November 20, 2017
SQL Server 2017	You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see Amazon RDS for Microsoft SQL Server.	November 17, 2017

Change	Description	Date changed
Restore MySQL backups from Amazon S3	You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see Restoring a backup into an Amazon RDS for MySQL DB instance.	November 17, 2017
Auto Scaling with Aurora Replicas	Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see Amazon Aurora Auto Scaling with Aurora replicas.	November 17, 2017
Oracle default edition support	Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see Setting the default edition for a DB instance.	November 3, 2017
Oracle DB instance file validation	Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see Validating database files in RDS for Oracle.	November 3, 2017
Management Agent for OEM 13c	Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	November 1, 2017
Storage reconfiguration for Microsoft SQL Server snapshots	You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see Restoring to a DB instance.	October 26, 2017

Change	Description	Date changed
Asynchronous key prefetch for Aurora MySQL-Compatible Edition	Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see Working with asynchronous key prefetch in Amazon Aurora.	October 26, 2017
MySQL 5.7.19, 5.6.37, and 5.5.57	You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see MySQL on Amazon RDS versions.	October 25, 2017
General availability of Amazon Aurora with PostgreSQL compatibility	Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see Working with Amazon Aurora PostgreSQL.	October 24, 2017
Amazon RDS for Oracle DB instances support new DB instance classes	Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see DB instance classes and RDS for Oracle DB instance classes.	October 23, 2017

Change	Description	Date changed
New feature	Your new and existing Reserved Instances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see Size-flexible reserved DB instances.	October 11, 2017
New feature	You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see Oracle SQLT.	September 22, 2017
New feature	If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see Upgrading an Oracle DB snapshot.	September 20, 2017
New feature	You can now use Oracle Spatial to store, retrieve, update, and query spatial data in your Amazon RDS DB instances running Oracle. For more information, see Oracle Spatial.	September 15, 2017
New feature	You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see Oracle Locator.	September 15, 2017
New feature	You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle.	September 15, 2017

Change	Description	Date changed
New feature	You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see Publishing Aurora MySQL logs to Amazon CloudWatch Logs.	September 14, 2017
New feature	Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see Oracle Application Express (APEX).	September 13, 2017
New feature	You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see Migrating an RDS for MySQL snapshot to Aurora and Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica.	September 5, 2017
New feature	You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see Compliance program support for Microsoft SQL Server DB instances.	August 31, 2017
New feature	You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see Amazon RDS for MariaDB.	August 31, 2017
New feature	You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see Amazon RDS DB instance storage.	August 22, 2017

Change	Description	Date changed
New feature	You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.	August 3, 2017
New feature	You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see MariaDB on Amazon RDS versions.	July 17, 2017
New feature	Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see Licensing Microsoft SQL Server on Amazon RDS.	July 13, 2017
New feature	Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory managemen t, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle ver sions 12.1.0.2 and 11.2.0.4. For more information, see Turning on HugePages for an RDS for Oracle instance.	July 7, 2017
New feature	Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see Availability of Amazon RDS encryption.	June 27, 2017
New feature	Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see Availability for Amazon Aurora MySQL.	June 16, 2017

Change	Description	Date changed
New feature	You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see Considerations for option groups.	June 12, 2017
New feature	You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see Copying a DB snapshot.	June 12, 2017
New feature	Amazon Aurora now allows you to quickly and cost-effectively copy all of your databases in an Amazon Aurora DB cluster. For more information, see Cloning databases in an Aurora DB cluster.	June 12, 2017
New feature	Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see Amazon RDS for Microsoft SQL Server.	June 7, 2017
Preview	Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see Working with Amazon Aurora PostgreSQL.	April 19, 2017
New feature	Amazon Aurora now allows you to run an ALTER TABLE *tbl_name* ADD COLUMN *col_name column_definition* operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. For more information, see Altering tables in Amazon Aurora using fast DDL.	April 5, 2017
New feature	We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see Displaying volume status for an Aurora DB cluster.	April 5, 2017

Change	Description	Date changed
New feature	You can now use your own custom logic in your custom password verification functions for Oracle on Amazon RDS. For more information, see Creating custom functions to verify passwords.	March 21, 2017
New feature	You can now access your online and archived redo log files on your Oracle DB instances on Amazon RDS. For more information, see Accessing online and archived redo logs.	March 21, 2017
New feature	You can now copy both encrypted and unencrypted DB cluster snapshots between accounts in the same region. For more information, see Copying a DB cluster snapshot across accounts.	March 7, 2017
New feature	You can now share encrypted DB cluster snapshots between accounts in the same region. For more information, see Sharing a DB cluster snapshot.	March 7, 2017
New feature	You can now replicate encrypted Amazon Aurora MySQL DB clusters to create cross-region Aurora Replicas. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions.	March 7, 2017
New feature	You can now require that all connections to your DB instance running Microsoft SQL Server use Secure Sockets Layer (SSL). For more information, see Using SSL with a Microsoft SQL Server DB instance.	February 27, 2017
New feature	You can now set your local time zone to one of 15 additional time zones. For more information, see Supported time zones.	February 27, 2017

Change	Description	Date changed
New feature	You can now use the Amazon RDS procedure `msdb.dbo.rds_shrink_tempdbfile` to shrink the tempdb database on your DB instances running Microsoft SQL Server. For more information, see Shrinking the tempdb database.	February 17, 2017
New feature	You can now compress your backup file when you export your Enterprise and Standard Edition Microsoft SQL Server database from an Amazon RDS DB instance to Amazon S3. For more information, see Compressing backup files.	February 17, 2017
New feature	Amazon RDS now supports custom DNS servers to resolve DNS names used in outbound network access on your DB instances running Oracle. For more information, see Setting up a custom DNS server.	January 26, 2017
New feature	Amazon RDS now supports creating an encrypted read replica in another region. For more information, see Creating a read replica in a different AWS Region and CreateDBInstanceReadReplica.	January 23, 2017
New feature	Amazon RDS now supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.	January 20, 2017
New feature	Amazon RDS now supports copying an encrypted DB snapshot to another region for the MariaDB, MySQL, Oracle, PostgreSQL, and Microsoft SQL Server database engines. For more information, see Copying a DB snapshot and CopyDBSnapshot.	December 20, 2016

Change	Description	Date changed
New feature	Amazon Aurora MySQL now supports spatial indexing. Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see Amazon Aurora MySQL and spatial data.	December 14, 2016
New feature	Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use utl_http, utl_tcp, and utl_smtp to connect from your DB instance to the network. For more information, see Configuring UTL_HTTP access using certificates and an Oracle wallet.	December 5, 2016
New feature	Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see Supported storage engines for RDS for MySQL.	November 15, 2016
New feature	Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see Amazon RDS for Microsoft SQL Server.	November 4, 2016
New feature	Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see Upgrading the RDS for Oracle DB engine.	November 2, 2016
New feature	You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see Amazon RDS for Microsoft SQL Server.	October 25, 2016

Change	Description	Date changed
New feature	Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see Integrating Aurora MySQL with other AWS services.	October 18, 2016
New feature	You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS.	September 29, 2016
New feature	You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see Oracle UTL_MAIL.	September 20, 2016
New features	You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see Local time zone for Microsoft SQL Server DB instances.	September 19, 2016
New feature	You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see Oracle Label Security.	September 8, 2016

Change	Description	Date changed
New feature	You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see Amazon Aurora endpoints.	September 8, 2016
New feature	You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.	September 1, 2016
New feature	This release adds support to get an ARN for a resource. For more information, see Getting an existing ARN for Amazon RDS.	August 23, 2016
New feature	You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see Tagging Amazon RDS resources.	August 19, 2016

Change	Description	Date changed
New feature	Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see Creating an Amazon RDS DB instance. You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see Licensing Microsoft SQL Server on Amazon RDS and RDS for Oracle licensing options.	August 5, 2016
New feature	Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see Importing and exporting SQL Server databases using native backup and restore.	July 27, 2016
New feature	You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using `mysqldump` . For more information, see Migrating data from an external MySQL database to an Aurora MySQL DB cluster.	July 20, 2016

Change	Description	Date changed
New feature	You can now restore an unencrypted Amazon Aurora DB cluster snapshot to create an encrypted Amazon Aurora DB cluster by including an AWS Key Management Service (AWS KMS) encryption key during the restore operation. For more information, see Encrypting Amazon RDS resources.	June 30, 2016
New feature	You can use the Oracle Repository Creation Utility (RCU) to create a repository on Amazon RDS for Oracle. For more information, see Using the Oracle Repository Creation Utility on RDS for Oracle.	June 17, 2016
New feature	Adds support for PostgreSQL cross-region read replicas. For more information, see Creating a read replica in a different AWS Region.	June 16, 2016
New feature	You can now use the AWS Management Console to easily add Multi-AZ with Mirroring to a Microsoft SQL Server DB instance. For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance.	June 9, 2016
New feature	You can now use Multi-AZ Deployments Using SQL Server Mirroring in the following additional regions: Asia Pacific (Sydney), Asia Pacific (Tokyo), and South America (São Paulo). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.	June 9, 2016
New feature	Updated to support MariaDB version 10.1. For more information, see Amazon RDS for MariaDB.	June 1, 2016
New feature	Updated to support Amazon Aurora cross-region DB clusters that are read replicas. For more informati on, see Replicating Aurora MySQL DB clusters across AWS Regions.	June 1, 2016

Change	Description	Date changed
New feature	Enhanced Monitoring is now available for Oracle DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring and Modifying an Amazon RDS DB instance.	May 27, 2016
New feature	Updated to support manual snapshot sharing for Amazon Aurora DB cluster snapshots. For more information, see Sharing a DB cluster snapshot.	May 18, 2016
New feature	You can now use the MariaDB Audit Plugin to log database activity on MariaDB and MySQL database instances. For more information, see Options for MariaDB database engine and Options for MySQL DB instances.	April 27, 2016
New feature	In-place, major version upgrades are now available for upgrading from MySQL version 5.6 to version 5.7. For more information, see Upgrades of the RDS for MySQL DB engine.	April 26, 2016
New feature	Enhanced Monitoring is now available for Microsoft SQL Server DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring.	April 22, 2016
New feature	Updated to provide an Amazon Aurora **Clusters** view in the Amazon RDS console. For more information, see Viewing an Aurora DB cluster.	April 1, 2016
New feature	Updated to support SQL Server Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server.	March 31, 2016

Change	Description	Date changed
New feature	Updated to support Amazon Aurora Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see Availability for Amazon Aurora MySQL.	March 31, 2016
New feature	PostgreSQL DB instances have the ability to require connections to use SSL. For more information, see Using SSL with a PostgreSQL DB instance.	March 25, 2016
New feature	Enhanced Monitoring is now available for PostgreSQL DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring.	March 25, 2016
New feature	Microsoft SQL Server DB instances can now use Windows Authentication for user authentication. For more information, see Working with AWS Managed Active Directory with RDS for SQL Server.	March 23, 2016
New feature	Enhanced Monitoring is now available in the Asia Pacific (Seoul) region. For more information, see Monitoring OS metrics with Enhanced Monitoring.	March 16, 2016
New feature	You can now customize the order in which Aurora Replicas are promoted to primary instance during a failover. For more information, see Fault tolerance for an Aurora DB cluster.	March 14, 2016
New feature	Updated to support encryption when migrating to an Aurora DB cluster. For more information, see Migrating data to an Aurora DB cluster.	March 2, 2016
New feature	Updated to support local time zone for Aurora DB clusters. For more information, see Local time zone for Aurora DB clusters.	March 1, 2016
New feature	Updated to add support for MySQL version 5.7 for current generation Amazon RDS DB instance classes.	February 22, 2016

Change	Description	Date changed
New feature	Updated to support *db.r3* and *db.t2* DB instance classes in the AWS GovCloud (US-West) region.	February 11, 2016
New feature	Updated to support encrypting copies of DB snapshots and sharing encrypted DB snapshots. For more information, see Copying a DB snapshot for Amazon RDS and Sharing a DB snapshot for Amazon RDS.	February 11, 2016
New feature	Updated to support Amazon Aurora in the Asia Pacific (Sydney) region. For more information, see Availability for Amazon Aurora MySQL.	February 11, 2016
New feature	Updated to support SSL for Oracle DB instances. For more information, see Using SSL with an RDS for Oracle DB instance.	February 9, 2016
New feature	Updated to support local time zone for MySQL and MariaDB DB instances. For more information, see Local time zone for MySQL DB instances and Local time zone for MariaDB DB instances.	December 21, 2015
New feature	Updated to support Enhanced Monitoring of OS metrics for MySQL and MariaDB instances and Aurora DB clusters. For more information, see Viewing metrics in the Amazon RDS console.	December 18, 2015
New feature	Updated to support db.t2, db.r3, and db.m4 DB instance classes for MySQL version 5.5. For more information, see DB instance classes.	December 4, 2015
New feature	Updated to support modifying the database port for an existing DB instance.	December 3, 2015

Change	Description	Date changed
New feature	Updated to support major version upgrades of the database engine for PostgreSQL instances. For more information, see Upgrades of the RDS for PostgreSQL DB engine.	November 19, 2015
New feature	Updated to support modifying the public accessibi lity of an existing DB instance. Updated to support db.m4 standard DB instance classes.	November 11, 2015
New feature	Updated to support manual DB snapshot sharing. For more information, see Sharing a DB snapshot for Amazon RDS.	October 28, 2015
New feature	Updated to support Microsoft SQL Server 2014 for the Web, Express, and Standard editions.	October 26, 2015
New feature	Updated to support the MySQL-based MariaDB database engine. For more information, see Amazon RDS for MariaDB.	October 7, 2015
New feature	Updated to support Amazon Aurora in the Asia Pacific (Tokyo) region. For more information, see Availabil ity for Amazon Aurora MySQL.	October 7, 2015
New feature	Updated to support db.t2 burst-capable DB instance classes for all DB engines and the addition of the db.t2.large DB instance class. For more information, see DB instance classes.	September 25, 2015
New feature	Updated to support Oracle DB instances on R3 and T2 DB instance classes. For more information, see DB instance classes.	August 5, 2015
New feature	Microsoft SQL Server Enterprise Edition is now available with the License Included service model. For more information, see Licensing Microsoft SQL Server on Amazon RDS.	July 29, 2015

Change	Description	Date changed
New feature	Amazon Aurora has officially released. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. For detailed information, see What is Amazon Aurora?.	July 27, 2015
New feature	Updated to support copying tags to DB snapshots.	July 20, 2015
New feature	Updated to support increases in storage size for all DB engines and an increase in Provisioned IOPS for SQL Server.	June 18, 2015
New feature	Updated options for reserved DB instances.	June 15, 2015
New feature	Updated to support using Amazon CloudHSM with Oracle DB instances using TDE.	January 8, 2015
New feature	Updated to support encrypting data at rest and new API version 2014-10-31.	January 6, 2015
New feature	Updated to include the new Amazon DB engine: Aurora. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. Amazon Aurora is currently in preview release and is subject to change. For detailed information, see What is Amazon Aurora?.	November 12, 2014
New feature	Updated to support PostgreSQL read replicas.	November 10, 2014
New API and features	Updated to support the GP2 storage type and new API version 2014-09-01. Updated to support the ability to copy an existing option or parameter group to create a new option or parameter group.	October 7, 2014
New feature	Updated to support InnoDB Cache Warming for DB instances running MySQL version 5.6.19 and later.	September 3, 2014

Change	Description	Date changed
New feature	Updated to support SSL certificate verification when connecting to MySQL version 5.6, SQL Server, and PostgreSQL database engines.	August 5, 2014
New feature	Updated to support the db.t2 burstable DB instance classes.	August 4, 2014
New feature	Updated to support the db.r3 memory optimized DB instance classes for use with the MySQL (version 5.6), SQL Server, and PostgreSQL database engines.	May 28, 2014
New feature	Updated to support SQL Server Multi-AZ deployments using SQL Server Mirroring.	May 19, 2014
New feature	Updated to support upgrades from MySQL version 5.5 to version 5.6.	April 23, 2014
New feature	Updated to support Oracle GoldenGate.	April 3, 2014
New feature	Updated to support the M3 DB instance classes.	February 20, 2014
New feature	Updated to support the Oracle Timezone option.	January 13, 2014
New feature	Updated to support replication between MySQL DB instances in different regions.	November 26, 2013
New feature	Updated to support the PostgreSQL DB engine.	November 14, 2013
New feature	Updated to support SQL Server transparent data encryption (TDE).	November 7, 2013
New API and new feature	Updated to support cross region DB snapshot copies; new API version, 2013-09-09.	October 31, 2013
New features	Updated to support Oracle Statspack.	September 26, 2013

Change	Description	Date changed
New features	Updated to support using replication to import or export data between instances of MySQL running in Amazon RDS and instances of MySQL running on-premises or on Amazon EC2.	September 5, 2013
New features	Updated to support the db.cr1.8xlarge DB instance class for MySQL 5.6.	September 4, 2013
New feature	Updated to support replication of read replicas.	August 28, 2013
New feature	Updated to support parallel read replica creation.	July 22, 2013
New feature	Updated to support fine-grained permissions and tagging for all Amazon RDS resources.	July 8, 2013
New feature	Updated to support MySQL 5.6 for new instances , including support for the MySQL 5.6 memcached interface and binary log access.	July 1, 2013
New feature	Updated to support major version upgrades from MySQL 5.1 to MySQL 5.5.	June 20, 2013
New feature	Updated DB parameter groups to allow expressions for parameter values.	June 20, 2013
New API and new feature	Updated to support read replica status; new API version, 2013-05-15.	May 23, 2013
New features	Updated to support Oracle Advanced Security features for native network encryption and Oracle Transparent Data Encryption.	April 18, 2013
New features	Updated to support major version upgrades for SQL Server and additional functionality for Provisioned IOPS.	March 13, 2013
New feature	Updated to support VPC By Default for RDS.	March 11, 2013

Change	Description	Date changed
New API and feature	Updated to support log access; new API version 2013-02-12	March 4, 2013
New feature	Updated to support RDS event notification subscriptions.	February 4, 2013
New API and feature	Updated to support DB instance renaming and the migration of DB security group members in a VPC to a VPC security group.	January 14, 2013
New feature	Updated for AWS GovCloud (US-West) support.	December 17, 2012
New feature	Updated to support m1.medium and m1.xlarge DB instance classes.	November 6, 2012
New feature	Updated to support read replica promotion.	October 11, 2012
New feature	Updated to support SSL in Microsoft SQL Server DB instances.	October 10, 2012
New feature	Updated to support Oracle micro DB instances.	September 27, 2012
New feature	Updated to support SQL Server 2012.	September 26, 2012
New API and feature	Updated to support provisioned IOPS. API version 2012-09-17.	September 25, 2012
New features	Updated for SQL Server support for DB instances in VPC and Oracle support for Data Pump.	September 13, 2012
New feature	Updated for support for SQL Server Agent.	August 22, 2012
New feature	Updated for support for tagging of DB instances.	August 21, 2012

Change	Description	Date changed
New features	Updated for support for Oracle APEX and XML DB, Oracle time zones, and Oracle DB instances in a VPC.	August 16, 2012
New features	Updated for support for SQL Server Database Engine Tuning Advisor and Oracle DB instances in VPC.	July 18, 2012
New feature	Updated for support for option groups and first option, Oracle Enterprise Manager Database Control.	May 29, 2012
New feature	Updated for support for read replicas in Amazon Virtual Private Cloud.	May 17, 2012
New feature	Updated for Microsoft SQL Server support.	May 8, 2012
New features	Updated for support for forced failover, Multi-AZ deployment of Oracle DB instances, and nondefault character sets for Oracle DB Instances.	May 2, 2012
New feature	Updated for Amazon Virtual Private Cloud (VPC) Support.	February 13, 2012
Updated content	Updated for new Reserved Instance types.	December 19, 2011
New feature	Updated for Oracle engine support.	May 23, 2011
Updated content	Console updates.	May 13, 2011
Updated content	Edited content for shortened backup and maintenance windows.	February 28, 2011
New feature	Added support for MySQL 5.5.	January 31, 2011
New feature	Added support for read replicas.	October 4, 2010
New feature	Added support for AWS Identity and Access Management (IAM).	September 2, 2010

Change	Description	Date changed
New feature	Added DB engine Version Management.	August 16, 2010
New feature	Added Reserved DB instances.	August 16, 2010
New Feature	Amazon RDS now supports SSL connections to your DB instances.	June 28, 2010
New Guide	This is the first release of the Amazon RDS User Guide.	June 7, 2010

AWS Glossary

For the latest AWS terminology, see the AWS glossary in the *AWS Glossary Reference*.
