 setting values for the condition key {{keyName}}. Add {{actionName}} to the action
 block."
```

Resolving the error

The condition key in the `Condition` element of the policy statement is not evaluated unless the specified action is in the `Action` element. To ensure that the condition keys you specify are effectively allowed or denied by your policy, add the action to the `Action` element.

Error – Invalid federated principal syntax in role trust policy

Issue code: INVALID_FEDERATED_PRINCIPAL_SYNTAX_IN_ROLE_TRUST_POLICY

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid federated principal syntax in role trust policy: The principal value specifies
 a federated principal that does not match the expected format. Update the federated
 principal to a domain name or a SAML metadata ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The principal value specifies a federated principal that does not
 match the expected format. Update the federated principal to a domain name or a SAML
 metadata ARN."
```

Resolving the error

The principal value specifies a federated principal that does not match the expected format. Update the format of the federated principal to a valid domain name or a SAML metadata ARN.

Related terms

- Federated users and roles

Error – Mismatched action for principal

Issue code: MISMATCHED_ACTION_FOR_PRINCIPAL

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Mismatched action for principal: The {{actionName}} action is invalid with the
 following principal(s): {{principalNames}}. Use a SAML provider principal with
 the sts:AssumeRoleWithSAML action or use an OIDC provider principal with the
 sts:AssumeRoleWithWebIdentity action. Ensure the provider is Federated if you use
 either of the two options.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{actionName}} action is invalid with the following
 principal(s): {{principalNames}}. Use a SAML provider principal with the
 sts:AssumeRoleWithSAML action or use an OIDC provider principal with the
 sts:AssumeRoleWithWebIdentity action. Ensure the provider is Federated if you use
 either of the two options."
```

Resolving the error

The action specified in the `Action` element of the policy statement is invalid with the principal specified in the `Principal` element. For example, you can't use a SAML provider principal with the `sts:AssumeRoleWithWebIdentity` action. You should use a SAML provider principal with the `sts:AssumeRoleWithSAML` action or use an OIDC provider principal with the `sts:AssumeRoleWithWebIdentity` action.

Related terms

- AssumeRoleWithSAML

Error – Missing action for roles anywhere trust policy

Issue code: MISSING_ACTION_FOR_ROLES_ANYWHERE_TRUST_POLICY

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Missing action for roles anywhere trust policy: The rolesanywhere.amazonaws.com service
 principal requires the sts:AssumeRole, sts:SetSourceIdentity, and sts:TagSession
 permissions to assume a role. Add the missing permissions to the policy.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The rolesanywhere.amazonaws.com service principal requires the
 sts:AssumeRole, sts:SetSourceIdentity, and sts:TagSession permissions to assume a
 role. Add the missing permissions to the policy."
```

Resolving the error

For IAM Roles Anywhere to be able to assume a role and deliver temporary AWS credentials, the role must trust the IAM Roles Anywhere service principal. The IAM Roles Anywhere service principal requires the `sts:AssumeRole`, `sts:SetSourceIdentity`, and `sts:TagSession` permissions to assume a role. If any of the permissions are missing, you must add them to your policy.

- Trust model in AWS Identity and Access Management Roles Anywhere

Error – Policy size exceeds RCP quota

Issue code: POLICY_SIZE_EXCEEDS_RCP_QUOTA

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds RCP quota: The {{policySize}} characters in the resource control
 policy (RCP) exceed the {{policySizeQuota}} character maximum for RCPs. We recommend
 that you use multiple granular policies.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{policySize}} characters in the resource control policy (RCP)
 exceed the {{policySizeQuota}} character maximum for RCPs. We recommend that you use
 multiple granular policies."
```

Resolving the error

AWS Organizations resource control policies (RCPs) support specifying values in the `Action` element. However, these values can include wildcards (*) only at the end of the string. This means that you can specify `s3:Get*` but not `s3:*Object`.

To specify multiple actions, AWS recommends that you list them individually.

Related terms

Error – RCP syntax error principal

Issue code: RCP_SYNTAX_ERROR_PRINCIPAL

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
RCP syntax error principal: The Principal element contents are not valid. RCPs only
 support specifying all principals ("*") in the Principal element. The NotPrincipal
 element is not supported for RCPs.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Principal element contents are not valid. RCPs only support
 specifying all principals ("*") in the Principal element. The NotPrincipal element is
 not supported for RCPs."
```

Resolving the error

AWS Organizations resource control policies (RCPs) only support specifying all principals ("*") in the `Principal` element. The `NotPrincipal` element is not supported for RCPs.

Related terms

- RCP syntax
- Properties of the principal

Error – RCP syntax error allow

Issue code: RCP_SYNTAX_ERROR_ALLOW

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
RCP syntax error allow: RCPs only support specifying all principals ("*") in the
 Principal element, all resources ("*") in the Resource element, and no Condition
 element with an effect of Allow.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "RCPs only support specifying all principals ("*") in the Principal
 element, all resources ("*") in the Resource element, and no Condition element with an
 effect of Allow."
```

Resolving the error

AWS Organizations resource control policies (RCPs) only support specifying all principals ("*") in the `Principal` element and all resources ("*") in the `Resource` element. The `Condition` element with an effect of `Allow` is not supported for RCPs.

Related terms

Error – RCP syntax error NotAction

Issue code: RCP_SYNTAX_ERROR_NOTACTION

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
RCP syntax error NotAction: RCPs do not support the NotAction element. Update to use
 the Action element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "RCPs do not support the NotAction element. Update to use the Action
 element."
```

Resolving the error

AWS Organizations resource control policies (RCPs) do not support the `NotAction` element. Use the `Action` element.

Related terms

- RCP syntax

Error – Missing ARN account

Issue code: MISSING_ARN_ACCOUNT

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Missing ARN account: The resource {{resourceName}} in the arn is missing an account id.
 Please provide a 12 digit account id.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The resource {{resourceName}} in the arn is missing an account id.
 Please provide a 12 digit account id."
```

Resolving the error

Include an account ID in the resource ARN. Account IDs are 12-digit integers. To learn how to view your account ID, see Finding your AWS account ID.

Error – Invalid kms key value

Issue code: INVALID_KMS_KEY_VALUE

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid kms key value: The {{key}} condition key value must be valid a KMS key ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{key}} condition key value must be valid a KMS key ARN."
```

Resolving the error

An AWS KMS key ARN (Amazon Resource Name) is a unique, fully qualified identifier for a KMS key. A key ARN includes the AWS account, Region, and the key ID. A key ARN follows this format:

`arn:aws:kms:`*`region`*`:`*`account-id`*`:key/`*`key-id`*

Error – Variable usage too permissive

Issue code: VARIABLE_USAGE_TOO_PERMISSIVE

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Variable usage too permissive: Overly permissive use of policy variable for the {{key}}
 condition key. Use the policy variable preceded by 6 consecutive characters.
```

```
The policy variable is not allowed in the condition key {{key}}. We consider the key to
 be sensitive and policy variables can be evaluated as effective wildcards. Therefore
 policy variables are not allowed to be used with sensitive keys. Refer to https://
docs.aws.amazon.com/IAM/latest/UserGuide/reference_policies_condition-keys.html for the
 list of sensitive keys.
```

```
Overly permissive use of policy variable with aws:userID. Use the policy variable on
 the right side of colon or as the only character on the left side of a colon.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Overly permissive use of policy variable for the {{key}} condition
 key. Use the policy variable preceded by 6 consecutive characters."
```

```
"findingDetails": "The policy variable is not allowed in the condition key {{key}}.
 We consider the key to be sensitive and policy variables can be evaluated as
 effective wildcards. Therefore policy variables are not allowed to be used
 with sensitive keys. Refer to https://docs.aws.amazon.com/IAM/latest/UserGuide/
reference_policies_condition-keys.html for the list of sensitive keys."
```

```
"findingDetails": "Overly permissive use of policy variable with aws:userID. Use the
 policy variable on the right side of colon or as the only character on the left side
 of a colon."
```

Resolving the error

There are three possible finding messages for this error.

- For the first error message, modify your policy variable usage to be more specific. Add at least 6 consecutive characters before the policy variable to reduce the scope of permissions. For example, instead of using `${aws:username}`, use `prefix-${aws:username}` or `myapp-${aws:username}`. This ensures that the policy variable doesn't grant overly broad access.

- For the second error message, remove the policy variable from the specified condition key. Policy variables can act as effective wildcards and are not permitted with sensitive condition keys for security reasons. Instead, use specific static values or consider restructuring your policy to use non-sensitive condition keys that support policy variables.
- For the third error message, modify your `aws:userID` policy variable usage to be more restrictive. Place the policy variable on the right side of a colon (after the account ID) or use it as the only character on the left side of a colon. For example, use `AIDACKCEVSQ6C2EXAMPLE:${aws:userid}` or `${aws:userid}:*` instead of `${aws:userid}`.

Error – Wildcard usage too permissive

Issue code: WILDCARD_USAGE_TOO_PERMISSIVE

Finding type: ERROR

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Wildcard usage too permissive: Overly permissive use of wildcard for the {{key}}
 condition key. Use the wildcard preceded by 6 consecutive characters.
```

```
The wildcard is not allowed in the condition key {{key}}. We consider the key to
 be sensitive and wildcards are not allowed to be used with sensitive keys. Refer
 to https://docs.aws.amazon.com/IAM/latest/UserGuide/reference_policies_condition-
keys.html for the list of sensitive keys.
```

```
Overly permissive use of wildcard with aws:userID. Use the wildcard on the right side
 of colon or as the only character on the left side of a colon.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Overly permissive use of wildcard for the {{key}} condition key. Use
 the wildcard preceded by 6 consecutive characters."
```

```
"findingDetails": "The wildcard is not allowed in the condition key {{key}}.
 We consider the key to be sensitive and wildcards are not allowed to be used
 with sensitive keys. Refer to https://docs.aws.amazon.com/IAM/latest/UserGuide/
reference_policies_condition-keys.html for the list of sensitive keys."
```

```
"findingDetails": "Overly permissive use of wildcard with aws:userID. Use the wildcard
 on the right side of colon or as the only character on the left side of a colon."
```

Resolving the error

There are three possible finding messages for this error.

- For the first error message, make your wildcard usage more specific by adding at least 6 consecutive characters before the wildcard. For example, instead of using `*`, use `prefix-*` or `prefix-*-suffix`. This reduces the scope of the condition and follows the principle of least privilege.
- For the second error message, remove the wildcard from the specified condition key. Wildcards are not permitted with sensitive condition keys for security reasons. Replace the wildcard with specific values that match your intended access pattern, or consider using a different, non-sensitive condition key that supports wildcards.
- For the third error message, modify your `aws:userID` wildcard usage to be more restrictive. Place the wildcard on the right side of a colon (after the account ID) or use it as the only character on the left side of a colon. For example, use `AIDACKCEVSQ6C2EXAMPLE:*` or `*:*` instead of `*`.

General Warning – Create SLR with NotResource

Issue code: CREATE_SLR_WITH_NOT_RESOURCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with NotResource: Using the iam:CreateServiceLinkedRole action with
 NotResource can allow creation of unintended service-linked roles for multiple
 resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:CreateServiceLinkedRole action with NotResource can
 allow creation of unintended service-linked roles for multiple resources. We recommend
 that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using `iam:CreateServiceLinkedRole` in a policy with the `NotResource` element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the `Resource` element instead.

- CreateServiceLinkedRole operation
- IAM JSON policy elements: NotResource
- IAM JSON policy elements: Resource

General Warning – Create SLR with star in action and NotResource

Issue code: CREATE_SLR_WITH_STAR_IN_ACTION_AND_NOT_RESOURCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in action and NotResource: Using an action with a wildcard(*) and
 NotResource can allow creation of unintended service-linked roles because it can allow
 iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you
 specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using an action with a wildcard(*) and NotResource can
 allow creation of unintended service-linked roles because it can allow
 iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you
 specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Policies with a wildcard (*) in the `Action` and that include the `NotResource` element can allow creation of unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the `Resource` element instead.

- CreateServiceLinkedRole operation
- IAM JSON policy elements: NotResource
- IAM JSON policy elements: Resource

General Warning – Create SLR with NotAction and NotResource

Issue code: CREATE_SLR_WITH_NOT_ACTION_AND_NOT_RESOURCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with NotAction and NotResource: Using NotAction with NotResource
 can allow creation of unintended service-linked roles because it allows
```

```
iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you
specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using NotAction with NotResource can allow creation of unintended
 service-linked roles because it allows iam:CreateServiceLinkedRole permissions on
 multiple resources. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using the `NotAction` element with the `NotResource` element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you rewrite the policy to allow `iam:CreateServiceLinkedRole` on a limited list of ARNs in the `Resource` element instead. You can also add `iam:CreateServiceLinkedRole` to the `NotAction` element.

- CreateServiceLinkedRole operation
- IAM JSON policy elements: NotAction
- IAM JSON policy elements: Action
- IAM JSON policy elements: NotResource
- IAM JSON policy elements: Resource

General Warning – Create SLR with star in resource

Issue code: CREATE_SLR_WITH_STAR_IN_RESOURCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in resource: Using the iam:CreateServiceLinkedRole action with
 wildcards (*) in the resource can allow creation of unintended service-linked roles.
 We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:CreateServiceLinkedRole action with wildcards (*) in
 the resource can allow creation of unintended service-linked roles. We recommend that
 you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using `iam:CreateServiceLinkedRole` in a policy with a wildcard (*) in the `Resource` element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the `Resource` element instead.

- CreateServiceLinkedRole operation
- IAM JSON policy elements: Resource

AWS managed policies with this general warning

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

Some of those use cases are for power users within your account. The following AWS managed policies provide power user access and grant permissions to create service-linked roles for any AWS service. AWS recommends that you attach the following AWS managed policies to only IAM identities that you consider power users.

- PowerUserAccess
- AlexaForBusinessFullAccess
- AWSOrganizationsServiceTrustPolicy – This AWS managed policy provides permissions for use by the AWS Organizations service-linked role. This role allows Organizations to create additional service-linked roles for other services in your AWS organization.

General Warning – Create SLR with star in action and resource

Issue code: CREATE_SLR_WITH_STAR_IN_ACTION_AND_RESOURCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in action and resource: Using wildcards (*) in the action and
 the resource can allow creation of unintended service-linked roles because it allows
 iam:CreateServiceLinkedRole permissions on all resources. We recommend that you
 specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using wildcards (*) in the action and the resource
 can allow creation of unintended service-linked roles because it allows
 iam:CreateServiceLinkedRole permissions on all resources. We recommend that you
 specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Policies with a wildcard (*) in the `Action` and `Resource` elements can allow creating unintended service-linked roles for multiple resources. This allows creating a service-linked role when you specify `"Action": "*"`, `"Action": "iam:*"`, or `"Action": "iam:Create*"`. AWS recommends that you specify allowed ARNs in the `Resource` element instead.

- CreateServiceLinkedRole operation
- IAM JSON policy elements: Action
- IAM JSON policy elements: Resource

AWS managed policies with this general warning

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

Some of those use cases are for administrators within your account. The following AWS managed policies provide administrator access and grant permissions to create service-linked roles for any

AWS service. AWS recommends that you attach the following AWS managed policies to only the IAM identities that you consider administrators.

- AdministratorAccess
- IAMFullAccess

General Warning – Create SLR with star in resource and NotAction

Issue code: CREATE_SLR_WITH_STAR_IN_RESOURCE_AND_NOT_ACTION

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in resource and NotAction: Using a resource with wildcards (*)
 and NotAction can allow creation of unintended service-linked roles because it allows
 iam:CreateServiceLinkedRole permissions on all resources. We recommend that you
 specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using a resource with wildcards (*) and NotAction can allow creation
 of unintended service-linked roles because it allows iam:CreateServiceLinkedRole
 permissions on all resources. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using the `NotAction` element in a policy with a wildcard (*) in the `Resource` element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the `Resource` element instead. You can also add `iam:CreateServiceLinkedRole` to the `NotAction` element.

- CreateServiceLinkedRole operation
- IAM JSON policy elements: NotAction
- IAM JSON policy elements: Action

- IAM JSON policy elements: Resource

General Warning – Deprecated global condition key

Issue code: DEPRECATED_GLOBAL_CONDITION_KEY

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Deprecated global condition key: We recommend that you update aws:ARN to use the newer
 condition key aws:PrincipalArn.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend that you update aws:ARN to use the newer condition key
 aws:PrincipalArn."
```

Resolving the general warning

The policy includes a deprecated global condition key. Update the condition key in the condition key-value pair to use a supported global condition key.

- Global condition keys

General Warning – Invalid date value

Issue code: INVALID_DATE_VALUE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid date value: The date {{date}} might not resolve as expected. We recommend that
 you use the YYYY-MM-DD format.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The date {{date}} might not resolve as expected. We recommend that
 you use the YYYY-MM-DD format."
```

Resolving the general warning

Unix Epoch time describes a point in time that has elapsed since January 1, 1970, minus leap seconds. Epoch time might not resolve to the precise time that you expect. AWS recommends that you use the W3C standard for date and time formats. For example, you could specify a complete date, such as YYYY-MM-DD (1997-07-16), or you could also append the time to the second, such as YYYY-MM-DDThh:mm:ssTZD (1997-07-16T19:20:30+01:00).

- W3C Date and Time Formats
- IAM JSON policy elements: Version
- aws:CurrentTime global condition key

General Warning – Invalid role reference

Issue code: INVALID_ROLE_REFERENCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid role reference: The Principal element includes the IAM role ID {{roleid}}. We
 recommend that you use a role ARN instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Principal element includes the IAM role ID {{roleid}}. We
 recommend that you use a role ARN instead."
```

Resolving the general warning

AWS recommends that you specify the Amazon Resource Name (ARN) for an IAM role instead of its principal ID. When IAM saves the policy, it will transform the ARN into the principal ID for the existing role. AWS includes a safety precaution. If someone deletes and recreates the role, it will have a new ID, and the policy won't match the new role's ID.

- Specifying a principal: IAM roles
- IAM ARNs
- IAM unique IDs

General Warning – Invalid user reference

Issue code: INVALID_USER_REFERENCE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid user reference: The Principal element includes the IAM user ID {{userid}}. We
 recommend that you use a user ARN instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Principal element includes the IAM user ID {{userid}}. We
 recommend that you use a user ARN instead."
```

Resolving the general warning

AWS recommends that you specify the Amazon Resource Name (ARN) for an IAM user instead of its principal ID. When IAM saves the policy, it will transform the ARN into the principal ID for the existing user. AWS includes a safety precaution. If someone deletes and recreates the user, it will have a new ID, and the policy won't match the new user's ID.

- Specifying a principal: IAM users
- IAM ARNs
- IAM unique IDs

General Warning – Missing version

Issue code: MISSING_VERSION

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Missing version: We recommend that you specify the Version element to help you with
 debugging permission issues.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend that you specify the Version element to help you with
 debugging permission issues."
```

Resolving the general warning

AWS recommends that you include the optional `Version` parameter in your policy. If you do not include a Version element, the value defaults to `2012-10-17`, but newer features, such as policy variables, will not work with your policy. For example, variables such as `${aws:username}` aren't recognized as variables and are instead treated as literal strings in the policy.

- IAM JSON policy elements: Version

General Warning – Unique Sids recommended

Issue code: UNIQUE_SIDS_RECOMMENDED

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Unique Sids recommended: We recommend that you use statement IDs that are unique to
 your policy. Update the Sid value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend that you use statement IDs that are unique to your
 policy. Update the Sid value."
```

Resolving the general warning

AWS recommends that you use unique statement IDs. The `Sid` (statement ID) element allows you to enter an optional identifier that you provide for the policy statement. You can assign a statement ID value to each statement in a statement array using the `SID` element.

Related terms

- IAM JSON policy elements: Sid

General Warning – Wildcard without like operator

Issue code: WILDCARD_WITHOUT_LIKE_OPERATOR

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Wildcard without like operator: Your condition value includes a * or ? character. If
 you meant to use a wildcard (*, ?), update the condition operator to include Like.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Your condition value includes a * or ? character. If you meant to
 use a wildcard (*, ?), update the condition operator to include Like."
```

Resolving the general warning

The `Condition` element structure requires that you use a condition operator and a key-value pair. When you specify a condition value that uses a wildcard (*, ?), you must use the `Like` version of the condition operator. For example, instead of the `StringEquals` string condition operator, use `StringLike`.

```
"Condition": {"StringLike": {"aws:PrincipalTag/job-category": "admin-*"}}
```

- IAM JSON policy elements: Condition operators
- IAM JSON policy elements: Condition

AWS managed policies with this general warning

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

The following AWS managed policies include wildcards in their condition value without a condition operator that includes `Like` for pattern-matching. When using the AWS managed policy as a reference to create your customer managed policy, AWS recommends that you use a condition operator that supports pattern-matching with wildcards (*, ?), such as `StringLike`.

- AWSGlueConsoleSageMakerNotebookFullAccess

General Warning – Policy size exceeds identity policy quota

Issue code: POLICY_SIZE_EXCEEDS_IDENTITY_POLICY_QUOTA

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds identity policy quota: The {{policySize}} characters in the
 identity policy, excluding whitespace, exceed the {{policySizeQuota}} character
 maximum for inline and managed policies. We recommend that you use multiple granular
 policies.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{policySize}} characters in the identity policy, excluding
 whitespace, exceed the {{policySizeQuota}} character maximum for inline and managed
 policies. We recommend that you use multiple granular policies."
```

Resolving the general warning

You can attach up to 10 managed policies to an IAM identity (user, group of users, or role). However, the size of each managed policy cannot exceed the default quota of 6,144 characters. IAM does not count white space when calculating the size of a policy against this quota. Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account.

Additionally, you can add as many inline policies as you want to an IAM identity. However, the sum size of all inline policies per identity cannot exceed the specified quota.

If your policy is larger than the quota, you can organize your policy into multiple statements and group the statements into multiple policies.

AWS managed policies with this general warning

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

The following AWS managed policies grant permissions to actions across many AWS services and exceed the maximum policy size. When using the AWS managed policy as a reference to create your managed policy, you must split the policy into multiple policies.

- ReadOnlyAccess
- AWSSupportServiceRolePolicy

General Warning – Policy size exceeds resource policy quota

Issue code: POLICY_SIZE_EXCEEDS_RESOURCE_POLICY_QUOTA

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds resource policy quota: The {{policySize}} characters in the
 resource policy exceed the {{policySizeQuota}} character maximum for resource
 policies. We recommend that you use multiple granular policies.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{policySize}} characters in the resource policy exceed the
 {{policySizeQuota}} character maximum for resource policies. We recommend that you use
 multiple granular policies."
```

Resolving the general warning

Resource-based policies are JSON policy documents that you attach to a resource, such as an Amazon S3 bucket. These policies grant the specified principal permission to perform specific actions on that resource and define under what conditions this applies. The size of resource-based policies cannot exceed the quota set for that resource. Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account.

If your policy is larger than the quota, you can organize your policy into multiple statements and group the statements into multiple policies.

Related terms

General Warning – Type mismatch

Issue code: TYPE_MISMATCH

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch: Use the operator type {{allowed}} instead of operator {{operator}} for
 the condition key {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Use the operator type {{allowed}} instead of operator {{operator}}
 for the condition key {{key}}."
```

Resolving the general warning

Update the text to use the supported condition operator data type.

For example, the `aws:MultiFactorAuthPresent` global condition key requires a condition operator with the `Boolean` data type. If you provide a date or an integer, the data type won't match.

Related terms

- Global condition keys
- IAM JSON policy elements: Condition operators

General Warning – Type mismatch Boolean

Issue code: TYPE_MISMATCH_BOOLEAN

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch Boolean: Add a valid Boolean value (true or false) for the condition
 operator {{operator}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a valid Boolean value (true or false) for the condition operator
 {{operator}}."
```

Resolving the general warning

Update the text to use a Boolean condition operator data type, such as `true` or `false`.

For example, the `aws:MultiFactorAuthPresent` global condition key requires a condition operator with the `Boolean` data type. If you provide a date or an integer, the data type won't match.

Related terms

- Boolean condition operators
- IAM JSON policy elements: Condition operators

General Warning – Type mismatch date

Issue code: TYPE_MISMATCH_DATE

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch date: The date condition operator is used with an invalid value. Specify
 a valid date using YYYY-MM-DD or other ISO 8601 date/time format.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The date condition operator is used with an invalid value. Specify a
 valid date using YYYY-MM-DD or other ISO 8601 date/time format."
```

Resolving the general warning

Update the text to use the date condition operator data type, in a YYYY-MM-DD or other ISO 8601 date time format.

Related terms

- Date condition operators
- IAM JSON policy elements: Condition operators

General Warning – Type mismatch number

Issue code: TYPE_MISMATCH_NUMBER

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch number: Add a valid numeric value for the condition operator
 {{operator}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a valid numeric value for the condition operator {{operator}}."
```

Resolving the general warning

Update the text to use the numeric condition operator data type.

Related terms

- Numeric condition operators
- IAM JSON policy elements: Condition operators

General Warning – Type mismatch string

Issue code: TYPE_MISMATCH_STRING

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch string: Add a valid base64-encoded string value for the condition
 operator {{operator}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a valid base64-encoded string value for the condition operator
 {{operator}}."
```

Resolving the general warning

Update the text to use the string condition operator data type.

Related terms

- String condition operators
- IAM JSON policy elements: Condition operators

General Warning – Specific github repo and branch recommended

Issue code: SPECIFIC_GITHUB_REPO_AND_BRANCH_RECOMMENDED

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Specific github repo and branch recommended: Using a wildcard (*) in
 token.actions.githubusercontent.com:sub can allow requests from more sources than
 you intended. Specify the value of token.actions.githubusercontent.com:sub with the
 repository and branch name.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using a wildcard (*) in token.actions.githubusercontent.com:sub
 can allow requests from more sources than you intended. Specify the value of
 token.actions.githubusercontent.com:sub with the repository and branch name."
```

Resolving the general warning

If you use GitHub as an OIDC IdP, best practice is to limit the entities that can assume the role associated with the IAM IdP. When you include a `Condition` statement in a role trust policy, you can limit the role to a specific GitHub organization, repository, or branch. You can use the condition key `token.actions.githubusercontent.com:sub` to limit access. We recommend that you limit the condition to a specific set of repositories or branches. If you use a wildcard (*) in `token.actions.githubusercontent.com:sub`, then GitHub Actions from organizations or repositories outside of your control are able to assume roles associated with the GitHub IAM IdP in your AWS account.

Related terms

- Configuring a role for GitHub OIDC identity provider

General Warning – Policy size exceeds role trust policy quota

Issue code: POLICY_SIZE_EXCEEDS_ROLE_TRUST_POLICY_QUOTA

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds role trust policy quota: The characters in the role trust policy,
 excluding whitespace, exceed the character maximum. We recommend that you request a
 role trust policy length quota increase using Service Quotas and AWS Support Center.
 If the quotas have already been increased, then you can ignore this warning.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The characters in the role trust policy, excluding whitespace,
 exceed the character maximum. We recommend that you request a role trust policy length
```

```
quota increase using Service Quotas and AWS Support Center. If the quotas have already
been increased, then you can ignore this warning."
```

Resolving the general warning

IAM and AWS STS have quotas that limit the size of role trust policies. The characters in the role trust policy, excluding whitespace, exceed the character maximum. We recommend that you request a role trust policy length quota increase using Service Quotas and the AWS Support Center Console.

Related terms

- IAM and AWS STS quotas, name requirements, and character limits

General Warning – RCP missing related principal condition key

Issue code: RCP_MISSING_RELATED_PRINCIPAL_CONDITION_KEY

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
RCP missing related principal condition key: RCPs impact IAM roles, users, and AWS
 service principals. To prevent unintended impact to services acting on your behalf
 using a service principal, an additional statement should be added to the Condition
 block "BoolIfExists": { "aws:PrincipalIsAWSService": "false"} whenever a principal key
 {{conditionKeyName}} is used.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "RCPs impact IAM roles, users, and AWS service principals. To prevent
 unintended impact to services acting on your behalf using a service principal,
 an additional statement should be added to the Condition block "BoolIfExists":
 { "aws:PrincipalIsAWSService": "false"} whenever a principal key {{conditionKeyName}}
 is used."
```

Resolving the general warning

AWS Organizations resource control policies (RCPs) can impact IAM roles, users, and AWS service principals. To prevent unintended impact to services acting on your behalf using a service principal, add the following statement to your `Condition` element:

```
"BoolIfExists": { "aws:PrincipalIsAWSService": "false"}
```

Related terms

- RCP syntax
- Properties of the principal

General Warning – RCP missing related service principal condition key

Issue code: RCP_MISSING_RELATED_SERVICE_PRINCIPAL_CONDITION_KEY

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
RCP missing related service principal condition key: RCPs impact IAM roles, users,
 and AWS service principals. To prevent unintended impact to your principals,
 an additional statement should be added to the Condition block "BoolIfExists":
 { "aws:PrincipalIsAWSService": "true"} whenever the key {{conditionKeyName}} is used.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "RCPs impact IAM roles, users, and AWS service principals. To prevent
 unintended impact to your principals, an additional statement should be added to the
 Condition block "BoolIfExists": { "aws:PrincipalIsAWSService": "true"} whenever the
 key {{conditionKeyName}} is used."
```

Resolving the general warning

AWS Organizations resource control policies (RCPs) can impact IAM roles, users, and AWS service principals. To prevent unintended impact to your principals, add the following statement to your `Condition` element:

```
"BoolIfExists": { "aws:PrincipalIsAWSService": "true"}
```

Related terms

- RCP syntax
- Properties of the principal

General Warning – RCP missing service condition key null check

Issue code: RCP_MISSING_SERVICE_CONDITION_KEY_NULL_CHECK

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
RCP missing service condition key null check: The specified service may have a service
 integration that does not require the use of the the {{conditionKeyName}} condition
 key. To prevent unintended impact to services acting on your behalf using a service
 principal, an additional statement should be added to the Condition block "Null":
 { "aws:SourceAccount": "false"} or "Null": { "aws:SourceArn": "false"} whenever the
 key {{conditionKeyName}} is used.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The specified service may have a service integration that does not
 require the use of the the {{conditionKeyName}} condition key. To prevent unintended
 impact to services acting on your behalf using a service principal, an additional
 statement should be added to the Condition block "Null": { "aws:SourceAccount":
 "false"} or "Null": { "aws:SourceArn": "false"} whenever the key {{conditionKeyName}}
 is used."
```

Resolving the general warning

AWS Organizations resource control policies (RCPs) can impact IAM roles, users, and AWS service principals. To prevent unintended impact to services acting on your behalf using a service principal, add one of the following statements to your `Condition` element whenever the specified key is used:

```
"Null": { "aws:SourceAccount": "false"}
```

or

```
"Null": { "aws:SourceArn": "false"}
```

Related terms

- RCP syntax
- Properties of the principal

General Warning – Use condition key only with supported services

Issue code: USE_CONDITION_KEY_ONLY_WITH_SUPPORTED_SERVICES

Finding type: GENERAL_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Use condition key only with supported services: The condition key {{key}} works only
 with specific AWS services and must be scoped to supported services in your policies.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{key}} works only with specific AWS services and
 must be scoped to supported services in your policies.
```

Resolving the general warning

Review the AWS documentation to identify which AWS services support this condition key. If any services in your policy don't support the condition key, modify your policy to scope the condition key to only the AWS services that support it.

Related terms

Security Warning – Untrustworthy condition key

Issue code: UNTRUSTWORTHY_CONDITION_KEY

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Untrustworthy condition key: The {{key}} condition key is not recommended for access
 control as it can be spoofed/manipulated by the caller.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{key}} condition key is not recommended for access control as
 it can be spoofed/manipulated by the caller."
```

Resolving the security warning

Do not use this condition key for access control. The caller can potentially manipulate or spoof the key value, which creates a security risk.

Related terms

- AWS global condition context keys

Security Warning – Allow with NotPrincipal

Issue code: ALLOW_WITH_NOT_PRINCIPAL

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Allow with NotPrincipal: Using Allow with NotPrincipal can be overly permissive. We
 recommend that you use Principal instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using Allow with NotPrincipal can be overly permissive. We recommend
 that you use Principal instead."
```

Resolving the security warning

Using `"Effect": "Allow"` with the `NotPrincipal` can be overly permissive. For example, this can grant permissions to anonymous principals. AWS recommends that you specify principals that need access using the `Principal` element. Alternatively, you can allow broad access and then add another statement that uses the `NotPrincipal` element with `“Effect”: “Deny”`.

- AWS JSON policy elements: Principal
- AWS JSON policy elements: NotPrincipal

Security Warning – ForAllValues with single valued key

Issue code: FORALLVALUES_WITH_SINGLE_VALUED_KEY

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
ForAllValues with single valued key: Using ForAllValues qualifier with the single-
valued condition key {{key}} can be overly permissive. We recommend that you remove
 ForAllValues:.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using ForAllValues qualifier with the single-valued condition key
 {{key}} can be overly permissive. We recommend that you remove ForAllValues:."
```

Resolving the security warning

AWS recommends that you use the `ForAllValues` only with multivalued conditions. The `ForAllValues` set operator tests whether the value of every member of the request set is a subset of the condition key set. The condition returns true if every key value in the request matches at least one value in the policy. It also returns true if there are no keys in the request, or if the key values resolve to a null data set, such as an empty string.

To learn whether a condition supports a single value or multiple values, review the Actions, resources, and condition keys page for the service. Condition keys with the `ArrayOf` data type prefix are multivalued condition keys. For example, Amazon SES supports keys with single values (`String`) and the `ArrayOfString` multivalued data type.

- Multivalued context keys

Security Warning – Pass role with NotResource

Issue code: PASS_ROLE_WITH_NOT_RESOURCE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with NotResource: Using the iam:PassRole action with NotResource can be
 overly permissive because it can allow iam:PassRole permissions on multiple resources.
 We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:PassRole action with NotResource can be overly
 permissive because it can allow iam:PassRole permissions on multiple resources. We
 recommend that you specify resource ARNs instead."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Using

`iam:PassRole` in a policy with the `NotResource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- Passing a role to a service
- iam:PassedToService
- IAM JSON policy elements: NotResource
- IAM JSON policy elements: Resource

Security Warning – Pass role with star in action and NotResource

Issue code: PASS_ROLE_WITH_STAR_IN_ACTION_AND_NOT_RESOURCE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with star in action and NotResource: Using an action with a wildcard (*) and
 NotResource can be overly permissive because it can allow iam:PassRole permissions on
 multiple resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using an action with a wildcard (*) and NotResource can be overly
 permissive because it can allow iam:PassRole permissions on multiple resources. We
 recommend that you specify resource ARNs instead."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Policies with a wildcard (*) in the `Action` and that include the `NotResource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- Passing a role to a service
- iam:PassedToService
- IAM JSON policy elements: NotResource
- IAM JSON policy elements: Resource

Security Warning – Pass role with NotAction and NotResource

Issue code: PASS_ROLE_WITH_NOT_ACTION_AND_NOT_RESOURCE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with NotAction and NotResource: Using NotAction with NotResource can
 be overly permissive because it can allow iam:PassRole permissions on multiple
 resources.. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using NotAction with NotResource can be overly permissive because
 it can allow iam:PassRole permissions on multiple resources.. We recommend that you
 specify resource ARNs instead."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Using the `NotAction` element and listing some resources in the `NotResource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- Passing a role to a service
- iam:PassedToService
- IAM JSON policy elements: NotAction

- IAM JSON policy elements: Action
- IAM JSON policy elements: NotResource
- IAM JSON policy elements: Resource

Security Warning – Pass role with star in resource

Issue code: PASS_ROLE_WITH_STAR_IN_RESOURCE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with star in resource: Using the iam:PassRole action with wildcards (*)
 in the resource can be overly permissive because it allows iam:PassRole permissions
 on multiple resources. We recommend that you specify resource ARNs or add the
 iam:PassedToService condition key to your statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:PassRole action with wildcards (*) in the resource can
 be overly permissive because it allows iam:PassRole permissions on multiple resources.
 We recommend that you specify resource ARNs or add the iam:PassedToService condition
 key to your statement."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Policies that allow `iam:PassRole` and that include a wildcard (*) in the `Resource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

Some AWS services include their service namespace in the name of their role. This policy check takes these conventions into account while analyzing the policy to generate findings. For example, the following resource ARN might not generate a finding:

```
arn:aws:iam::*:role/Service*
```

- Passing a role to a service
- iam:PassedToService
- IAM JSON policy elements: Resource

AWS managed policies with this security warning

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

One of those use cases is for administrators within your account. The following AWS managed policies provide administrator access and grant permissions to pass any IAM role to any service. AWS recommends that you attach the following AWS managed policies only to IAM identities that you consider administrators.

- AdministratorAccess-Amplify

The following AWS managed policies include permissions to `iam:PassRole` with a wildcard (*) in the resource and are on a deprecation path. For each of these policies, we updated the permission guidance, such as recommending a new AWS managed policy that supports the use case. To view alternatives to these policies, see the guides for each service.

- AWSElasticBeanstalkFullAccess
- AWSElasticBeanstalkService
- AWSLambdaFullAccess
- AWSLambdaReadOnlyAccess
- AWSOpsWorksFullAccess
- AWSOpsWorksRole
- AWSDataPipelineRole
- AmazonDynamoDBFullAccesswithDataPipeline
- AmazonElasticMapReduceFullAccess
- AmazonDynamoDBFullAccesswithDataPipeline
- AmazonEC2ContainerServiceFullAccess

The following AWS managed policies provide permissions for only service-linked roles, which allow AWS services to perform actions on your behalf. You cannot attach these policies to your IAM identities.

- AWSServiceRoleForAmazonEKSNodegroup

Security Warning – Pass role with star in action and resource

Issue code: PASS_ROLE_WITH_STAR_IN_ACTION_AND_RESOURCE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with star in action and resource: Using wildcards (*) in the action and the
 resource can be overly permissive because it allows iam:PassRole permissions on all
 resources. We recommend that you specify resource ARNs or add the iam:PassedToService
 condition key to your statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using wildcards (*) in the action and the resource can be overly
 permissive because it allows iam:PassRole permissions on all resources. We recommend
 that you specify resource ARNs or add the iam:PassedToService condition key to your
 statement."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Policies with a wildcard (*) in the `Action` and `Resource` elements can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- Passing a role to a service
- iam:PassedToService

- IAM JSON policy elements: Action
- IAM JSON policy elements: Resource

AWS managed policies with this security warning

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

Some of those use cases are for administrators within your account. The following AWS managed policies provide administrator access and grant permissions to pass any IAM role to any AWS service. AWS recommends that you attach the following AWS managed policies to only the IAM identities that you consider administrators.

- AdministratorAccess
- IAMFullAccess

Security Warning – Pass role with star in resource and NotAction

Issue code: PASS_ROLE_WITH_STAR_IN_RESOURCE_AND_NOT_ACTION

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with star in resource and NotAction: Using a resource with wildcards (*) and
 NotAction can be overly permissive because it allows iam:PassRole permissions on all
 resources. We recommend that you specify resource ARNs or add the iam:PassedToService
 condition key to your statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using a resource with wildcards (*) and NotAction can be overly
 permissive because it allows iam:PassRole permissions on all resources. We recommend
 that you specify resource ARNs or add the iam:PassedToService condition key to your
 statement."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Using the `NotAction` element in a policy with a wildcard (*) in the `Resource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- Passing a role to a service
- iam:PassedToService
- IAM JSON policy elements: NotAction
- IAM JSON policy elements: Action
- IAM JSON policy elements: Resource

Security Warning – Missing paired condition keys

Issue code: MISSING_PAIRED_CONDITION_KEYS

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Missing paired condition keys: Using the condition key {{conditionKeyName}}
 can be overly permissive without also using the following condition keys:
 {{recommendedKeys}}. Condition keys like this one are more secure when paired with
 a related key. We recommend that you add the related condition keys to the same
 condition block.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the condition key {{conditionKeyName}} can be overly
 permissive without also using the following condition keys: {{recommendedKeys}}.
 Condition keys like this one are more secure when paired with a related key. We
 recommend that you add the related condition keys to the same condition block."
```

Resolving the security warning

Some condition keys are more secure when paired with other related condition keys. AWS recommends that you include the related condition keys in the same condition block as the existing condition key. This makes the permissions granted through the policy more secure.

For example, you can use the `aws:VpcSourceIp` condition key to compare the IP address from which a request was made with the IP address that you specify in the policy. AWS recommends that you add the related `aws:SourceVPC` condition key. This checks whether the request comes from the VPC that you specify in the policy *and* the IP address that you specify.

Security Warning – Deny with unsupported tag condition key for service

Issue code: DENY_WITH_UNSUPPORTED_TAG_CONDITION_KEY_FOR_SERVICE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Deny with unsupported tag condition key for service: Using the effect Deny with the
 tag condition key {{conditionKeyName}} and actions for services with the following
 prefixes can be overly permissive: {{serviceNames}}. Actions for the listed services
 are not denied by this statement. We recommend that you move these actions to a
 different statement without this condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Deny with the tag condition key
 {{conditionKeyName}} and actions for services with the following prefixes can be
```

```
overly permissive: {{serviceNames}}. Actions for the listed services are not denied
by this statement. We recommend that you move these actions to a different statement
without this condition key."
```

Resolving the security warning

Using unsupported tag condition keys in the `Condition` element of a policy with `"Effect": "Deny"` can be overly permissive, because the condition is ignored for that service. AWS recommends that you remove the service actions that don't support the condition key and create another statement to deny access to specific resources for those actions.

If you use the `aws:ResourceTag` condition key and it's not supported by a service action, then the key is not included in the request context. In this case, the condition in the `Deny` statement always returns `false` and the action is never denied. This happens even if the resource is tagged correctly.

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as attribute-based access control (ABAC). Services that don't support these keys require you to control access to resources using resource-based access control (RBAC).

> **Note**
>
> Some services allow support for the `aws:ResourceTag` condition key for a subset of their resources and actions. IAM Access Analyzer returns findings for the service actions that are not supported. For example, Amazon S3 supports `aws:ResourceTag` for a subset of its resources. To view all of the resource types available in Amazon S3 that support the `aws:ResourceTag` condition key, see Resource types defined by Amazon S3 in the Service Authorization Reference.

For example, assume that you want to deny access to untag delete specific resources that are tagged with the key-value pair `status=Confidential`. Also assume that AWS Lambda allows you to tag and untag resources, but doesn't support the `aws:ResourceTag` condition key. To deny the delete actions for AWS App Mesh and AWS Backup if this tag is present, use the `aws:ResourceTag` condition key. For Lambda, use a resource naming convention that includes the `"Confidential"` prefix. Then include a separate statement that prevents deleting resources with that naming convention.

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyDeleteSupported",
            "Effect": "Deny",
            "Action": [
                "appmesh:DeleteMesh",
                "backup:DeleteBackupPlan"
                ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/status": "Confidential"
                }
            }
        },
        {
            "Sid": "DenyDeleteUnsupported",
            "Effect": "Deny",
            "Action": "lambda:DeleteFunction",
            "Resource": "arn:aws:lambda:*:123456789012:function:status-Confidential*"
        }
    ]
}
```

Warning

Do not use the …IfExists version of the condition operator as a workaround for this finding. This means "Deny the action if the key is present in the request context and the values match. Otherwise, deny the action." In the previous example, including the `lambda:DeleteFunction` action in the `DenyDeleteSupported` statement with the `StringEqualsIfExists` operator always denies the action. For that action, the key is not present in the context, and every attempt to delete that resource type is denied, regardless of whether the resource is tagged.

Security Warning – Deny NotAction with unsupported tag condition key for service

Issue code: DENY_NOTACTION_WITH_UNSUPPORTED_TAG_CONDITION_KEY_FOR_SERVICE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Deny NotAction with unsupported tag condition key for service: Using the effect Deny
 with NotAction and the tag condition key {{conditionKeyName}} can be overly permissive
 because some service actions are not denied by this statement. This is because the
 condition key doesn't apply to some service actions. We recommend that you use Action
 instead of NotAction.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Deny with NotAction and the tag condition key
 {{conditionKeyName}} can be overly permissive because some service actions are not
 denied by this statement. This is because the condition key doesn't apply to some
 service actions. We recommend that you use Action instead of NotAction."
```

Resolving the security warning

Using tag condition keys in the `Condition` element of a policy with the element `NotAction` and `"Effect": "Deny"` can be overly permissive. The condition is ignored for service actions that don't support the condition key. AWS recommends that you rewrite the logic to deny a list of actions.

If you use the `aws:ResourceTag` condition key with `NotAction`, any new or existing service actions that don't support the key are not denied. AWS recommends that you explicitly list the actions that you want to deny. IAM Access Analyzer returns a separate finding for listed actions that

don't support the `aws:ResourceTag` condition key. For more information, see Security Warning – Deny with unsupported tag condition key for service.

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as attribute-based access control (ABAC). Services that don't support these keys require you to control access to resources using resource-based access control (RBAC).

Security Warning – Restrict access to service principal

Issue code: RESTRICT_ACCESS_TO_SERVICE_PRINCIPAL

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Restrict access to service principal: Granting access to a service principal without
 specifying a source is overly permissive. Use aws:SourceArn, aws:SourceAccount,
 aws:SourceOrgID, or aws:SourceOrgPaths condition key to grant fine-grained access.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Granting access to a service principal without specifying a source
 is overly permissive. Use aws:SourceArn, aws:SourceAccount, aws:SourceOrgID, or
 aws:SourceOrgPaths condition key to grant fine-grained access."
```

Resolving the security warning

You can specify AWS services in the `Principal` element of a resource-based policy using a service principal, which is an identifier for the service. When granting access to a service principal to act on your behalf, restrict access. You can prevent overly permissive policies by using the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` condition keys to restrict access to a specific source, such as a specific resource ARN, AWS account, organization ID, or organization paths. Restricting access helps you prevent a security issue called *the confused deputy problem*.

Related terms

- AWS service principals

Security Warning – Missing condition key for oidc principal

Issue code: MISSING_CONDITION_KEY_FOR_OIDC_PRINCIPAL

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Missing condition key for oidc principal: Using an Open ID Connect principal without a
 condition can be overly permissive. Add condition keys with a prefix that matches your
 federated OIDC principals to ensure that only the intended identity provider assumes
 the role.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using an Open ID Connect principal without a condition can be
 overly permissive. Add condition keys with a prefix that matches your federated OIDC
 principals to ensure that only the intended identity provider assumes the role."
```

Resolving the security warning

Using an Open ID Connect principal without a condition can be overly permissive. Add condition keys with a prefix that matches your federated OIDC principals to ensure that only the intended identity provider assumes the role.

Related terms

- Creating a role for web identity or OpenID Connect Federation (console)

Security Warning – Missing github repo condition key

Issue code: MISSING_GITHUB_REPO_CONDITION_KEY

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Missing github repo condition key: Granting a federated GitHub principal permissions
 without a condition key can allow more sources to assume the role than you intended.
 Add the token.actions.githubusercontent.com:sub condition key and specify the branch
 and repository name in the value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Granting a federated GitHub principal permissions without a
 condition key can allow more sources to assume the role than you intended. Add the
 token.actions.githubusercontent.com:sub condition key and specify the branch and
 repository name in the value."
```

Resolving the security warning

If you use GitHub as an OIDC IdP, best practice is to limit the entities that can assume the role associated with the IAM IdP. When you include a `Condition` statement in a role trust policy, you can limit the role to a specific GitHub organization, repository, or branch. You can use the condition key `token.actions.githubusercontent.com:sub` to limit access. We recommend that you

limit the condition to a specific set of repositories or branches. If you do not include this condition, then GitHub Actions from organizations or repositories outside of your control are able to assume roles associated with the GitHub IAM IdP in your AWS account.

Related terms

- Configuring a role for GitHub OIDC identity provider

Security Warning – String like operator with ARN condition keys

Issue code: STRING_LIKE_OPERATOR_WITH_ARN_CONDITION_KEYS

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
String like operator with ARN condition keys: Use the operator type {{allowed}} instead
 of operator {{operator}} for the condition key {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Use the operator type {{allowed}} instead of operator {{operator}}
 for the condition key {{key}}."
```

Resolving the security warning

AWS recommends that you use ARN operators instead of string operators when comparing ARNs to ensure proper access restriction based on ARN condition values. Update the `StringLike` operator to the `ArnLike` operator in your `Condition` element whenever the specified key is used.

These AWS managed policies are exceptions to this security warning:

- AmazonSecurityLakeAdministrator
- AWSCodePipeline_FullAccess
- AWSCodePipeline_ReadOnlyAccess

- S3UnlockBucketPolicy
- SecurityLakeResourceManagementServiceRolePolicy
- SQSUnlockQueuePolicy

Related terms

Security Warning – ForAnyValue with audience claim type

Issue code: FORANYVALUE_WITH_AUDIENCE_CLAIM_TYPE

Finding type: SECURITY_WARNING

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
ForAnyValue with audience claim type: Using ForAnyValue qualifier with the single-
valued condition key {{key}} can be overly permissive. We recommend that you remove
 ForAnyValue:.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using ForAnyValue qualifier with the single-valued condition key
 {{key}} can be overly permissive. We recommend that you remove ForAnyValue:."
```

Resolving the security warning

AWS recommends that you do not use the `ForAnyValue` set operator with single-valued condition keys. Use set operators only with multivalued condition keys. Remove the `ForAnyValue` set operator.

Related terms

Suggestion – Empty array action

Issue code: EMPTY_ARRAY_ACTION

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array action: This statement includes no actions and does not affect the policy.
 Specify actions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no actions and does not affect the policy.
 Specify actions."
```

Resolving the suggestion

Statements must include either an `Action` or `NotAction` element that includes a set of actions. When the element is empty, the policy statement provides no permissions. Specify actions in the `Action` element.

- IAM JSON policy elements: Action

Suggestion – Empty array condition

Issue code: EMPTY_ARRAY_CONDITION

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition: There are no values for the condition key {{key}} and it does
 not affect the policy. Specify conditions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "There are no values for the condition key {{key}} and it does not
 affect the policy. Specify conditions."
```

Resolving the suggestion

The optional `Condition` element structure requires that you use a condition operator and a key-value pair. When the condition value is empty, the condition returns `true` and the policy statement provides no permissions. Specify a condition value.

- IAM JSON policy elements: Condition

Suggestion – Empty array condition ForAllValues

Issue code: EMPTY_ARRAY_CONDITION_FORALLVALUES

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition ForAllValues: The ForAllValues prefix with an empty condition key
 matches only if the key {{key}} is missing from the request context. To determine if
 the request context is empty, we recommend that you use the Null condition operator
 with the value of true instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The ForAllValues prefix with an empty condition key matches only
 if the key {{key}} is missing from the request context. To determine if the request
 context is empty, we recommend that you use the Null condition operator with the value
 of true instead."
```

Resolving the suggestion

The `Condition` element structure requires that you use a condition operator and a key-value pair. The `ForAllValues` set operator tests whether the value of every member of the request set is a subset of the condition key set.

When you use `ForAllValues` with an empty condition key, the condition matches only if there are no keys in the request. AWS recommends that if you want to test whether a request context is empty, use the `Null` condition operator instead.

- Multivalued context keys
- Null condition operator
- IAM JSON policy elements: Condition

Suggestion – Empty array condition ForAnyValue

Issue code: EMPTY_ARRAY_CONDITION_FORANYVALUE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition ForAnyValue: The ForAnyValue prefix with an empty condition key
 {{key}} never matches the request context and it does not affect the policy. Specify
 conditions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The ForAnyValue prefix with an empty condition key {{key}} never
 matches the request context and it does not affect the policy. Specify conditions."
```

Resolving the suggestion

The `Condition` element structure requires that you use a condition operator and a key-value pair. The `ForAnyValues` set operator tests whether at least one member of the set of request values matches at least one member of the set of condition key values.

When you use `ForAnyValues` with an empty condition key, the condition never matches. This means that the statement has no effect on the policy. AWS recommends that you rewrite the condition.

- Multivalued context keys
- IAM JSON policy elements: Condition

Suggestion – Empty array condition IfExists

Issue code: EMPTY_ARRAY_CONDITION_IFEXISTS

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition IfExists: The IfExists suffix with an empty condition key matches
 only if the key {{key}} is missing from the request context. To determine if the
 request context is empty, we recommend that you use the Null condition operator with
 the value of true instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The IfExists suffix with an empty condition key matches only if the
 key {{key}} is missing from the request context. To determine if the request context
 is empty, we recommend that you use the Null condition operator with the value of true
 instead."
```

Resolving the suggestion

The `...IfExists` suffix edits a condition operator. It means that if the policy key is present in the context of the request, process the key as specified in the policy. If the key is not present, evaluate the condition element as true.

When you use `...IfExists` with an empty condition key, the condition matches only if there are no keys in the request. AWS recommends that if you want to test whether a request context is empty, use the `Null` condition operator instead.

- ...IfExists condition operators
- IAM JSON policy elements: Condition

Suggestion – Empty array principal

Issue code: EMPTY_ARRAY_PRINCIPAL

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array principal: This statement includes no principals and does not affect the
 policy. Specify principals.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no principals and does not affect the
 policy. Specify principals."
```

Resolving the suggestion

You must use the `Principal` or `NotPrincipal` element in the trust policies for IAM roles and in resource-based policies. Resource-based policies are policies that you embed directly in a resource.

When you provide an empty array in a statement's `Principal` element, the statement has no effect on the policy. AWS recommends that you specify the principals that should have access to the resource.

- IAM JSON policy elements: Principal
- IAM JSON policy elements: NotPrincipal

Suggestion – Empty array resource

Issue code: EMPTY_ARRAY_RESOURCE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array resource: This statement includes no resources and does not affect the
 policy. Specify resources.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no resources and does not affect the policy.
 Specify resources."
```

Resolving the suggestion

Statements must include either a `Resource` or a `NotResource` element.

When you provide an empty array in a statement's resource element, the statement has no effect on the policy. AWS recommends that you specify Amazon Resource Names (ARNs) for resources.

- IAM JSON policy elements: Resource
- IAM JSON policy elements: NotResource

Suggestion – Empty object condition

Issue code: EMPTY_OBJECT_CONDITION

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty object condition: This condition block is empty and it does not affect the
 policy. Specify conditions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This condition block is empty and it does not affect the policy.
 Specify conditions."
```

Resolving the suggestion

The `Condition` element structure requires that you use a condition operator and a key-value pair.

When you provide an empty object in a statement's condition element, the statement has no effect on the policy. Remove the optional element or specify conditions.

- IAM JSON policy elements: Condition

Suggestion – Empty object principal

Issue code: EMPTY_OBJECT_PRINCIPAL

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty object principal: This statement includes no principals and does not affect the
 policy. Specify principals.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no principals and does not affect the
 policy. Specify principals."
```

Resolving the suggestion

You must use the `Principal` or `NotPrincipal` element in the trust policies for IAM roles and in resource-based policies. Resource-based policies are policies that you embed directly in a resource.

When you provide an empty object in a statement's `Principal` element, the statement has no effect on the policy. AWS recommends that you specify the principals that should have access to the resource.

- IAM JSON policy elements: Principal
- IAM JSON policy elements: NotPrincipal

Suggestion – Empty Sid value

Issue code: EMPTY_SID_VALUE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Empty Sid value: Add a value to the empty string in the Sid element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a value to the empty string in the Sid element."
```

Resolving the suggestion

The optional `Sid` (statement ID) element allows you to enter an identifier that you provide for the policy statement. You can assign an `Sid` value to each statement in a statement array. If you choose to use the `Sid` element, you must provide a string value.

Related terms

- IAM JSON policy elements: Sid

Suggestion – Equivalent to null false

Issue code: EQUIVALENT_TO_NULL_FALSE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Equivalent to null false: We recommend replacing the key {{key}} in the condition block
 of {{operator}} with {{{recommendedKey}}: false} to ensure better enforcement of the
 condition.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend replacing the key {{key}} in the condition block of
 {{operator}} with {{{recommendedKey}}: false} to ensure better enforcement of the
 condition."
```

Resolving the suggestion

Replace the current condition key with the recommended key set to `false`. This change improves policy clarity and ensures more reliable condition evaluation. Update your condition block to use `{recommendedKey}: false` instead of the current key-operator combination.

Related terms

- IAM policy elements: Condition
- Conditions with multiple context keys or values
- AWS global condition context keys

Suggestion – Equivalent to null true

Issue code: EQUIVALENT_TO_NULL_TRUE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Equivalent to null true: We recommend replacing the key {{key}} in the condition block
 of {{operator}} with {{{recommendedKey}}: true} to ensure better enforcement of the
 condition.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend replacing the key {{key}} in the condition block of
 {{operator}} with {{{recommendedKey}}: true} to ensure better enforcement of the
 condition."
```

Resolving the suggestion

Replace the current condition key with the recommended key set to `true`. This change improves policy clarity and ensures more reliable condition evaluation. Update your condition block to use `{recommendedKey}: true` instead of the current key-operator combination.

Related terms

- IAM policy elements: Condition
- Conditions with multiple context keys or values

Suggestion – Improve IP range

Issue code: IMPROVE_IP_RANGE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Improve IP range: The non-zero bits in the IP address after the masked bits are
 ignored. Replace address with {{addr}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The non-zero bits in the IP address after the masked bits are
 ignored. Replace address with {{addr}}."
```

Resolving the suggestion

IP address conditions must be in the standard CIDR format, such as 203.0.113.0/24 or 2001:DB8:1234:5678::/64. When you include non-zero bits after the masked bits, they are not

considered for the condition. AWS recommends that you use the new address included in the message.

- IP address condition operators
- IAM JSON policy elements: Condition

Suggestion – Null with qualifier

Issue code: NULL_WITH_QUALIFIER

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Null with qualifier: Avoid using the Null condition operator with the ForAllValues or
 ForAnyValue qualifiers because they always return a true or false respectively.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Avoid using the Null condition operator with the ForAllValues or
 ForAnyValue qualifiers because they always return a true or false respectively."
```

Resolving the suggestion

In the `Condition` element, you build expressions in which you use condition operators like equal or less than to compare a condition in the policy against keys and values in the request context. For requests that include multiple values for a single condition key, you must use the `ForAllValues` or `ForAnyValue` set operators.

When you use the `Null` condition operator with `ForAllValues`, the statement always returns `true`. When you use the `Null` condition operator with `ForAnyValue`, the statement always returns `false`. AWS recommends that you use the `StringLike` condition operator with these set operators.

Related terms

- Multivalued context keys

- Null condition operator
- Condition element

Suggestion – Private IP address subset

Issue code: PRIVATE_IP_ADDRESS_SUBSET

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Private IP address subset: The values for condition key aws:SourceIp include a mix
 of private and public IP addresses. The private addresses will not have the desired
 effect. aws:SourceIp works only for public IP address ranges. To define permissions
 for private IP ranges, use aws:VpcSourceIp.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The values for condition key aws:SourceIp include a mix of private
 and public IP addresses. The private addresses will not have the desired effect.
 aws:SourceIp works only for public IP address ranges. To define permissions for
 private IP ranges, use aws:VpcSourceIp."
```

Resolving the suggestion

The global condition key `aws:SourceIp` works only for public IP address ranges.

When your `Condition` element includes a mix of private and public IP addresses, the statement might not have the desired effect. You can specify private IP addresses using `aws:VpcSourceIP`.

> **Note**
>
> The global condition key `aws:VpcSourceIP` matches only if the request originates from the specified IP address and it goes through a VPC endpoint.

- aws:SourceIp global condition key

- aws:VpcSourceIp global condition key
- IP address condition operators
- IAM JSON policy elements: Condition

Suggestion – Private NotIpAddress subset

Issue code: PRIVATE_NOT_IP_ADDRESS_SUBSET

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Private NotIpAddress subset: The values for condition key aws:SourceIp include a mix of
 private and public IP addresses. The private addresses have no effect. aws:SourceIp
 works only for public IP address ranges. To define permissions for private IP ranges,
 use aws:VpcSourceIp.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The values for condition key aws:SourceIp include a mix of private
 and public IP addresses. The private addresses have no effect. aws:SourceIp works
 only for public IP address ranges. To define permissions for private IP ranges, use
 aws:VpcSourceIp."
```

Resolving the suggestion

The global condition key `aws:SourceIp` works only for public IP address ranges.

When your `Condition` element includes the `NotIpAddress` condition operator and a mix of private and public IP addresses, the statement might not have the desired effect. Every public IP addresses that is not specified in the policy will match. No private IP addresses will match. To achieve this effect, you can use `NotIpAddress` with `aws:VpcSourceIP` and specify the private IP addresses that should not match.

- aws:SourceIp global condition key
- aws:VpcSourceIp global condition key

- IP address condition operators
- IAM JSON policy elements: Condition

Suggestion – Redundant action

Issue code: REDUNDANT_ACTION

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant action: The {{redundantActionCount}} action(s) are redundant because they
 provide similar permissions. Update the policy to remove the redundant action such as:
 {{redundantAction}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{redundantActionCount}} action(s) are redundant because they
 provide similar permissions. Update the policy to remove the redundant action such as:
 {{redundantAction}}."
```

Resolving the suggestion

When you use wildcards (*) in the `Action` element, you can include redundant permissions. AWS recommends that you review your policy and include only the permissions that you need. This can help you remove redundant actions.

For example, the following actions include the `iam:GetCredentialReport` action twice.

```
"Action": [
        "iam:Get*",
        "iam:List*",
        "iam:GetCredentialReport"
    ],
```

In this example, permissions are defined for every IAM action that begins with `Get` or `List`. When IAM adds additional get or list operations, this policy will allow them. You might want to allow all

of these read-only actions. The `iam:GetCredentialReport` action is already included as part of `iam:Get*`. To remove the duplicate permissions, you could remove `iam:GetCredentialReport`.

You receive a finding for this policy check when all of the contents of an action are redundant. In this example, if the element included `iam:*CredentialReport`, it is not considered redundant. That includes `iam:GetCredentialReport`, which is redundant, and `iam:GenerateCredentialReport`, which is not. Removing either `iam:Get*` or `iam:*CredentialReport` would change the policy's permissions.

- IAM JSON policy elements: Action

AWS managed policies with this suggestion

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

Redundant actions do not affect the permissions granted by the policy. When using an AWS managed policy as a reference to create your customer managed policy, AWS recommends that you remove redundant actions from your policy.

Suggestion – Redundant condition value num

Issue code: REDUNDANT_CONDITION_VALUE_NUM

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant condition value num: Multiple values in {{operator}} are redundant. Replace
 with the {{greatest/least}} single value for {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Multiple values in {{operator}} are redundant. Replace with the
 {{greatest/least}} single value for {{key}}."
```

Resolving the suggestion

When you use numeric condition operators for similar values in a condition key, you can create an overlap that results in redundant permissions.

For example, the following `Condition` element includes multiple `aws:MultiFactorAuthAge` conditions that have an age overlap of 1200 seconds.

```
"Condition": {
        "NumericLessThan": {
          "aws:MultiFactorAuthAge": [
            "2700",
            "3600"
          ]
        }
      }
```

In this example, the permissions are defined if multi-factor authentication (MFA) was completed less than 3600 seconds (1 hour) ago. You could remove the redundant `2700` value.

- Numeric condition operators
- IAM JSON policy elements: Condition

Suggestion – Redundant resource

Issue code: REDUNDANT_RESOURCE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant resource: The {{redundantResourceCount}} resource ARN(s) are redundant
 because they reference the same resource. Review the use of wildcards (*)
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{redundantResourceCount}} resource ARN(s) are redundant because
 they reference the same resource. Review the use of wildcards (*)"
```

Resolving the suggestion

When you use wildcards (*) in Amazon Resource Names (ARNs), you can create redundant resource permissions.

For example, the following `Resource` element includes multiple ARNs with redundant permissions.

```
"Resource": [
            "arn:aws:iam::111122223333:role/jane-admin",
            "arn:aws:iam::111122223333:role/jane-s3only",
            "arn:aws:iam::111122223333:role/jane*"
        ],
```

In this example, the permissions are defined for any role with a name starting with `jane`. You could remove the redundant `jane-admin` and `jane-s3only` ARNs without changing the resulting permissions. This does make the policy dynamic. It will define permissions for any future roles that begin with `jane`. If the intention of the policy is to allow access to a static number of roles, then remove the last ARN and list only the ARNs that should be defined.

- IAM JSON policy elements: Resource

AWS managed policies with this suggestion

AWS managed policies enable you to get started with AWS by assigning permissions based on general AWS use cases.

Redundant resources do not affect the permissions granted by the policy. When using an AWS managed policy as a reference to create your customer managed policy, AWS recommends that you remove redundant resources from your policy.

Suggestion – Redundant statement

Issue code: REDUNDANT_STATEMENT

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant statement: The statements are redundant because they provide identical
 permissions. Update the policy to remove the redundant statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The statements are redundant because they provide identical
 permissions. Update the policy to remove the redundant statement."
```

Resolving the suggestion

The `Statement` element is the main element for a policy. This element is required. The `Statement` element can contain a single statement or an array of individual statements.

When you include the same statement more than once in a long policy, the statements are is redundant. You can remove one of the statements without affecting the permissions granted by the policy. When someone edits a policy, they might change one of the statements without updating the duplicate. This might result in more permissions than intended.

- IAM JSON policy elements: Statement

Suggestion – Wildcard in service name

Issue code: WILDCARD_IN_SERVICE_NAME

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Wildcard in service name: Avoid using wildcards (*, ?) in the service name because it
 might grant unintended access to other AWS services with similar names.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Avoid using wildcards (*, ?) in the service name because it might
 grant unintended access to other AWS services with similar names."
```

Resolving the suggestion

When you include the name of an AWS service in a policy, AWS recommends that you do not include wildcards (*, ?). This might add permissions for future services that you do not intend. For example, there are more than a dozen AWS services with the word `*code*` in their name.

```
"Resource": "arn:aws:*code*::111122223333:*"
```

- IAM JSON policy elements: Resource

Suggestion – Allow with unsupported tag condition key for service

Issue code: ALLOW_WITH_UNSUPPORTED_TAG_CONDITION_KEY_FOR_SERVICE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Allow with unsupported tag condition key for service: Using the effect Allow with the
 tag condition key {{conditionKeyName}} and actions for services with the following
 prefixes does not affect the policy: {{serviceNames}}. Actions for the listed service
 are not allowed by this statement. We recommend that you move these actions to a
 different statement without this condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Allow with the tag condition key
 {{conditionKeyName}} and actions for services with the following prefixes does not
 affect the policy: {{serviceNames}}. Actions for the listed service are not allowed
 by this statement. We recommend that you move these actions to a different statement
 without this condition key."
```

Resolving the suggestion

Using unsupported tag condition keys in the `Condition` element of a policy with `"Effect": "Allow"` does not affect the permissions granted by the policy, because the condition is ignored

for that service action. AWS recommends that you remove the actions for services that don't support the condition key and create another statement to allow access to specific resources in that service.

If you use the `aws:ResourceTag` condition key and it's not supported by a service action, then the key is not included in the request context. In this case, the condition in the `Allow` statement always returns `false` and the action is never allowed. This happens even if the resource is tagged correctly.

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as attribute-based access control (ABAC). Services that don't support these keys require you to control access to resources using resource-based access control (RBAC).

> **Note**
>
> Some services allow support for the `aws:ResourceTag` condition key for a subset of their resources and actions. IAM Access Analyzer returns findings for the service actions that are not supported. For example, Amazon S3 supports `aws:ResourceTag` for a subset of its resources. To view all of the resource types available in Amazon S3 that support the `aws:ResourceTag` condition key, see Resource types defined by Amazon S3 in the Service Authorization Reference.

For example, assume that you want to allow team members to view details for specific resources that are tagged with the key-value pair `team=BumbleBee`. Also assume that AWS Lambda allows you to tag resources, but doesn't support the `aws:ResourceTag` condition key. To allow view actions for AWS App Mesh and AWS Backup if this tag is present, use the `aws:ResourceTag` condition key. For Lambda, use a resource naming convention that includes the team name as a prefix. Then include a separate statement that allows viewing resources with that naming convention.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowViewSupported",
            "Effect": "Allow",
            "Action": [
```

```
                "appmesh:DescribeMesh",
                "backup:GetBackupPlan"
                ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/team": "BumbleBee"
                }
            }
        },
        {
            "Sid": "AllowViewUnsupported",
            "Effect": "Allow",
            "Action": "lambda:GetFunction",
            "Resource": "arn:aws:lambda:*:123456789012:function:team-BumbleBee*"
        }
    ]
}
```

Warning

Do not use the `Not` version of the condition operator with `"Effect": "Allow"` as a workaround for this finding. These condition operators provide negated matching. This means that after the condition is evaluated, the result is negated. In the previous example, including the `lambda:GetFunction` action in the `AllowViewSupported` statement with the `StringNotEquals` operator always allows the action, regardless of whether the resource is tagged.

Do not use the `...IfExists` version of the condition operator as a workaround for this finding. This means "Allow the action if the key is present in the request context and the values match. Otherwise, allow the action." In the previous example, including the `lambda:GetFunction` action in the `AllowViewSupported` statement with the `StringEqualsIfExists` operator always allows the action. For that action, the key is not present in the context, and every attempt to view that resource type is allowed, regardless of whether the resource is tagged.

Suggestion – Allow NotAction with unsupported tag condition key for service

Issue code: ALLOW_NOTACTION_WITH_UNSUPPORTED_TAG_CONDITION_KEY_FOR_SERVICE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Allow NotAction with unsupported tag condition key for service: Using the effect Allow
 with NotAction and the tag condition key {{conditionKeyName}} allows only service
 actions that support the condition key. The condition key doesn't apply to some
 service actions. We recommend that you use Action instead of NotAction.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Allow with NotAction and the tag condition key
 {{conditionKeyName}} allows only service actions that support the condition key. The
 condition key doesn't apply to some service actions. We recommend that you use Action
 instead of NotAction."
```

Resolving the suggestion

Using unsupported tag condition keys in the `Condition` element of a policy with the element `NotAction` and `"Effect": "Allow"` does not affect the permissions granted by the policy. The condition is ignored for service actions that don't support the condition key. AWS recommends that you rewrite the logic to allow a list of actions.

If you use the `aws:ResourceTag` condition key with `NotAction`, any new or existing service actions that don't support the key are not allowed. AWS recommends that you explicitly list the actions that you want to allow. IAM Access Analyzer returns a separate finding for listed actions that don't support the `aws:ResourceTag` condition key. For more information, see Suggestion – Allow with unsupported tag condition key for service.

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as attribute-based access control (ABAC). Services that

don't support these keys require you to control access to resources using resource-based access control (RBAC).

Suggestion – Recommended condition key for service principal

Issue code: RECOMMENDED_CONDITION_KEY_FOR_SERVICE_PRINCIPAL

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Recommended condition key for service principal: To restrict access to the service
 principal {{servicePrincipalPrefix}} operating on your behalf, we recommend
 aws:SourceArn, aws:SourceAccount, aws:SourceOrgID, or aws:SourceOrgPaths instead of
 {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "To restrict access to the service principal
 {{servicePrincipalPrefix}} operating on your behalf, we recommend aws:SourceArn,
 aws:SourceAccount, aws:SourceOrgID, or aws:SourceOrgPaths instead of {{key}}."
```

Resolving the suggestion

You can specify AWS services in the `Principal` element of a resource-based policy using a *service principal*, which is an identifier for the service. You should use the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` condition keys when

granting access to service principals instead of other condition keys, such as `aws:Referer`. This helps you prevent a security issue called *the confused deputy problem*.

Related terms

- AWS service principals

Suggestion – Irrelevant condition key in policy

Issue code: IRRELEVANT_CONDITION_KEY_IN_POLICY

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Irrelevant condition key in policy: The condition key {{condition-key}} is not relevant
 for the {{resource-type}} policy.  Use this key in an identity-based policy to govern
 access to this resource.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{condition-key}} is not relevant for the
 {{resource-type}} policy.  Use this key in an identity-based policy to govern access
 to this resource."
```

Resolving the suggestion

Some condition keys aren't relevant for resource-based policies. For example, the `s3:ResourceAccount` condition key isn't relevant for the resource-based policy attached to an Amazon S3 bucket or Amazon S3 access point resource type.

You should use the condition key in an identity-based policy to control access to the resource.

Related terms

- Identity-based policies and resource-based policies

Suggestion – Redundant key due to wildcard in condition

Issue code: REDUNDANT_KEY_DUE_TO_WILDCARD_IN_CONDITION

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant key due to wildcard in condition: The key {{key}} in the condition block of
 {{operator}} is redundant because it is always matched. Remove this key to simplify
 the condition.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The key {{key}} in the condition block of {{operator}} is redundant
 because it is always matched. Remove this key to simplify the condition."
```

Resolving the suggestion

Remove the redundant condition key from your policy. The key is always matched due to the wildcard pattern, making it unnecessary. Simplify your condition block by removing this key while maintaining the same effective permissions.

Related terms

- IAM policy elements: Condition
- Conditions with multiple context keys or values
- AWS global condition context keys

Suggestion – Redundant principal in role trust policy

Issue code: REDUNDANT_PRINCIPAL_IN_ROLE_TRUST_POLICY

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant principal in role trust policy: The assumed-role principal
 {{redundant_principal}} is redundant with its parent role {{parent_role}}. Remove the
 assumed-role principal.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The assumed-role principal {{redundant_principal}} is redundant with
 its parent role {{parent_role}}. Remove the assumed-role principal."
```

Resolving the suggestion

If you specify both an assumed-role principal and its parent role in the `Principal` element of a policy, it does not allow or deny any different permissions. For example, it is redundant if you specify the `Principal` element using the following format:

```
"Principal": {
            "AWS": [
            "arn:aws:iam::AWS-account-ID:role/rolename",
            "arn:aws:iam::AWS-account-ID:assumed-role/rolename/rolesessionname"
        ]
```

We recommend removing the assumed-role principal.

Related terms

- Role session principals

Suggestion – Redundant statement due to wildcard in condition

Issue code: REDUNDANT_STATEMENT_DUE_TO_WILDCARD_IN_CONDITION

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant statement due to wildcard in condition: The key {{key}} in the condition
 block of {{operator}} does not match any values. Remove this key to simplify the
 condition.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The key {{key}} in the condition block of {{operator}} does not
 match any values. Remove this key to simplify the condition."
```

Resolving the suggestion

Remove the condition key that doesn't match any values. This key creates an unreachable condition that will never be satisfied, making it redundant. Clean up your policy by removing this key to improve readability and performance.

Suggestion – Confirm audience claim type

Issue code: CONFIRM_AUDIENCE_CLAIM_TYPE

Finding type: SUGGESTION

Finding details

In the AWS Management Console, the finding for this check includes the following message:

```
Confirm audience claim type: The "{{key}}" ({{audienceType}}) claim key identifies
 the recipients that the JSON web token is intended for. Because this claim is single-
valued, do not use a qualifier.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The "{{key}}" ({{audienceType}}) claim key identifies the recipients
 that the JSON web token is intended for. Because this claim is single-valued, do not
 use a qualifier."
```

Resolving the suggestion

The aud (audience) claim key is a unique identifier for your app that is issued to you when you register your app with the IdP and identifies the recipients that the JSON web token is intended for. Audience claims can be multivalued or single-valued. If the claim is multivalued, use a `ForAllValues` or `ForAnyValue` condition set operator. If the claim is single-valued, do not use a condition set operator.

Related terms

- Creating a role for web identity or OpenID Connect Federation (console)

Validate policies with IAM Access Analyzer custom policy checks

You can use custom policy checks to check for new access based on your security standards. A charge is associated with each check for new access. For more details about pricing, see IAM Access Analyzer pricing.

Validating policies with custom policy checks (console)

As an optional step, you can run a custom policy check when editing a policy in the JSON policy editor in the IAM console. You can check whether the updated policy grants new access compared to the existing version.

To check for new access when editing IAM JSON policies

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose **Policies**.
3. In the list of policies, choose the policy name of the policy that you want to edit. You can use the search box to filter the list of policies.
4. Choose the **Permissions** tab, and then choose **Edit**.

5. Choose the **JSON** option and make updates to your policy.
6. In the policy validation pane below the policy, choose the **Check for new access** tab and then choose **Check policy**. If the modified permissions grant new access, the statement will be highlighted in the policy validation pane.
7. If you don't intend to grant new access, update the policy statement and choose **Check policy** until no new access is detected.

> **Note**
>
> A charge is associated with each check for new access. For more details about pricing, see IAM Access Analyzer pricing.

8. Choose **Next**.
9. On the **Review and save** page, review **Permissions defined in this policy** and then choose **Save changes**.

Validating policies with custom policy checks (AWS CLI or API)

You can run IAM Access Analyzer custom policy checks from the AWS CLI or the IAM Access Analyzer API.

To run IAM Access Analyzer custom policy checks (AWS CLI)

- To check whether new access is allowed for an updated policy when compared to the existing policy, run the following command: check-no-new-access
- To check whether the specified access isn't allowed by a policy, run the following command: check-access-not-granted
- To check whether a resource policy can grant public access to a specified resource type, run the following command: check-no-public-access

To run IAM Access Analyzer custom policy checks (API)

- To check whether new access is allowed for an updated policy when compared to the existing policy, use the CheckNoNewAccess API operation.
- To check whether the specified access isn't allowed by a policy, use the CheckAccessNotGranted API operation.

- To check whether a resource policy can grant public access to a specified resource type, use the CheckNoPublicAccess API operation.

IAM Access Analyzer policy generation

As an administrator or developer, you might grant permissions to IAM entities (users or roles) beyond what they require. IAM provides several options to help you refine the permissions that you grant. One option is to generate an IAM policy that is based on access activity for an entity. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that the entity used in your specified date range. You can use the template to create a policy with fine-grained permissions that grant only the permissions that are required to support your specific use case.

Topics

- How policy generation works
- Service and action-level information
- Things to know about generating policies
- Permissions required to generate a policy
- Generate a policy based on CloudTrail activity (console)
- Generate a policy using AWS CloudTrail data in another account
- Generate a policy based on CloudTrail activity (AWS CLI)
- Generate a policy based on CloudTrail activity (AWS API)
- IAM Access Analyzer policy generation services

How policy generation works

IAM Access Analyzer analyzes your CloudTrail events to identify actions and services that have been used by an IAM entity (user or role). It then generates an IAM policy that is based on that activity. You can refine an entity's permissions when you replace a broad permissions policy attached to the entity with the generated policy. The following is a high-level overview of the policy generation process.

- **Set up for policy template generation** – You specify a time period of up to 90 days for IAM Access Analyzer to analyze your historical AWS CloudTrail events. You must specify an existing

service role or create a new one. The service role gives IAM Access Analyzer access to your CloudTrail trail and service last accessed information to identify the services and actions that were used. You must specify the CloudTrail trail that is logging events for the account before you can generate a policy. For more information about IAM Access Analyzer quotas for CloudTrail data, see IAM Access Analyzer quotas.

- **Generate policy** – IAM Access Analyzer generates a policy based on the access activity in your CloudTrail events.
- **Review and customize policy** – After the policy is generated, you can review the services and actions that were used by the entity during the specified date range. You can further customize the policy by adding or removing permissions, specifying resources, and adding conditions to the policy template.
- **Create and attach policy** – You have the option to save the generated policy by creating a managed policy. You can attach the policy that you create to the user or role whose activity was used to generate the policy.

Service and action-level information

When IAM Access Analyzer generates an IAM policy, information is returned to help you to further customize the policy. Two categories of information can be returned when a policy is generated:

- **Policy with action-level information –** For some AWS services, such as Amazon EC2, IAM Access Analyzer can identify the actions found in your CloudTrail events and lists the actions used in the policy it generates. For a list of supported services, see IAM Access Analyzer policy generation services. For some services, IAM Access Analyzer prompts you to add actions for the services to the generated policy.
- **Policy with service-level information –** IAM Access Analyzer uses last accessed information to create a policy template with all of the recently used services. When using the AWS Management Console, we prompt you to review the services and add actions to complete the policy.

For a list of actions in each service, see Actions, Resources, and Condition Keys for AWS Services in the Service Authorization Reference.

Things to know about generating policies

Before you generate a policy, review the following important details.

- **Enable a CloudTrail trail** – You must have a CloudTrail trail enabled for your account to generate a policy based on access activity. When you create a CloudTrail trail, CloudTrail sends events related to your trail to an Amazon S3 bucket that you specify. To learn how to create a CloudTrail trail, see Creating a trail for your AWS account in the *AWS CloudTrail User Guide*.
- **Data events not available** – IAM Access Analyzer does not identify action-level activity for data events, such as Amazon S3 data events, in generated policies.
- **PassRole** – The `iam:PassRole` action is not tracked by CloudTrail and is not included in generated policies.
- **Reduce policy generation time** – To generate a policy faster, reduce the date range that you specify during setup for policy generation.
- **Use CloudTrail for auditing** – Do not use policy generation for auditing purposes; use CloudTrail instead. For more information about using CloudTrail, see Logging IAM and AWS STS API calls with AWS CloudTrail.
- **Denied actions** – Policy generation reviews all CloudTrail events, including denied actions.
- **One policy IAM console** – You can have one generated policy at a time in the IAM console.
- **Generated policy availability IAM console** – You can review a generated policy in the IAM console for up to 7 days after it is generated. After 7 days, you must generate a new policy.
- **Policy generation quotas** – For additional information about IAM Access Analyzer policy generation quotas, see IAM Access Analyzer quotas.
- **Amazon S3 standard rates apply** – When you use the policy generation feature, IAM Access Analyzer reviews CloudTrail logs in your S3 bucket. There are no additional storage charges to access your CloudTrail logs for policy generation. AWS charges standard Amazon S3 rates for requests and data transfer of CloudTrail logs stored in your S3 bucket.
- **AWS Control Tower support** – Policy generation does not support using AWS CloudTrail trails that AWS Control Tower creates when generating policies, for these reasons:
  - The CloudTrail data from the organization is logged in another account, the AWS Control Tower Log Archive account.
  - Permissions for the S3 bucket where these logs are stored cannot be reconfigured due to the restrictions on the S3 logging bucket set by AWS Control Tower's service control policies (SCPs).

Permissions required to generate a policy

The permissions that you need to generate a policy for the first time differ from those that you need to generate a policy for subsequent uses. For more information, see Getting started with AWS Identity and Access Management Access Analyzer.

First-time setup

When you generate a policy for the first time, you must choose a suitable existing service role in your account or create a new service role. The service role gives IAM Access Analyzer access to CloudTrail and service last accessed information in your account. Only administrators should have the permissions necessary to create and configure roles. Therefore, we recommend that an administrator creates the service role during the first-time setup. To learn more about the permissions required to create service roles, see Creating a role to delegate permissions to an AWS service.

Permissions required for service role

When you create a service role, you configure two policies for the role. You attach an IAM *permissions policy* to the role that specifies what the role can do. You also attach a *role trust policy* to the role that specifies the principal who can use the role.

The first example policy shows the permissions policy for the service role that is required to generate a policy. The second example policy shows the role trust policy that is required for the service role. You can use these policies to help you create a service role when you use the AWS API or AWS CLI to generate a policy. When you use the IAM console to create a service role as part of the policy generation process, we generate these policies for you.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "cloudtrail:GetTrail",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetServiceLastAccessedDetails",
```

```
                "iam:GenerateServiceLastAccessedDetails"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket",
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        }
    ]
}
```

The following example policy shows the role trust policy with the permissions that allows IAM Access Analyzer to assume the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "access-analyzer.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Subsequent uses

To generate policies in the AWS Management Console, an IAM user must have a permissions policy that allows them to pass the service role that is used for policy generation to IAM Access Analyzer. `iam:PassRole` is usually accompanied by `iam:GetRole` so that the user can get the details of the role to be passed. In this example, the user can pass only roles that exist in the specified account with names that begin with `AccessAnalyzerMonitorServiceRole*`. To learn more about passing IAM roles to AWS services, see Granting a user permissions to pass a role to an AWS service.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowUserToPassRole",
      "Effect": "Allow",
      "Action": [
        "iam:GetRole",
        "iam:PassRole"
      ],
      "Resource": "arn:aws:iam::123456789012:role/service-role/
AccessAnalyzerMonitorServiceRole*"
    }
  ]
}
```

You must also have the following IAM Access Analyzer permissions to generate policies in the AWS Management Console, AWS API, or AWS CLI as shown in the following policy statement.

```
{
  "Sid": "AllowUserToGeneratePolicy",
  "Effect": "Allow",
  "Action": [
    "access-analyzer:CancelPolicyGeneration",
    "access-analyzer:GetGeneratedPolicy",
    "access-analyzer:ListPolicyGenerations",
    "access-analyzer:StartPolicyGeneration"
  ],
  "Resource": "*"
}
```

For both first-time and subsequent uses

When you use the AWS Management Console to generate a policy, you must have `cloudtrail:ListTrails` permission to list the CloudTrail trails in your account as shown in the following policy statement.

```
{
  "Sid": "AllowUserToListTrails",
  "Effect": "Allow",
  "Action": [
```

```
    "CloudTrail:ListTrails"
  ],
  "Resource": "*"
}
```

Generate a policy based on CloudTrail activity (console)

You can generate a policy for an IAM user or role.

Step 1: Generate a policy based on CloudTrail activity

The following procedure explains how to generate a policy for a role using the AWS Management Console.

Generate a policy for an IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose **Roles**.

   > **Note**
   >
   > The steps to generate a policy based on activity for an IAM user are almost identical. To do this, choose **Users** instead of **Roles**.

3. In the list of roles in your account, choose the name of the role whose activity you want to use to generate a policy.
4. On the **Permissions** tab, in the **Generate policy based on CloudTrail events** section, choose **Generate policy**.
5. On the **Generate policy** page, specify the time period that you want IAM Access Analyzer to analyze your CloudTrail events for actions taken with the role. You can choose a range of up to 90 days. We recommend that you choose the shortest time period possible to reduce the policy generation time.
6. In the **CloudTrail access** section, choose a suitable existing role or create a new role if a suitable role does not exist. The role gives IAM Access Analyzer permissions to access your CloudTrail data on your behalf to review access activity to identify the services and actions that have been used. To learn more about the permissions required for this role, see Permissions required to generate a policy.

7. In the **CloudTrail trail to be analyzed** section, specify the CloudTrail trail that logs events for the account.

   If you choose a CloudTrail trail that stores logs in a different account, an information box about cross-account access is displayed. Cross-account access requires additional set up. To learn more, see Choose a role for cross-account access later in this topic.
8. Choose **Generate policy**.
9. While policy generation is in progress, you are returned to the **Roles Summary** page on the **Permissions** tab. Wait until the status in the **Policy request details** section displays **Success**, and then choose **View generated policy**. You can view the generated policy for up to seven days. If you generate another policy, the existing policy is replaced with the new one that you generate.

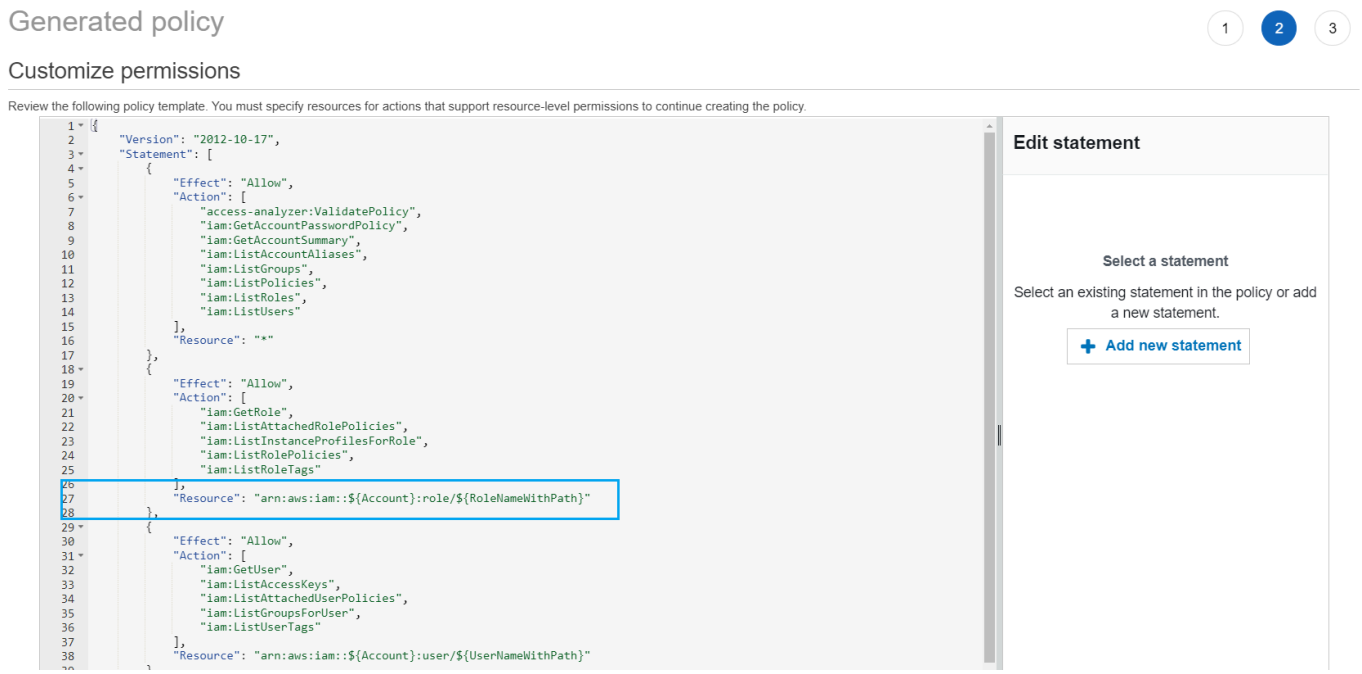
Step 2: Review permissions and add actions for services used

Review the services and actions that IAM Access Analyzer identified that the role used. You can add actions for any services that were used to the generated policy template.

1. Review the following sections:

   - On the **Review permissions** page, review the list of **Actions included in the generated policy**. The list displays the services *and* actions that IAM Access Analyzer identified were used by the role in the specified date range.
   - The **Services used** section displays additional services that IAM Access Analyzer identified that were used by the role in the specified date range. Information about which actions were used might not be available for the services listed in this section. Use the menus for each service listed to manually choose the actions that you want to include in the policy.
2. When you are done adding actions, choose **Next**.

Step 3: Further customize the generated policy



You can further customize the policy by adding or removing permissions or specifying resources.

To customize the generated policy

1. Update the policy template. The policy template contains resource ARN placeholders for actions that support resource-level permissions, as shown in the following image. *Resource-*

level permissions refers to the ability to specify which resources users are allowed to perform actions on. We recommend that you use ARNs to specify your individual resources in the policy for actions that support resource-level permissions. You can replace the placeholder resource ARNs with valid resource ARNs for your use case.

If an action does not support resource-level permissions, you must use a wildcard (*) to specify that all resources can be affected by the action. To learn which AWS services support resource-level permissions, see AWS services that work with IAM. For a list of actions in each service, and to learn which actions support resource-level permissions, see Actions, Resources, and Condition Keys for AWS Services.

2. (Optional) Add, modify, or remove JSON policy statements in the template. To learn more about writing JSON policies, see Creating IAM policies (console).
3. When you are done customizing the policy template, you have the following options:

   - (Optional) You can copy the JSON in the template to use separately outside of the **Generated policy** page. For example, if you want to use the JSON to create a policy in a different account. If the policy in your template exceeds the 6,144 character limit for JSON policies, the policy is split into multiple policies.
   - Choose **Next** to review and create a managed policy in the same account.

Step 4: Review and create a managed policy

If you have permissions to create and attach IAM policies, you can create a managed policy from the policy that was generated. You can then attach the policy to a user or role in your account.

To review and create a policy

1. On the **Review and create managed policy** page, enter a **Name** and **Description** (optional) for the policy that you are creating.
2. (Optional) In the **Summary** section, you can review the permissions that will be included in the policy.
3. (Optional) Add metadata to the policy by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM resources.
4. When you are finished, do one of the following:
   - You can attach the new policy directly to the role that was used to generate the policy. To do this, near the bottom of the page, select the checkbox next to the **Attach policy to *YourRoleName***. Then choose **Create and attach policy**.
   - Otherwise, choose **Create policy**. You can find the policy that you created in the list of policies in the **Policies** navigation pane of the IAM console.
5. You can attach the policy that you created to an entity in your account. After you attach the policy, you can remove any other overly broad policies that might be attached to the entity. To learn how to attach a managed policy, see Adding IAM identity permissions (console).

Generate a policy using AWS CloudTrail data in another account

You might create CloudTrail trails that store data in central accounts to streamline governing activities. For example, you can use AWS Organizations to create a trail that logs all events for all of the AWS accounts in that organization. The trail belongs to a central account. If you want to generate a policy for a user or role in an account that is different from the account where your CloudTrail log data is stored, you must grant cross-account access. To do this, you need both a role and a bucket policy that grant IAM Access Analyzer permissions to your CloudTrail logs. For more information about creating Organizations trails, see Creating a trail for an organization.

In this example, assume that you want to generate a policy for a user or role in account A. The CloudTrail trail in account A stores CloudTrail logs in a bucket in account B. Before you can generate a policy, you must make the following updates:

1. Choose an existing role, or create a new service role that grants IAM Access Analyzer access to the bucket in account B (where your CloudTrail logs are stored).
2. Verify your Amazon S3 bucket object ownership and bucket permissions policy in account B so that IAM Access Analyzer can access objects in the bucket.

Step 1: Choose or create a role for cross-account access

- On the **Generate policy** screen, the option to **Use an existing role** is pre-selected for you if a role with the required permissions exists in your account. Otherwise, choose **Create and use a new service role**. The new role is used to grant IAM Access Analyzer access to your CloudTrail logs in account B.

Step 2: Verify or update your Amazon S3 bucket configuration in account B

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. In the **Buckets** list, choose the name of the bucket where your CloudTrail trail logs are stored.
3. Choose the **Permissions** tab and go to the **Object Ownership** section.

   Use Amazon S3 Object Ownership bucket settings to control ownership of objects that you upload to your buckets. By default, when other AWS accounts upload objects to your bucket, the uploading account owns the objects. To generate a policy, the bucket owner must own all of the objects in the bucket. Depending on your ACL use case, you might need to change the **Object Ownership** setting for your bucket. Set **Object Ownership** to one of the following options.

   - **Bucket owner enforced** (recommended)
   - **Bucket owner preferred**

   > **Important**
   >
   > To successfully generate a policy, the objects in the bucket must be owned by the bucket owner. If you choose to use **Bucket owner preferred**, you can only generate a policy for the time period after the object ownership change was made.

To learn more about object ownership in Amazon S3, see Controlling ownership of objects and disabling ACLs for your bucket in the *Amazon S3 User Guide*.

4. Add permissions to your Amazon S3 bucket policy in account B to allow access for the role in account A.

   The following example policy allows `ListBucket` and `GetObject` for the bucket named `amzn-s3-demo-bucket`. It allows access if the role accessing the bucket belongs to an account in your organization and has a name that starts with `AccessAnalyzerMonitorServiceRole`. Using `aws:PrincipalArn` as a `Condition` in the `Resource` element ensures that the role can only access activity for the account if it belongs to account A. You can replace `amzn-s3-demo-bucket` with your bucket name, `optional-prefix` with an optional prefix for the bucket, and `organization-id` with your organization ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PolicyGenerationBucketPolicy",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/optional-prefix/AWSLogs/organization-id/
${aws:PrincipalAccount}/*"
      ],
      "Condition": {
        "StringEquals": {
          "aws:PrincipalOrgID": "organization-id"
        },
        "StringLike": {
          "aws:PrincipalArn": "arn:aws:iam::${aws:PrincipalAccount}:role/service-
role/AccessAnalyzerMonitorServiceRole*"
        }
```

```
      }
    }
  ]
}
```

5. If you encrypt your logs using AWS KMS, update your AWS KMS key policy in the account where you store the CloudTrail logs to grant IAM Access Analyzer access to use your key, as shown in the following policy example. Replace `CROSS_ACCOUNT_ORG_TRAIL_FULL_ARN` with the ARN for your trail and `organization-id` with your organization ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "kms:Decrypt",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "kms:EncryptionContext:aws:cloudtrail:arn":
 "CROSS_ACCOUNT_ORG_TRAIL_FULL_ARN",
          "aws:PrincipalOrgID": "organization-id"
        },
        "StringLike": {
          "kms:ViaService": [
            "access-analyzer.*.amazonaws.com",
            "s3.*.amazonaws.com"
          ],
          "aws:PrincipalArn": "arn:aws:iam::${aws:PrincipalAccount}:role/service-
role/AccessAnalyzerMonitorServiceRole*"
        }
      }
    }
  ]
}
```

Generate a policy based on CloudTrail activity (AWS CLI)

You can use the following commands to generate a policy using the AWS CLI.

To generate a policy

- aws accessanalyzer start-policy-generation

To view a generated policy

- aws accessanalyzer get-generated-policy

To cancel a policy generation request

- aws accessanalyzer cancel-policy-generation

To view a list of policy generation requests

- aws accessanalyzer list-policy-generations

Generate a policy based on CloudTrail activity (AWS API)

You can use the following operations to generate a policy using the AWS API.

To generate a policy

- StartPolicyGeneration

To view a generated policy

- GetGeneratedPolicy

To cancel a policy generation request

- CancelPolicyGeneration

To view a list of policy generation requests

- ListPolicyGenerations

IAM Access Analyzer policy generation services

The following table lists the AWS services for which IAM Access Analyzer generates policies with action-level information. For a list of actions in each service, see Actions, resources, and condition keys for AWS services in the Service Authorization Reference.

AWS provides policy generation information in JSON format to streamline the automation of policy management workflows. With the service reference information, you can access policy generation information across AWS services from machine-readable files. For more information, see Simplified AWS service information for programmatic access in the Service Authorization Reference.

Service	Service prefix
AWS Identity and Access Management Access Analyzer	access-analyzer

Actions for policy generation information

The following table lists the actions for which IAM Access Analyzer generates policies with action-level information.

Important

The `iam:UpdateAccountName` action will be deprecated on April 22, 2026. After April 22, 2026, only the `account:PutAccountName` permission will control account name update

access. We strongly recommend that you update any service control policies (SCPs) that control account name updates to use the `account:PutAccountName` permission.

IAM Access Analyzer quotas

IAM Access Analyzer has the following quotas:

Resource	Default quota	Maximum quota
Maximum account-level analyzers per analyzer type per AWS account per Region	1	1
Maximum organization-level external or unused access analyzers per analyzer type per AWS account per Region	5	20[1]
Maximum organization-level internal access analyzers per AWS organization per Region	1	1
Maximum archive rules per analyzer	100 Each archive rule can have up to 20 values per criterion.	1,000[1]
Maximum number of access previews per analyzer per hour	1,000	1,000
AWS CloudTrail log files processed per policy generations	100,000	100,000
Concurrent policy generations	1	1
Policy generation AWS CloudTrail data size	25 GB	25 GB
Policy generation AWS CloudTrail time range	90 days	90 days
Policy generations per day	Africa (Cape Town): 5 Asia Pacific (Hong Kong): 5	Africa (Cape Town): 5 Asia Pacific (Hong Kong): 5

Resource	Default quota	Maximum quota
	Asia Pacific (Jakarta): 5 Europe (Milan): 5 Middle East (Bahrain): 5 All other supported regions: 50 **Note** Canceled policy generation requests apply to the daily quota.	Asia Pacific (Jakarta): 5 Europe (Milan): 5 Middle East (Bahrain): 5 All other supported regions: 50

[1]Some quotas are customer-configurable using Service Quotas.

Troubleshoot IAM

Use the information here to help you diagnose and fix common issues when you work with AWS Identity and Access Management (IAM).

Issues

- I can't sign in to my AWS account
- I lost my access keys
- Policy variables aren't working
- Changes that I make are not always immediately visible
- I am not authorized to perform: iam:DeleteVirtualMFADevice
- How do I securely create IAM users?
- Additional resources
- Troubleshoot access denied error messages
- Troubleshoot issues with the root user
- Troubleshoot IAM policies
- Troubleshoot Passkeys and FIDO Security Keys
- Troubleshoot IAM roles
- Troubleshoot IAM and Amazon EC2
- Troubleshoot IAM and Amazon S3
- Troubleshoot SAML federation with IAM

I can't sign in to my AWS account

Verify that you have the correct credentials and that you are using the correct method to sign in. For more information, see Troubleshooting sign-in issues in the *AWS Sign-In User Guide*.

I lost my access keys

Access keys consist of two parts:

- **The access key identifier**. This is not a secret, and can be seen in the IAM console wherever access keys are listed, such as on the user summary page.

- **The secret access key**. This is provided when you initially create the access key pair. Just like a password, it ***cannot be retrieved later***. If you lost your secret access key, then you must create a new access key pair. If you already have the maximum number of access keys, you must delete an existing pair before you can create another.

If you lose your secret access key, you must delete the access key and create a new one. For more instructions, see Update access keys.

Policy variables aren't working

If your policy variables are not working, one of the following errors has occurred:

The date is wrong in the Version policy element.

Verify that all policies that include variables include the following version number in the policy: `"Version": "2012-10-17"`. Without the correct version number, the variables are not replaced during evaluation. Instead, the variables are evaluated literally. Policies that don't include variables still work when you include the latest version number.

A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version is created when you modify a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see IAM JSON policy elements: Version. To learn more about policy versions, see the section called “Versioning IAM policies”.

Variable characters are in the wrong letter case.

Verify that your policy variables are in the right case. For details, see IAM policy elements: Variables and tags.

Changes that I make are not always immediately visible

As a service that is accessed through computers in data centers around the world, IAM uses a distributed computing model called eventual consistency. Any changes that you make in IAM (or other AWS services), including attribute-based access control (ABAC) tags, take time to become visible from all possible endpoints. Some delay results from the time it takes to send data from server to server, replication zone to replication zone, and Region to Region. IAM also uses caching

to improve performance, but in some cases this can add time. The change might not be visible until the previously cached data times out.

You must design your global applications to account for these potential delays. Ensure that they work as expected, even when a change made in one location is not instantly visible at another. Such changes include creating or updating users, groups, roles, or policies. We recommend that you do not include such IAM changes in the critical, high availability code paths of your application. Instead, make IAM changes in a separate initialization or setup routine that you run less frequently. Also, be sure to verify that the changes have been propagated before production workflows depend on them.

For more information about how some other AWS services are affected by this, consult the following resources:

- **Amazon DynamoDB**: Read consistency in the *DynamoDB Developer Guide*, and Read Consistency in the Amazon DynamoDB Developer Guide.
- **Amazon EC2**: EC2 Eventual Consistency in the *Amazon EC2 API Reference*.
- **Amazon EMR**: Ensuring Consistency When Using Amazon S3 and Amazon EMR for ETL Workflows in the AWS Big Data Blog
- **Amazon Redshift**: Managing Data Consistency in the *Amazon Redshift Database Developer Guide*
- **Amazon S3**: Amazon S3 Data Consistency Model in the *Amazon Simple Storage Service User Guide*

I am not authorized to perform: iam:DeleteVirtualMFADevice

You might receive the following error when you attempt to assign or remove a virtual MFA device for yourself or others:

```
User: arn:aws:iam::123456789012:user/Diego is not authorized to
 perform: iam:DeleteVirtualMFADevice on resource: arn:aws:iam::123456789012:mfa/Diego
 with an explicit deny
```

This could happen if someone previously began assigning a virtual MFA device to a user in the IAM console and then cancelled the process. This creates a virtual MFA device for the user in IAM but never assigns it to the user. Delete the existing virtual MFA device before you create a new virtual MFA device with the same device name.

To fix this issue, an administrator should **not** edit policy permissions. Instead, the administrator must use the AWS CLI or AWS API to delete the existing but unassigned virtual MFA device.

To delete an existing but unassigned virtual MFA device

1. View the virtual MFA devices in your account.
   - AWS CLI: `aws iam list-virtual-mfa-devices`
   - AWS API: `ListVirtualMFADevices`
2. In the response, locate the ARN of the virtual MFA device for the user you are trying to fix.
3. Delete the virtual MFA device.
   - AWS CLI: `aws iam delete-virtual-mfa-device`
   - AWS API: `DeleteVirtualMFADevice`

How do I securely create IAM users?

If you have employees that require access to AWS, you might choose to create IAM users or use IAM Identity Center for authentication. If you use IAM, AWS recommends that you create an IAM user and securely communicate the credentials to the employee. If you are not physically located next to your employee, use a secure workflow to communicate credentials to employees.

Use the following secure workflow to create a new user in IAM:

1. Create a new user using the AWS Management Console. Choose to grant AWS Management Console access with a generated password. If necessary, select the **Users must create a new password at next sign-in** check box. Do not add a permissions policy to the user until after they have changed their password.
2. After the user is added, copy the sign-in URL, user name, and password for the new user. To view the password, choose **Show**.
3. Send the password to your employee using a secure communications method in your company, such as email, chat, or a ticketing system. Separately, provide your users with the IAM user console link and their user name. Tell the employee to confirm that they can sign in successfully before you will grant them permissions.
4. After the employee confirms, add the permissions that they need. As a security best practice, add a policy that requires the user to authenticate using MFA to manage their credentials.

For an example policy, see AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page.

Additional resources

The following resources can help you troubleshoot as you work with AWS.

- **AWS CloudTrail User Guide** – Use AWS CloudTrail to track a history of API calls made to AWS and store that information in log files. This helps you determine which users and accounts accessed resources in your account, when the calls were made, what actions were requested, and more. For more information, see Logging IAM and AWS STS API calls with AWS CloudTrail.
- **AWS Knowledge Center** – Find FAQs and links to other resources to help you troubleshoot issues.
- **AWS Support Center** – Get technical support.
- **AWS Premium Support Center** – Get premium technical support.

Troubleshoot access denied error messages

The following information can help you identify, diagnose, and resolve access denied errors with AWS Identity and Access Management. Access denied errors appear when AWS explicitly or implicitly denies an authorization request.

- An *explicit denial* occurs when a policy contains a `Deny` statement for the specific AWS action.
- An *implicit denial* occurs when there is no applicable `Deny` statement and also no applicable `Allow` statement. Because an IAM policy denies an IAM principal by default, the policy must explicitly allow the principal to perform an action. Otherwise, the policy implicitly denies access. For more information, see The difference between explicit and implicit denies.

When you make a request to a service or resource, multiple policies may apply to the request. Review all applicable policies in addition to the policy specified in the error message.

- If multiple policies of the same policy type deny a request, the access denied error message doesn't specify the number of policies evaluated.
- If multiple policy types deny an authorization request, AWS includes only one of those policy types in the error message.

> **Important**
>
> **Having trouble signing in to AWS?** Make sure that you're on the correct AWS sign-in page for your type of user. If you are the AWS account root user (account owner), you can sign in to AWS using the credentials that you set up when you created the AWS account. If you are an IAM user, your account administrator can give you AWS sign-in credentials. If you need to request support, do not use the feedback link on this page. The form is received by the AWS Documentation team, not Support. Instead, on the Contact Us page choose **Still unable to log into your AWS account** and then choose one of the available support options.

I get "access denied" when I make a request to an AWS service

- Check if the error message includes the type of policy responsible for denying access. For example, if the error mentions that access is denied due to a Service Control Policy (SCP), then you can focus on troubleshooting SCP issues. Once you identify the policy type, you can check for deny statements or missing allow actions in those policy types. If the error message doesn't mention the policy type responsible for denying access, use the rest of the guidelines in this section to troubleshoot further.
- Verify that you have the identity-based policy permission to call the action and resource that you have requested. If any conditions are set, you must also meet those conditions when you send the request. For information about viewing or modifying policies for an IAM user, group, or role, see Manage IAM policies.
- If the AWS Management Console returns a message stating that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator provided you with your sign-in credentials or sign-in link.

  The following example error occurs when the `mateojackson` IAM user attempts to use the console to view details about a fictional *`my-example-widget`* resource but does not have the fictional `widgets:`*`GetWidget`* permissions.

  ```
  User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
   widgets:GetWidget on resource: my-example-widget
  ```

  In this case, Mateo must ask his administrator to update his policies to allow access to the *`my-example-widget`* resource using the `widgets:`*`GetWidget`* action.

- Are you trying to access a service that supports resource-based policies, such as Amazon S3, Amazon SNS, or Amazon SQS? If so, verify that the policy specifies you as a principal and grants you access. If you make a request to a service within your account, either your identity-based policies or the resource-based policies can grant you permission. If you make a request to a service in a different account, then both your identity-based policies and the resource-based policies must grant you permission. To view the services that support resource-based policies, see AWS services that work with IAM.
- If your policy includes a condition with a key–value pair, review it carefully. Examples include the `aws:RequestTag/tag-key` global condition key, the AWS KMS `kms:EncryptionContext:encryption_context_key`, and the `ResourceTag/tag-key` condition key supported by multiple services. Make sure that the key name does not match multiple results. Because condition key names are not case sensitive, a condition that checks for a key named `foo` matches `foo`, `Foo`, or `F00`. If your request includes multiple key–value pairs with key names that differ only by case, then your access might be unexpectedly denied. For more information, see IAM JSON policy elements: Condition.
- If you have a permissions boundary, verify that the policy that is used for the permissions boundary allows your request. If your identity-based policies allow the request, but your permissions boundary does not, then the request is denied. A permissions boundary controls the maximum permissions that an IAM principal (user or role) can have. Resource-based policies are not limited by permissions boundaries. Permissions boundaries are not common. For more information about how AWS evaluates policies, see Policy evaluation logic.
- If you are signing requests manually (without using the AWS SDKs), verify that you have correctly signed the request.
- If you're using an Amazon VPC endpoint policy and you get an access denied error that is not logged in AWS CloudTrail, it might be because the VPC endpoint owner account is different from the calling account or target role account.

I get "access denied" when I make a request with temporary security credentials

- First, make sure that you are not denied access for a reason that is unrelated to your temporary credentials. For more information, see I get "access denied" when I make a request to an AWS service.
- Verify that the service accepts temporary security credentials, see AWS services that work with IAM.

- Verify that your requests are being signed correctly and that the request is well-formed. For details, see your toolkit documentation or Use temporary credentials with AWS resources.
- Verify that your temporary security credentials haven't expired. For more information, see Temporary security credentials in IAM.
- Verify that the IAM user or role has the correct permissions. Permissions for temporary security credentials are derived from an IAM user or role. As a result, the permissions are limited to those that are granted to the role whose temporary credentials you have assumed. For more information about how permissions for temporary security credentials are determined, see Permissions for temporary security credentials.
- If you assumed a role, your role session might be limited by session policies. When you request temporary security credentials programmatically using AWS STS, you can optionally pass inline or managed session policies. Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary credential session for a role. You can pass a single JSON inline session policy document using the `Policy` parameter. You can use the `PolicyArns` parameter to specify up to 10 managed session policies. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Alternatively, if your administrator or a custom program provides you with temporary credentials, they might have included a session policy to limit your access.
- If you are an AWS STS federated user principal, your session might be limited by session policies. You create a federated user session by signing in to AWS as an IAM user and then requesting a federation token. For more information, see Requesting credentials through a custom identity broker. If you or your identity broker passed session policies while requesting a federation token, then your session is limited by those policies. The resulting session's permissions are the intersection of your IAM user identity-based policies and the session policies. For more information about session policies, see Session policies.
- If you are accessing a resource that has a resource-based policy by using a role, verify that the policy grants permissions to the role. For example, the following policy allows `MyRole` from account `111122223333` to access `amzn-s3-demo-bucket`.

  JSON

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "S3BucketPolicy",
    "Effect": "Allow",
    "Principal": {"AWS": ["arn:aws:iam::111122223333:role/MyRole"]},
```

```
    "Action": ["s3:PutObject"],
    "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/*"]
  }]
}
```

Access denied error message examples

Most access denied error messages appear in the format `User` *`user`* `is not authorized to perform` *`action`* `on` *`resource`* `because` *`context`*. In this example, *`user`* is the Amazon Resource Name (ARN) that doesn't receive access, *`action`* is the service action that the policy denies, and *`resource`* is the ARN of the resource on which the policy acts. The *`context`* field represents additional context about the policy type that explains why the policy denied access.

When a policy explicitly denies access because the policy contains a `Deny` statement, then AWS includes the phrase `with an explicit deny in a` *`type`* `policy` in the access denied error message. When the policy implicitly denies access, then AWS includes the phrase `because no` *`type`* `policy allows the` *`action`* `action` in the access denied error message.

> **Note**
>
> Some AWS services do not support this access denied error message format. The content of access denied error messages can vary depending on the service making the authorization request.

The following examples show the format for different types of access denied error messages.

Access denied due to a service control policy – implicit denial

1. Check for a missing `Allow` statement for the action in your service control policies (SCPs). For the following example, the action is `codecommit:ListRepositories`.
2. Update your SCP by adding the `Allow` statement. For more information, see Updating an SCP in the *AWS Organizations User Guide*.

```
User: arn:aws:iam::777788889999:user/John is not authorized to perform:
codecommit:ListRepositories because no service control policy allows the
 codecommit:ListRespositories action
```

Access denied due to a service control policy – explicit denial

1. Check for a `Deny` statement for the action in your service control policies (SCPs). For the following example, the action is `codecommit:ListRepositories`.
2. Update your SCP by removing the `Deny` statement. For more information, see Update a service control policy (SCP) in the *AWS Organizations User Guide*.

```
User: arn:aws:iam::777788889999:user/John is not authorized to perform:
codecommit:ListRepositories with an explicit deny in a service control policy
```

Access denied due to a resource control policy – explicit denial

1. Check for a `Deny` statement for the action in your resource control policies (RCPs). For the following example, the action is `secretsmanager:GetSecretValue`.
2. Update your RCP by removing the `Deny` statement. For more information, see Update a resource control policy (RCP) in the *AWS Organizations User Guide*.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
secretsmanager:GetSecretValue on resource: arn:aws:secretsmanager:us-
east-1:123456789012:secret:* with an explicit deny in a resource control policy
```

Access denied due to a VPC endpoint policy – implicit denial

1. Check for a missing `Allow` statement for the action in your Virtual Private Cloud (VPC) endpoint policies. For the following example, the action is `codecommit:ListRepositories`.
2. Update your VPC endpoint policy by adding the `Allow` statement. For more information, see Update a VPC endpoint policy in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
codecommit:ListRepositories because no VPC endpoint policy allows the
 codecommit:ListRepositories action
```

Access denied due to a VPC endpoint policy – explicit denial

1. Check for an explicit `Deny` statement for the action in your Virtual Private Cloud (VPC) endpoint policies. For the following example, the action is `codedeploy:ListDeployments`.
2. Update your VPC endpoint policy by removing the `Deny` statement. For more information, see Update a VPC endpoint policy in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* with an explicit deny in a VPC endpoint policy
```

Access denied due to a permissions boundary – implicit denial

1. Check for a missing `Allow` statement for the action in your permissions boundary. For the following example, the action is `codedeploy:ListDeployments`.
2. Update your permissions boundary by adding the `Allow` statement to your IAM policy. For more information, see Permissions boundaries for IAM entities and Edit IAM policies.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* because no permissions boundary allows the
 codedeploy:ListDeployments action
```

Access denied due to a permissions boundary – explicit denial

1. Check for an explicit `Deny` statement for the action in your permissions boundary. For the following example, the action is `sagemaker:ListModels`.
2. Update your permissions boundary by removing the `Deny` statement from your IAM policy. For more information, see Permissions boundaries for IAM entities and Edit IAM policies.

```
User: arn:aws:iam::777788889999:user/John is not authorized to perform:
sagemaker:ListModels with an explicit deny in a permissions boundary
```

Access denied due to session policies – implicit denial

1. Check for a missing `Allow` statement for the action in your session policies. For the following example, the action is `codecommit:ListRepositories`.
2. Update your session policy by adding the `Allow` statement. For more information, see Session policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
codecommit:ListRepositories because no session policy allows the
 codecommit:ListRepositories action
```

Access denied due to session policies – explicit denial

1. Check for an explicit `Deny` statement for the action in your session policies. For the following example, the action is `codedeploy:ListDeployments`.
2. Update your session policy by removing the `Deny` statement. For more information, see Session policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* with an explicit deny in a sessions policy
```

Access denied due to resource-based policies – implicit denial

1. Check for a missing `Allow` statement for the action in your resource-based policy. For the following example, the action is `secretsmanager:GetSecretValue`.
2. Update your policy by adding the `Allow` statement. For more information, see Resource-based policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
secretsmanager:GetSecretValue because no resource-based policy allows the
 secretsmanager:GetSecretValue action
```

Access denied due to resource-based policies – explicit denial

1. Check for an explicit `Deny` statement for the action in your resource-based policy. For the following example, the action is `secretsmanager:GetSecretValue`.
2. Update your policy by removing the `Deny` statement. For more information, see Resource-based policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
secretsmanager:GetSecretValue on resource: arn:aws:secretsmanager:us-
east-1:123456789012:secret:* with an explicit deny in a resource-based policy
```

Access denied due to role trust policies – implicit denial

1. Check for a missing `Allow` statement for the action in your role trust policy. For the following example, the action is `sts:AssumeRole`.
2. Update your policy by adding the `Allow` statement. For more information, see Resource-based policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:user/John is not authorized to perform:
sts:AssumeRole because no role trust policy allows the sts:AssumeRole action
```

Access denied due to role trust policies – explicit denial

1. Check for an explicit `Deny` statement for the action in your role trust policy. For the following example, the action is `sts:AssumeRole`.
2. Update your policy by removing the `Deny` statement. For more information, see Resource-based policies and Edit IAM policies.

```
User: arn:aws:iam::777788889999:user/John is not authorized to perform:
sts:AssumeRole with an explicit deny in the role trust policy
```

Access denied due to identity-based policies – implicit denial

1. Check for a missing `Allow` statement for the action in identity-based policies attached to the identity. For the following example, the action is `codecommit:ListRepositories` attached to the role HR.
2. Update your policy by adding the `Allow` statement. For more information, see Identity-based policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:role/HR is not authorized to perform:
codecommit:ListRepositories because no identity-based policy allows the
 codecommit:ListRepositories action
```

Access is denied due to identity-based policies – explicit denial

1. Check for an explicit `Deny` statement for the action in identity-based policies attached to the identity. For the following example, the action is `codedeploy:ListDeployments` attached to the role HR.
2. Update your policy by removing the `Deny` statement. For more information, see Identity-based policies and Edit IAM policies.

```
User: arn:aws:iam::123456789012:role/HR is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* with an explicit deny in an identity-based policy
```

Access is denied when a VPC request fails due to another policy

1. Check for an explicit `Deny` statement for the action in your Service Control Policies (SCPs). For the following example, the action is `SNS:Publish`.
2. Update your SCP by removing the `Deny` statement. For more information, see Updating an SCP in the *AWS IAM Identity Center User Guide*.

```
User: arn:aws:sts::111122223333:assumed-role/role-name/role-session-name is not
 authorized to perform:
SNS:Publish on resource: arn:aws:sns:us-east-1:444455556666:role-name-2
```

```
with an explicit deny in a VPC endpoint policy transitively through a service control
 policy
```

Troubleshoot issues with the root user

Use the information here to help you troubleshoot issues related to the root user of an AWS account.

> **Note**
>
> AWS accounts managed using AWS Organizations may have centralized root access enabled for member accounts. These member accounts do not have root user credentials, can't sign in as a root user, and are prevented from recovering the root user password. Contact your administrator if you need to perform a task that requires root user credentials.

I can't perform tasks that I expect to be able to do when signed in as the account root user

Your account might be a member of an organization in AWS Organizations. Your organizational administrator may have a service control policy (SCP) to limit the permissions of your account. SCPs impact all users, including the root user. For more information, see Service control policies in the *AWS Organizations User Guide*.

I forgot the root user password for my AWS account

If you're a root user and you have lost or forgot the password for your AWS account, you can reset your password. You must know the email address used to create the AWS account, and you must have access to the email account. For more information, see Reset a lost or forgotten root user password.

I don't have access to the email for my AWS account

When you create an AWS account, you provide an email address and password. These are the credentials for the AWS account root user. If you aren't sure of the email address associated with your AWS account, search for messages sent from `@signin.aws` or `@verify.signin.aws` to any email address for your organization that might have been used to open the AWS account.

If you know the email address but no longer have access to the email, try to recover access to the email. Use one of the following options to regain access to your email:

- If you own the domain for the email address, you can restore a deleted email address. Alternatively, you can set up a catch-all for your email account. A catch-all collects all messages sent to email addresses that no longer exist in the mail server and redirects them to another email address.
- If the email address on the account is part of your corporate email system, we recommend that you contact your IT system administrators. They might be able to help you regain access to the email.

If you're still not able to sign in to your AWS account, you can find alternate support options at Contact us.

Troubleshoot IAM policies

A policy is an entity in AWS that, when attached to an identity or resource, defines their permissions. AWS evaluates these policies when a principal, such as a user, makes a request. Permissions in the policies determine whether the request is allowed or denied. Policies are stored in AWS as JSON documents that are attached to principals as *identity-based policies* or to resources as *resource-based policies*. You can attach an identity-based policy to a principal (or identity), such as an IAM group, user, or role. Identity-based policies include AWS managed policies, customer managed policies, and inline policies. You can create and edit customer managed policies in the AWS Management Console using both **Visual** and **JSON** editor options. When you view a policy in the AWS Management Console, you can see a summary of the permissions that are granted by that policy. You can use the visual editor and policy summaries to help you diagnose and fix common errors encountered while managing IAM policies.

Keep in mind that all IAM policies are stored using syntax that begins with the rules of JavaScript Object Notation (JSON). You do not have to understand this syntax to create or manage your policies. You can create and edit a policy using the visual editor in the AWS Management Console. To learn more about JSON syntax in IAM policies, see Grammar of the IAM JSON policy language .

Troubleshooting IAM Policy Topics

- Troubleshoot using the visual editor
  - Policy restructuring

- Choosing a resource ARN in the visual editor
- Denying permissions in the visual editor
- Specifying multiple services in the visual editor
- Reducing the size of your policy in the visual editor
- Fixing unrecognized services, actions, or resource types in the visual editor
- Troubleshoot with policy summaries
  - Missing policy summary
  - Policy summary includes unrecognized services, actions, or resource types
  - Service does not support IAM policy summaries
  - My policy does not grant the expected permissions
- Troubleshoot policy management
  - Attaching or detaching a policy in an IAM account
  - Changing policies for your IAM identities based on their activity
- Troubleshoot JSON policy documents
  - Validate your policies
  - I don't have permissions for policy validation in the JSON editor
  - More than one JSON policy object
  - More than one JSON statement element
  - More than one effect, action, or resource element in a JSON statement element
  - Missing JSON version element

Troubleshoot using the visual editor

When you create or edit a customer managed policy, you can use information in the **Visual** editor to help you troubleshoot errors in your policy. To view an example of using the visual editor to create a policy, see the section called “Controlling access to identities”.

Policy restructuring

When you create a policy, AWS validates, processes, and transforms the policy before storing it. When the policy is retrieved, AWS transforms it back to a human-readable format without changing permissions. This can result in differences in what you see in the policy visual editor or **JSON** tab.

- Visual editor permission blocks can be added, removed, or reordered, and content within a block can be optimized.
- In the **JSON** tab, insignificant white space can be removed, and elements within JSON maps can be reordered. In addition, AWS account IDs within the principal elements can be replaced by the Amazon Resource Name (ARN) of the AWS account root user.

Because of these possible changes, you should not compare JSON policy documents as strings.

When you create a customer managed policy in the AWS Management Console, you can choose to work entirely in the **JSON** editor. If you never change the policy in the **Visual** editor and choose **Next** from the **JSON** editor, the policy is less likely to be restructured. When you use the **Visual** editor, IAM might restructure the policy to optimize its appearance. This restructuring exists only in your editing session and is not saved automatically.

If your policy is restructured in your editing session, IAM determines whether to save the restructuring based on the following situations:

Using this editor option	**If you edit your policy**	**And then choose *Next* from this tab**	**When you choose *Save changes***
Visual	Edited	**Visual**	The policy is restructured
Visual	Edited	**JSON**	The policy is restructured
Visual	Not Edited	**Visual**	The policy is restructured
JSON	Edited	**Visual**	The policy is restructured
JSON	Edited	**JSON**	The policy structure is not changed
JSON	Not Edited	**JSON**	The policy structure is not changed

IAM might restructure complex policies or policies that have permission blocks or statements that allow multiple services, resource types, or condition keys.

Choosing a resource ARN in the visual editor

When you create or edit a policy using the visual editor, you must first choose a service, and then choose actions from that service. If the service and actions that you selected support choosing specific resources, then the visual editor lists the supported resource types. You can then choose **Add ARN** to provide the details about your resource. You can choose from the following options for adding an ARN for a resource type.

- **Use the ARN builder** – You might see different fields to build your ARN based on the resource type. You can also choose **Any** to provide permissions for any value for the specified setting. For example, if you selected the Amazon EC2 **Read** access level group, then the actions in your policy support the `instance` resource type. Provide the **Region**, **Account**, and **InstanceId** values for your resource. The policy grants permissions to any instance in your account if you provide your account ID and choose **Any** for the Region and instance ID.
- **Type or paste the ARN** – You can specify resources by their Amazon Resource Name (ARN). You can include a wildcard character (*) in any field of the ARN (between each pair of colons). For more information, see IAM JSON policy elements: Resource.

Denying permissions in the visual editor

By default, the policy that you create using the visual editor allows the actions that you choose. To deny the chosen actions instead, choose **Switch to deny permissions**. Because requests are *denied by default*, we recommend that you allow permissions to only those actions and resources that a user needs. You should create a deny statement only if you want to override a permission separately that is allowed by another statement or policy. We recommend that you limit the number of deny permissions to a minimum because they can increase the difficulty of troubleshooting permissions. For more information about how IAM evaluates policy logic, see Policy evaluation logic.

> **Note**
>
> By default, only the AWS account root user has access to all the resources in that account. So if you are not signed in as the root user, you must have permissions granted by a policy.

Specifying multiple services in the visual editor

When you use the visual editor to construct a policy, you can select only one service at a time. This is a best practice because the visual editor then allows you to choose from the actions for that one service. You then choose from the resources supported by that service and the selected actions. This makes it easier to create and troubleshoot your policy.

You can also use a wildcard character (*) to manually specify multiple services. For example, type **`Code*`** to provide permissions for all services beginning with `Code`, such as `CodeBuild` and `CodeCommit`. However, you must then type the actions and resource ARNs to complete your policy. Additionally, when you save your policy, it might be restructured to include each service in a separate permission block.

Alternatively, to use JSON syntax (such as wildcards) for services, create, edit, and save your policy using the **JSON** editor option.

Reducing the size of your policy in the visual editor

When you use the visual editor to create a policy, IAM creates a JSON document to store your policy. You can view this document by switching to the **JSON** editor option. If this JSON document exceeds the size limit of a policy, the visual editor displays an error message. You will not be able to review and save the policy. To view the IAM limitation on the size of a managed policy, see IAM and STS character limits.

To reduce the size of your policy in the visual editor, edit your policy or move permission blocks to another policy. The error message includes the number of characters that your policy document contains. You can use this information to help you reduce the size of your policy.

Fixing unrecognized services, actions, or resource types in the visual editor

You might see a warning in the visual editor that your policy includes an unrecognized service, action, or resource type.

> **Note**
>
> IAM reviews service names, actions, and resource types for services that support policy summaries. However, your policy summary might include a resource value or condition that does not exist. Always test your policies with the policy simulator.

If your policy includes unrecognized services, actions or resource types, one of the following errors has occurred:

- **Preview service** – Services that are in preview do not support the visual editor. If you are participating in the preview, you must manually type the actions and resource ARNs to complete your policy. You can ignore any warnings and continue. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.
- **Custom service** – Custom services do not support the visual editor. If you are using a custom service, you must manually type the actions and resource ARNs to complete your policy. You can ignore any warnings and continue. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.
- **Service does not support the visual editor** – If your policy includes a generally available (GA) service that does not support the visual editor, you must manually type the actions and resource ARNs to complete your policy. You can ignore any warnings and continue. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.

  Generally available services are services that are released publicly and are not preview or custom services. If an unrecognized service is generally available and the name is spelled correctly, then the service does not support the visual editor. To learn how to request visual editor or policy summary support for a GA service, see Service does not support IAM policy summaries.
- **Action does not support the visual editor** – If your policy includes a supported service with an unsupported action, you must manually type the actions and resource ARNs to complete your policy. You can ignore any warnings and continue. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.

  If your policy includes a supported service with an unsupported action, then the service does not fully support the visual editor. To learn how to request visual editor or policy summary support for a GA service, see Service does not support IAM policy summaries.
- **Resource type does not support the visual editor** – If your policy includes a supported action with an unsupported resource type, you can ignore the warning and continue. However, IAM cannot confirm that you have included resources for all of your selected actions, and you might see additional warnings.
- **Typo** – When you manually type a service, action, or resource in the visual editor, you can create a policy that includes a typo. We recommend that you use the visual editor by selecting from the list of services and actions. Then, complete the resource section according to the prompts. If a

service does not fully support the visual editor, you might have to manually type parts of your policy.

If you are certain that your policy contains none of the errors above, then your policy might include a typo. Check for the following issues:

- Misspelled service, action, and resource type names, such as `s2` instead of `s3` or `ListMyBuckets` instead of `ListAllMyBuckets`
- Unnecessary text in ARNs, such as `arn:aws:s3: : :*`
- Missing colons in actions, such as `iam.CreateUser`

You can evaluate a policy that might include typos by choosing **Next** to review the policy summary. Then, confirm whether the policy provides the permissions you intended.

Troubleshoot with policy summaries

You can diagnose and resolve issues related to policy summaries.

Missing policy summary

The IAM console includes *policy summary* tables that describe the access level, resources, and conditions that are allowed or denied for each service in a policy. Policies are summarized in three tables: the policy summary, the service summary, and the action summary. The *policy summary* table includes a list of services and summaries of the permissions that are defined by the chosen policy. You can view the policy summary for any policies that are attached to an entity on the **Policy details** page for that policy. You can view the policy summary for managed policies on the **Policies** page. If AWS is unable to render a summary for a policy, you will see the JSON policy document and the following error:

A summary for this policy cannot be generated. You can still view or edit the JSON policy document.

If your policy does not include a summary, one of the following errors has occurred:

- **Unsupported policy element** – IAM does not support generating policy summaries for policies that include one of the following policy elements:
  - `Principal`
  - `NotPrincipal`
  - `NotResource`

- **No policy permissions** – If a policy does not provide any effective permissions, then the policy summary cannot be generated. For example, if a policy includes a single statement with the element `"NotAction": "*"`, then it grants access to all actions except "all actions" (*). This means it grants `Deny` or `Allow` access to nothing.

  > **Note**
  >
  > Be careful when using these policy elements such as `NotPrincipal`, `NotAction`, and `NotResource`. For information about using policy elements, see IAM JSON policy element reference.

  If you provide mismatched services and resources, you can create a policy that does not provide effective permissions. This can occur when you specify actions in one service and resources from another service. In this case, the policy summary does appear. The only indication that there is a problem is that the resource column in the summary can include a resource from a different service. If this column includes a mismatched resource, then you should review your policy for errors. Test your policies with the policy simulator to better understand the policy.

Policy summary includes unrecognized services, actions, or resource types

In the IAM console, if a policy summary includes a warning symbol
( ),
then the policy might include an unrecognized service, action, or resource type. To learn about warnings within a policy summary, see Policy summary (list of services).

> **Note**
>
> IAM reviews service names, actions, and resource types for services that support policy summaries. However, your policy summary might include a resource value or condition that does not exist. Always test your policies with the policy simulator.

If your policy includes unrecognized services, actions or resource types, one of the following errors has occurred:

- **Preview service** – Services that are in preview do not support policy summaries.

- **Custom service** – Custom services do not support policy summaries.
- **Service does not support summaries** – If your policy includes a generally available (GA) service that does not support policy summaries, then the service is included in the **Unrecognized services** section of the policy summary table. Generally available services are services that are released publicly and are not preview or custom services. If an unrecognized service is generally available and the name is spelled correctly, then the service does not support IAM policy summaries. To learn how to request policy summary support for a GA service, see Service does not support IAM policy summaries.
- **Action does not support summaries** – If your policy includes a supported service with an unsupported action, then the action is included in the **Unrecognized actions** section of the service summary table. To learn about warnings within a service summary, see Service summary (list of actions).
- **Resource type does not support summaries** – If your policy includes a supported action with an unsupported resource type, then the resource is included in the **Unrecognized resource types** section of the service summary table. To learn about warnings within a service summary, see Service summary (list of actions).
- **Typo** – AWS checks that the JSON is syntactically correct, and that the policy does not include typos or other errors as part of policy validation.

> **Note**
>
> As a best practice, we recommend that you use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions. We recommend that you open your existing policies and review and resolve any policy validation recommendations.

Service does not support IAM policy summaries

It is possible for the IAM policy summaries or the visual editor to not support a generally available (GA) service or action. Generally available services are services that are released publicly and are not previewed or custom services. If an unrecognized service is generally available and the name is spelled correctly, then the service does not support these features. If your policy includes a supported service with an unsupported action, then the service does not fully support IAM policy summaries.

To request that a service add IAM policy summary or visual editor support

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Locate the policy that includes the unsupported service:
   - If the policy is a managed policy, choose **Policies** in the navigation pane. In the list of policies, choose the name of the policy that you want to view.
   - If the policy is an inline policy attached to the user, choose **Users** in the navigation pane. In the list of users, choose the name of the user whose policy you want to view. In the table of policies for the user, expand the header for the policy summary that you want to view.
3. In the left side on the AWS Management Console footer, choose **Feedback**. In the **Feedback for IAM** box, type **`I request that the <ServiceName> service add support for IAM policy summaries and the visual editor`**. If you want more than one service to support summaries, type **`I request that the <ServiceName1>, <ServiceName2>, and <ServiceName3> services add support for IAM policy summaries and the visual editor`**.

To request that a service add IAM policy summary support for a missing action

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Locate the policy that includes the unsupported service:
   - If the policy is a managed policy, choose **Policies** in the navigation pane. In the list of policies, choose the name of the policy that you want to view.
   - If the policy is an inline policy attached to the user, choose **Users** in the navigation pane. In the list of users, choose the name of the user whose policy you want to view. In the table of policies for the user, choose the name of the policy that you want to view to expand the policy summary.
3. In the policy summary, choose the name of the service that includes an unsupported action.
4. In the left side on the AWS Management Console footer, choose **Feedback**. In the **Feedback for IAM** box, type **`I request that the <ServiceName> service add IAM policy summary and the visual editor support for the <ActionName> action`**. If you want to report more than one unsupported action, type **`I request that the`**

`<ServiceName> service add IAM policy summary and the visual editor support for the <ActionName1>, <ActionName2>, and <ActionName3> actions`.

To request that a different service includes missing actions, repeat the last three steps.

My policy does not grant the expected permissions

To assign permissions to a user, group, role, or resource, you create a *policy*, which is a document that defines permissions. The policy document includes the following elements:

- **Effect** – whether the policy allows or denies access
- **Action** – the list of actions that are allowed or denied by the policy
- **Resource** – the list of resources on which the actions can occur
- **Condition** (Optional) – the circumstances under which the policy grants permission

To learn about these and other policy elements, see IAM JSON policy element reference.

To grant access, your policy must define an action with a supported resource. If your policy also includes a condition, that condition must include a global condition key or must apply to the action. To learn which resources are supported by an action, see the AWS documentation for your service. To learn which conditions are supported by an action, see Actions, Resources, and Condition Keys for AWS Services.

Check whether your policy defines an action, resource, or condition that does not grant permissions. View the policy summary for your policy using the IAM console at https://console.aws.amazon.com/iam/. You can use policy summaries to identify and correct problems in your policy.

There are several reasons why an element might not grant permissions despite being defined in the IAM policy:

- **An action is defined without an applicable resource**
- **A resource is defined without an applicable action**
- **A condition is defined without an applicable action**

To view examples of policy summaries that include warnings, see the section called “Policy summary (list of services)”.

An action is defined without an applicable resource

The policy below defines all `ec2:Describe*` actions and defines a specific resource. None of the `ec2:Describe` actions are granted because none of these actions support resource-level permissions. Resource-level permissions mean that the action supports resources using ARNs in the policy's `Resource` element. If an action does not support resource-level permissions, then that statement in the policy must use a wildcard (*) in the `Resource` element. To learn which services support resource-level permissions, see AWS services that work with IAM.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:Describe*",
            "Resource": "arn:aws:ec2:us-east-2:111122223333:instance/*"
        }
    ]
}
```

This policy does not provide any permissions, and the policy summary includes the following error:

`This policy does not grant any permissions. To grant access, policies must have an action that has an applicable resource or condition.`

To fix this policy, you must use * in the `Resource` element.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "ec2:Describe*",
        "Resource": "*"
    }]
}
```

A resource is defined without an applicable action

The policy below defines an Amazon S3 bucket resource but does not include an S3 action that can be performed on that resource. This policy also grants full access to all Amazon CloudFront actions.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
        "Effect": "Allow",
        "Action": "cloudfront:*",
        "Resource": [
            "arn:aws:cloudfront:*",
            "arn:aws:s3:::amzn-s3-demo-bucket"
        ]
        }
    ]
}
```

This policy provides permissions for all CloudFront actions. But because the policy defines the S3 `amzn-s3-demo-bucket` resource without defining any S3 actions, the policy summary includes the following warning:

`This policy defines some actions, resources, or conditions that do not provide permissions. To grant access, policies must have an action that has an applicable resource or condition.`

To fix this policy to provide S3 bucket permissions, you must define S3 actions that can be performed on a bucket resource.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "cloudfront:*",
                "s3:CreateBucket",
                "s3:ListBucket*",
                "s3:PutBucket*",
                "s3:GetBucket*"
            ],
            "Resource": [
                "arn:aws:cloudfront:*",
                "arn:aws:s3:::amzn-s3-demo-bucket"
            ]
        }
    ]
}
```

Alternately, to fix this policy to provide only CloudFront permissions, remove the S3 resource.

A condition is defined without an applicable action

The policy below defines two Amazon S3 actions for all S3 resources, if the S3 prefix equals `custom` and the version ID equals `1234`. However, the `s3:VersionId` condition key is used for object version tagging and is not supported by the defined bucket actions. To learn which conditions are supported by an action, see Actions, Resources, and Condition Keys for AWS Services and choose the service to view service documentation for condition keys.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucketVersions",
                "s3:ListBucket"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "s3:prefix": [
                        "custom"
                    ],
```

```
                    "s3:VersionId": [
                        "1234"
                    ]
                }
            }
        }
    ]
}
```

This policy provides permissions for the `s3:ListBucketVersions` action and the `s3:ListBucket` action if the bucket name includes the `custom` prefix. But because the `s3:VersionId` condition is not supported by any of the defined actions, the policy summary includes the following error:

`This policy does not grant any permissions. To grant access, policies must have an action that has an applicable resource or condition.`

To fix this policy to use S3 object version tagging, you must define an S3 action that supports the `s3:VersionId` condition key.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucketVersions",
                "s3:ListBucket",
                "s3:GetObjectVersion"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "s3:prefix": [
                        "custom"
                    ],
                    "s3:VersionId": [
                        "1234"
                    ]
```

```
                }
            }
        }
    ]
}
```

This policy provides permissions for every action and condition in the policy. However, the policy still does not provide any permissions because there is no case where a single action matches both conditions. Instead, you must create two separate statements that each include only actions with the conditions to which they apply.

To fix this policy, create two statements. The first statement includes the actions that support the `s3:prefix` condition, and the second statement includes the actions that support the `s3:VersionId` condition.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucketVersions",
                "s3:ListBucket"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "s3:prefix": "custom"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "s3:GetObjectVersion",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "s3:VersionId": "1234"
                }
```

```
            }
        }
    ]
}
```

Troubleshoot policy management

You can diagnose and resolve issues relating to policy management.

Attaching or detaching a policy in an IAM account

Some AWS managed policies are linked to a service. These policies are used only with a service-linked role for that service. In the IAM console, when you view the **Policy details** page, the page includes a banner to indicate that the policy is linked to a service. You cannot attach this policy to a user, group, or role within IAM. When you create a service-linked role for the service, this policy is automatically attached to your new role. Because the policy is required, you cannot detach the policy from the service-linked role.

Changing policies for your IAM identities based on their activity

You can update policies for your IAM identities (users, groups, and roles) based on their activity. To do this, view your account's events in CloudTrail **Event history**. CloudTrail event logs include detailed event information that you can use to change the policy's permissions.

A user or role is attempting to perform an action in AWS and that request is denied.

Consider whether the user or role should have permission to perform the action. If so, you can add the action and even the ARN of the resource that they attempted to access to their policy.

A user or role has permissions that they are not using.

Consider removing those permissions from their policy. Make sure that your policies grant the least privilege that is needed to perform only the necessary actions.

For more information about using CloudTrail, see Viewing CloudTrail Events in the CloudTrail Console in the *AWS CloudTrail User Guide*.

Troubleshoot JSON policy documents

You can diagnose and resolve issues relating to JSON policy documents.

Validate your policies

When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see IAM policy validation. To learn more about IAM Access Analyzer policy checks and actionable recommendations, see IAM Access Analyzer policy validation.

I don't have permissions for policy validation in the JSON editor

In the AWS Management Console, you might receive the following error if you do not have permissions to view IAM Access Analyzer policy validation results:

`You need permissions. You do not have the permissions required to perform this operation. Ask your administrator to add permissions.`

To fix this error, ask your administrator to add the `access-analyzer:ValidatePolicy` permission for you.

More than one JSON policy object

An IAM policy must consist of only one JSON object. You denote an object by placing { } braces around it. You can nest other objects within a JSON object by embedding additional { } braces within the outer pair. A policy must contain only one outermost pair of { } braces. The following example is incorrect because it contains two objects at the top level (called out in *red*):

JSON

```
{
      "Version": "2012-10-17",
      "Statement":
      {
         "Effect":"Allow",
         "Action":"ec2:Describe*",
         "Resource":"*"
      }
   }
   {
      "Statement": {
         "Effect": "Allow",
         "Action": "s3:*",
```

```
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
      }
    }
```

You can, however, meet the intention of the previous example with the use of correct policy grammar. Instead of including two complete policy objects each with its own `Statement` element, you can combine the two blocks into a single `Statement` element. The `Statement` element has an array of two objects as its value, as shown in the following example (called out in **bold**):

JSON

```
{
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Action": "ec2:Describe*",
          "Resource":"*"
        },
        {
          "Effect": "Allow",
          "Action": "s3:*",
          "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
      ]
    }
```

More than one JSON statement element

This error might at first appear to be a variation on the previous section. However, syntactically it is a different type of error. The following example has only one policy object as denoted by a single pair of { } braces at the top level. However, that object contains two `Statement` elements within it.

An IAM policy must contain only one `Statement` element, consisting of the name (`Statement`) appearing to the left of a colon, followed by its value on the right. The value of a `Statement` element must be an object, denoted by { } braces, containing one `Effect` element, one `Action` element, and one `Resource` element. The following example is incorrect because it contains two `Statement` elements in the policy object (called out in *red*):

JSON

```
{
      "Version": "2012-10-17",
      "Statement": {
        "Effect": "Allow",
        "Action": "ec2:Describe*",
        "Resource": "*"
      },
      "Statement": {
        "Effect": "Allow",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
      }
    }
```

A value object can be an array of multiple value objects. To solve this problem, combine the two `Statement` elements into one element with an object array, as shown in the following example (called out in **bold**):

JSON

```
{
      "Version": "2012-10-17",
      "Statement": [    {
          "Effect": "Allow",
          "Action": "ec2:Describe*",
          "Resource":"*"
        },
        {
          "Effect": "Allow",
          "Action": "s3:*",
          "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
     ]
    }
```

The value of the `Statement` element is an object array. The array in this example consists of two objects, each of which is by itself is a correct value for a `Statement` element. Each object in the array is separated by commas.

More than one effect, action, or resource element in a JSON statement element

On the value side of the `Statement` name/value pair, the object must consist of only one `Effect` element, one `Action` element, and one `Resource` element. The following policy is incorrect because it has two `Effect` elements in the `Statement`:

JSON

```
{
      "Version": "2012-10-17",
      "Statement": {
        "Effect": "Deny",
        "Effect": "Allow",
        "Action": "ec2:* ",
        "Resource": "*"
      }
    }
```

Note

The policy engine does not allow such errors in new or edited policies. However, the policy engine continues to permit policies that were saved before the engine was updated. The behavior of existing policies with the error is as follows:

- Multiple `Effect` elements: only the last `Effect` element is observed. The others are ignored.
- Multiple `Action` elements: all `Action` elements are combined internally and treated as if they are a single list.
- Multiple `Resource` elements: all `Resource` elements are combined internally and treated as if they are a single list.

> The policy engine does not allow you to save any policy with syntax errors. Correct the errors in the policy before saving. Review and correct any policy validation recommendations for your policies.

In each case, the solution is to remove the incorrect extra element. For `Effect` elements, this is straightforward: if you want the previous example to *deny* permissions to Amazon EC2 instances, then you must remove the line `"Effect": "Allow",` from the policy, as follows:

JSON

```
{
      "Version": "2012-10-17",
      "Statement": {
        "Effect": "Deny",
        "Action": "ec2:*",
        "Resource": "*"
      }
    }
```

However, if the duplicate element is `Action` or `Resource`, then the resolution can be more complicated. You might have multiple actions that you want to allow (or deny) permission to, or you might want to control access to multiple resources. For example, the following example is incorrect because it has multiple `Resource` elements (called out in *`red`*):

JSON

```
{
      "Version": "2012-10-17",
      "Statement": {
        "Effect": "Allow",
        "Action": "s3:*",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
        "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
      }
    }
```

Each of the required elements in a `Statement` element's value object can be present only once. The solution is to place each value in an array. The following example illustrates this by making the two separate resource elements into one `Resource` element with an array as the value object (called out in **bold**):

JSON

```
{
      "Version": "2012-10-17",
      "Statement": {
        "Effect": "Allow",
        "Action": "s3:*",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*"
        ]
      }
    }
```

Missing JSON version element

A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. In comparison, a policy version is created when you change a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see IAM JSON policy elements: Version. To learn more about policy versions, see the section called “Versioning IAM policies”.

As AWS features evolve, new capabilities are added to IAM policies to support those features. Sometimes, an update to the policy syntax includes a new version number. If you use newer features of the policy grammar in your policy, then you must tell the policy parsing engine which version you are using. The default policy version is "2008-10-17." If you want to use any policy feature that was introduced later, then you must specify the version number that supports the feature you want. We recommend that you *always* include the latest policy syntax version number, which is currently `"Version": "2012-10-17"`. For example, the following policy is incorrect because it uses a policy variable `${...}` in the ARN for a resource. But it fails to specify a policy syntax version that supports policy variables (called out in *red*):

```
{
  "Statement":
  {
    "Action": "iam:*AccessKey*",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::123456789012:user/${aws:username}"
  }
}
```

Adding a `Version` element at the top of the policy with the value `2012-10-17`, the first IAM API version that supports policy variables, solves this problem (called out in **bold**):

JSON

```
{
  "Version": "2012-10-17",
  "Statement":
  {
    "Action": "iam:*AccessKey*",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::123456789012:user/${aws:username}"
  }
}
```

Troubleshoot Passkeys and FIDO Security Keys

Use the information here to help you diagnose common issues that you might encounter when working with FIDO2 security keys.

Topics

- I can't enable my FIDO security key
- I can't sign in using my FIDO security key
- I lost or broke my FIDO security key
- Other issues

I can't enable my FIDO security key

Consult the following solutions depending on your status as an IAM user or system administrator

IAM users

If you can't enable your FIDO security key, check the following:

- Are you using a supported configuration?

  IAM supports FIDO2 security devices that connect to your devices through USB, Bluetooth, or NFC. IAM also supports platform authenticators such as TouchID or FaceID. IAM does not support local passkey registration for Windows Hello. To create and use passkeys, Windows users should use cross-device authentication where you use a passkey from one device like a mobile device or hardware security key to sign in on another device like a laptop.

  For information on devices and browsers you can use with WebAuthn and AWS, see Supported configurations for using passkeys and security keys.

- Are you using any browser plugins?

  AWS does not support the use of plugins to add WebAuthn browser support. Instead, use a browser that offers native support of the WebAuthn standard.

  Even if you're using a supported browser, you may have a plugin that is incompatible with WebAuthn. An incompatible plugin may prevent you from enabling and using your FIDO-compliant security key. Disable any plugins that might be incompatible and restart your browser. Then, retry enabling the FIDO security key.

- Do you have the appropriate permissions?

  If you don't have any of the above compatibility issues, you may not have the appropriate permissions. Contact your system administrator.

System administrators

If your IAM users can't enable their FIDO security keys despite using a supported configuration, check their permissions. For a detailed example, see IAM tutorial: Permit users to manage their credentials and MFA settings.

I can't sign in using my FIDO security key

If you can't sign in to the AWS Management Console using your FIDO security key, first see Supported configurations for using passkeys and security keys. If you're using a supported configuration but cannot sign in, contact your system administrator for assistance.

I lost or broke my FIDO security key

Up to **eight** MFA devices of any combination of the currently supported MFA types can be assigned to a user. With multiple MFA devices, you only need one MFA device to sign in to the AWS Management Console. Replacing a FIDO security key is similar to replacing a hardware TOTP token. If you lose or break any type of MFA device, see Recover an MFA protected identity in IAM.

Other issues

If you have an issue with FIDO security keys that is not covered here, do one of the following:

- IAM users: Contact your system administrator.
- AWS account root users: Contact AWS Support.

Troubleshoot IAM roles

Use the information here to help you diagnose and fix common issues that you might encounter when working with IAM roles.

Topics

- I can't assume a role
- A new role appeared in my AWS account
- I can't edit or delete a role in my AWS account
- I'm not authorized to perform: iam:PassRole
- Why can't I assume a role with a 12-hour session? (AWS CLI, AWS API)
- I receive an error when I try to switch roles in the IAM console
- My role has a policy that allows me to perform an action, but I get "access denied"
- The service did not create the role's default policy version
- There is no use case for a service role in the console

I can't assume a role

Check the following:

- To allow users to assume the current role again within a role session, specify the role ARN or AWS account ARN as a principal in the role trust policy. AWS services that provide compute resources such as Amazon EC2, Amazon ECS, Amazon EKS, and Lambda provide temporary credentials and automatically update these credentials. This ensures that you always have a valid set of credentials. For these services, it's not necessary to assume the current role again to obtain temporary credentials. However, if you intend to pass session tags or a session policy, you need to assume the current role again. To learn how to modify a role trust policy to add the principal role ARN or AWS account ARN, see Update a role trust policy .
- When you assume a role using the AWS Management Console, make sure to use the exact name of your role. Role names are case sensitive when you assume a role.
- When you assume a role using AWS STS API or AWS CLI, make sure to use the exact name of your role in the ARN. Role names are case sensitive when you assume a role.
- When you assume a role using a SAML-based federated identity provider and SAML encryption is enabled, make sure you have uploaded a valid private decryption key for the SAML identity provider. For more information, see Manage SAML encryption keys.
- Verify that your IAM policy grants you permission to call `sts:AssumeRole` for the role that you want to assume. The `Action` element of your IAM policy must allow you to call the `AssumeRole` action. In addition, the `Resource` element of your IAM policy must specify the role that you want to assume. For example, the `Resource` element can specify a role by its Amazon Resource Name (ARN) or by a wildcard (*). For example, at least one policy applicable to you must grant permissions similar to the following:

```
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::account_id_number:role/role-name-you-want-to-assume"
```

- Verify that your IAM identity is tagged with any tags that the IAM policy requires. For example, in the following policy permissions, the `Condition` element requires that you, as the principal requesting to assume the role, must have a specific tag. You must be tagged with `department = HR` or `department = CS`. Otherwise, you cannot assume the role. To learn about tagging IAM users and roles, see the section called “Tags for IAM resources”.

```
    "Effect": "Allow",
```

```
    "Action": "sts:AssumeRole",
    "Resource": "*",
    "Condition": {"StringEquals": {"aws:PrincipalTag/department": [
            "HR",
            "CS"
        ]}}
```

- Verify that you meet all the conditions that are specified in the role's trust policy. A `Condition` can specify an expiration date, an external ID, or that a request must come only from specific IP addresses. Consider the following example: If the current date is any time after the specified date, then the policy never matches and cannot grant you the permission to assume the role.

```
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::account_id_number:role/role-name-you-want-to-assume"
    "Condition": {
        "DateLessThan" : {
            "aws:CurrentTime" : "2016-05-01T12:00:00Z"
        }
    }
```

- Verify that the AWS account from which you are calling `AssumeRole` is a trusted entity for the role that you are assuming. Trusted entities are defined as a `Principal` in a role's trust policy. The following example is a trust policy that is attached to the role that you want to assume. In this example, the account ID with the IAM user that you signed in with must be 123456789012. If your account number is not listed in the `Principal` element of the role's trust policy, then you cannot assume the role. It does not matter what permissions are granted to you in access policies. Note that the example policy limits permissions to actions that occur between July 1, 2017 and December 31, 2017 (UTC), inclusive. If you log in before or after those dates, then the policy does not match, and you cannot assume the role.

```
    "Effect": "Allow",
    "Principal": { "AWS": "arn:aws:iam::123456789012:root" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "DateGreaterThan": {"aws:CurrentTime": "2017-07-01T00:00:00Z"},
      "DateLessThan": {"aws:CurrentTime": "2017-12-31T23:59:59Z"}
    }
```

- **Source Identity** – Administrators can configure roles to require identities to pass a custom string that identifies the person or application that is performing actions in AWS, called *source*

identity. Verify whether the role being assumed requires that a source identity is set. For more information about source identity, see Monitor and control actions taken with assumed roles.

A new role appeared in my AWS account

Some AWS services require that you use a unique type of service role that is linked directly to the service. This service-linked role is predefined by the service and includes all the permissions that the service requires. This makes setting up a service easier because you don't have to manually add the necessary permissions. For general information about service-linked roles, see Create a service-linked role.

You might already be using a service when it begins supporting service-linked roles. If so, you might receive an email telling you about a new role in your account. This role includes all the permissions that the service needs to perform actions on your behalf. You don't need to take any action to support this role. However, you should not delete the role from your account. Doing so could remove permissions that the service needs to access AWS resources. You can view the service-linked roles in your account by going to the IAM **Roles** page of the IAM console. Service-linked roles appear with **(Service-linked role)** in the **Trusted entities** column of the table.

For information about which services support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. For information about using the service-linked role for a service, choose the **Yes** link.

I can't edit or delete a role in my AWS account

You cannot delete or edit the permissions for a service-linked role in IAM. These roles include predefined trusts and permissions that are required by the service in order to perform actions on your behalf. You can use the IAM console, AWS CLI, or API to edit only the description of a service-linked role. You can view the service-linked roles in your account by going to the IAM **Roles** page in the console. Service-linked roles appear with **(Service-linked role)** in the **Trusted entities** column of the table. A banner on the role's **Summary** page also indicates that the role is a service-linked role. You can manage and delete these roles only through the linked service, if that service supports the action. Be careful when modifying or deleting a service-linked role because doing so could remove permissions that the service needs to access AWS resources.

For information about which services support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column.

I'm not authorized to perform: iam:PassRole

When you create a service-linked role, you must have permission to pass that role to the service. Some services automatically create a service-linked role in your account when you perform an action in that service. For example, Amazon EC2 Auto Scaling creates the `AWSServiceRoleForAutoScaling` service-linked role for you the first time that you create an Auto Scaling group. If you try to create an Auto Scaling group without the `PassRole` permission, you receive the following error:

```
ClientError: An error occurred (AccessDenied) when calling the
PutLifecycleHook operation: User: arn:aws:sts::111122223333:assumed-role/
Testrole/Diego is not authorized to perform: iam:PassRole on resource:
arn:aws:iam::111122223333:role/aws-service-role/autoscaling.amazonaws.com/
AWSServiceRoleForAutoScaling
```

To fix this error, ask your administrator to add the `iam:PassRole` permission for you.

To learn which services support service-linked roles, see AWS services that work with IAM. To learn whether a service automatically creates a service-linked role for you, choose the **Yes** link to view the service-linked role documentation for the service.

Why can't I assume a role with a 12-hour session? (AWS CLI, AWS API)

When you use the AWS STS `AssumeRole*` API or `assume-role*` CLI operations to assume a role, you can specify a value for the `DurationSeconds` parameter. You can specify a value from 900 seconds (15 minutes) up to the **Maximum session duration** setting for the role. If you specify a value higher than this setting, the operation fails. This setting can have a maximum value of 12 hours. For example, if you specify a session duration of 12 hours, but your administrator set the maximum session duration to 6 hours, your operation fails. To learn how to view the maximum value for your role, see Update the maximum session duration for a role.

If you use *role chaining* (using a role to assume a second role), your session is limited to a maximum of one hour. If you then use the `DurationSeconds` parameter to provide a value greater than one hour, the operation fails.

I receive an error when I try to switch roles in the IAM console

The information you enter on the **Switch Role** page must match the information for the role. Otherwise, the operation fails and you receive the following error:

```
Invalid information in one or more fields. Check your information or
contact your administrator.
```

If you receive this error, confirm that the following information is correct:

- **Account ID or alias** – The AWS account ID is a 12-digit number. Your account might have an alias, which is a friendly identifier such as your company name that can be used instead of your AWS account ID. You can use either the account ID or the alias in this field.
- **Role name** – Role names are case sensitive. The account ID and role name must match what is configured for the role.

If you continue to receive an error message, contact your administrator to verify the previous information. The role trust policy or the IAM user policy might limit your access. Your administrator can verify the permissions for these policies.

My role has a policy that allows me to perform an action, but I get "access denied"

Your role session might be limited by session policies. When you request temporary security credentials programmatically using AWS STS, you can optionally pass inline or managed session policies. Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary credential session for a role. You can pass a single JSON inline session policy document using the `Policy` parameter. You can use the `PolicyArns` parameter to specify up to 10 managed session policies. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Alternatively, if your administrator or a custom program provides you with temporary credentials, they might have included a session policy to limit your access.

The service did not create the role's default policy version

A service role is a role that a service assumes to perform actions in your account on your behalf. When you set up some AWS service environments, you must define a role for the service to assume. In some cases, the service creates the service role and its policy in IAM for you. Although you can modify or delete the service role and its policy from within IAM, AWS does not recommend this. The role and policy are intended for use only by that service. If you edit the policy and set up another environment, when the service tries to use the same role and policy, the operation can fail.

For example, when you use AWS CodeBuild for the first time, the service creates a role named `codebuild-RWBCore-service-role`. That service role uses the policy named `codebuild-RWBCore-managed-policy`. If you edit the policy, it creates a new version and saves that version as the default version. If you perform a subsequent operation in AWS CodeBuild, the service might try to update the policy. If it does, you receive the following error:

```
codebuild.amazon.com did not create the default version (V2) of the
codebuild-RWBCore-managed-policy policy that is attached to the codebuild-
RWBCore-service-role role. To continue, detach the policy from any other
identities and then delete the policy and the role.
```

If you receive this error, you must make changes in IAM before you can continue with your service operation. First, set the default policy version to V1 and try the operation again. If V1 was previously deleted, or if choosing V1 doesn't work, then clean up and delete the existing policy and role.

For more information on editing managed policies, see Editing customer managed policies (console). For more information about policy versions, see Versioning IAM policies.

To delete a service role and its policy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy that you want to delete.
4. Choose the **Entities attached** tab to view which IAM users, groups, or roles use this policy. If any of these identities use the policy, complete the following tasks:
    a. Create a new managed policy with the necessary permissions. To ensure that the identities have the same permissions before and after your actions, copy the JSON policy document from the existing policy. Then create the new managed policy and paste the JSON document as described in Creating Policies using the JSON editor.
    b. For each affected identity, attach the new policy and then detach the old one. For more information, see Adding and removing IAM identity permissions.
5. In the navigation pane, choose **Roles**.
6. In the list of roles, choose the name of the role that you want to delete.

7. Choose the **Trust relationships** tab to view which entities can assume the role. If any entity other than the service is listed, complete the following tasks:

   a. Create a new role that trusts those entities.

   b. The policy that you created in the previous step. If you skipped that step, create the new managed policy now.

   c. Notify anyone who was assuming the role that they can no longer do so. Provide them with information about how to assume the new role and have the same permissions.

8. Delete the policy.

9. Delete the role.

There is no use case for a service role in the console

Some services require that you manually create a service role to grant the service permissions to perform actions on your behalf. If the service is not listed in the IAM console, you must manually list the service as the trusted principal. If the documentation for the service or feature that you are using does not include instructions for listing the service as the trusted principal, provide feedback for the page.

To manually create a service role, you must know the service principal for the service that will assume the role. A service principal is an identifier that is used to grant permissions to a service. The service principal is defined by the service.

You can find the service principal for some services by checking the following:

1. Open AWS services that work with IAM.
2. Check whether the service has **Yes** in the **Service-linked roles** column.
3. Choose the **Yes** link to view the service-linked role documentation for that service.
4. Find the Service-linked role permissions section for that service to view the service principal.

You can manually create a service role using AWS CLI commands or AWS API operations. To manually create a service role using the IAM console, complete the following tasks:

1. Create an IAM role using your account ID. Do not attach a policy or grant any permissions. For details, see Create a role to give permissions to an IAM user.

2. Open the role and edit the trust relationship. Instead of trusting the account, the role must trust the service. For example, update the following `Principal` element:

   ```
   "Principal": { "AWS": "arn:aws:iam::123456789012:root" }
   ```

   Change the principal to the value for your service, such as IAM.

   ```
   "Principal": { "Service": "iam.amazonaws.com" }
   ```

3. Add the permissions that the service requires by attaching permissions policies to the role.
4. Return to the service that requires the permissions and use the documented method to notify the service about the new service role.

Troubleshoot IAM and Amazon EC2

The following information can help you troubleshoot IAM issues with Amazon EC2.

Topics

- When I try to launch an instance, I don't see the role in the Amazon EC2 console IAM Role list
- The credentials on my instance are for the wrong role
- When I attempt to call the AddRoleToInstanceProfile, I get an AccessDenied error
- Amazon EC2: When I try to launch an instance with a role, I get an AccessDenied error
- I can't access the temporary security credentials on my EC2 instance
- What do the errors from the info document in the IAM subtree mean?

When I try to launch an instance, I don't see the role in the Amazon EC2 console IAM Role list

Check the following:

- If you are signed in as an IAM user, verify that you have permission to call `ListInstanceProfiles`. For information about the permissions necessary to work with roles, see Permissions required for using roles with Amazon EC2. For information about adding permissions to a user, see Manage IAM policies.

If you cannot modify your own permissions, you must contact an administrator who can work with IAM in order to update your permissions.

- If you created a role using the IAM CLI or API, verify the following:
  - You created an instance profile and added the role to that instance profile.
  - You used the same name for the role and the instance profile. If you name your role and instance profile differently, you won't see the correct role name in the Amazon EC2 console.

  The **IAM Role** list in the Amazon EC2 console lists the names of instance profiles, not the names of roles. You will have to select the name of the instance profile that contains the role you want. For details about instance profiles, see Use instance profiles.

  > **Note**
  >
  > If you use the IAM console to create roles, you don't need to work with instance profiles. For each role that you create in the IAM console, an instance profile is created with the same name as the role, and the role is automatically added to that instance profile. An instance profile can contain only one IAM role, and that limit cannot be increased.

The credentials on my instance are for the wrong role

The role in the instance profile might have been replaced recently. If so, your application will need to wait for the next automatically scheduled credential rotation before credentials for your role become available.

To force the change, you must disassociate the instance profile and then associate the instance profile, or you can stop your instance and then restart it.

When I attempt to call the `AddRoleToInstanceProfile`, I get an `AccessDenied` error

If you are making requests as an IAM user, verify that you have the following permissions:

- `iam:AddRoleToInstanceProfile` with the resource matching the instance profile ARN (for example, `arn:aws:iam::999999999999:instance-profile/ExampleInstanceProfile`).

For more information about the permissions necessary to work with roles, see How do I get started?. For information about adding permissions to a user, see Manage IAM policies.

Amazon EC2: When I try to launch an instance with a role, I get an `AccessDenied` error

Check the following:

- Launch an instance without an instance profile. This will help ensure that the problem is limited to IAM roles for Amazon EC2 instances.
- If you are making requests as an IAM user, verify that you have the following permissions:
  - `ec2:RunInstances` with a wildcard resource ("*")
  - `iam:PassRole` with the resource matching the role ARN (for example, `arn:aws:iam::999999999999:role/ExampleRoleName`)
- Call the IAM `GetInstanceProfile` action to ensure that you are using a valid instance profile name or a valid instance profile ARN. For more information, see Using IAM roles with Amazon EC2 instances.
- Call the IAM `GetInstanceProfile` action to ensure that the instance profile has a role. Empty instance profiles will fail with an `AccessDenied` error. For more information about creating a role, see IAM role creation.

For more information about the permissions necessary to work with roles, see see How do I get started?. For information about adding permissions to a user, see Manage IAM policies.

I can't access the temporary security credentials on my EC2 instance

To access temporary security credentials on your EC2 instance, you must first use the IAM console to create a role. Then you launch an EC2 instance that uses that role and examine the running instance. For more information, see **How Do I Get Started?** in Use an IAM role to grant permissions to applications running on Amazon EC2 instances.

If you still can't access your temporary security credentials on your EC2 instance, check the following:

- Can you access another part of the Instance Metadata Service (IMDS)? If not, check that you have no firewall rules blocking access to requests to the IMDS.

```
[ec2-user@domU-12-31-39-0A-8D-DE ~]$ GET http://169.254.169.254/latest/meta-data/
hostname; echo
```

- Does the `iam` subtree of the IMDS exist? If not, verify that your instance has an IAM instance profile associated with it by calling the EC2 `DescribeInstances` API operation or using the `aws ec2 describe-instances` CLI command.

```
[ec2-user@domU-12-31-39-0A-8D-DE ~]$ GET http://169.254.169.254/latest/meta-data/iam;
 echo
```

- Check the `info` document in the IAM subtree for an error. If you have an error, see [What do the errors from the `info` document in the IAM subtree mean?] for more information.

```
[ec2-user@domU-12-31-39-0A-8D-DE ~]$ GET http://169.254.169.254/latest/meta-data/iam/
info; echo
```

What do the errors from the `info` document in the IAM subtree mean?

The `iam/info` document indicates `"Code":"InstanceProfileNotFound"`

Your IAM instance profile has been deleted and Amazon EC2 can no longer provide credentials to your instance. You must attach a valid instance profile to your Amazon EC2 instance.

If an instance profile with that name exists, check that the instance profile wasn't deleted and another was created with the same name:

1. Call the IAM `GetInstanceProfile` operation to get the `InstanceProfileId`.
2. Call the Amazon EC2 `DescribeInstances` operation to get the `IamInstanceProfileId` for the instance.
3. Verify that the `InstanceProfileId` from the IAM operation matches the `IamInstanceProfileId` from the Amazon EC2 operation.

If the IDs are different, then the instance profile attached to your instances is no longer valid. You must attach a valid instance profile to the instance.

The `iam/info` document indicates a success but indicates `"Message":"Instance Profile does not contain a role..."`

The role has been removed from the instance profile by the IAM `RemoveRoleFromInstanceProfile` action. You can use the IAM `AddRoleToInstanceProfile` action to attach a role to the instance profile. Your application will need to wait until the next scheduled refresh to access the credentials for the role.

To force the change, you must disassociate the instance profile and then associate the instance profile, or you can stop your instance and then restart it.

The `iam/security-credentials/[role-name]` document indicates `"Code":"AssumeRoleUnauthorizedAccess"`

Amazon EC2 does not have permission to assume the role. Permission to assume the role is controlled by the trust policy attached to the role, like the example that follows. Use the IAM `UpdateAssumeRolePolicy` API to update the trust policy.

JSON

```
{"Version": "2012-10-17","Statement": [{"Effect": "Allow","Principal":
 {"Service": ["ec2.amazonaws.com"]},"Action": ["sts:AssumeRole"]}]}
```

Your application will need to wait until the next automatically scheduled refresh to access the credentials for the role.

To force the change, you must disassociate the instance profile and then associate the instance profile, or you can stop your instance and then restart it.

Troubleshoot IAM and Amazon S3

Use the information here to help you troubleshoot and fix issues that you might encounter when working with Amazon S3 and IAM.

How do I grant anonymous access to an Amazon S3 bucket?

You use an Amazon S3 bucket policy that specifies a wildcard (*) in the `principal` element, which means anyone can access the bucket. With anonymous access, anyone (including users without an

AWS account) will be able to access the bucket. For a sample policy, see Example Cases for Amazon S3 Bucket Policies in the *Amazon Simple Storage Service User Guide*.

I'm signed in as an AWS account root user. Why can't I access an Amazon S3 bucket under my account?

In some cases, you might have an IAM user with full access to IAM and Amazon S3. If the IAM user assigns a bucket policy to an Amazon S3 bucket and doesn't specify the root user as a principal, the root user is denied access to that bucket. However, as the root user, you can still access the bucket. To do that, modify the bucket policy to allow root user access from the Amazon S3 console or the AWS CLI. Use the following principal, replacing *123456789012* with the ID of the AWS account.

```
"Principal": { "AWS": "arn:aws:iam::123456789012:root" }
```

Troubleshoot SAML federation with IAM

Use the information here to help you diagnose and fix issues that you might encounter when working with SAML 2.0 and federation with AWS Identity and Access Management.

Topics

- Error: Your request included an invalid SAML response. To logout, click here.
- Error: RoleSessionName is required in AuthnResponse (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

- Error: RoleSessionName in AuthnResponse must match [a-zA-Z_0-9+=,.@-]{2,64} (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)
- Error: Source Identity must match [a-zA-Z_0-9+=,.@-]{2,64} and not begin with "aws:" (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)
- Error: Response signature invalid (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)
- Error: Invalid private key.
- Error: Failed to remove private key.
- Error: Failed to remove private key because the Key ID does not match a private key.

- Error: Failed to assume role: Issuer not present in specified provider (service: AWSOpenIdDiscoveryService; status code: 400; error code: AuthSamlInvalidSamlResponseException)
- Error: Could not parse metadata.
- Error: Unable to update identity provider. No updates are defined for metadata or encryption assertion.
- Error: Unable to set assertion encryption mode to Required because no private key is provided.
- Error: Unable to add and remove private keys in the same request. Set a value for only one of the two parameters.
- Error: Specified provider doesn't exist.
- Error: Requested DurationSeconds exceeds MaxSessionDuration set for this role.
- Error: Private key limit of 2 is reached.
- Error: Response does not contain the required audience.

Error: Your request included an invalid SAML response. To logout, click here.

This error can occur when the SAML response from the identity provider does not include an attribute with the `Name` set to `https://aws.amazon.com/SAML/Attributes/Role`. The attribute must contain one or more `AttributeValue` elements, each containing a comma-separated pair of strings:

- The ARN of a role that the user can be mapped to
- The ARN of the SAML provider

The error can also occur when the SAML attribute values sent by the identity provider have either a leading or trailing whitespace, or other invalid characters in the SAML attribute values. For more information on the expected values for SAML attributes, see Configure SAML assertions for the authentication response

For more information, see Configure SAML assertions for the authentication response. To view the SAML response in your browser, follow the steps listed in View a SAML response in your browser.

Error: RoleSessionName is required in AuthnResponse (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur when the SAML response from the identity provider does not include an attribute with the `Name` set to `https://aws.amazon.com/SAML/Attributes/RoleSessionName`. The attribute value is an identifier for the user and is typically a user ID or an email address.

For more information, see Configure SAML assertions for the authentication response. To view the SAML response in your browser, follow the steps listed in View a SAML response in your browser.

Error: Not authorized to perform sts:AssumeRoleWithSAML (service: AWSSecurityTokenService; status code: 403; error code: AccessDenied)

This error can occur if the IAM role specified in the SAML response is misspelled or does not exist. Make sure to use the exact name of your role, because role names are case sensitive. Correct the name of the role in the SAML service provider configuration.

You are allowed access only if your role trust policy includes the `sts:AssumeRoleWithSAML` action. If your SAML assertion is configured to use the `PrincipalTag` attribute, your trust policy must also include the `sts:TagSession` action. For more information about session tags, see Pass session tags in AWS STS.

This error can occur if you do not have `sts:SetSourceIdentity` permissions in your role trust policy. If your SAML assertion is configured to use the `SourceIdentity` attribute, then your trust policy must also include the `sts:SetSourceIdentity` action. For more information about source identity, see Monitor and control actions taken with assumed roles.

This error can also occur if a federated principal does not have permissions to assume the role. The role must have a trust policy that specifies the ARN of the IAM SAML identity provider as the `Principal`. The role also contains conditions that control which users can assume the role. Ensure that your users meet the requirements of the conditions.

This error can also occur if the SAML response does not include a `Subject` containing a `NameID`.

For more information, see Enabling SAML 2.0 federated principals to access the AWS Management Console and Configure SAML assertions for the authentication response. To view the SAML response in your browser, follow the steps listed in View a SAML response in your browser.

Error: RoleSessionName in AuthnResponse must match [a-zA-Z_0-9+=,.@-]{2,64} (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur if the `RoleSessionName` attribute value is too long or contains invalid characters. The maximum valid length is 64 characters.

For more information, see Configure SAML assertions for the authentication response. To view the SAML response in your browser, follow the steps listed in View a SAML response in your browser.

Error: Source Identity must match [a-zA-Z_0-9+=,.@-]{2,64} and not begin with "aws:" (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur if the `sourceIdentity` attribute value is too long or contains invalid characters. The maximum valid length is 64 characters. For more information about source identity, see Monitor and control actions taken with assumed roles.

For more information about creating SAML assertions, see Configure SAML assertions for the authentication response. To view the SAML response in your browser, follow the steps listed in View a SAML response in your browser.

Error: Response signature invalid (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur when federation metadata of the identity provider does not match the metadata of the IAM identity provider. For example, the metadata file for the identity service provider might have changed to update an expired certificate. Download the updated SAML metadata file from your identity service provider. Then update it in the AWS identity provider entity that you define in IAM with the `aws iam update-saml-provider` cross-platform CLI command or the `Update-IAMSAMLProvider` PowerShell cmdlet.

Error: Invalid private key.

This error can occur if you do not format your private key file properly. This error may provide additional detail about why the private key is invalid:

- Key is encrypted.

- Key format is not recognized. Private key file must be a .pem file.

When you Create a SAML identity provider in IAM in the AWS Management Console, you must download the private key from your identity provider to provide to IAM to enable encryption. The private key must be a .pem file that uses AES-GCM or AES-CBC encryption algorithm to decrypt SAML assertions.

Error: Failed to remove private key.

This error can occur when SAML encryption is set to Required, and your request would remove the only private decryption key for the IAM SAML provider. For more information about rotating private keys, see Manage SAML encryption keys.

Error: Failed to remove private key because the Key ID does not match a private key.

This error can occur if the `keyId` value for the private key does not match either Key ID for the identity provider's private key files.

When you use update-saml-provider or UpdateSAMLProvider API operations to remove SAML encryption private keys, the value in `RemovePrivateKey` must be a valid Key ID for a private key attached to your identity provider.

Error: Failed to assume role: Issuer not present in specified provider (service: AWSOpenIdDiscoveryService; status code: 400; error code: AuthSamlInvalidSamlResponseException)

This error can occur if the issuer in the SAML response does not match the issuer declared in the federation metadata file. The metadata file was uploaded to AWS when you created the identity provider in IAM.

Error: Could not parse metadata.

This error can occur if you do not format your metadata file properly.

When you create or manage a SAML identity provider in the AWS Management Console, you must retrieve the SAML metadata document from your identity provider.

This metadata file includes the issuer name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) received from the IdP. The metadata file must be encoded in UTF-8 format without a byte order mark (BOM). To remove the BOM, you can encode the file as UTF-8 using a text editing tool, such as Notepad++.

The X.509 certificate included as part of the SAML metadata document must use a key size of at least 1024 bits. Also, the X.509 certificate must also be free of any repeated extensions. You can use extensions, but the extensions can only appear once in the certificate. If the X.509 certificate does not meet either condition, IdP creation fails and returns an "Unable to parse metadata" error.

As defined by the SAML V2.0 Metadata Interoperability Profile Version 1.0, IAM does not evaluate or take action on the expiration of X.509 certificates in SAML metadata documents. If you are concerned about expired X.509 certificates, we recommend monitoring certificate expiration dates and rotating certificates according to your organization's governance and security policies.

Error: Unable to update identity provider. No updates are defined for metadata or encryption assertion.

This error can occur if you use the `update-saml-provider` CLI or `UpdateSAMLProvider` API operations, but don't provide update values in your request parameters. For more information on updating your IAM SAML provider, see Create a SAML identity provider in IAM.

Error: Unable to set assertion encryption mode to Required because no private key is provided.

This error can occur when you haven't previously uploaded a private decryption key and you attempt to set SAML encryption to Required without including a private key in your request.

Make sure that a private key is defined for your IAM SAML provider when using `create-saml-provider` CLI, `CreateSAMLProvider` API, `update-saml-provider` CLI, or `UpdateSAMLProvider` API operations to require encrypted SAML assertions.

Error: Unable to add and remove private keys in the same request. Set a value for only one of the two parameters.

This error can occur if both add and remove private key values are included in the same request.

When you use update-saml-provider or UpdateSAMLProvider API operations to rotate SAML encryption private key files, you can only add or remove a private key in your request. If you add a

private key while removing a private key, the operation fails. For more information about rotating private keys, see Manage SAML encryption keys.

Error: Specified provider doesn't exist.

This error can occur if the name of the provider in the SAML assertion does not match the name of the provider in IAM. For more information about viewing the provider name, see Create a SAML identity provider in IAM.

Error: Requested DurationSeconds exceeds MaxSessionDuration set for this role.

This error can occur if you assume a role from the AWS CLI or API.

When you use the assume-role-with-saml CLI or AssumeRoleWithSAML API operations to assume a role, you can specify a value for the `DurationSeconds` parameter. You can specify a value from 900 seconds (15 minutes) up to the maximum session duration setting for the role. If you specify a value higher than this setting, the operation fails. For example, if you specify a session duration of 12 hours, but your administrator set the maximum session duration to 6 hours, your operation fails. To learn how to view the maximum value for your role, see Update the maximum session duration for a role.

Error: Private key limit of 2 is reached.

This error can occur if you try to add a private key to your identity provider.

You can save up to two private keys for each identity provider. When you use update-saml-provider or UpdateSAMLProvider API operations to add a third private key, the operation fails.

Remove private keys that have expired before adding a new private key. For more information about rotating private keys, see Manage SAML encryption keys.

Error: Response does not contain the required audience.

This error can occur if there is a mismatch between the audience URL and the identity provider in the SAML configuration. Make sure that your identity provider (IdP) relying party identifier exactly matches the audience URL (entity ID) provided in the SAML configuration.

How IAM works with other AWS services

While IAM is the primary AWS service you will use to manage IAM resources, all other AWS services work with IAM to control access to the resources in your account.

- AWS CloudFormation

  AWS CloudFormation integrates with IAM by allowing you to define and manage IAM resources as part of your AWS CloudFormation templates. You can use AWS CloudFormation to specify the necessary IAM permissions for other AWS resources you provision. AWS CloudFormation also supports the use of IAM roles to manage the credentials required for provisioning and managing your AWS infrastructure, and its drift detection feature helps you maintain the integrity of your IAM configurations.

- AWS CloudShell

  When you access AWS CloudShell, your authentication and authorization are handled through IAM. AWS CloudShell runs within the context of an IAM role assigned to your user or account. When you launch AWS CloudShell, it automatically generates temporary security credentials based on the IAM role assigned to you.

- AWS SDKs

  The AWS SDKs work with IAM by handling the authentication and authorization process, managing AWS credentials, and respecting the permissions and policies defined in IAM to ensure your application can only access the resources it is authorized to use. The SDKs provide mechanisms for obtaining and using temporary security credentials, as well as validating the permissions required for your application's operations.

For a list of AWS services that work with IAM and the IAM features the services support, see AWS services that work with IAM.

Create IAM resources with AWS CloudFormation

AWS Identity and Access Management is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as access keys, groups, group policies, instance profiles, managed

policies, OIDC providers, inline policies, roles, role policies, SAML providers, server certificates, service-linked roles, users (and adding users to groups), user policies, and virtual MFA devices), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your IAM resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

IAM and AWS CloudFormation templates

To provision and configure resources for IAM and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the *AWS CloudFormation User Guide*.

IAM supports creating access keys, groups, group policies, instance profiles, managed policies, OIDC providers, inline policies, roles, role policies, SAML providers, server certificates, service-linked roles, users (and adding users to groups), user policies, and virtual MFA devices in AWS CloudFormation. For more information, including examples of JSON and YAML templates for IAM resources, see the AWS Identity and Access Management resource type reference in the *AWS CloudFormation User Guide*.

You can also create templates that create related resources, such as roles and managed policies.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide

Use AWS CloudShell to work with AWS Identity and Access Management

AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. You can run AWS CLI commands against AWS services (including AWS Identity and Access Management) using your preferred shell (Bash, PowerShell or Z shell). And you can do this without needing to download or install command line tools.

You launch AWS CloudShell from the AWS Management Console, and the AWS credentials you used to sign in to the console are automatically available in a new shell session. This pre-authentication of AWS CloudShell users allows you to skip configuring credentials when interacting with AWS services such as IAM using AWS CLI version 2 (pre-installed on the shell's compute environment).

Obtain IAM permissions for AWS CloudShell

Using the access management resources provided by AWS Identity and Access Management, administrators can grant permissions to IAM users so they can access AWS CloudShell and use the environment's features.

The quickest way for an administrator to grant access to users is through an AWS managed policy. An AWS managed policy is a standalone policy that's created and administered by AWS. The following AWS managed policy for CloudShell can be attached to IAM identities:

- `AWSCloudShellFullAccess`: Grants permission to use AWS CloudShell with full access to all features.

If you want to limit the scope of actions that an IAM user can perform with AWS CloudShell, you can create a custom policy that uses the `AWSCloudShellFullAccess` managed policy as a template. For more information about limiting the actions that are available to users in CloudShell, see Managing AWS CloudShell access and usage with IAM policies in the *AWS CloudShell User Guide*.

Interact with IAM

After you launch AWS CloudShell from the AWS Management Console, you can immediately start to interact with IAM using the command line interface.

> **Note**
>
> When using AWS CLI in AWS CloudShell, you don't need to download or install any additional resources. Moreover, because you're already authenticated within the shell, you don't need to configure credentials before making calls.

Create an IAM group and add an IAM user to the group using AWS CloudShell

The following example uses CloudShell to create an IAM group, add an IAM user to the group, and then verify that the command succeeded.

1. From the AWS Management Console, you can launch CloudShell by choosing the following options available on the navigation bar:
   - Choose the CloudShell icon.
   - Start typing "cloudshell" in Search box and then choose the CloudShell option.
2. To create an IAM group, enter the following command in the CloudShell command line. In this example we named the group *east_coast*:

   ```
   aws iam create-group --group-name east_coast
   ```

   If the call is successful, the command line displays a response from the service similar to the following output:

   ```
   {
      "Group": {
          "Path": "/",
          "GroupName": "east_coast",
          "GroupId": "AGPAYBDBW4JBY3EXAMPLE",
          "Arn": "arn:aws:iam::111122223333:group/east_coast",
          "CreateDate": "2023-09-11T21:02:21+00:00"
       }
   }
   ```

3. To add a user to the group that you created, use the following command, specifying the group name and username. In this example we named the group *east_coast* and the user *john*:

```
aws iam add-user-to-group --group-name east_coast --user-name john
```

4. To verify that the user is in the group, use the following command, specifying the group name. In this example we continue using the group *east_coast* :

```
aws iam get-group --group-name east_coast
```

If the call is successful, the command line displays a response from the service similar to the following output:

```
      {
        "Users": [
          {
              "Path": "/",
              "UserName": "john",
              "UserId": "AIDAYBDBW4JBXGEXAMPLE",
              "Arn": "arn:aws:iam::552108220995:user/john",
              "CreateDate": "2023-09-11T20:43:14+00:00",
              "PasswordLastUsed": "2023-09-11T20:59:14+00:00"
          }
        ],
        "Group": {
              "Path": "/",
              "GroupName": "east_coast",
              "GroupId": "AGPAYBDBW4JBY3EXAMPLE",
              "Arn": "arn:aws:iam::111122223333:group/east_coast",
              "CreateDate": "2023-09-11T21:02:21+00:00"
           }
       }
```

Using this service with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS Tools for PowerShell	AWS Tools for PowerShell code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to this service, see Code examples for IAM using AWS SDKs.

Reference information for AWS Identity and Access Management

Use the topics in this section to find detailed reference material for various aspects of IAM and AWS STS.

Topics

- Identify AWS resources with Amazon Resource Names (ARNs)
- IAM identifiers
- IAM and AWS STS quotas
- Dual-stack endpoint support
- Interface VPC endpoints
- AWS services that work with IAM
- AWS Signature Version 4 for API requests
- IAM JSON policy reference

- Simplified AWS service information for programmatic access

Identify AWS resources with Amazon Resource Names (ARNs)

Amazon Resource Names (ARNs) uniquely identify AWS resources. We require an ARN when you need to specify a resource unambiguously across all of AWS, such as in IAM policies, Amazon Relational Database Service (Amazon RDS) tags, and API calls. While ARNs, like any identifying information, should be used and shared carefully, they are not considered secret, sensitive, or confidential information.

ARN format

The following are the general formats for ARNs. The specific formats depend on the resource. To use an ARN, replace the *italicized* text with the resource-specific information. Be aware that the ARNs for some resources omit the Region, the account ID, or both the Region and the account ID.

```
arn:partition:service:region:account-id:resource-id
```

```
arn:partition:service:region:account-id:resource-type/resource-id
arn:partition:service:region:account-id:resource-type:resource-id
```

partition

The partition in which the resource is located. A *partition* is a group of AWS Regions. Each AWS account is scoped to one partition.

The following are the supported partitions:

- aws - AWS Regions
- aws-cn - China Regions
- aws-us-gov - AWS GovCloud (US) Regions

service

The service namespace that identifies the AWS product.

region

The Region code. For example, us-east-2 for US East (Ohio). For the list of Region codes, see Regional endpoints in the *AWS General Reference*.

account-id

The ID of the AWS account that owns the resource, without the hyphens. For example, 123456789012.

resource-type

The resource type. For example, vpc for a virtual private cloud (VPC).

resource-id

The resource identifier. This is the name of the resource, the ID of the resource, or a resource path. Some resource identifiers include a parent resource (sub-resource-type/parent-resource/sub-resource) or a qualifier such as a version (resource-type:resource-name:qualifier).

Examples

IAM user

arn:aws:iam::*123456789012*:user/*john*

SNS topic

arn:aws:sns:*us-east-1*:*123456789012*:*example-sns-topic-name*

VPC

arn:aws:ec2:*us-east-1*:*123456789012*:vpc/*vpc-0e9801d129EXAMPLE*

Look up the ARN format for a resource

The exact format of an ARN depends on the service and resource type. Some resource ARNs can include a path, a variable, or a wildcard. To look up the ARN format for a specific AWS resource, open the Service Authorization Reference, open the page for the service, and navigate to the resource types table.

Paths in ARNs

Resource ARNs can include a path. For example, in Amazon S3, the resource identifier is an object name that can include forward slashes (/) to form a path. Similarly, IAM user names and group names can include paths. Only alphanumeric characters and the following characters are allowed in IAM paths: forward slash (/), plus (+), equals (=), comma (,), period (.), at (@), underscore (_), and hyphen (-).

Using wildcards in paths

Paths can include a wildcard character, namely an asterisk (*). Some policy elements allow wildcards while others don't. You can use wildcards for the Resource or NotResource elements but not for the Principal or NotPrincipal elements. For more information, see IAM JSON policy reference.

You can specify `role/*` to mean all roles in the account 123456789012 as in the following example:

```
arn:aws:iam::123456789012:role/*
```

You can also end a resource name with a wildcard. For example, you can specify **`service-*`** to mean all roles starting with `service` and ending with different characters like `service-role1` or `service-test`:

```
arn:aws:iam::123456789012:role/service-*
```

The following example shows ARNs for objects in an Amazon S3 bucket in which the resource name includes a path. The ARN `arn:aws:s3:::amzn-s3-demo-bucket/*` is for all objects within that bucket, regardless of prefix. The ARN `arn:aws:s3:::amzn-s3-demo-bucket/Development/*` is for all objects created within the **`/Development/`** prefix.

You can also use the ? wildcard character to specify one character in an ARN. For example, you could use the following ARN for all folders starting with four characters and ending in **`-test`** in the S3 bucket named amzn-s3-demo-bucket. Some folders that would match this include `1234-test`, `2024-test`, or `a100-test`.

```
arn:aws:s3:::amzn-s3-demo-bucket/????-test
```

You can also use wildcards in the different sections of an ARN, deliminated by a colon ":". In the following example, two wildcards are used to match all Amazon Q applications and resources within the applications in all regions for account 123456789012:

```
arn:aws:qbusiness:*:123456789012:*
```

Similarly, the following example matches all Amazon VPCs in all regions for account 123456789012:

```
arn:aws:ec2:*:123456789012:vpc/*
```

The following example matches all Amazon EBS volumes in all regions for account 123456789012:

```
arn:aws:ec2:*:123456789012:volume/*
```

Limitations on wildcard usage within ARNs

You cannot use a wildcard in the portion of the ARN that specifics the resource type. The following example ARN with a wildcard within the resource type is not valid:

```
arn:aws:lambda:us-east-2:123456789012:functi*:my-function <== not allowed
```

> **Note**
>
> When you specify an incomplete ARN (one with fewer than the standard six fields) in an identity-based policy, AWS automatically completes the ARN by adding wildcard

characters (*) to all missing fields. For example, specifying `arn:aws:sqs` is equivalent to `arn:aws:sqs:*:*:*`, which grants access to all Amazon SQS resources across all regions and accounts.

You also cannot use a wildcard in the prefix ARN, or have a wildcard in the partition section of an ARN.

```
arn:aws:redshift:us-east-1:123456789012:? <== not allowed
```

IAM identifiers

IAM uses a few different identifiers for users, IAM groups, roles, policies, and server certificates. This section describes the identifiers and when you use each.

Topics

- Friendly names and paths
- IAM ARNs
- Unique identifiers
- Understanding unique ID prefixes
- Getting the unique identifier

Friendly names and paths

When you create a user, a role, a user group, or a policy, or when you upload a server certificate, you give it a friendly name. Examples include Bob, TestApp1, Developers, ManageCredentialsPermissions, or ProdServerCert.

If you use the IAM API or AWS Command Line Interface (AWS CLI) to create IAM resources, you can add an optional path. You can use a single path, or nest multiple paths as a folder structure. For example, you could use the nested path `/division_abc/subdivision_xyz/product_1234/engineering/` to match your company organizational structure. You could then create a policy to allow all users in that path to access the policy simulator API. To view this policy, see IAM: Access the policy simulator API based on user path. For information about how a friendly name can be specified, see the User API documentation. For additional examples of how you might use paths, see IAM ARNs.

When you use AWS CloudFormation to create resources, you can specify a path for users, IAM groups, and roles, and customer managed policies.

If you have a user and user group in the same path, IAM doesn't automatically put the user in that user group. For example, you might create a Developers user group and specify the path as `/division_abc/subdivision_xyz/product_1234/engineering/`. If you create a user named Bob and add the same path to him, this doesn't automatically put Bob in the Developers user group. IAM doesn't enforce any boundaries between users or IAM groups based on their paths. Users with different paths can use the same resources if they've been granted permission to those resources. The number and size of IAM resources in an AWS account are limited. For more information, see IAM and AWS STS quotas.

IAM ARNs

Most resources have a friendly name for example, a user named Bob or a user group named `Developers`. However, the permissions policy language requires you to specify the resource or resources using the following *Amazon Resource Name (ARN)* format.

```
arn:partition:service:region:account:resource
```

Where:

- `partition` identifies the partition for the resource. For standard AWS Regions, the partition is `aws`. If you have resources in other partitions, the partition is `aws-partitionname`. For example, the partition for resources in the China (Beijing) Region is `aws-cn`. You cannot delegate access between accounts in different partitions.
- `service` identifies the AWS product. IAM resources always use `iam`.
- `region` identifies the Region of the resource. For IAM resources, this is always kept blank.
- `account` specifies the AWS account ID with no hyphens.
- `resource` identifies the specific resource by name.

You can specify IAM and AWS STS ARNs using the following syntax. The Region portion of the ARN is blank because IAM resources are global.

Syntax:

```
arn:aws:iam::account:root
arn:aws:iam::account:user/user-name-with-path
```

```
arn:aws:iam::account:group/group-name-with-path
arn:aws:iam::account:role/role-name-with-path
arn:aws:iam::account:policy/policy-name-with-path
arn:aws:iam::account:instance-profile/instance-profile-name-with-path
arn:aws:sts::account:federated-user/user-name
arn:aws:sts::account:assumed-role/role-name/role-session-name
arn:aws:sts::account:self
arn:aws:iam::account:mfa/virtual-device-name-with-path
arn:aws:iam::account:u2f/u2f-token-id
arn:aws:iam::account:server-certificate/certificate-name-with-path
arn:aws:iam::account:saml-provider/provider-name
arn:aws:iam::account:oidc-provider/provider-name
arn:aws:iam::aws:contextProvider/context-provider-name
```

Many of the following examples include paths in the resource part of the ARN. Paths cannot be created or manipulated in the AWS Management Console. To use paths, you must work with the resource by using the AWS API, the AWS CLI, or the Tools for Windows PowerShell.

Examples:

```
arn:aws:iam::123456789012:root
arn:aws:iam::123456789012:user/John
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/Jane
arn:aws:iam::123456789012:group/Developers
arn:aws:iam::123456789012:group/division_abc/subdivision_xyz/product_A/Developers
arn:aws:iam::123456789012:role/S3Access
arn:aws:iam::123456789012:role/application_abc/component_xyz/RDSAccess
arn:aws:iam::123456789012:role/aws-service-role/access-analyzer.amazonaws.com/
AWSServiceRoleForAccessAnalyzer
arn:aws:iam::123456789012:role/service-role/QuickSightAction
arn:aws:iam::123456789012:policy/UsersManageOwnCredentials
arn:aws:iam::123456789012:policy/division_abc/subdivision_xyz/UsersManageOwnCredentials
arn:aws:iam::123456789012:instance-profile/Webserver
arn:aws:sts::123456789012:federated-user/John
arn:aws:sts::123456789012:assumed-role/Accounting-Role/Jane
arn:aws:sts::123456789012:self
arn:aws:iam::123456789012:mfa/JaneMFA
arn:aws:iam::123456789012:u2f/user/John/default (U2F security key)
arn:aws:iam::123456789012:server-certificate/ProdServerCert
arn:aws:iam::123456789012:server-certificate/division_abc/subdivision_xyz/
ProdServerCert
arn:aws:iam::123456789012:saml-provider/ADFSProvider
```

```
arn:aws:iam::123456789012:oidc-provider/GoogleProvider
arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-west-2.amazonaws.com/id/
a1b2c3d4567890abcdefEXAMPLE11111
arn:aws:iam::123456789012:oidc-provider/server.example.org
arn:aws:iam::aws:contextProvider/IdentityCenter
```

The following examples provide more detail to help you understand the ARN format for different types of IAM and AWS STS resources.

- An IAM user in the account:

> **Note**
>
> Each IAM user name is unique. The user name is case-insensitive for the user, such as during the sign in process, but is case-sensitive when you use it in a policy or as part of an ARN.

```
arn:aws:iam::123456789012:user/John
```

- Another user with a path reflecting an organization chart:

```
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/Jane
```

- An IAM user group:

```
arn:aws:iam::123456789012:group/Developers
```

- An IAM user group with a path:

```
arn:aws:iam::123456789012:group/division_abc/subdivision_xyz/product_A/Developers
```

- An IAM role:

```
arn:aws:iam::123456789012:role/S3Access
```

- A service-linked role:

```
arn:aws:iam::123456789012:role/aws-service-role/access-analyzer.amazonaws.com/
AWSServiceRoleForAccessAnalyzer
```

- A service role:

```
arn:aws:iam::123456789012:role/service-role/QuickSightAction
```

- A managed policy:

```
arn:aws:iam::123456789012:policy/ManageCredentialsPermissions
```

- An instance profile that can be associated with an Amazon EC2 instance:

```
arn:aws:iam::123456789012:instance-profile/Webserver
```

- An AWS STS federated user principal identified in IAM as "Paulo":

```
arn:aws:sts::123456789012:federated-user/Paulo
```

- The active session of someone assuming the role of "Accounting-Role", with a role session name of "Mary":

```
arn:aws:sts::123456789012:assumed-role/Accounting-Role/Mary
```

- Represents the caller's own session when used as a resource in an API call, such as the AWS STS SetContext API, that operates on the calling session:

```
arn:aws:sts::123456789012:self
```

- The multi-factor authentication device assigned to the user named Jorge:

```
arn:aws:iam::123456789012:mfa/Jorge
```

- A server certificate:

```
arn:aws:iam::123456789012:server-certificate/ProdServerCert
```

- A server certificate with a path that reflects an organization chart:

```
arn:aws:iam::123456789012:server-certificate/division_abc/subdivision_xyz/
ProdServerCert
```

- Identity providers (SAML and OIDC):

```
arn:aws:iam::123456789012:saml-provider/ADFSProvider
arn:aws:iam::123456789012:oidc-provider/GoogleProvider
arn:aws:iam::123456789012:oidc-provider/server.example.org
```

- OIDC identity provider with a path that reflects an Amazon EKS OIDC identity provider URL:

```
arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-west-2.amazonaws.com/id/
a1b2c3d4567890abcdefEXAMPLE11111
```

- The context provider ARN used with AWS IAM Identity Center trusted identity propagation, from which the trusted context assertion was generated:

```
arn:aws:iam::aws:contextProvider/IdentityCenter
```

Another important ARN is the root user ARN. Although this is not an IAM resource, you should be familiar with the format of this ARN. It is often used in the `Principal` element of a resource-based policy.

- The AWS account displays the following:

```
arn:aws:iam::123456789012:root
```

The following example shows a policy you could assign to Richard to allow him to manage his access keys. Notice that the resource is the IAM user Richard.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ManageRichardAccessKeys",
            "Effect": "Allow",
            "Action": [
                "iam:*AccessKey*",
                "iam:GetUser"
            ],
```

```
            "Resource": "arn:aws:iam::*:user/division_abc/subdivision_xyz/
Richard"
        },
        {
            "Sid": "ListForConsole",
            "Effect": "Allow",
            "Action": "iam:ListUsers",
            "Resource": "*"
        }
    ]
}
```

> **Note**
>
> When you use ARNs to identify resources in an IAM policy, you can include *policy variables*. Policy variables can include placeholders for runtime information (such as the user's name) as part of the ARN. For more information, see IAM policy elements: Variables and tags

Using wildcards and paths in ARNs

You can use wildcards in the *`resource`* portion of the ARN to specify multiple users or IAM groups or policies. For example, to specify all users working on product_1234, you use:

```
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/product_1234/*
```

If you have users whose names start with the string app_, you could refer to them all with the following ARN.

```
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/product_1234/app_*
```

To specify all users, IAM groups, or policies in your AWS account, use a wildcard after the `user/`, `group/`, or `policy/` part of the ARN, respectively.

```
arn:aws:iam::123456789012:user/*
arn:aws:iam::123456789012:group/*
arn:aws:iam::123456789012:policy/*
```

If you specify the following ARN for a user `arn:aws:iam::111122223333:user/*` it matches both of the following examples.

```
arn:aws:iam::111122223333:user/John
arn:aws:iam::111122223333:user/division_abc/subdivision_xyz/JaneDoe
```

But, if you specify the following ARN for a user `arn:aws:iam::111122223333:user/division_abc*` it matches the second example, but not the first.

```
arn:aws:iam::111122223333:user/John
arn:aws:iam::111122223333:user/division_abc/subdivision_xyz/Jane
```

Don't use a wildcard in the `user/`, `group/`, or `policy/` part of the ARN. For example, IAM does not allow the following:

```
arn:aws:iam::123456789012:u*
```

> **Note**
>
> When you specify an incomplete ARN (one with fewer than the standard six fields) in an identity-based policy, AWS automatically completes the ARN by adding wildcard characters (*) to all missing fields. For example, specifying `arn:aws:sqs` is equivalent to `arn:aws:sqs:*:*:*`, which grants access to all Amazon SQS resources across all regions and accounts.

Example Example use of paths and ARNs for a project-based user group

Paths cannot be created or manipulated in the AWS Management Console. To use paths you must work with the resource by using the AWS API, the AWS CLI, or the Tools for Windows PowerShell.

In this example, Jules in the Marketing_Admin user group creates a project-based user group within the /marketing/ path. Jules assigns users from different parts of the company to the user group. This example illustrates that a user's path isn't related to the user groups the user is in.

The marketing group has a new product they'll be launching, so Jules creates a new user group in the /marketing/ path called Widget_Launch. Jules then assigns the following policy to the user group, which gives the user group access to objects in the part of the `example_bucket` that is designated to this particular launch.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::example_bucket/marketing/newproductlaunch/widget/
*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket*",
      "Resource": "arn:aws:s3:::example_bucket",
      "Condition": {"StringLike": {"s3:prefix": "marketing/newproductlaunch/
widget/*"}}
    }
  ]
}
```

Jules then assigns the users who are working on this launch to the user group. This includes Patricia and Eli from the /marketing/ path. It also includes Chris and Chloe from the /sales/ path, and Alice and Jim from the /legal/ path.

Unique identifiers

When IAM creates a user, user group, role, policy, instance profile, or server certificate, it assigns a unique ID to each resource. The unique ID looks like this:

`AIDAJQABLZS4A3QDU576Q`

For the most part, you use friendly names and ARNs when you work with IAM resources. That way you don't need to know the unique ID for a specific resource. However, the unique ID can sometimes be useful when it isn't practical to use friendly names.

One example reuses friendly names in your AWS account. Within your account, a friendly name for a user, user group, role, or policy must be unique. For example, you might create an IAM user named `John`. Your company uses Amazon S3 and has a bucket with folders for each employee. IAM user `John` is a member of an IAM user group named `User-S3-Access` with permissions

that allows users access only to their own folders in the bucket. For an example of how you might create an identity-based policy that allows IAM users to access their own bucket object in S3 using the friendly name of users, see Amazon S3: Allows IAM users access to their S3 home directory, programmatically and in the console.

Suppose that the employee named John leaves your company and you delete the corresponding IAM user named `John`. But later another employee named John starts, and you create a new IAM user named `John`. You add the new IAM user named `John` to the existing IAM user group `User-S3-Access`. If the policy associated to the user group specifies the friendly IAM user name `John`, the policy allows the new John to access information that was left by the former John.

In general, we recommend that you specify the ARN for the resource in your policies instead of its unique ID. However, every IAM user has a unique ID, even if you create a new IAM user that reuses a friendly name you deleted before. In the example, the old IAM user `John` and the new IAM user `John` have different unique IDs. You can create resource-based policies that grant access by unique ID and not just by user name. Doing so reduces the chance that you could inadvertently grant access to information that an employee should not have.

The following example shows how you might specify unique IDs in the `Principal` element of a resource-based policy.

```
"Principal": {
  "AWS": [
    "arn:aws:iam::111122223333:role/role-name",
    "AIDACKCEVSQ6C2EXAMPLE",
    "AROADBQP57FF2AEXAMPLE"
  }
```

The following example shows how you might specify unique IDs in the `Condition` element of a policy using global condition key `aws:userid`.

```
"Condition": {
    "StringLike": {
      "aws:userId": [
        "AIDACKCEVSQ6C2EXAMPLE",
        "AROADBQP57FF2AEXAMPLE:role-session-name",
        "AROA1234567890EXAMPLE:*",
        "111122223333"
      ]
    }
```

```
}
```

Another example where user IDs can be useful is if you maintain your own database (or other store) of IAM user or role information. The unique ID can provide a unique identifier for each IAM user or role you create. This is the case when you have IAM users or roles that reuse a name, as in the previous example.

Understanding unique ID prefixes

IAM uses the following prefixes to indicate what type of resource each unique ID applies to. Prefixes may vary based on when they were created.

Prefix	Resource type
ABIA	AWS STS service bearer token
ACCA	Context-specific credential
AGPA	User group
AIDA	IAM user
AIPA	Amazon EC2 instance profile
AKIA	Access key
ANPA	Managed policy
ANVA	Version in a managed policy
APKA	Public key
AROA	Role
ASCA	Certificate
ASIA	Temporary (AWS STS) access key IDs use this prefix, but are unique only in combination with the secret access key and the session token.

Getting the unique identifier

The unique ID for an IAM resource is not available in the IAM console. To get the unique ID, you can use the following AWS CLI commands or IAM API calls.

AWS CLI:

- get-caller-identity
- get-group
- get-role
- get-user
- get-policy
- get-instance-profile
- get-server-certificate

IAM API:

- GetCallerIdentity
- GetGroup
- GetRole
- GetUser
- GetPolicy
- GetInstanceProfile
- GetServerCertificate

IAM and AWS STS quotas

AWS Identity and Access Management (IAM) and AWS Security Token Service (STS) have quotas that limit the size of objects. This affects how you name an object, the number of objects you can create, and the number of characters you can use when you pass an object.

> **Note**
>
> To get account-level information about IAM usage and quotas, use the GetAccountSummary API operation or the get-account-summary AWS CLI command.

IAM name requirements

IAM names have the following requirements and restrictions:

- Policy documents can contain only the following Unicode characters: horizontal tab (U+0009), linefeed (U+000A), carriage return (U+000D), and characters in the range U+0020 to U+00FF.
- Names of users, groups, roles, policies, instance profiles, server certificates, and paths must be alphanumeric, including the following common characters: plus (+), equals (=), comma (,), period (.), at (@), underscore (_), and hyphen (-). Path names must begin and end with a forward slash (/).
- Names of users, groups, roles, and instance profiles must be unique within the account. They aren't distinguished by case, for example, you can't create groups named both **`ADMINS`** and **`admins`**.
- The external ID value that a third party uses to assume a role must have a minimum of 2 characters and a maximum of 1,224 characters. The value must be alphanumeric without white space. It can also include the following symbols: plus (+), equal (=), comma (,), period (.), at (@), colon (:), forward slash (/), and hyphen (-). For more information about the external ID, see Access to AWS accounts owned by third parties.
- Policy names for inline policies must be unique to the user, group, or role they're embedded in. The names can contain any Basic Latin (ASCII) characters except for the following reserved characters: backward slash (\), forward slash (/), asterisk (*), question mark (?), and white space. These characters are reserved according to RFC 3986, section 2.2.
- User passwords (login profiles) can contain any Basic Latin (ASCII) characters.
- AWS account ID aliases must be unique across AWS products, and must be alphanumeric following DNS naming conventions. An alias must be lowercase, it must not start or end with a hyphen, it can't contain two consecutive hyphens, and it can't be a 12-digit number.

For a list of Basic Latin (ASCII) characters, go to the Library of Congress Basic Latin (ASCII) Code Table.

IAM object quotas

Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account. Use Service Quotas to manage your IAM quotas.

For the list of IAM service endpoints and service quotas, see AWS Identity and Access Management endpoints and quotas in the *AWS General Reference*.

To request a quota increase

1. Follow the sign-in procedure appropriate to your user type as described in the topic How to sign in to AWS in the *AWS Sign-In User Guide* to sign in to the AWS Management Console.
2. Open the Service Quotas console.
3. In the navigation pane, choose **AWS services**.
4. On the navigation bar, choose the **US East (N. Virginia)** Region. Then search for **`IAM`**.
5. Choose **AWS Identity and Access Management (IAM)**, choose a quota, and follow the directions to request a quota increase.

For more information, see Requesting a Quota Increase in the *Service Quotas User Guide*.

To see an example of how to request an IAM quota increase using the Service Quotas console, watch the following video.

Request an IAM quota increase using the Service Quotas console.

You can request an increase to default quotas for adjustable IAM quotas. Requests up to the maximum quota are automatically approved and completed within a few minutes.

The following table lists the resources for which quota increases area can be automatically approved.

Resource	Default quota	Maximum quota
Customer managed policies per account	1500	5000
Groups per account	300	500

Resource	Default quota	Maximum quota
Instance profiles per account	1000	5000
Managed policies per role	10	20
Managed policies per user	10	20
Managed policies per group	10	10
Role trust policy length	2048 characters	4096 characters
Roles per account	1000	5000
Server certificates per account	20	1000

IAM Access Analyzer quotas

For the list of IAM Access Analyzer service endpoints and service quotas, see IAM Access Analyzer endpoints and quotas in the *AWS General Reference*.

IAM Roles Anywhere quotas

For the list of IAM Roles Anywhere service endpoints and service quotas, see AWS Identity and Access Management Roles Anywhere endpoints and quotas in the *AWS General Reference*.

STS request quotas

The AWS Security Token Service (AWS STS) enforces the following request quotas.

For AWS STS requests made using AWS credentials, the default request quota is **600 requests per second**, per account, per Region. The following AWS STS operations share this quota:

- AssumeRole
- DecodeAuthorizationMessage
- GetAccessKeyInfo
- GetCallerIdentity
- GetFederationToken
- GetSessionToken

> **Note**
>
> Requests to AWS STS by AWS service principals, such as those used to assume roles for use with an AWS service, do not consume STS request per second quota in your accounts.

For example, if an AWS account makes 100 GetCallerIdentity requests per second and 100 AssumeRole calls per second in the same region, that account is consuming 200 of its available 600 STS requests per second for that region.

For cross-account AssumeRole requests, only the account making the AssumeRole request impacts the STS quota. The target account does not have any of it's quota consumed.

To request an increase to STS request quotas, please open a ticket with AWS support.

> **Note**
>
> With the upcoming changes to the AWS STS global endpoint (`https://sts.amazonaws.com`), requests to the global endpoint will not share a requests per second (RPS) quota with AWS STS Regional endpoints in Regions that are enabled by default. When a request to the AWS STS global endpoint originates from a single Region, it will count against the global endpoint's RPS quota. However, when requests come from multiple Regions, each additional Region will receive its own independent RPS quota. For more information about the AWS STS global endpoint changes, see AWS STS global endpoint changes.

IAM and STS character limits

The following are the maximum character counts and size limits for IAM and AWS STS. You can't request an increase for the following limits.

Description	Limit
Alias for an AWS account ID	3–63 characters
For inline policies	You can add as many inline policies as you want to an IAM user, role, or group. But the

Description	Limit
	total aggregate policy size (the sum size of all inline policies) per entity can't exceed the following limits: • User policy size can't exceed 2,048 characters. • Role policy size can't exceed 10,240 characters. • Group policy size can't exceed 5,120 characters. **Note** IAM doesn't count white space when calculating the size of a policy against these limits.
For managed policies	• The size of each managed policy can't exceed 6,144 characters. **Note** IAM doesn't count white space when calculating the size of a policy against this limit.
Group name	128 characters
Instance profile name	128 characters
Password for a login profile	1–128 characters
Path	512 characters

Description	Limit
Policy name	128 characters
Role name	64 characters **Important** If you intend to use a role with the **Switch Role** feature in the AWS Management Console, then the combined `Path` and `RoleName` can't exceed 64 characters.
Role session duration	12 hours When you assume a role from the AWS CLI or API, you can use the `duration-seconds` CLI parameter or the `DurationSeconds` API parameter to request a longer role session. You can specify a value from 900 seconds (15 minutes) up to the maximum session duration setting for the role, which can range 1–12 hours. If you don't specify a value for the `DurationSeconds` parameter, your security credentials are valid for one hour. IAM users who switch roles in the console are granted the maximum session duration, or the remaining time in the user's session, whichever is less. The maximum session duration setting doesn't limit sessions assumed by AWS services. To learn how to view the maximum value for your role, see Update the maximum session duration for a role.
Role session name	64 characters

Description	Limit
Role session policies	• The size of the passed JSON policy document and all passed managed policy ARN characters combined can't exceed 2,048 characters. • You can pass a maximum of 10 managed policy ARNs when you create a session. • You can pass only one JSON policy document when you programmatically create a temporary session for a role or AWS STS federated user principal. • Additionally, an AWS conversion compresses the passed session policies and session tags into a packed binary format that has **a separate limit**. The `PackedPolicySize` response element indicates by percentage how close the policies and tags for your request are to the upper size limit. • We recommend that you pass session policies using the AWS CLI or AWS API. The AWS Management Console might add additional console session information to the packed policy.

Description	Limit
Role session tags	• Session tags must meet the tag key limit of 128 characters and the tag value limit of 256 characters. • You can pass up to 50 session tags. • An AWS conversion compresses the passed session policies and session tags into a packed binary format that has a separate limit. You can pass session tags using the AWS CLI or AWS API. The `PackedPolicySize` response element indicates by percentage how close the policies and tags for your request are to the upper size limit.
SAML authentication response base64 encoded	100,000 characters This character limit applies to `assume-role-with-saml` CLI or `AssumeRoleWithSAML` API operation.
Tag key	128 characters This character limit applies to tags on IAM resources and session tags.
Tag value	256 characters This character limit applies to tags on IAM resources and session tags. Tag values can be empty which means tag values can have a length of 0 characters.

Description	Limit
Unique IDs created by IAM	128 characters. For example: • User IDs that begin with AIDA • Group IDs that begin with AGPA • Role IDs that begin with AROA • Managed policy IDs that begin with ANPA • Server certificate IDs that begin with ASCA **Note** This isn't intended to be an exhaustiv e list, nor is it a guarantee that IDs of a certain type begin only with the specified letter combination.
User name	64 characters

Dual-stack endpoint support

IAM provides a dual-stack public endpoint that supports both IPv4 and IPv6 clients. A dual-stack endpoint enables clients to communicate with IAM using either IPv4 or IPv6 addresses.

The IAM dual-stack public endpoint at `https://iam.global.api.aws` supports both IPv4 and IPv6 clients. The IAM dual-stack public endpoint can also be accessed privately from your virtual private cloud (VPC) using AWS PrivateLink. For more information about creating private interface VPC endpoints for IAM, see Create a VPC endpoint for IAM.

The IAM public endpoint at `https://iam.amazonaws.com`, unlike the dual-stack public endpoint, supports only IPv4 clients. When accessed privately from your VPC using AWS PrivateLink, the IAM public endpoint can support both IPv4 and IPv6 clients.

For more information about IPv6 addressing for your VPCs, see IP addressing for your VPCs and subnets in the *Amazon VPC User Guide*. For more information about how to configure your VPC for dual-stack mode, see IPv6 support for your VPC in the *Amazon VPC User Guide*.

Interface VPC endpoints

If you use Amazon Virtual Private Cloud (Amazon VPC) to host your AWS resources, you can establish a private connection between your VPC and AWS Identity and Access Management (IAM) or AWS Security Token Service (AWS STS). You can use this connection to enable IAM or AWS STS to communicate with your resources in your VPC without going through the public internet.

Amazon VPC is an AWS service that you can use to launch AWS resources in a virtual network that you define. With a VPC, you have control over your network settings, such as the IP address range, subnets, route tables, and network gateways. To connect your VPC to IAM or AWS STS, you define an *interface VPC endpoint* for each service. The endpoint provides reliable, scalable connectivity to IAM or AWS STS without requiring an internet gateway, network address translation (NAT) instance, or VPN connection. For more information, see What Is Amazon VPC? in the *Amazon VPC User Guide*.

Interface VPC endpoints are powered by AWS PrivateLink an AWS technology that enables private communication between AWS services using an elastic network interface with private IP addresses. For more information, see AWS PrivateLink for AWS Services.

The following information is for users of Amazon VPC. For more information, see Getting Started with Amazon VPC in the *Amazon VPC User Guide*.

Topics

- VPC endpoint availability
- Create a VPC endpoint for IAM
- Create a VPC endpoint for AWS STS

VPC endpoint availability

> **Important**
>
> Interface VPC endpoints for IAM can only be created in the Region where the IAM control plane is located. If your VPC is in a different Region from the IAM control plane Region, you must use AWS Transit Gateway to allow access to the IAM interface VPC endpoint from another Region. For more information, see Create a VPC endpoint for IAM.

IAM currently supports VPC endpoints in the following Regions:

- US East (N. Virginia)
- China (Beijing)
- AWS GovCloud (US-West)

AWS STS currently supports VPC endpoints in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Melbourne)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Milan)
- Europe (Paris)

- Europe (Spain)
- Europe (Stockholm)
- Europe (Zurich)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- Middle East (UAE)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Create a VPC endpoint for IAM

To start using IAM with your VPC, create an interface VPC endpoint for IAM. For more information, see Access an AWS service using an interface VPC endpoint in the *Amazon VPC User Guide*.

Interface VPC endpoints for IAM can only be created in the Region where the IAM control plane is located. In commercial AWS Regions, the IAM control plane is located in the US East (N. Virginia) Region (us-east-1). The AWS PrivateLink interface VPC endpoint service name for IAM is `com.amazonaws.iam`. For a list of AWS Regions that support VPC endpoints for IAM, see VPC endpoint availability.

If your VPC is in a different Region from the IAM control plane Region, you must use AWS Transit Gateway to allow access to the IAM interface VPC endpoint from another Region.

To access an IAM interface VPC endpoint from a VPC in a different Region using AWS Transit Gateway

1. Create a transit gateway, or use an existing transit gateway to interconnect your virtual private clouds (VPCs). A transit gateway is required for each Region. For more information, see Create a transit gateway in the *AWS Transit Gateway Guide*.
2. Create transit gateway VPC attachments to connect each VPC to the transit gateway. For more information, see Create a transit gateway attachment to a VPC in the *AWS Transit Gateway Guide*.
3. Create a transit gateway VPC peering attachment to route traffic between peered VPCs. For more information, see Create a peering attachment in the *AWS Transit Gateway Guide*.

> **Note**
>
> VPC peering connections can also route traffic between peered VPCs, but this method does not scale well with a large number of VPCs. Instead of VPC peering, we recommend AWS Transit Gateway peering attachments which improve VPC and on-premises network management through a scalable central hub. For more information about VPC peering connections, see Work with VPC peering connections in the *Amazon VPC Peering Guide*.

Create a VPC endpoint for AWS STS

To start using AWS STS with your VPC, create an interface VPC endpoint for AWS STS. For more information, see Access an AWS service using an interface VPC endpoint in the *Amazon VPC User Guide*.

After you create the VPC endpoint, you must use the matching regional endpoint to send your AWS STS requests. AWS STS recommends that you use both the `setRegion` and `setEndpoint` methods to make calls to a Regional endpoint. You can use the `setRegion` method alone for manually enabled Regions, such as Asia Pacific (Hong Kong). In this case, the calls are directed to the STS Regional endpoint. To learn how to manually enable a Region, see Managing AWS Regions in the *AWS General Reference*. If you use the `setRegion` method alone for Regions enabled by default, the calls are directed to the global endpoint of `https://sts.amazonaws.com` .

When you use regional endpoints, AWS STS calls other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, assume that you have created an interface VPC endpoint for AWS STS and have already requested temporary credentials from AWS STS from resources that are located in your VPC. In that case, these credentials begin flowing through the interface VPC endpoint by default. For more information about making Regional requests using AWS STS, see Manage AWS STS in an AWS Region.

AWS services that work with IAM

The AWS services listed below are grouped alphabetically and include information about what IAM features they support:

- **Service** – You can choose the name of a service to view the AWS documentation about IAM authorization and access for that service.

- **Actions** – You can specify individual actions in a policy. If the service does not support this feature, then **All actions** is selected in the visual editor. In a JSON policy document, you must use `*` in the `Action` element. For a list of actions in each service, see Actions, Resources, and Condition Keys for AWS Services.
- **Resource-level permissions** – You can use ARNs to specify individual resources in the policy. If the service does not support this feature, then **All resources** is chosen in the policy visual editor. In a JSON policy document, you must use `*` in the `Resource` element. Some actions, such as `List*` actions, do not support specifying an ARN because they are designed to return multiple resources. If a service supports this feature for some resources but not others, it is indicated by **Partial** in the table. See the documentation for that service for more information.
- **Resource-based policies** – You can attach resource-based policies to a resource within the service. Resource-based policies include a `Principal` element to specify which IAM identities can access that resource. For more information, see Identity-based policies and resource-based policies.
- **ABAC (authorization based on tags)** – To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/`*`key-name`*, `aws:RequestTag/`*`key-name`*, or `aws:TagKeys` condition keys. If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**. For more information about defining permissions based on attributes such as tags, see Define permissions based on attributes with ABAC authorization. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC).
- **Temporary credentials** – You can use short-term credentials that you obtain when you sign in using IAM Identity Center, switch roles in the console, or that you generate using AWS STS in the AWS CLI or AWS API. You can access services with a **No** value only while using your long-term IAM user credentials. This includes a user name and password or your user access keys. For more information, see Temporary security credentials in IAM.
- **Service-linked roles** – A service-linked role is a special type of service role that gives the service permission to access resources in other services on your behalf. Choose the **Yes** or **Partial** link to see the documentation for services that support these roles. This column does not indicate if the service uses standard service roles. For more information, see Service-linked roles.
- **More information** – If a service doesn't fully support a feature, you can review the footnotes for an entry to view the limitations and links to related information.

Services that work with IAM

Service	Actions	Resource-level permissions	Resource-based policies	ABAC	Temporary credentials	Service-linked roles
AWS Account Management	Yes	Yes	No	No	Yes	No
AWS Activate Console	Yes	No	No	No	Yes	No
Amazon AI Operations	Yes	Yes	No	Yes	Yes	No

More information

AWS CloudTrail

CloudTrail supports resource-based policies on CloudTrail Lake event data stores, dashboards, and channels used for integrations with event sources outside of AWS.

Amazon CloudWatch

CloudWatch service-linked roles cannot be created using the AWS Management Console, and support only the Alarm Actions feature.

AWS CodeBuild

CodeBuild supports cross-account resource sharing using AWS RAM.

CodeBuild supports ABAC for project-based actions.

AWS Config

AWS Config supports resource-level permissions for multi-account multi-Region data aggregation and AWS Config Rules. For a list of supported resources, see the **Multi-Account Multi-Region Data Aggregation** section and **AWS Config Rules** section of the AWS Config API Guide.

AWS Database Migration Service

You can create and modify policies that are attached to AWS KMS encryption keys you create to encrypt data migrated to supported target endpoints. The supported target endpoints include Amazon Redshift and Amazon S3. For more information, see Creating and Using AWS KMS Keys to Encrypt Amazon Redshift Target Data and Creating AWS KMS Keys to Encrypt Amazon S3 Target Objects in the *AWS Database Migration Service User Guide*.

Amazon Elastic Compute Cloud

Amazon EC2 service-linked roles can be used only for the following features: Spot Instance Requests, Spot Fleet Requests, Amazon EC2 Fleets, and Fast launching for Windows instances.

Amazon Elastic Container Service

Only some Amazon ECS actions support resource-level permissions.

AWS Elemental MediaPackage

MediaPackage supports service-linked roles for publishing customer access logs to CloudWatch but not for other API actions.

AWS Identity and Access Management

IAM supports only one type of resource-based policy called a role *trust policy*, which is attached to an IAM role. For more information, see Grant a user permissions to switch roles.

IAM supports tag-based access control for most IAM resources. For more information, see Tags for AWS Identity and Access Management resources.

Only some of the API actions for IAM can be called with temporary credentials. For more information, see Comparing your API options.

AWS IoT

Devices connected to AWS IoT are authenticated by using X.509 certificates or using Amazon Cognito Identities. You can attach AWS IoT policies to an X.509 certificate or Amazon Cognito Identity to control what the device is authorized to do. For more information, see Security and Identity for AWS IoT in the *AWS IoT Developer Guide*.

AWS Lambda

Lambda supports attribute-based access control (ABAC) for functions, event source mappings, and code signing configurations. Layers are not supported. For more information, see Using attribute-based access control in Lambda.

Lambda doesn't have service-linked roles, but Lambda@Edge does. For more information, see Service-Linked Roles for Lambda@Edge in the *Amazon CloudFront Developer Guide*.

Amazon Lightsail

Lightsail partially supports resource-level permissions and ABAC. For more information, see Actions, resources, and condition keys for Amazon Lightsail.

Amazon Managed Streaming for Apache Kafka (MSK)

You can attach a cluster policy to an Amazon MSK cluster that has been configured for multi-VPC connectivity.

Multi-party approval

For Multi-party approval identity sources and approval teams, you can use all three ABAC condition keys: `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, and `aws:TagKeys`.

For sessions, you can only use the `aws:ResourceTag/key-name` condition key because:

- Sessions are not directly taggable resources.
- Sessions inherit tags from the approval team associated with them.

AWS Network Manager

AWS Cloud WAN also supports service-linked roles. For more information, see AWS Cloud WAN service-linked roles in the *Amazon VPC AWS Cloud WAN Guide*.

Amazon Redshift Serverless

Redshift Serverless supports resource-based policies to share snapshots.

Amazon Relational Database Service

Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. You can choose the Aurora MySQL or Aurora PostgreSQL as the DB engine option

when setting up new database servers through Amazon RDS. For more information, see Identity and access management for Amazon Aurora in the *Amazon Aurora User Guide*.

Amazon Rekognition

Resource-based policies are only supported for copying Amazon Rekognition Custom Labels models.

AWS Resource Groups

Users can assume a role with a policy that allows Resource Groups operations.

Amazon SageMaker AI

Service-linked roles are currently available for SageMaker AI Studio and SageMaker AI training jobs.

AWS Security Token Service

AWS STS does not have "resources," but does allow restricting access in a similar way to users. For more information, see Denying Access to Temporary Security Credentials by Name.

Only some of the API operations for AWS STS support calling with temporary credentials. For more information, see Comparing your API options.

Amazon Simple Email Service

You can only use resource-level permissions in policy statements that refer to actions related to sending email, such as `ses:SendEmail` or `ses:SendRawEmail`. For policy statements that refer to any other actions, the Resource element can only contain `*`.

Only the Amazon SES API supports temporary security credentials. The Amazon SES SMTP interface does not support SMTP credentials that are derived from temporary security credentials.

Amazon Simple Storage Service

Amazon S3 supports tag-based authorization for directory buckets, object resources, Amazon S3 Storage Lens, Storage Lens groups, and access points.

Amazon S3 supports service-linked roles for Amazon S3 Storage Lens.

AWS Trusted Advisor

API access to Trusted Advisor is through the Support API and is controlled by Support IAM policies.

Amazon Virtual Private Cloud

Amazon VPC supports attaching a single resource policy to a VPC endpoint to restrict what can be accessed through that endpoint. For more information about using resource-based policies to control access to resources from specific Amazon VPC endpoints, see Control access to services using endpoint policies in the *AWS PrivateLink Guide*.

AWS X-Ray

X-Ray does not support resource-level permissions for all actions.

X-Ray supports tag-based access control for groups and sampling rules.

AWS Signature Version 4 for API requests

> **Important**
>
> If you use an AWS SDK (see Sample Code and Libraries) or AWS Command Line Interface (AWS CLI) tool to send API requests to AWS, you can skip the signature process, as the SDK and CLI clients authenticate your requests by using the access keys that you provide. Unless you have a good reason not to, we recommend that you always use an SDK or the CLI.
> In Regions that support multiple signature versions, manually signing requests means you must specify which signature version to use. When you supply requests to Multi-Region Access Points, SDKs and the CLI automatically switch to using Signature Version 4A without additional configuration.

Authentication information that you send in a request must include a signature. AWS Signature Version 4 (SigV4) is the AWS signing protocol for adding authentication information to AWS API requests.

You don't use your secret access key to sign API requests. Instead, you use the SigV4 signing process. Signing requests involves:

1. Creating a canonical request based on the request details.
2. Calculating a signature using your AWS credentials.
3. Adding this signature to the request as an Authorization header.

AWS then replicates this process and verifies the signature, granting or denying access accordingly.

Symmetric SigV4 requires you to derive a key that is scoped to a single AWS service, in a single AWS region, on a particular day. This makes the key and calculated signature different for each region, meaning you must know the region the signature is destined for.

Asymmetric Signature Version 4 (SigV4a) is an extension that supports signing with a new algorithm, and generating individual signatures that are verifiable in more than one AWS region. With SigV4a, you can sign a request for multiple regions, with seamless routing and failover between regions. When you use the AWS SDK or AWS CLI to invoke functionality that requires multi-region signing, the signature type is automatically changed to use SigV4a. For details, see How AWS SigV4a works.

How AWS SigV4 works

The following steps describe the general process of computing a signature with SigV4:

1. The **string to sign** depends on the request type. For example, when you use the HTTP Authorization header or the query parameters for authentication, you use a combination of request elements to create the string to sign. For an HTTP POST request, the POST policy in the request is the string you sign.
2. The **signing key** is a series of calculations, with the result of each step fed into the next. The final step is the signing key.
3. When an AWS service receives an authenticated request, it recreates the **signature** using the authentication information contained in the request. If the signatures match, the service processes the request. Otherwise, it rejects the request.

For more information, see Elements of an AWS API request signature.

How AWS SigV4a works

SigV4a uses asymmetric signatures based on public-private key cryptography. SigV4a goes through a similar scoped credentials derivation process as SigV4, except Sigv4a uses the same key to sign all requests without needing to derive a distinct signing key based on the date, service, and region. An Elliptic Curve Digital Signature Algorithm (ECDSA) keypair can be derived from your existing AWS secret access key.

The system uses asymmetric cryptography to verify multi-region signatures, so that AWS only needs to store your public keys. Public keys are not secret and can't be used to sign requests.

Asymmetric signatures are required for multi-region API requests, such as with Amazon S3 Multi-Region Access Points.

The following steps describe the general process of computing a signature with SigV4a:

1. The **string to sign** depends on the request type. For example, when you use the HTTP Authorization header or the query parameters for authentication, you use a combination of request elements to create the string to sign. For an HTTP POST request, the POST policy in the request is the string you sign.
2. The **signing key** is derived from an AWS secret access key through a series of calculations, with the result of each step fed into the next. The final step produces the keypair.
3. When an AWS service receives a request signed with Sigv4a, AWS verifies the signature using only the public half of the keypair. If the signature is valid, the request is authenticated and the service processes the request. Requests with invalid signatures is rejected.

For more information about SigV4a for multi-Region API requests, see the sigv4a-signing-examples project on GitHub.

When to sign requests

When you write custom code that sends API requests to AWS, you must include code that signs the requests. You might write custom code because:

- You are working with a programming language for which there is no AWS SDK.
- You need complete control over how requests are sent to AWS.

While API requests authenticate access with AWS SigV4, AWS SDKs and the AWS CLI authenticate your requests by using the access keys that you provide. For more information about authenticating with AWS SDKs and the AWS CLI, see Additional resources.

Why requests are signed

The signing process helps secure requests in the following ways:

- **Verify the identity of the requester**

  Authenticated requests require a signature that you create by using your access keys (access key ID, secret access key). If you are using temporary security credentials, the signature calculations

also require a security token. For more information, see AWS security credentials programmatic access.

- **Protect data in transit**

  To prevent tampering with a request while it's in transit, some of the request elements are used to calculate a hash (digest) of the request, and the resulting hash value is included as part of the request. When an AWS service receives the request, it uses the same information to calculate a hash and matches it against the hash value in your request. If the values don't match, AWS denies the request.

- **Protect against potential replay attacks**

  In most cases, a request must reach AWS within five minutes of the time stamp in the request. Otherwise, AWS denies the request.

AWS SigV4 can be expressed in the HTTP Authorization header or as a query string in the URL. For more information, see Authentication methods.

Additional resources

- For more information about the SigV4 signing process for different services, see Request signature examples.
- To configure credentials for programmatic access for the AWS CLI, see Authentication and access credentials in the *AWS Command Line Interface User Guide*.
- The AWS SDKs include source code on GitHub for signing AWS API requests. For code samples, see Example projects in AWS samples repository.
  - AWS SDK for .NET – AWS4Signer.cs
  - AWS SDK for C++ – AWSAuthV4Signer.cpp
  - AWS SDK for Go – sigv4.go
  - AWS SDK for Java – BaseAws4Signer.java
  - AWS SDK for JavaScript – signature-v4
  - AWS SDK for PHP – SignatureV4.php
  - AWS SDK for Python (Boto) – signers.py
  - AWS SDK for Ruby – signer.rb

Elements of an AWS API request signature

> **Important**
>
> Unless you are using the AWS SDKs or CLI, you must write code to calculate signatures that provide authentication information in your requests. Signature calculation in AWS Signature Version 4 can be a complex undertaking, and we recommend that you use the AWS SDKs or CLI whenever possible.

Each HTTP/HTTPS request that uses Signature Version 4 signing must contain these elements.

Elements

- Endpoint specification
- Action
- Action parameters
- Date
- Authentication information

Endpoint specification

Specifies the DNS name of the endpoint to which you send the request. This name usually contains the service code and the Region. For example, the endpoint for Amazon DynamoDB in the `us-east-1` Region is `dynamodb.us-east-1.amazonaws.com`.

For HTTP/1.1 requests, you must include the `Host` header. For HTTP/2 requests, you can include the `:authority` header or the `Host` header. Use only the `:authority` header for compliance with the HTTP/2 specification. Not all services support HTTP/2 requests.

For the endpoints supported by each service, see Service endpoints and quotas in the *AWS General Reference*.

Action

Specifies an API action for the service. For example, the DynamoDB `CreateTable` action or the Amazon EC2 `DescribeInstances` action.

For the actions supported by each service, see the Service Authorization Reference.

Action parameters

Specifies the parameters for the action specified in the request. Each AWS API action has a set of required and optional parameters. The API version is usually a required parameter.

For the parameters supported by an API action, see the API Reference for the service.

Date

Specifies the date and time of the request. Including the date and time in a request helps prevent third parties from intercepting your request and resubmitting it later. The date that you specify in the credential scope must match the date of your request.

The time stamp must be in UTC and use the following ISO 8601 format: *YYYYMMDD*T*HHMMSS*Z. For example, `20220830T123600Z`. Do not include milliseconds in the time stamp.

You can use a `date` or an `x-amz-date` header, or include `x-amz-date` as a query parameter. If we can't find an `x-amz-date` header, then we look for a `date` header.

Authentication information

Each request that you send must include the following information. AWS uses this information to ensure the validity and authenticity of the request.

- Algorithm – The algorithm that you're using as part of the signing process.
  - SigV4 – Use `AWS4-HMAC-SHA256` to specify Signature Version 4 with the `HMAC-SHA256` hash algorithm.
  - SigV4a – Use `AWS4-ECDSA-P256-SHA256` to specify the `ECDSA-P256-SHA-256` hash algorithm.
- Credential – A string that is formed by concatenating your access key ID and your credential scope components.
  - SigV4 – Credential scope includes your access key ID, the date in *YYYYMMDD* format, the Region code, the service code, and the `aws4_request` termination string, separated by slashes (/). The Region code, service code, and termination string must use lowercase characters.

```
AKIAIOSFODNN7EXAMPLE/YYYYMMDD/region/service/aws4_request
```

- SigV4a – Credential scope includes the date in YYYYMMDD format, the service name, and the `aws4_request` termination string, separated by slashes (/). Note that credential scope does not include the region as the region is covered in a separate header `X-Amz-Region-Set`.

  ```
  AKIAIOSFODNN7EXAMPLE/YYYYMMDD/service/aws4_request
  ```

- Signed headers – The HTTP headers to include in the signature, separated by semicolons (;). For example, `host;x-amz-date`.

  For SigV4a, you must include a region set header that specifies the set of regions the request will be valid in. The header `X-Amz-Region-Set` is specified as a list of comma separated values. The following example shows a region header that allows a request to be made in both us-east-1 and us-west-1 regions.

  ```
  X-Amz-Region-Set=us-east-1,us-west-1
  ```

  You can use wildcards (*) in regions to specify multiple regions. In the following example, the header allows a request to be made in both us-west-1 and us-west-2.

  ```
  X-Amz-Region-Set=us-west-*
  ```

- Signature – A hexadecimal-encoded string that represents the calculated signature. You must calculate the signature using the algorithm that you specified in the `Algorithm` parameter.

For more information, see Authentication methods

Authentication methods

> **Important**
>
> Unless you are using the AWS SDKs or CLI, you must write code to calculate signatures that provide authentication information in your requests. Signature calculation in AWS Signature Version 4 can be a complex undertaking, and we recommend that you use the AWS SDKs or CLI whenever possible.

You can express authentication information by using one of the following methods.

HTTP authorization header

The HTTP `Authorization` header is the most common method of authenticating a request. All REST API operations (except for browser-based uploads using POST requests) require this header.

The following examples show the `Authorization` header value for SigV4 and SigV4a. Line breaks are added to this example for readability. In your code, the header must be a continuous string. There is no comma between the algorithm and Credential, but the other elements must be separated by commas.

Example SigV4

```
Authorization: AWS4-HMAC-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20130524/us-east-1/s3/aws4_request,
SignedHeaders=host;range;x-amz-date,
Signature=fe5f80f77d5fa3beca038a248ff027d0445342fe2855ddc963176630326f1024
```

Example SigV4a

```
Authorization: AWS4-ECDSA-P256-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20130524/s3/aws4_request,
SignedHeaders=host;range;x-amz-date;x-amz-region-set,
Signature=fe5f80f77d5fa3beca038a248ff027d0445342fe2855ddc963176630326f1024
```

The following table describes the various components of the Authorization header value in the preceding example:

Component	Description
Authorization	The algorithm that was used to calculate the signature. • SigV4 – Use `AWS4-HMAC-SHA256` . This string identifies AWS SigV4 (`AWS4`) and the `HMAC-SHA256` algorithm. • SigV4a – Use `AWS4-ECDSA-P256-SHA256` . This string identifies AWS SigV4 (`AWS4`) and the `ECDSA-P256-SHA-256` algorithm.

Component	Description

Credential	Your access key ID and the scope information.
	• SigV4 – Include the date, Region, and service that were used to calculate the signature. This string has the following form:
	`<your-access-key-id>/<date>/ <aws-region>/<aws-service>/ aws4_request`
	• SigV4a – Include the date and service that were used to calculate the signature. This string has the following form:
	`<your-access-key-id>/<date>/ <aws-service>/aws4_request`
	The <date> value is specified using YYYYMMDD format. <aws-service> value is S3 when sending request to Amazon S3.

SignedHeaders	A semicolon-separated list of request headers that you used to compute Signature. The list includes header names only, and the header names must be in lowercase. For example: `host;range;x-amz-date` For SigV4a, you must include a region set header that specifies the set of regions the request will be valid in. The header X-Amz-Region-Set is specified as a list of comma separated values.

Component	Description
Signature	The 256-bit signature expressed as 64 lowercase hexadecimal characters. For example:`fe5f80f77d5fa3beca038a248ff027d0445342fe2855ddc963176630326f1024` Note that the signature calculations vary depending on the option you choose to transfer the payload.

Query string parameters

You can use a query string to express a request entirely in a URL. In this case, you use query parameters to provide request information, including the authentication information. Because the request signature is part of the URL, this type of URL is often referred to as a presigned URL. You can use presigned URLs to embed clickable links in HTML, which can be valid for up to seven days. For more information, see Authenticating Requests: Using Query Parameters (AWS Signature Version 4) in the *Amazon S3 API Reference*.

The following examples show presigned URLs for SigV4 and SigV4a. Line breaks are added to this example for readability:

Example SigV4

```
https://s3.amazonaws.com/amzn-s3-demo-bucket/test.txt ?
X-Amz-Algorithm=AWS4-HMAC-SHA256 &
X-Amz-Credential=<your-access-key-id>/20130721/<region>/s3/aws4_request &
X-Amz-Date=20130721T201207Z &
X-Amz-Expires=86400 &
X-Amz-SignedHeaders=host &X-Amz-Signature=<signature-value>
```

Example SigV4a

```
http://s3.amazonaws.com/amzn-s3-demo-bucket/test.txt ?
X-Amz-Algorithm=AWS4-ECDSA-P256-SHA256 &
X-Amz-Credential=<your-access-key-id>/20240721/s3/aws4_request &
X-amz-Region-Set=<regionset> &
```

```
X-Amz-Date=20240721T201207Z &
X-Amz-Expires=86400 &
X-Amz-SignedHeaders=host;x-amz-region-set &
X-Amz-Signature=<signature-value>
```

Note

The `X-Amz-Credential` value in the URL shows the "/" character only for readability. In practice, it should be encoded as %2F. For example: `&X-Amz-Credential=<your-access-key-id>%2F20130721%2Fus-east-1%2Fs3%2Faws4_request`

The following table describes the query parameters in the URL that provide authentication information.

Query string parameter name	Description
X-Amz-Algorithm	The version of AWS signature and the algorithm that you used to calculate the signature. • SigV4 – Use `AWS4-HMAC-SHA256` . This string identifies AWS SigV4 (`AWS4`) and the `HMAC-SHA256` algorithm. • SigV4a – Use `AWS4-ECDSA-P256-SHA256` . This string identifies AWS SigV4 (`AWS4`) and the `ECDSA-P256-SHA-256` algorithm.
X-Amz-Credential	In addition to your access key ID, this parameter also provides scope for which the signature is valid. This value must match the scope you use in signature calculations, discussed in the following section. • SigV4 – The general form for this parameter value is as follows: `<your-access-key-`

Query string parameter name	Description
	id>/<date>/<AWS Region>/<AWS-service>/aws4_request For example: AKIAIOSFODNN7EXAMPLE/20130721/us-east-1/s3/aws4_request • SigV4a – The general form for this parameter value is as follows: <your-access-key-id>/<date>/<AWS-service>/aws4_request For example: AKIAIOSFODNN7EXAMPLE/20130721/s3/aws4_request The region for SigV4a is defined in the region set header X-Amz-Region-Set . For a list of AWS regional strings, see Regional Endpoints in the *AWS General Reference*.
X-Amz-Region-Set	The set of regions the request will be valid in. The header x-amz-region-set is specified as a list of comma separated values.
X-Amz-Date	The date and time format must follow the ISO 8601 standard, and must be formatted with the yyyyMMddTHHmmssZ format. For example if the date and time was "08/01/2016 15:32:41.982-700" then it must first be converted to UTC (Coordinated Universal Time) and then submitted as "20160801T223241Z".

Query string parameter name	Description
X-Amz-Expires	Provides the time period, in seconds, for which the generated presigned URL is valid. For example, 86400 (24 hours). This value is an integer. The minimum value you can set is 1, and the maximum is 604800 (seven days).A presigned URL can be valid for a maximum of seven days because the signing key you use in signature calculation is valid for up to seven days.
X-Amz-SignedHeaders	Lists the headers that you used to calculate the signature. The following headers are required in the signature calculations: • The HTTP host header. • Any x-amz-* headers that you plan to add to the request. • For SigV4a, X-Amz-Region-Set is required to specify the regions in which the request can be made. For added security, you should sign all the request headers that you plan to include in your request.
X-Amz-Signature	Provides the signature to authenticate your request. This signature must match the signature the service calculates; otherwise, the service denies the request. For example, `733255ef022bec3f2a8701cd61d4b371f3f28c9f193a1f02279211d48d5193d7` Signature calculations are described in the following section.

Query string parameter name	Description
X-Amz-Security-Token	Optional credential parameter if using credentials sourced from the STS service.

Create a signed AWS API request

> **Important**
>
> If you use an AWS SDK (see Sample Code and Libraries) or AWS Command Line Interface (AWS CLI) tool to send API requests to AWS, you can skip this section because the SDK and CLI clients authenticate your requests by using the access keys that you provide. Unless you have a good reason not to, we recommend that you always use an SDK or the CLI.
> In Regions that support multiple signature versions, manually signing requests means you must specify which signature version is used. When you supply requests to Multi-Region Access Points, SDKs and the CLI automatically switch to using Signature Version 4A without additional configuration.

You can use the AWS SigV4 signing protocol to create a signed request for AWS API requests.

1. Creating a canonical request based on the request details.
2. Calculating a signature using your AWS credentials.
3. Adding this signature to the request as an Authorization header.

AWS then replicates this process and verifies the signature, granting or denying access accordingly.

To see how you can use AWS SigV4 to sign API requests, see Request signature examples.

The following table describes the functions that are used in the process of creating a signed request. You need to implement code for these functions. For more information, see the code examples in the AWS SDKs.

Function	Description
`Lowercase()`	Convert the string to lowercase.

Function	Description
`Hex()`	Lowercase base 16 encoding.
`SHA256Hash()`	Secure Hash Algorithm (SHA) cryptographic hash function.
`HMAC-SHA256()`	Computes HMAC by using the SHA256 algorithm with the signing key provided. This is the final signature when you sign with SigV4.
`ECDSA-Sign`	Elliptic Curve Digital Signature Algorithm (ECDSA) signature computed by using asymmetric signatures based on public-private key cryptography.
`KDF(K, Label, Context, L)`	A NIST SP800-108 KDF in Counter Mode using the PRF function HMAC-SHA256 as defined in NIST SP 800-108r1.
`Oct2Int(byte[ ])`	An octet to integer function as described in ANSI X9.62.
`Trim()`	Remove any leading or trailing whitespace.

Function	Description
`UriEncode()`	URI encode every byte. UriEncode() must enforce the following rules: • URI encode every byte except the unreserved characters: 'A'-'Z', 'a'-'z', '0'-'9', '-', '.', '_', and '~'. • The space character is a reserved character and must be encoded as "%20" (and not as "+"). • Each URI encoded byte is formed by a '%' and the two-digit hexadecimal value of the byte. • Letters in the hexadecimal value must be uppercase, for example "%1A". • Encode the forward slash character, '/', everywhere except in the object key name. For example, if the object key name is `photos/Jan/sample.jpg` , the forward slash in the key name is not encoded. **Important** The standard UriEncode functions provided by your development platform may not work because of differences in implementation and related ambiguity in the underlying RFCs. We recommend that you write your own custom UriEncode function to ensure that your encoding will work.

Function	Description
	To see an example of a UriEncode function in Java, see Java Utilities on the GitHub website.

> **Note**
>
> When signing your requests, you can use either AWS SigV4 or AWS SigV4a. The key difference between the two is determined by how the signature is calculated. With SigV4a, the region set is included in the string to sign, but is not part of the credential derivation step.

Signing requests with temporary security credentials

Instead of using long-term credentials to sign a request, you can use temporary security credentials provided by AWS Security Token Service (AWS STS).

When you use temporary security credentials, you must add `X-Amz-Security-Token` to the Authorization header or include it in the query string to hold the session token. Some services require that you add `X-Amz-Security-Token` to the canonical request. Other services require only that you add `X-Amz-Security-Token` at the end, after you calculate the signature. Check the documentation for each AWS service for specific requirements.

Summary of signing steps

Create a canonical request

Arrange the contents of your request (host, action, headers, etc.) into a standard canonical format. The canonical request is one of the inputs used to create the string to sign. For details on creating the canonical request, see Elements of an AWS API request signature.

Create a hash of the canonical request

Hash the canonical request using the same algorithm that you used to create the hash of the payload. The hash of the canonical request is a string of lowercase hexadecimal characters.

Create a string to sign

Create a string to sign with the canonical request and extra information such as the algorithm, request date, credential scope, and the hash of the canonical request.

Derive a signing key

Use the secret access key to derive the key used to sign the request.

Calculate the signature

Perform a keyed hash operation on the string to sign using the derived signing key as the hash key.

Add the signature to the request

Add the calculated signature to an HTTP header or to the query string of the request.

Create a canonical request

To create a canonical request, concatenate the following strings, separated by newline characters. This helps ensure that the signature that you calculate can match the signature that AWS calculates.

```
<HTTPMethod>\n
<CanonicalURI>\n
<CanonicalQueryString>\n
<CanonicalHeaders>\n
<SignedHeaders>\n
<HashedPayload>
```

- *HTTPMethod* – The HTTP method, such as GET, PUT, HEAD, and DELETE.
- *CanonicalUri* – The URI-encoded version of the absolute path component URI, starting with the / that follows the domain name and up to the end of the string or to the question mark character (?) if you have query string parameters. If the absolute path is empty, use a forward slash character (/). The URI in the following example, /amzn-s3-demo-bucket/myphoto.jpg, is the absolute path and you don't encode the / in the absolute path:

  ```
  http://s3.amazonaws.com/amzn-s3-demo-bucket/myphoto.jpg
  ```

- *CanonicalQueryString* – The URI-encoded query string parameters. You URI-encode each name and value individually. You must also sort the parameters in the canonical query string alphabetically by key name. The sorting occurs after encoding. The query string in the following URI example is:

```
http://s3.amazonaws.com/amzn-s3-demo-bucket?prefix=somePrefix&marker=someMarker&max-keys=2
```

The canonical query string is as follows (line breaks are added to this example for readability):

```
UriEncode("marker")+"="+UriEncode("someMarker")+"&"+
UriEncode("max-keys")+"="+UriEncode("20") + "&" +
UriEncode("prefix")+"="+UriEncode("somePrefix")
```

When a request targets a subresource, the corresponding query parameter value will be an empty string (""). For example, the following URI identifies the ACL subresource on the amzn-s3-demo-bucket bucket:

```
http://s3.amazonaws.com/amzn-s3-demo-bucket?acl
```

In this case, the CanonicalQueryString would be:

```
UriEncode("acl") + "=" + ""
```

If the URI does not include a ?, there is no query string in the request, and you set the canonical query string to an empty string (""). You will still need to include the newline character ("\n").

- *CanonicalHeaders* – A list of request headers with their values. Individual header name and value pairs are separated by the newline character ("\n"). The following is an example of a CanonicalHeader:

```
Lowercase(<HeaderName1>)+":"+Trim(<value>)+"\n"
Lowercase(<HeaderName2>)+":"+Trim(<value>)+"\n"
...
Lowercase(<HeaderNameN>)+":"+Trim(<value>)+"\n"
```

CanonicalHeaders list must include the following:

- HTTP host header.
- If the Content-Type header is present in the request, you must add it to the *CanonicalHeaders* list.

- Any `x-amz-*` headers that you plan to include in your request must also be added. For example, if you are using temporary security credentials, you need to include `x-amz-security-token` in your request. You must add this header in the list of *`CanonicalHeaders`*.
- For SigV4a, you must include a region set header that specifies the set of regions the request will be valid in. The header `X-Amz-Region-Set` is specified as a list of comma separated values. The following example shows a region header that allows a request to be made in both us-east-1 and us-west-1 regions.

  ```
  X-Amz-Region-Set=us-east-1,us-west-1
  ```

  You can use wildcards (*) in regions to specify multiple regions. In the following example, the header allows a request to be made in both us-west-1 and us-west-2.

  ```
  X-Amz-Region-Set=us-west-*
  ```

> **Note**
>
> The `x-amz-content-sha256` header is required for Amazon S3 AWS requests. It provides a hash of the request payload. If there is no payload, you must provide the hash of an empty string.

Each header name must:

- use lowercase characters.
- appear in alphabetical order.
- be followed by a colon (`:`).

For values, you must:

- trim any leading or trailing spaces.
- convert sequential spaces to a single space.
- separate the values for a multi-value header using commas.
- You must include the host header (HTTP/1.1) or the :authority header (HTTP/2), and any `x-amz-*` headers in the signature. You can optionally include other standard headers in the signature, such as content-type.

The `Lowercase()` and `Trim()` functions used in this example are described in the preceding section.

The following is an example `CanonicalHeaders` string. The header names are in lowercase and sorted.

```
host:s3.amazonaws.com
x-amz-content-sha256:e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855
x-amz-date:20130708T220855Z
```

> **Note**
>
> For the purpose of calculating an authorization signature, only the host and any `x-amz-*` headers are required; however, in order to prevent data tampering, you should consider including additional headers in the signature calculation.
> Do not include hop-by-hop headers that are frequently altered during transit across a complex system. This includes all volatile transport headers that are mutated by proxies, load balancers, and the nodes in a distributed system, including `connection`, `x-amzn-trace-id`, `user-agent`, `keep-alive`, `transfer-encoding`, `TE`, `trailer`, `upgrade`, `proxy-authorization`, and `proxy-authenticate`.

- *`SignedHeaders`* – An alphabetically sorted, semicolon-separated list of lowercase request header names. The request headers in the list are the same headers that you included in the `CanonicalHeaders` string. For the previous example, the value of *`SignedHeaders`* would be as follows:

  ```
  host;x-amz-content-sha256;x-amz-date
  ```

- *`HashedPayload`* – A string created using the payload in the body of the HTTP request as input to a hash function. This string uses lowercase hexadecimal characters.

  ```
  Hex(SHA256Hash(<payload>))
  ```

  If there is no payload in the request, you compute a hash of the empty string, such as when you retrieve an object by using a `GET` request, there is nothing in the payload.

```
Hex(SHA256Hash(""))
```

> **Note**
>
> For Amazon S3, include the literal string `UNSIGNED-PAYLOAD` when constructing a canonical request, and set the same value as the `x-amz-content-sha256` header value when sending the request.
> `Hex(SHA256Hash("UNSIGNED-PAYLOAD"))`

Create a hash of the canonical request

Create a hash (digest) of the canonical request using the same algorithm that you used to create the hash of the payload. The hash of the canonical request is a string of lowercase hexadecimal characters.

Create a string to sign

To create a string to sign, concatenate the following strings, separated by newline characters. Do not end this string with a newline character.

```
Algorithm \n
RequestDateTime \n
CredentialScope  \n
HashedCanonicalRequest
```

- *`Algorithm`* – The algorithm used to create the hash of the canonical request.
  - SigV4 – Use `AWS4-HMAC-SHA256` to specify the `HMAC-SHA256` hash algorithm.
  - SigV4a – Use `AWS4-ECDSA-P256-SHA256` to specify the `ECDSA-P256-SHA-256` hash algorithm.
- *`RequestDateTime`* – The date and time used in the credential scope. This value is the current UTC time in ISO 8601 format (for example, `20130524T000000Z`).
- *`CredentialScope`* – The credential scope, which restricts the resulting signature to the specified Region and service.
  - SigV4 – Credentials include your access key ID, the date in `YYYYMMDD` format, the Region code, the service code, and the `aws4_request` termination string, separated by slashes (/). The

Region code, service code, and termination string must use lowercase characters. The string has the following format: `YYYYMMDD/region/service/aws4_request`.

- SigV4a – Credentials include the date in `YYYYMMDD` format, the service name, and the `aws4_request` termination string, separated by slashes (/). Note that credential scope does not include the region as the region is covered in a separate header `X-Amz-Region-Set`. The string has the following format: `YYYYMMDD/service/aws4_request`.

- *`HashedCanonicalRequest`* – The hash of the canonical request, calculated in the previous step.

The following is an example string to sign.

```
"<Algorithm>" + "\n" +
timeStampISO8601Format + "\n" +
<Scope> + "\n" +
Hex(<Algorithm>(<CanonicalRequest>))
```

Derive a signing key

To derive a signing key, choose one of the following processes to compute a signing key for either SigV4 or SigV4a.

Deriving a signing key for SigV4

To derive a signing key for SigV4, perform a succession of keyed hash operations (HMAC) on the request date, Region, and service, with your AWS secret access key as the key for the initial hashing operation.

For each step, call the hash function with the required key and data. The result of each call to the hash function becomes the input for the next call to the hash function.

The following example shows how you derive the `SigningKey` used in the next section of this procedure, showing the order in which your input is concatenated and hashed. `HMAC-SHA256` is the hash function used to hash the data as shown.

```
DateKey = HMAC-SHA256("AWS4"+"<SecretAccessKey>", "<YYYYMMDD>")
DateRegionKey = HMAC-SHA256(<DateKey>, "<aws-region>")
DateRegionServiceKey = HMAC-SHA256(<DateRegionKey>, "<aws-service>")
SigningKey = HMAC-SHA256(<DateRegionServiceKey>, "aws4_request")
```

Required input

- `Key` – A string that contains your secret access key.
- `Date` – A string that contains the date used in the credential scope, in the format *YYYYMMDD*.
- `Region` – A string that contains the Region code (for example, `us-east-1`).

  For a list of Region strings, see Regional Endpoints in the *AWS General Reference*.
- `Service` – A string that contains the service code (for example, `ec2`).
- The string to sign that you created in the previous step.

To derive a signing key for SigV4

1. Concatenate `"AWS4"` and the secret access key. Call the hash function with the concatenated string as the key and the date string as the data.

   ```
   DateKey = hash("AWS4" + Key, Date)
   ```

2. Call the hash function with the result of the previous call as the key and the Region string as the data.

   ```
   DateRegionKey = hash(kDate, Region)
   ```

3. Call the hash function with the result of the previous call as the key and the service string as the data.

   The service code is defined by the service. You can use get-products in the *AWS Pricing CLI* to return the service code for a service.

   ```
   DateRegionServiceKey = hash(kRegion, Service)
   ```

4. Call the hash function with the result of the previous call as the key and "aws4_request" as the data.

   ```
   SigningKey = hash(kService, "aws4_request")
   ```

Deriving a signing key for SigV4a

To create a signing key for SigV4a, use the following process to derive a key pair from the secret access key. For an example of an implementation of this derivation, see the C99 library implementation of AWS client-side authentication

```
n = [NIST P-256 elliptic curve group order]
G = [NIST P-256 elliptic curve base point]
label = "AWS4-ECDSA-P256-SHA256"

akid = [AWS access key ID as a UTF8 string]
sk = [AWS secret access Key as a UTF8 Base64 string]

input_key = "AWS4A" || sk
count = 1
while (counter != 255) {
  context = akid || counter // note: counter is one byte
  key = KDF(input_key, label, context, 256)
  c = Oct2Int(key)
  if (c > n - 2) {
    counter++
  } else {
    k = c + 1   // private key
    Q = k * G   // public key
  }
}

if (c < 255) {
  return [k, Q]
} else {
  return FAILURE
}
```

Calculate the signature

Once you have derived the signing key, calculate the signature to add to your request. This procedure varies based on the siganture version you use.

To calculate a signature for SigV4

1. Call the hash function with the result of the previous call as the key and the **string to sign** as the data. Use the derived signing key as the hash key for this operation. The result is the signature as a binary value.

```
signature = hash(SigningKey, string-to-sign)
```

2. Convert the signature from binary to hexadecimal representation, in lowercase characters.

To calculate a signature for SigV4a

1. Using the digital signing algorithm (ECDSA P-256), sign the **string to sign** you created in the previous step. The key used for this signature is the private asymmetric key derived from the secret access key as described above.

```
signature = base16(ECDSA-Sign(k, string-to-sign))
```

2. Convert the signature from binary to hexadecimal representation, in lowercase characters.

Add the signature to the request

Add the calculated signature to your request.

Example Example: Authorization header

SigV4

The following example shows an `Authorization` header for the `DescribeInstances` action using AWS SigV4. For readability, this example is formatted with line breaks. In your code, this must be a continuous string. There is no comma between the algorithm and `Credential`. However, the other elements must be separated by commas.

```
Authorization: AWS4-HMAC-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20220830/us-east-1/ec2/aws4_request,
SignedHeaders=host;x-amz-date,
Signature=calculated-signature
```

SigV4a

The following example shows an Authorization header for the `CreateBucket` action using AWS SigV4a. For readability, this example is formatted with line breaks. In your code, this must be a continuous string. There is no comma between the algorithm and Credential. However, the other elements must be separated by commas.

```
Authorization: AWS4-ECDSA-P256-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20220830/s3/aws4_request,
SignedHeaders=host;x-amz-date;x-amz-region-set,
Signature=calculated-signature
```

Example Example: Request with authentication parameters in the query string

SigV4

The following example shows a query for the `DescribeInstances` action using AWS SigV4 that includes the authentication information. For readability, this example is formatted with line breaks and is not URL encoded. In your code, the query string must be a continuous string that is URL encoded.

```
https://ec2.amazonaws.com/?
Action=DescribeInstances&
Version=2016-11-15&
X-Amz-Algorithm=AWS4-HMAC-SHA256&
X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20220830/us-east-1/ec2/aws4_request&
X-Amz-Date=20220830T123600Z&
X-Amz-SignedHeaders=host;x-amz-date&
X-Amz-Signature=calculated-signature
```

SigV4a

The following example shows a query for the `CreateBucket` action using AWS SigV4a that includes the authentication information. For readability, this example is formatted with line breaks and is not URL encoded. In your code, the query string must be a continuous string that is URL encoded.

```
https://ec2.amazonaws.com/?
Action=CreateBucket&
Version=2016-11-15&
X-Amz-Algorithm=AWS4-ECDSA-P256-SHA256&
X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20220830/s3/aws4_request&
```

```
X-Amz-Region-Set=us-west-1&
X-Amz-Date=20220830T123600Z&
X-Amz-SignedHeaders=host;x-amz-date;x-amz-region-set&
X-Amz-Signature=calculated-signature
```

Request signature examples

The following examples of AWS signing requests show you how you can use SigV4 to sign requests sent without the AWS SDK or AWS command line tool.

Browser based Amazon S3 upload using HTTP POST

Authenticating Requests: Browser-Based Uploads describes the signature and relevant information that Amazon S3 uses to calculate the signature upon receiving the request.

Example: Browser-Based Upload using HTTP POST (Using AWS Signature Version 4) provides more information with a sample POST policy and a form that you can use to upload a file. The example policy and fictitious credentials show you the workflow and resulting signature and policy hash.

VPC Lattice authenticated requests

Examples for Signature Version 4 (SigV4) authenticated requests provides Python and Java examples showing how you can perform request signing with and without custom interceptors.

Using Signature Version 4 with Amazon Translate

Live Translations in the Metaverse shows how to build an application that produces a near real-time translation solution. This speech-to-speech translator solution uses AWS SigV4 in event stream encoding to produce real-time transcriptions.

Using Signature Version 4 with Neptune

Example: Connecting to Neptune Using Python with Signature Version 4 Signing shows how to make signed requests to Neptune using Python. This example includes variations for using an access key or temporary credentials.

Signing HTTP requests to S3 Glacier

Example Signature Calculation for Streaming API walks you through the details of creating a signature for Upload Archive (POST archive), one of the two streaming APIs in S3 Glacier.

Making HTTP Requests to Amazon SWF

Making HTTP Requests to Amazon SWF shows the header contents for a JSON request to Amazon SWF.

Signature calculation for streaming APIs in Amazon OpenSearch Service

Signing an Amazon OpenSearch Service search request with AWS SDK for PHP Version 3 includes an example of how to send signed HTTP requests to Amazon OpenSearch Service.

Example projects in AWS samples repository

The following example projects show how to sign requests to make Rest API requests to AWS services with common languages such as Python, Node.js, Java, C#, Go and Rust.

Signature Version 4a projects

The sigv4-signing-examples project provides examples of how to sign requests with SigV4 to make Rest API requests to AWS services with common languages such as Python, Node.js, Java, C#, Go and Rust.

The sigv4a-signing-examples project provides examples for signing multi-Region API requests, for example Multi-Region Access Points in Amazon S3.

Publish to AWS IoT Core

Python code to publish to AWS IoT Core using HTTPs protocol provides guidance on how to publish messages to AWS IoT Core using HTTPS protocol and AWS SigV4 authentication. It has two reference implementations - one in Python and other in NodeJs.

.Net Framework application to publish to AWS IoT Core using HTTPs protocol provides guidance on how to publish messages to AWS IoT Core using HTTPS protocol and AWS SigV4 authentication. This project also includes a .NET core equivalent implementation.

Troubleshoot Signature Version 4 signing for AWS API requests

> **Important**
>
> Unless you are using the AWS SDKs or CLI, you must write code to calculate signatures that provide authentication information in your requests. SigV4 signature calculation can be

a complex undertaking, and we recommend that you use the AWS SDKs or CLI whenever possible.

When you develop code that creates a signed request, you might receive HTTP 403 `SignatureDoesNotMatch` from AWS services. These errors mean that the signature value in your HTTP request to AWS did not match the signature that the AWS service calculated. HTTP 401 `Unauthorized` errors return when permissions do not allow the caller to make the request.

API requests might return an error if:

- The API request isn't signed and the API request uses IAM authentication.
- The IAM credentials used to sign the request are incorrect or don't have permissions to invoke the API.
- The signature of the signed API request doesn't match the signature that the AWS service calculated.
- The API request header is incorrect.

Note

Update your signing protocol from AWS Signature version 2 (SigV2) to AWS Signature version 4 (SigV4) before exploring other error solutions. Services, such as Amazon S3, and Regions no longer support SigV2 signing.

Possible causes

- Credential errors
- Canonical request and signing string errors
- Credential scope errors
- Key signing errors

Credential errors

Make sure that the API request is signed with SigV4. If the API request isn't signed, then you might receive the error: `Missing Authentication Token`. Add the missing signature and resend the request.

Verify that the authentication credentials for the access key and secret key are correct. If the access key is incorrect, then you might receive the error: `Unauthorized`. Make sure the entity used to sign the request is authorized to make the request. For details, see Troubleshoot access denied error messages.

Canonical request and signing string errors

If you incorrectly calculated the canonical request in Create a hash of the canonical request or Create a string to sign, the signature verification step performed by the service fails with the error message:

```
The request signature we calculated does not match the signature you provided
```

When the AWS service receives a signed request, it recalculates the signature. If there are differences in the values, then the signatures don't match. Compare the canonical request and string to your signed request with the value in the error message. Modify the signing process if there are any differences.

> **Note**
>
> You can also verify that you didn't send the request through a proxy that modifies the headers or the request.

Example Example canonical request

```
GET                                                     -------- HTTP method
/                                                       -------- Path. For API stage
 endpoint, it should be /{stage-name}/{resource-path}
                                                        -------- Query string key-
value pair. Leave it blank if the request doesn't have a query string.
content-type:application/json                           -------- Header key-value
 pair. One header per line.
host:0123456789.execute-api.us-east-1.amazonaws.com     -------- Host and x-amz-date
 are required headers for all signed requests.
x-amz-date:20220806T024003Z

content-type;host;x-amz-date                            -------- A list of signed
 headers
```

```
d167e99c53f15b0c105101d468ae35a3dc9187839ca081095e340f3649a04501        -------- Hash
 of the payload
```

To verify that the secret key matches the access key ID, you can test them with a known working implementation. For example, use an AWS SDK or the AWS CLI to make a request to AWS.

API request header

When the authorization header is empty, the credential key or signature is missing or incorrect, the header doesn't start with an algorithm name, or the key value pairs don't include an equal sign, you receive one of the following errors:

- Authorization header cannot be empty.
- Authorization header requires 'Credential' parameter.
- Authorization header requires 'Signature' parameter.
- The signature contains an invalid key=value pair (missing equal-sign) in Authorization header.

Make sure that the SigV4 authorization header you added in Calculate the signature includes the correct credential key, and also includes the request date using either HTTP Date or the `x-amz-date` header.

If you received an IncompleteSignatureException error and the construction of the signature is correct, you can verify that the authorization header was not modified in transit to the AWS service by computing a SHA-256 hash and B64 encoding of the authorization header in your client-side request.

1. Get the authorization header you sent in the request. Your authorization header appears similar to the following example:

   ```
   Authorization: AWS4-HMAC-SHA256
   Credential=AKIAIOSFODNN7EXAMPLE/20130524/us-east-1/s3/aws4_request,
   SignedHeaders=host;range;x-amz-date,
   Signature=example-generated-signature
   ```

2. Compute a SHA-256 hash of the authorization header.

   ```
   hashSHA256(rawAuthorizationHeader) = hashedAuthorizationHeader
   ```

3. Encode the hashed authorization header to Base64 format.

```
base64(hashedAuthorizationHeader) = encodedHashedAuthorizationHeader
```

4. Compare the hashed and encoded string you just calculated against the string you received in your error message. Your error message should be similar to the following example:

```
com.amazon.coral.service#IncompleteSignatureException:
The signature contains an in-valid key=value pair (missing equal-sign)
in Authorization header (hashed with SHA-256 and encoded with Base64):
'9c574f83b4b950926da4a99c2b43418b3db8d97d571b5e18dd0e4f3c3ed1ed2c'.
```

- If the two hashes differ, then some part of the authorization header changed in transit. This change could be due to your network or client handlers attaching signed headers or changing the authorization header in some way.
- If the two hashes match, the authorization header you sent in the request matches what AWS received. Review the error message you received to determine if the issue is the result of incorrect credentials or signature. These errors are covered in the other sections on this page.

Credential scope errors

The credential scope you created in Create a string to sign restricts a signature to a specific date, Region, and service. This string has the following format:

```
YYYYMMDD/region/service/aws4_request
```

> **Note**
>
> If you are using SigV4a, the Region is not included in credential scope.

Date

If the credential scope does not specify the same date as the x-amz-date header, the signature verification step fails with the following error message:

```
Date in Credential scope does not match YYYYMMDD from ISO-8601 version of date from
 HTTP
```

If the request specifies a time in the future, the signature verification step fails with the following error message:

```
Signature not yet current: date is still later than date
```

If the request has expired, the signature verification step fails with the following error message:

```
Signature expired: date is now earlier than date
```

Region

If the credential scope does not specify the same Region as the request, the signature verification step fails with the following error message:

```
Credential should be scoped to a valid Region, not region-code
```

Service

If the credential scope does not specify the same service as the host header, the signature verification step fails with the following error message:

```
Credential should be scoped to correct service: 'service'
```

Termination string

If the credential scope does not end with aws4_request, the signature verification step fails with the following error message:

```
Credential should be scoped with a valid terminator: 'aws4_request'
```

Key signing errors

Errors that are caused by incorrect derivation of the signing key or improper use of cryptography are more difficult to troubleshoot. After you verify that the canonical string and the string to sign are correct, you can also check for one of the following issues:

- The secret access key does not match the access key ID that you specified.
- There is a problem with your key derivation code.

To verify that the secret key matches the access key ID, you can test them with a known working implementation. For example, use an AWS SDK or the AWS CLI to make a request to AWS. For examples, see Request signature examples

IAM JSON policy reference

This section presents detailed syntax, descriptions, and examples of the elements, variables, and evaluation logic of JSON policies in IAM. For more general information, see Overview of JSON policies.

This reference includes the following sections.

- IAM JSON policy element reference — Learn more about the elements that you can use when you create a policy. View additional policy examples and learn about conditions, supported data types, and how they are used in various services.
- Policy evaluation logic — This section describes AWS requests, how they are authenticated, and how AWS uses policies to determine access to resources.
- Grammar of the IAM JSON policy language — This section presents a formal grammar for the language that is used to create policies in IAM.
- AWS managed policies for job functions — This section lists all the AWS managed policies that directly map to common job functions in the IT industry. Use these policies to grant the permissions that are needed to carry out the tasks expected of someone in a specific job function. These policies consolidate permissions for many services into a single policy.
- AWS global condition context keys — This section includes a list of all the AWS global condition keys that you can use to limit permissions in an IAM policy.
- IAM and AWS STS condition context keys — This section includes a list of all the IAM and AWS STS condition keys that you can use to limit permissions in an IAM policy.
- Actions, Resources, and Condition Keys for AWS Services — This section presents a list of all the AWS API operations that you can use as permissions in an IAM policy. It also includes the service-specific condition keys that can be used to further refine the request.

IAM JSON policy element reference

JSON policy documents are made up of elements. The elements are listed here in the general order you use them in a policy. The order of the elements doesn't matter—for example, the `Resource` element can come before the `Action` element. You're not required to specify any `Condition`

elements in the policy. To learn more about the general structure and purpose of a JSON policy document, see Overview of JSON policies.

Some JSON policy elements are mutually exclusive. This means that you cannot create a policy that uses both. For example, you cannot use both `Action` and `NotAction` in the same policy statement. Other pairs that are mutually exclusive include `Principal`/`NotPrincipal` and `Resource`/`NotResource`.

The details of what goes into a policy vary for each service, depending on what actions the service makes available, what types of resources it contains, and so on. When you're writing policies for a specific service, it's helpful to see examples of policies for that service. For a list of all the services that support IAM, and for links to the documentation in those services that discusses IAM and policies, see AWS services that work with IAM.

When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see IAM policy validation. To learn more about IAM Access Analyzer policy checks and actionable recommendations, see IAM Access Analyzer policy validation.

IAM JSON policy elements: Version

Disambiguation note

This `Version` JSON policy element is different from a *policy version*. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you make changes to a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. If you were searching for information about the multiple version support available for managed policies, see the section called “Versioning IAM policies”.

The `Version` policy element specifies the language syntax rules that are to be used to process a policy. To use all of the available policy features, include the following `Version` element **outside** the `Statement` element in all of your policies.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    }
  ]
}
```

IAM supports the following `Version` element values:

- `2012-10-17`. This is the current version of the policy language, and you should always include a `Version` element and set it to `2012-10-17`. Otherwise, you cannot use features such as policy variables that were introduced with this version.
- `2008-10-17`. This was an earlier version of the policy language. You might see this version on older existing policies. Do not use this version for any new policies or when you update any existing policies. Newer features, such as policy variables, will not work with your policy. For

example, variables such as `${aws:username}` aren't recognized as variables and are instead treated as literal strings in the policy.

IAM JSON policy elements: Id

The `Id` element specifies an optional identifier for the policy. The ID is used differently in different services. ID is allowed in resource-based policies, but not in identity-based policies.

For services that let you set an `ID` element, we recommend you use a UUID (GUID) for the value, or incorporate a UUID as part of the ID to ensure uniqueness.

JSON

```
{
  "Version": "2012-10-17",
  "Id": "cd3ad3d9-2776-4ef1-a904-4c229d1642ee",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    }
  ]
}
```

Note

Some AWS services (for example, Amazon SQS or Amazon SNS) might require this element and have uniqueness requirements for it. For service-specific information about writing policies, refer to the documentation for the service you're working with.

IAM JSON policy elements: Statement

The `Statement` element is the main element for a policy. This element is required. The `Statement` element can contain a single statement or an array of individual statements. Each individual statement block must be enclosed in curly braces { }. For multiple statements, the array must be enclosed in square brackets [ ].

```
"Statement": [{...},{...},{...}]
```

The following example shows a policy that contains an array of three statements inside a single `Statement` element. (The policy allows you to access your own "home folder" in the Amazon S3 console.) The policy includes the `aws:username` variable, which is replaced during policy evaluation with the user name from the request. For more information, see Introduction.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListAllMyBuckets",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
      "Condition": {"StringLike": {"s3:prefix": [
        "",
        "home/",
        "home/${aws:username}/"
      ]}}
    },
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/home/${aws:username}",
        "arn:aws:s3:::amzn-s3-demo-bucket/home/${aws:username}/*"
      ]
    }
  ]
}
```

IAM JSON policy elements: Sid

You can provide a `Sid` (statement ID) as an optional identifier for the policy statement. You can assign a `Sid` value to each statement in a statement array. You can use the `Sid` value as a description for the policy statement. In services that let you specify an `ID` element, such as SQS and SNS, the `Sid` value is just a sub-ID of the policy document ID. In IAM, the `Sid` value must be unique within a JSON policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExampleStatementID",
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    }
  ]
}
```

The `Sid` element supports ASCII uppercase letters (A-Z), lowercase letters (a-z), and numbers (0-9).

IAM does not expose the `Sid` in the IAM API. You can't retrieve a particular statement based on this ID.

> **Note**
>
> Some AWS services (for example, Amazon SQS or Amazon SNS) might require this element and have uniqueness requirements for it. For service-specific information about writing policies, refer to the documentation for the service you work with.

IAM JSON policy elements: Effect

The `Effect` element is required and specifies whether the statement results in an allow or an explicit deny. Valid values for `Effect` are `Allow` and `Deny`. The `Effect` value is case sensitive.

```
"Effect":"Allow"
```

By default, access to resources is denied. To allow access to a resource, you must set the `Effect` element to `Allow`. To override an allow (for example, to override an allow that is otherwise in force), you set the `Effect` element to `Deny`. For more information, see Policy evaluation logic.

AWS JSON policy elements: Principal

Use the `Principal` element in a resource-based JSON policy to specify the principal that is allowed or denied access to a resource.

You must use the `Principal` element in resource-based policies. Several services support resource-based policies, including IAM. The IAM resource-based policy type is a role trust policy. In IAM roles, use the `Principal` element in the role trust policy to specify who can assume the role. For cross-account access, you must specify the 12-digit identifier of the trusted account. To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see What is IAM Access Analyzer?.

> **Note**
>
> After you create the role, you can change the account to "*" to allow everyone to assume the role. If you do this, we strongly recommend that you limit who can access the role through other means, such as a `Condition` element that limits access to only certain IP addresses. Do not leave your role accessible to everyone!

Other examples of resources that support resource-based policies include an Amazon S3 bucket or an AWS KMS key.

You cannot use the `Principal` element in an identity-based policy. Identity-based policies are permissions policies that you attach to IAM identities (users, groups, or roles). In those cases, the principal is implicitly the identity where the policy is attached.

Topics

- How to specify a principal
- AWS account principals
- IAM role principals

- Role session principals
- Assumed-role session principals
- OIDC federated principals
- SAML federated principals
- IAM user principals
- IAM Identity Center principals
- AWS STS federated user principals
- AWS service principals
- AWS service principals in opt-in Regions
- All principals
- More information

How to specify a principal

You specify a principal in the `Principal` element of a resource-based policy or in condition keys that support principals.

You can specify any of the following principals in a policy:

- AWS account and root user
- IAM roles
- Role sessions
- IAM users
- Federated user principals
- AWS services
- All principals

You cannot identify a user group as a principal in a policy (such as a resource-based policy) because groups relate to permissions, not authentication, and principals are authenticated IAM entities.

You can specify more than one principal for each of the principal types in following sections using an array. Arrays can take one or more values. When you specify more than one principal in an element, you grant permissions to each principal. This is a logical `OR` and not a logical `AND`, because you authenticate as one principal at a time. If you include more than one value, use square brackets

([and]) and comma-delimit each entry for the array. The following example policy defines permissions for the 123456789012 account or the 555555555555 account.

```
"Principal" : {
"AWS": [
  "123456789012",
  "555555555555"
  ]
}
```

> **Note**
>
> You cannot use a wildcard to match part of a principal name or ARN.

AWS account principals

You can specify AWS account identifiers in the `Principal` element of a resource-based policy or in condition keys that support principals. This delegates authority to the account. When you allow access to a different account, an administrator in that account must then grant access to an identity (IAM user or role) in that account. When you specify an AWS account, you can use the account ARN (arn:aws:iam::*account-ID*:root), or a shortened form that consists of the `"AWS":` prefix followed by the account ID.

For example, given an account ID of `123456789012`, you can use either of the following methods to specify that account in the `Principal` element:

```
"Principal": { "AWS": "arn:aws:iam::123456789012:root" }
```

```
"Principal": { "AWS": "123456789012" }
```

The account ARN and the shortened account ID behave the same way. Both delegate permissions to the account. Using the account ARN in the `Principal` element does not limit permissions to only the root user of the account.

> **Note**
>
> When you save a resource-based policy that includes the shortened account ID, the service might convert it to the principal ARN. This does not change the functionality of the policy.

Some AWS services support additional options for specifying an account principal. For example, Amazon S3 lets you specify a canonical user ID using the following format:

```
"Principal": { "CanonicalUser":
 "79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be" }
```

You can also specify more than one AWS account, (or canonical user ID) as a principal using an array. For example, you can specify a principal in a bucket policy using all three methods.

```
"Principal": {
  "AWS": [
    "arn:aws:iam::123456789012:root",
    "999999999999"
  ],
  "CanonicalUser": "79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be"
}
```

IAM role principals

You can specify IAM role principal ARNs in the `Principal` element of a resource-based policy or in condition keys that support principals. IAM roles are identities. In IAM, identities are resources to which you can assign permissions. Roles trust another authenticated identity to assume that role. This includes a principal in AWS or a user from an external identity provider (IdP). When a principal or identity assumes a role, they receive temporary security credentials with the assumed role's permissions. When they use those session credentials to perform operations in AWS, they become a *role session principal*.

When you specify a role principal in a resource-based policy, the effective permissions for the principal are limited by any policy types that limit permissions for the role. This includes session policies and permissions boundaries. For more information about how the effective permissions for a role session are evaluated, see Policy evaluation logic.

To specify the role ARN in the `Principal` element, use the following format:

```
"Principal": { "AWS": "arn:aws:iam::AWS-account-ID:role/role-name" }
```

Important

If your `Principal` element in a role trust policy contains an ARN that points to a specific IAM role, then that ARN transforms to the role's unique principal ID when you save the policy. This helps mitigate the risk of someone escalating their privileges by removing and recreating the role. You don't normally see this ID in the console, because IAM uses a reverse transformation back to the role ARN when the trust policy is displayed. However, if you delete the role, then you break the relationship. The policy no longer applies, even if you recreate the role because the new role has a new principal ID that does not match the ID stored in the trust policy. When this happens, the principal ID appears in resource-based policies because AWS can no longer map it back to a valid ARN. The end result is that if you delete and recreate a role referenced in a trust policy's `Principal` element, you must edit the role in the policy to replace the principal ID with the correct ARN. The ARN once again transforms into the role's new principal ID when you save the policy. For more information, see Understanding AWS's Handling of Deleted IAM roles in Policies.

Alternatively, you can specify the role principal as the principal in a resource-based policy or create a broad-permission policy that uses the `aws:PrincipalArn` condition key. When you use this key, the role session principal is granted the permissions based on the ARN of role that was assumed, and not the ARN of the resulting session. Because AWS does not convert condition key ARNs to IDs, permissions granted to the role ARN persist if you delete the role and then create a new role with the same name. Identity-based policy types, such as permissions boundaries or session policies, do not limit permissions granted using the `aws:PrincipalArn` condition key with a wildcard(*) in the `Principal` element, unless the identity-based policies contain an explicit deny.

Role session principals

You can specify role sessions in the `Principal` element of a resource-based policy or in condition keys that support principals. When a principal or identity assumes a role, they receive temporary security credentials with the assumed role's permissions. When they use those session credentials to perform operations in AWS, they become a *role session principal*.

The format that you use for a role session principal depends on the AWS STS operation that was used to assume the role.

Additionally, administrators can design a process to control how role sessions are issued. For example, they can provide a one-click solution for their users that creates a predictable session name. If your administrator does this, you can use role session principals in your policies or condition keys. Otherwise, you can specify the role ARN as a principal in the `aws:PrincipalArn` condition key. How you specify the role as a principal can change the effective permissions for the resulting session. For more information, see IAM role principals.

Assumed-role session principals

An *assumed-role session principal* is a session principal that results from using the AWS STS `AssumeRole` operation. For more information about which principals can assume a role using this operation, see Compare AWS STS credentials.

To specify the assumed-role session ARN in the `Principal` element, use the following format:

```
"Principal": { "AWS": "arn:aws:sts::AWS-account-ID:assumed-role/role-name/role-session-name" }
```

When you specify an assumed-role session in a `Principal` element, you cannot use a wildcard "*" to mean all sessions. Principals must always name a specific session.

OIDC federated principals

An OIDC federated principal is the principal used when calling AWS STS `AssumeRoleWithWebIdentity` API with a JSON web token (JWT) from an OIDC compliant IDP, also known as OpenID Provider (OP), to request temporary AWS credentials. An OIDC federated principal can represent an OIDC IDP in your AWS account, or the 4 built in identity providers: Login with Amazon, Google, Facebook, and Amazon Cognito.

Users, workloads, or systems who've been issued a JWT from their OIDC IDP can call `AssumeRoleWithWebIdentity` using the JWT to request temporary AWS security credentials for an IAM role that is configured to trust the OIDC IDP that issued the JWT. The JWT can be an id token, access token, or a JWT token delivered by any other method as long as it meets the requirements listed by AWS STS. For more information, see Common scenarios and Requesting credentials through an OIDC provider.

Use this principal type in your role trust policy to allow or deny permissions to call `AssumeRoleWIthWebIdentity` using an OIDC IDP that exists in your AWS account, or one of the four built in IDPs. To specify the OIDC federated principal ARN in the `Principal` element of a role trust policy, use one of the following four formats for the built in OIDC IDPs:

```
"Principal": { "Federated": "cognito-identity.amazonaws.com" }
```

```
"Principal": { "Federated": "www.amazon.com" }
```

```
"Principal": { "Federated": "graph.facebook.com" }
```

```
"Principal": { "Federated": "accounts.google.com" }
```

When using a OIDC provider you add to your account, such as GitHub, you specify the provider's ARN in your role's trust policy. This configuration allows you to write IAM policies that control access specifically for users authenticated through your custom identity provider.

```
"Principal": { "Federated": "arn:aws:iam::AWS-account-ID:oidc-provider/full-OIDC-identity-provider-URL" }
```

For example, if GitHub was the trusted web identity provider, the OIDC role session ARN in the `Principal` element of a role trust policy uses the following format:

```
"Principal": { "Federated": "arn:aws:iam::AWS-account-ID:oidc-provider/tokens.actions.githubusercontent.com" }
```

See Configuring OpenID Connect in Amazon Web Services for more information.

OIDC federated principals are not supported in policy types other than role trust policies.

SAML federated principals

A *SAML federated principal* is a principal that is used when calling AWS STS `AssumeRoleWithSAML` API to request temporary AWS credentials using a SAML assertion. You can use your SAML identity provider (IDP) to sign in, and then assume an IAM role using this operation. Similar to `AssumeRoleWithWebIdentity`, `AssumeRoleWithSAML` doesn't require AWS credentials for authentication. Instead, users first authenticate with their SAML identity provider, then make the `AssumeRoleWithSAML` API call using their SAML assertion, or are redirected to the AWS Sign-In/SAML page to sign into the AWS Management Console. For more information about which principals can assume a role using this operation, see Compare AWS STS credentials.

Use this principal type in your role trust policy to allow or deny permissions based on the trusted SAML identity provider. To specify the SAML identity role session ARN in the `Principal` element of a role trust policy, use the following format:

```
"Principal": { "Federated": "arn:aws:iam::AWS-account-ID:saml-provider/provider-name" }
```

IAM user principals

You can specify IAM users in the `Principal` element of a resource-based policy or in condition keys that support principals.

> **Note**
>
> In a `Principal` element, the user name part of the *Amazon Resource Name* (ARN) is case sensitive.

```
"Principal": { "AWS": "arn:aws:iam::AWS-account-ID:user/user-name" }
```

```
"Principal": {
  "AWS": [
    "arn:aws:iam::AWS-account-ID:user/user-name-1",
    "arn:aws:iam::AWS-account-ID:user/user-name-2"
  ]
}
```

When you specify users in a `Principal` element, you cannot use a wildcard (*) to mean "all users". Principals must always name specific users.

> **Important**
>
> If your `Principal` element in a role trust policy contains an ARN that points to a specific IAM user, then IAM transforms the ARN to the user's unique principal ID when you save the policy. This helps mitigate the risk of someone escalating their privileges by removing and recreating the user. You don't normally see this ID in the console, because there is also a reverse transformation back to the user's ARN when the trust policy is displayed. However, if you delete the user, then you break the relationship. The policy no longer applies, even if you recreate the user. That's because the new user has a new principal ID that does not

match the ID stored in the trust policy. When this happens, the principal ID appears in resource-based policies because AWS can no longer map it back to a valid ARN. The result is that if you delete and recreate a user referenced in a trust policy `Principal` element, you must edit the role to replace the now incorrect principal ID with the correct ARN. IAM once again transforms ARN into the user's new principal ID when you save the policy.

IAM Identity Center principals

In IAM Identity Center, the principal in a resource-based policy must be defined as the AWS account principal. To specify access, reference the role ARN of the permission set in the condition block. For details, see Referencing permission sets in resource policies, Amazon EKS, and AWS KMS in the *IAM Identity Center User Guide*.

AWS STS federated user principals

You can specify *federated user sessions* in the `Principal` element of a resource-based policy or in condition keys that support principals.

Important

AWS recommends that you limit the use of AWS STS federated user sessions. Instead, use IAM roles.

An AWS STS federated user principal is created through the `GetFederationToken` operation called with long-lived IAM credentials. Federated user permissions are the intersection of the principal that called `GetFederationToken` and the session policies passed as parameters to the `GetFederationToken` API.

In AWS, IAM users or an AWS account root user can authenticate using long-term access keys. For more information about which principals can federate using this operation, see Compare AWS STS credentials.

- **IAM federated user** – An IAM user federates using the `GetFederationToken` operation that results in a federated user session for that IAM user.
- **Federated root user** – A root user federates using the `GetFederationToken` operation that results in a federated user session for that root user.

When an IAM user or root user requests temporary credentials from AWS STS using this operation, they begin a temporary federated user session. This session's ARN is based on the original identity that was federated.

To specify the federated user session ARN in the `Principal` element, use the following format:

```
"Principal": { "AWS": "arn:aws:sts::AWS-account-ID:federated-user/user-name" }
```

AWS service principals

You can specify AWS services in the `Principal` element of a resource-based policy or in condition keys that support principals. A *service principal* is an identifier for a service.

IAM roles that can be assumed by an AWS service are called *service roles*. Service roles must include a trust policy. *Trust policies* are resource-based policies attached to a role that defines which principals can assume the role. Some service roles have predefined trust policies. However, in some cases, you must specify the service principal in the trust policy. The service principal in an IAM policy can't be `"Service": "*"`.

> **Important**
>
> The identifier for a service principal includes the service name, and is usually in the following format:
> *service-name*`.amazonaws.com`

The service principal is defined by the service. You can find the service principal for some services by opening AWS services that work with IAM, checking whether the service has **Yes** in the **Service-linked role** column, and opening the **Yes** link to view the service-linked role documentation for that service. Find the **Service-Linked Role Permissions** section for that service to view the service principal.

The following example shows a policy that can be attached to a service role. The policy enables two services, Amazon ECS and Elastic Load Balancing, to assume the role. The services can then perform any tasks granted by the permissions policy assigned to the role (not shown). To specify multiple service principals, you do not specify two `Service` elements; you can have only one. Instead, you use an array of multiple service principals as the value of a single `Service` element.

```
"Principal": {
```

```
    "Service": [
        "ecs.amazonaws.com",
        "elasticloadbalancing.amazonaws.com"
   ]
}
```

AWS service principals in opt-in Regions

You can launch resources in several AWS Regions and some of those Regions you must opt in to. For a complete list of Regions you must opt in to, see Managing AWS Regions in the *AWS General Reference* guide.

When an AWS service in an opt-in Region makes a request within the same Region, the service principal name format is identified as the non-regionalized version of their service principal name:

service-name.amazonaws.com

When an AWS service in an opt-in Region makes a cross-region request to another Region, the service principal name format is identified as the regionalized version of their service principal name:

service-name.*{region}*.amazonaws.com

For example, you have an Amazon SNS topic located in Region `ap-southeast-1` and an Amazon S3 bucket located in opt-in Region `ap-east-1`. You want to configure S3 bucket notifications to publish messages to the SNS topic. To allow the S3 service to post messages to the SNS topic you must grant the S3 service principal `sns:Publish` permission via the resource-based access policy of the topic.

If you specify the non-regionalized version of the S3 service principal, `s3.amazonaws.com`, in the topic access policy, the `sns:Publish` request from the bucket to the topic will fail. The following example specifies the non-regionalized S3 service principal in the `Principal` policy element of the SNS topic access policy.

```
"Principal": { "Service": "s3.amazonaws.com" }
```

Since the bucket is located in an opt-in Region and the request is made outside of that same Region, the S3 service principal appears as the regionalized service principal name, `s3.ap-east-1.amazonaws.com`. You must use the regionalized service principal name when an AWS

service in an opt-in Region makes a request to another Region. After you specify the regionalized service principal name, if the bucket makes an `sns:Publish` request to the SNS topic located in another Region, the request will be successful. The following example specifies the regionalized S3 service principal in the `Principal` policy element of the SNS topic access policy.

```
"Principal": { "Service": "s3.ap-east-1.amazonaws.com" }
```

Resource policies or service principal-based allow-lists for cross-Region requests from an opt-in Region to another Region will only be successful if you specify the regionalized service principal name.

> **Note**
>
> For IAM role trust policies, we recommend using the non-regionalized service principal name. IAM resources are global and therefore the same role can be used in any Region.

All principals

You can use a wildcard (*) to specify all principals in the `Principal` element of a resource-based policy or in condition keys that support principals. Resource-based policies *grant* permissions and condition keys are used to limit the conditions of a policy statement.

> **Important**
>
> We strongly recommend that you do not use a wildcard (*) in the `Principal` element of a resource-based policy with an `Allow` effect unless you intend to grant public or anonymous access. Otherwise, specify intended principals, services, or AWS accounts in the `Principal` element and then further restrict access in the `Condition` element. This is especially true for IAM role trust policies, because they allow other principals to become a principal in your account.

For resource-based policies, using a wildcard (*) with an `Allow` effect grants access to all users, including anonymous users (public access). For IAM users and role principals within your account, no other permissions are required. For principals in other accounts, they must also have identity-based permissions in their account that allow them to access your resource. This is called cross-account access.

For anonymous users, the following elements are equivalent:

```
"Principal": "*"
```

```
"Principal" : { "AWS" : "*" }
```

You cannot use a wildcard to match part of a principal name or ARN.

The following example shows a resource-based policy that can be used instead of AWS JSON policy elements: NotPrincipal to explicitly deny all principals *except* for the ones specified in the `Condition` element. This policy should be added to an Amazon S3 bucket.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "UsePrincipalArnInsteadOfNotPrincipalWithDeny",
      "Effect": "Deny",
      "Action": "s3:*",
      "Principal": "*",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/*",
        "arn:aws:s3:::amzn-s3-demo-bucket"
      ],
      "Condition": {
        "ArnNotEquals": {
          "aws:PrincipalArn": "arn:aws:iam::444455556666:user/user-name"
        }
      }
    }
  ]
}
```

- Account identifiers in the *AWS General Reference*
- OIDC federation

AWS JSON policy elements: NotPrincipal

The `NotPrincipal` element uses `"Effect":"Deny"` to deny access to all principals ***except*** the principal specified in the `NotPrincipal` element. A principal can be an IAM user, AWS STS federated user principal, IAM role, assumed role session, AWS account, AWS service, or other principal type. For more information about principals, see AWS JSON policy elements: Principal.

`NotPrincipal` must be used with `"Effect":"Deny"`. Using it with `"Effect":"Allow"` is not supported.

> **Important**
>
> We do not recommend the use of `NotPrincipal` for new resource-based policies as part of your security and authorization strategy. When you use `NotPrincipal`, troubleshooting the effects of multiple policy types can be difficult. We recommend using the `aws:PrincipalArn` context key with ARN condition operators instead.

Key points

- The `NotPrincipal` element is supported in resource-based policies for some AWS services, including VPC endpoints. Resource-based policies are policies that you embed directly in a resource. You cannot use the `NotPrincipal` element in an IAM identity-based policy nor in an IAM role trust policy.
- Don't use resource-based policy statements that include a `NotPrincipal` policy element with a `Deny` effect for IAM users or roles that have a permissions boundary policy attached. The `NotPrincipal` element with a `Deny` effect will always deny any IAM principal that has a permissions boundary policy attached, regardless of the values specified in the `NotPrincipal` element. This causes some IAM users or roles that would otherwise have access to the resource to lose access. We recommend changing your resource-based policy statements to use the condition operator `ArnNotEquals` with the `aws:PrincipalArn` context key to limit access instead of

the `NotPrincipal` element. For information about permissions boundaries, see Permissions boundaries for IAM entities.

- When you use `NotPrincipal`, you must also specify the account ARN of the not-denied principal. Otherwise, the policy might deny access to the entire account containing the principal. Depending on the service that you include in your policy, AWS might validate the account first and then the user. If an assumed-role user (someone who is using a role) is being evaluated, AWS might validate the account first, then the role, and then the assumed-role user. The assumed-role user is identified by the role session name that is specified when they assumed the role. Therefore, we strongly recommend that you explicitly include the ARN for a user's account, or include both the ARN for a role and the ARN for the account containing that role.
- The `NotPrincipal` element isn't supported in Service Control Policies (SCP) and Resource Control Policies (RCP).

Alternatives to the `NotPrincipal` element

When managing access control in AWS, there may be scenarios where you need to explicitly deny all principals access to a resource, except for one or more principals you specify. AWS recommends using a Deny statement with global condition context keys for more precise control and easier troubleshooting. The following examples show alternative approaches using condition operators like `StringNotEquals` or `ArnNotEquals` to deny access to all principals except those specified in the Condition element.

Example scenario using an IAM role

You can use a resource-based policy with a Deny statement to prevent all IAM roles, except those specified in the Condition element, from accessing or manipulating your resources. This approach follows the AWS security principle that an explicit deny always takes precedence over any allow statements and helps maintain the principle of least privilege across your AWS infrastructure.

Instead of using `NotPrincipal`, we recommend using a Deny statement with global condition context keys and the condition operator like `ArnNotEquals` to explicitly allow an IAM role access to your resources. The following example uses aws:PrincipalArn to explicitly allow the role `read-only-role` to access Amazon S3 buckets in the `Bucket_Account_Audit` folder.

JSON

```
{
  "Version": "2012-10-17",
```

```
  "Statement": [
    {
      "Sid": "DenyCrossAuditAccess",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::Bucket_Account_Audit",
        "arn:aws:s3:::Bucket_Account_Audit/*"
      ],
      "Condition": {
        "ArnNotEquals": {
          "aws:PrincipalArn": "arn:aws:iam::444455556666:role/read-only-role"
        }
      }
    }
  ]
}
```

Example scenario using a service principal

You can use a Deny statement to prevent all service principals, except those specified in the `Condition` element, from accessing or manipulating your resources. This approach is particularly useful when you need to implement fine-grained access controls or establish security boundaries between different services and applications in your AWS environment.

Instead of using `NotPrincipal`, we recommend using a Deny statement with global condition context keys and the condition operator `StringNotEquals` to explicitly allow a service principal access to your resources. The following example uses `aws:PrincipalServiceName` to explicitly allow the AWS CodeBuild service principal to access Amazon S3 buckets in the BUCKETNAME folder.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyNotCodeBuildAccess",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
```

```
      "Resource": [
        "arn:aws:s3:::BUCKETNAME",
        "arn:aws:s3:::BUCKETNAME/*"
      ],
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:PrincipalServiceName": "codebuild.amazonaws.com"
        }
      }
    }
  ]
}
```

IAM JSON policy elements: Action

The `Action` element describes the specific action or actions that will be allowed or denied. Statements must include either an `Action` or `NotAction` element. Each AWS service has its own set of actions that describe tasks that you can perform with that service. For example, the list of actions for Amazon S3 can be found at Specifying Permissions in a Policy in the *Amazon Simple Storage Service User Guide*, the list of actions for Amazon EC2 can be found in the Amazon EC2 API Reference, and the list of actions for AWS Identity and Access Management can be found in the IAM API Reference. To find the list of actions for other services, consult the API reference documentation for the service.

AWS also provides service reference information in JSON format to streamline the automation of policy management workflows. With the service reference information, you can access available actions, resources, and condition keys across AWS services from machine-readable files. For more information, see Simplified AWS service information for programmatic access in the Service Authorization Reference.

You specify a value using a service namespace as an action prefix (`iam`, `ec2`, `sqs`, `sns`, `s3`, etc.) followed by the name of the action to allow or deny. The name must match an action that is supported by the service. The prefix and the action name are case insensitive. For example, `iam:ListAccessKeys` is the same as `IAM:listaccesskeys`. The following examples show `Action` elements for different services.

Amazon SQS action

```
"Action": "sqs:SendMessage"
```

Amazon EC2 action

```
"Action": "ec2:StartInstances"
```

IAM action

```
"Action": "iam:ChangePassword"
```

Amazon S3 action

```
"Action": "s3:GetObject"
```

You can specify multiple values for the `Action` element.

```
"Action": [ "sqs:SendMessage", "sqs:ReceiveMessage", "ec2:StartInstances",
 "iam:ChangePassword", "s3:GetObject" ]
```

You can use multi-character match wildcards (*) and single-character match wildcards (?) to give access to all the actions the specific AWS product offers. For example, the following `Action` element applies to all S3 actions.

```
"Action": "s3:*"
```

You can also use wildcards (* or ?) as part of the action name. For example, the following `Action` element applies to all IAM actions that include the string `AccessKey`, including `CreateAccessKey`, `DeleteAccessKey`, `ListAccessKeys`, and `UpdateAccessKey`.

```
"Action": "iam:*AccessKey*"
```

Some services let you limit the actions that are available. For example, Amazon SQS lets you make available just a subset of all the possible Amazon SQS actions. In that case, the * wildcard doesn't allow complete control of the queue; it allows only the subset of actions that you've shared. For more information, see Understanding Permissions in the *Amazon Simple Queue Service Developer Guide*.

IAM JSON policy elements: NotAction

`NotAction` is an advanced policy element that explicitly matches everything *except* the specified list of actions. Using `NotAction` can result in a shorter policy by listing only a few actions that

should not match, rather than including a long list of actions that will match. Actions specified in `NotAction` are not impacted by the `Allow` or `Deny` effect in a policy statement. This, in turn, means that all of the applicable actions or services that are not listed are allowed if you use the `Allow` effect. In addition, such unlisted actions or services are denied if you use the `Deny` effect. When you use `NotAction` with the `Resource` element, you provide scope for the policy. This is how AWS determines which actions or services are applicable. For more information, see the following example policy.

NotAction with Allow

You can use the `NotAction` element in a statement with `"Effect": "Allow"` to provide access to all of the actions in an AWS service, except for the actions specified in `NotAction`. You can use it with the `Resource` element to provide scope for the policy, limiting the allowed actions to the actions that can be performed on the specified resource.

The following example allows users to access all of the Amazon S3 actions that can be performed on any S3 resource *except* for deleting a bucket. This policy also does not allow actions in other services, because other service actions are not applicable to the S3 resources.

```
"Effect": "Allow",
"NotAction": "s3:DeleteBucket",
"Resource": "arn:aws:s3:::*",
```

Sometimes, you might want to allow access to a large number of actions. By using the `NotAction` element you effectively reverse the statement, resulting in a shorter list of actions. For example, because AWS has so many services, you might want to create a policy that allows the user to do everything except access IAM actions.

The following example allows users to access every action in every AWS service except for IAM.

```
"Effect": "Allow",
"NotAction": "iam:*",
"Resource": "*"
```

Be careful using the `NotAction` element and `"Effect": "Allow"` in the same statement or in a different statement within a policy. `NotAction` matches all services and actions that are not explicitly listed or applicable to the specified resource, and could result in granting users more permissions than you intended.

NotAction with Deny

You can use the `NotAction` element in a statement with `"Effect": "Deny"` to deny access to all of the listed resources except for the actions specified in the `NotAction` element. This combination does not allow the listed items, but instead explicitly denies the actions not listed. You must still allow actions that you want to allow.

The following conditional example denies access to non-IAM actions if the user is not signed in using MFA. If the user is signed in with MFA, then the `"Condition"` test fails and the final `"Deny"` statement has no effect. Note, however, that this would not grant the user access to any actions; it would only explicitly deny all other actions except IAM actions.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "DenyAllUsersNotUsingMFA",
        "Effect": "Deny",
        "NotAction": "iam:*",
        "Resource": "*",
        "Condition": {"BoolIfExists": {"aws:MultiFactorAuthPresent": "false"}}
    }]
}
```

For an example policy that denies access to actions outside of specific Regions, except for actions from specific services, see AWS: Denies access to AWS based on the requested Region.

IAM JSON policy elements: Resource

The `Resource` element in an IAM policy statement defines the object or objects that the statement applies to. Statements must include either a `Resource` or a `NotResource` element.

You specify a resource using an Amazon Resource Name (ARN). The format of the ARN depends on the AWS service and the specific resource you're referring to. Although the ARN format varies you always use an ARN to identify a resource. For more information about the format of ARNs, see IAM ARNs. For information about how to specify a resource, refer to the documentation for the service you want to write a statement.

> **Note**
>
> Some AWS services do not allow you to specify actions for individual resources. In these cases, any actions that you list in the `Action` or `NotAction` element apply to all resources in that service. When this is the case, you use the wildcard character (*) in the `Resource` element.

The following example refers to a specific Amazon SQS queue.

```
"Resource": "arn:aws:sqs:us-east-2:account-ID-without-hyphens:queue1"
```

The following example refers to the IAM user named Bob in an AWS account.

> **Note**
>
> In the `Resource` element, the IAM user name is case sensitive.

```
"Resource": "arn:aws:iam::account-ID-without-hyphens:user/Bob"
```

Using wildcards in resource ARNs

You can use wildcard characters (* and ?) within the individual segments of an ARN (the parts separated by colons) to represent:

- Any combination of characters (*)
- Any single character (?)

You can use multiple * or ? characters in each segment. If the * wildcard is the last character of a resource ARN segment, it can expand to match beyond the colon boundaries. We recommend you use wildcards (* and ?) within ARN segments separated by a colon.

> **Note**
>
> You can't use a wildcard in the service segment that identifies the AWS product. For more information about ARN segments, see Identify AWS resources with Amazon Resource Names (ARNs)

The following example refers to all IAM users whose path is `/accounting`.

```
"Resource": "arn:aws:iam::account-ID-without-hyphens:user/accounting/*"
```

The following example refers to all items within a specific Amazon S3 bucket.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

The asterisk (*) character can expand to replace everything within a segment, including characters like a forward slash (/) that may otherwise appear to be a delimiter within a given service namespace. For example, consider the following Amazon S3 ARN as the same wildcard expansion logic applies to all services.

```
"Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*/test/*"
```

The wildcards in the ARN apply to all of the following objects in the bucket, not only the first object listed.

```
amzn-s3-demo-bucket/1/test/object.jpg
amzn-s3-demo-bucket/1/2/test/object.jpg
amzn-s3-demo-bucket/1/2/test/3/object.jpg
amzn-s3-demo-bucket/1/2/3/test/4/object.jpg
amzn-s3-demo-bucket/1///test///object.jpg
amzn-s3-demo-bucket/1/test/.jpg
amzn-s3-demo-bucket//test/object.jpg
amzn-s3-demo-bucket/1/test/
```

Consider the last two objects in the previous list. An Amazon S3 object name can begin or end with the conventional delimiter forward slash (/) character. While / works as a delimiter, there is no specific significance when this character is used within a resource ARN. It is treated the same as any other valid character. The ARN would not match the following objects:

```
amzn-s3-demo-bucket/1-test/object.jpg
amzn-s3-demo-bucket/test/object.jpg
amzn-s3-demo-bucket/1/2/test.jpg
```

Specifying multiple resources

You can specify multiple resources in the `Resource` element by using an array of ARNs. The following example refers to two DynamoDB tables.

```
"Resource": [
    "arn:aws:dynamodb:us-east-2:account-ID-without-hyphens:table/books_table",
    "arn:aws:dynamodb:us-east-2:account-ID-without-hyphens:table/magazines_table"
]
```

Using policy variables in resource ARNs

In the `Resource` element, you can use JSON policy variables in the part of the ARN that identifies the specific resource (that is, in the trailing part of the ARN). For example, you can use the key `{aws:username}` as part of a resource ARN to indicate that the current user's name should be included as part of the resource's name. The following example shows how you can use the `{aws:username}` key in a `Resource` element. The policy allows access to a Amazon DynamoDB table that matches the current user's name.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "dynamodb:*",
        "Resource": "arn:aws:dynamodb:us-east-2:111122223333:table/
${aws:username}"
    }
}
```

For more information about JSON policy variables, see IAM policy elements: Variables and tags.

IAM JSON policy elements: NotResource

`NotResource` is an advanced policy element that explicitly matches every resource except those specified. Using `NotResource` can result in a shorter policy by listing only a few resources that should not match, rather than including a long list of resources that will match. This is particularly useful for policies that apply within a single AWS service.

For example, imagine you have a group named `HRPayroll`. Members of `HRPayroll` should not be allowed to access any Amazon S3 resources except the `Payroll` folder in the `HRBucket` bucket. The following policy explicitly denies access to all Amazon S3 resources other than the listed resources. Note, however, that this policy does not grant the user access to any resources.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "s3:*",
    "NotResource": [
      "arn:aws:s3:::HRBucket/Payroll",
      "arn:aws:s3:::HRBucket/Payroll/*"
    ]
  }
}
```

Normally, to explicitly deny access to a resource you would write a policy that uses `"Effect":"Deny"` and that includes a `Resource` element that lists each folder individually. However, in that case, each time you add a folder to `HRBucket`, or add a resource to Amazon S3 that should not be accessed, you must add its name to the list in the `Resource` element. If you use a `NotResource` element instead, users are automatically denied access to new folders unless you add the folder names to the `NotResource` element.

When using `NotResource`, you should keep in mind that resources specified in this element are the *only* resources that are not limited. This, in turn, limits all of the resources that would apply to the action. In the example above, the policy affects only Amazon S3 actions, and therefore only Amazon S3 resources. If the `Action` element also included Amazon EC2 actions, then the policy would deny access to any EC2 resources not specified in the `NotResource` element. To learn which

actions in a service allow specifying the ARN of a resource, see Actions, Resources, and Condition Keys for AWS Services.

NotResource with other elements

You should **never** use the `"Effect": "Allow"`, `"Action": "*"`, and `"NotResource": "arn:aws:s3:::HRBucket"` elements together. This statement is very dangerous, because it allows all actions in AWS on all resources except the `HRBucket` S3 bucket. This would even allow the user to add a policy to themselves that allows them to access `HRBucket`. Do not do this.

Be careful using the `NotResource` element and `"Effect": "Allow"` in the same statement or in a different statement within a policy. `NotResource` allows all services and resources that are not explicitly listed, and could result in granting users more permissions than you intended. Using the `NotResource` element and `"Effect": "Deny"` in the same statement denies services and resources that are not explicitly listed.

IAM JSON policy elements: Condition

The `Condition` element (or `Condition` *block*) lets you specify conditions for when a policy is in effect. The `Condition` element is optional. In the `Condition` element, you build expressions in which you use condition operators (equal, less than, and others) to match the context keys and values in the policy against keys and values in the request context. To learn more about the request context, see Components of a request.

```
"Condition" : { "{condition-operator}" : { "{condition-key}" : "{condition-value}" }}
```

The context key that you specify in a policy condition can be a global condition context key or a service-specific context key. Global condition context keys have the `aws:` prefix. Service-specific context keys have the service's prefix. For example, Amazon EC2 lets you write a condition using the `ec2:InstanceType` context key, which is unique to that service. To view service-specific IAM context keys with the `iam:` prefix, see IAM and AWS STS condition context keys.

Context key *names* are not case-sensitive. For example, including the `aws:SourceIP` context key is equivalent to testing for `AWS:SourceIp`. Case-sensitivity of context key *values* depends on the condition operator that you use. For example, the following condition includes the `StringEquals` operator to make sure that only requests made by `john` match. Users named `John` are denied access.

```
"Condition" : { "StringEquals" : { "aws:username" : "john" }}
```

The following condition uses the `StringEqualsIgnoreCase` operator to match users named `john` or `John`.

```
"Condition" : { "StringEqualsIgnoreCase" : { "aws:username" : "john" }}
```

Some context keys support key–value pairs that allow you to specify part of the key name. Examples include the `aws:RequestTag/tag-key` context key, the AWS KMS `kms:EncryptionContext:encryption_context_key`, and the `ResourceTag/tag-key` context key supported by multiple services.

- If you use the `ResourceTag/tag-key` context key for a service such as Amazon EC2, then you must specify a key name for the `tag-key`.
- **Key names are not case-sensitive.** This means that if you specify `"aws:ResourceTag/TagKey1": "Value1"` in the condition element of your policy, then the condition matches a resource tag key named either `TagKey1` or `tagkey1`, but not both.
- AWS services that support these attributes might allow you to create multiple key names that differ only by case. For example, you might tag an Amazon EC2 instance with `ec2=test1` and `EC2=test2`. When you use a condition such as `"aws:ResourceTag/EC2": "test1"` to allow access to that resource, the key name matches both tags, but only one value matches. This can result in unexpected condition failures.

> **Important**
>
> As a best practice, make sure that members of your account follow a consistent naming convention when naming key–value pair attributes. Examples include tags or AWS KMS encryption contexts. You can enforce this using the `aws:TagKeys` context key for tagging, or the `kms:EncryptionContextKeys` for the AWS KMS encryption context.

- For a list of all of the condition operators and a description of how they work, see Condition operators.
- Unless otherwise specified, all context keys can have multiple values. For a description of how to handle context keys that have multiple values, see Set operators for multivalued context keys.
- For a list of all of the globally available context keys, see AWS global condition context keys.
- For condition context keys that are defined by each service, see Actions, Resources, and Condition Keys for AWS Services.

The request context

When a principal makes a request to AWS, AWS gathers the request information into a request context. The request context includes information about the principal, resources, actions, and other environmental properties. Policy evaluation matches the properties in the policy against the properties sent in the request to evaluate and authorize actions you can perform in AWS.

You can use the `Condition` element of a JSON policy to test specific context keys against the request context. For example, you can create a policy that uses the aws:CurrentTime context key to allow a user to perform actions within only a specific range of dates.

The following example shows a representation of the request context when Martha Rivera sends a request to deactivate her MFA device.

```
Principal: AROA123456789EXAMPLE
Action: iam:DeactivateMFADevice
Resource: arn:aws:iam::user/martha
Context:
  - aws:UserId=AROA123456789EXAMPLE:martha
  - aws:PrincipalAccount=1123456789012
  - aws:PrincipalOrgId=o-example
  - aws:PrincipalARN=arn:aws:iam::1123456789012:assumed-role/TestAR
  - aws:MultiFactorAuthPresent=true
  - aws:MultiFactorAuthAge=2800
  - aws:CurrentTime=...
  - aws:EpochTime=...
  - aws:SourceIp=...
```

The request context is matched aginst a policy that allows users to remove their own multi-factor authentication (MFA) device, but only if they have signed in using MFA in the last hour (3,600 seconds).

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Sid": "AllowRemoveMfaOnlyIfRecentMfa",
        "Effect": "Allow",
        "Action": [
            "iam:DeactivateMFADevice"
```

```
        ],
        "Resource": "arn:aws:iam::*:user/${aws:username}",
        "Condition": {
            "NumericLessThanEquals": {"aws:MultiFactorAuthAge": "3600"}
        }
    }
}
```

In this example, the policy matches the request context: the action is the same, the resource matches the "*" wildcard, and the value for `aws:MultiFactorAuthAge` is 2800, which is less than 3600, so the policy allows this authorization request.

AWS evaluates each context key in the policy and returns a value of *true* or *false*. A context key that is not present in the request is considered a mismatch.

The request context can return the following values:

- **True** – If the requester signed in using MFA in the last one hour or less, then the condition returns *true*.
- **False** – If the requester signed in using MFA more than one hour ago, then the condition returns *false*.
  - **Not present** – If the requester made a request using their IAM user access keys in the AWS CLI or AWS API, the key is not present. In this case, the key is not present, and it won't match.

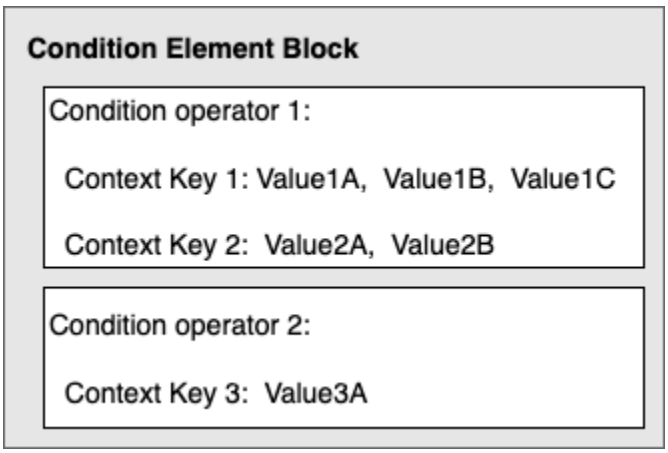
> **Note**
>
> In some cases, when the condition key value is not present, the condition can still return true. For example, if you add the `ForAllValues` qualifier, the request returns true if the context key is not in the request. To prevent missing context keys or context keys with empty values from evaluating to true, you can include the Null condition operator in your policy with a `false` value to check if the context key exists and its value is not null.

The condition block

The following example shows the basic format of a `Condition` element:

```
"Condition": {"StringLike": {"s3:prefix": ["jane/*"]}}
```

A value from the request is represented by a context key, in this case `s3:prefix`. The context key value is compared to a value that you specify as a literal value, such as `jane/*`. The type of comparison to make is specified by the condition operator (here, `StringLike`). You can create conditions that compare strings, dates, numbers, and more using typical Boolean comparisons such as equals, greater than, and less than. When you use string operators or ARN operators, you can also use a policy variable in the context key value. The following example includes the `aws:username` variable.



```
"Condition": {"StringLike": {"s3:prefix": ["${aws:username}/*"]}}
```

Under some circumstances, context keys can contain multiple values. For example, a request to Amazon DynamoDB might ask to return or update multiple attributes from a table. A policy for access to DynamoDB tables can include the `dynamodb:Attributes` context key, which contains all the attributes listed in the request. You can test the multiple attributes in the request against a list of allowed attributes in a policy by using set operators in the `Condition` element. For more information, see Set operators for multivalued context keys.

When the policy is evaluated during a request, AWS replaces the key with the corresponding value from the request. (In this example, AWS would use the date and time of the request.) The condition is evaluated to return true or false, which is then factored into whether the policy as a whole allows or denies the request.

Multiple values in a condition

A `Condition` element can contain multiple condition operators, and each condition operator can contain multiple context key-value pairs. The following figure illustrates this.

For more information, see Set operators for multivalued context keys.

IAM JSON policy elements: Condition operators

Use condition operators in the `Condition` element to match the condition key and value in the policy against values in the request context. For more information about the `Condition` element, see IAM JSON policy elements: Condition.

The condition operator that you can use in a policy depends on the condition key you choose. You can choose a global condition key or a service-specific condition key. To learn which condition operator you can use for a global condition key, see AWS global condition context keys. To learn which condition operator you can use for a service-specific condition key, see Actions, Resources, and Condition Keys for AWS Services and choose the service that you want to view.

> **Important**
>
> If the key that you specify in a policy condition is not present in the request context, the values do not match and the condition is *false*. If the policy condition requires that the key is *not* matched, such as `StringNotLike` or `ArnNotLike`, and the right key is not present, the condition is *true*. This logic applies to all condition operators except ...IfExists and Null check. These operators test whether the key is present (exists) in the request context.

The condition operators can be grouped into the following categories:

- String
- Numeric
- Date and time
- Boolean
- Binary
- IP address
- Amazon Resource Name (ARN) (available for only some services.)
- ...IfExists (checks if the key value exists as part of another check)
- Null check (checks if the key value exists as a standalone check)

String condition operators

String condition operators let you construct `Condition` elements that restrict access based on comparing a key to a string value.

- **Policy variables** – Supported
- **Wildcards** – Supported

Condition operator	Description
`StringEquals`	Exact matching, case sensitive
`StringNotEquals`	Negated matching
`StringEqualsIgnoreCase`	Exact matching, ignoring case
`StringNotEqualsIgnoreCase`	Negated matching, ignoring case
`StringLike`	Case-sensitive matching. The values can include multi-character match wildcards (*) and single-character match wildcards (?) anywhere in the string. You must specify wildcards to achieve partial string matches. **Note** If a key contains multiple values, `StringLike` can be qualified with set operators—`ForAllValues:StringLike` and `ForAnyValue:StringLike`. For more information, see Set operators for multivalued context keys.
`StringNotLike`	Negated case-sensitive matching. The values can include multi-character match wildcards (*) or single-character match wildcards (?) anywhere in the string.

Example string condition operator

For example, the following statement contains a `Condition` element that uses `aws:PrincipalTag` key to specify that the principal making the request must be tagged with the `iamuser-admin` job category.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iam:*AccessKey*",
        "Resource": "arn:aws:iam::111122223333:user/*",
        "Condition": {
            "StringEquals": {
                "aws:PrincipalTag/job-category": "iamuser-admin"
            }
        }
    }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. In this example, the `aws:PrincipalTag/job-category` key is present in the request context if the principal is using an IAM user with attached tags. It is also included for a principal using an IAM role with attached tags or session tags. If a user without the tag attempts to view or edit an access key, the condition returns `false` and the request is implicitly denied by this statement.

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy Condition	Request Context	Result
`"StringEquals": { "aws:PrincipalTag/ job-category": "iamuser-admin"`	`aws:PrincipalTag/job-category: - iamuser-admin`	Match

Policy Condition	Request Context	Result
`}`		
`"StringEquals": { "aws:PrincipalTag/job-category": "iamuser-admin" }`	`aws:PrincipalTag/job-category: - dev-ops`	No match
`"StringEquals": { "aws:PrincipalTag/job-category": "iamuser-admin" }`	No `aws:PrincipalTag/job-category` in the request context.	No match

Example using a policy variable with a string condition operator

The following example uses the `StringLike` condition operator to perform string matching with a policy variable to create a policy that lets an IAM user use the Amazon S3 console to manage his or her own "home directory" in an Amazon S3 bucket. The policy allows the specified actions on an S3 bucket as long as the `s3:prefix` matches any one of the specified patterns.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListAllMyBuckets",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket",
```

```
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
      "Condition": {
        "StringLike": {
          "s3:prefix": [
            "",
            "home/",
            "home/${aws:username}/"
          ]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/home/${aws:username}",
        "arn:aws:s3:::amzn-s3-demo-bucket/home/${aws:username}/*"
      ]
    }
  ]
}
```

The following table shows how AWS evaluates this policy for different users based on the aws:username value in the request context.

Policy condition	Request context	Result
`"StringLike": { "s3:prefix": [ "home/", "home/${aws:username}/" ] }`	`aws:username: - martha_rivera`	`"StringLike": { "s3:prefix": [ "home/", "home/martha_rivera /" ] }`
`"StringLike": { "s3:prefix": [ "home/", "home/${aws:username}/"`	`aws:username: - nikki_wolf`	`"StringLike": { "s3:prefix": [ "home/", "home/nikki_wolf /" ]`

Policy condition	Request context	Result
] }		}

"StringLike": {
"s3:prefix": [
"home/",
"home/${aws:username}/"
]
}
	No aws:username in the request context.	No match

For an example of a policy that shows how to use the Condition element to restrict access to resources based on an application ID and a user ID for OIDC federation, see Amazon S3: Allows Amazon Cognito users to access objects in their bucket.

Multivalued string condition operators

If a key in the request contains multiple values, string operators can be qualified with set operators ForAllValues and ForAnyValue. For more information on the evaluation logic of multiple context keys or values, see Set operators for multivalued context keys.

Condition operator	Description
ForAllValues:StringEquals ForAllValues:StringEqualsIgnoreCase	All of the values for the condition key in the request must match at least one of the values in your policy.
ForAnyValue:StringEquals ForAnyValue:StringEqualsIgnoreCase	At least one condition key value in the request must match one of the values in your policy.
ForAllValues:StringNotEquals ForAllValues:StringNotEqualsIgnoreCase	Negated matching.

Condition operator	Description
	None of the values of the context key in the request can match any of the context key values in your policy.

`ForAnyValue:StringNotEquals`
 	
`ForAnyValue:StringNotEquals IgnoreCase`
	Negated matching.
	
	At least one context key value in the request must NOT match any of values in the context key in your policy.

`ForAllValues:StringLike`	All of the values for the condition key in the request must match at least one of the values in your policy.
`ForAnyValue:StringLike`	At least one condition key value in the request must match one of the values in your policy.
`ForAllValues:StringNotLike`	Negated matching. None of the values of the context key in the request can match any of the context key values in your policy.
`ForAnyValue:StringNotLike`	Negated matching. At least one context key value in the request must NOT match any of values in the context key in your policy.

Example using `ForAnyValue` with a string condition operator

This example shows how you might create an identity-based policy that allows using the Amazon EC2 `CreateTags` action to attach tags to an instance. When you use `StringEqualsIgnoreCase`, you can attach tags only if the tag contains the `environment` key with the `preprod` or `storage` values. When you append `IgnoreCase` to the operator, you allow any existing tag value capitalization, such as `preprod`, `Preprod`, and `PreProd`, to resolve to true.

When you add the `ForAnyValue` modifier with the aws:TagKeys condition key, at least one tag key value in the request must match the value `environment`. `ForAnyValue` comparison is case sensitive, which stops users from using the incorrect case for the tag key, such as using `Environment` instead of `environment`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "ec2:CreateTags",
    "Resource": "arn:aws:ec2:*:*:instance/*",
    "Condition": {
      "StringEqualsIgnoreCase": {
        "aws:RequestTag/environment": [
          "preprod",
          "storage"
        ]
      },
      "ForAnyValue:StringEquals": {
        "aws:TagKeys": "environment"
      }
    }
  }
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"StringEqualsIgnoreCase": { "aws:RequestTag/environment": [ "preprod", "storage" ] },`	`aws:TagKeys: - environment aws:RequestTag/environment: - preprod`	Match

Policy condition	Request context	Result
`"ForAnyValue:StringEqu als": { "aws:TagKeys": "environment" }`		
`"StringEqualsIgnor eCase": { "aws:RequestTag/en vironment": [ "preprod", "storage" ] }, "ForAnyValue:StringEqu als": { "aws:TagKeys": "environment" }`	`aws:TagKeys: - environment - costcenter aws:RequestTag/e nvironment: - PreProd`	Match
`"StringEqualsIgnor eCase": { "aws:RequestTag/en vironment": [ "preprod", "storage" ] }, "ForAnyValue:StringEqu als": { "aws:TagKeys": "environment" }`	`aws:TagKeys: - Environment aws:RequestTag/ Environment: - preprod`	No match

Policy condition	Request context	Result
`"StringEqualsIgnoreCase": { "aws:RequestTag/environment": [ "preprod", "storage" ] }, "ForAnyValue:StringEquals": { "aws:TagKeys": "environment" }`	`aws:TagKeys: - costcenter aws:RequestTag/environment: - preprod`	No match
`"StringEqualsIgnoreCase": { "aws:RequestTag/environment": [ "preprod", "storage" ] }, "ForAnyValue:StringEquals": { "aws:TagKeys": "environment" }`	No `aws:TagKeys` in the request context. `aws:RequestTag/environment: - storage`	No match

Policy condition	Request context	Result
`"StringEqualsIgnoreCase": { "aws:RequestTag/environment": [ "preprod", "storage" ] }, "ForAnyValue:StringEquals": { "aws:TagKeys": "environment" }`	`aws:TagKeys: - environment` No `aws:RequestTag/environment` in the request context.	No match
`"StringEqualsIgnoreCase": { "aws:RequestTag/environment": [ "preprod", "storage" ] }, "ForAnyValue:StringEquals": { "aws:TagKeys": "environment" }`	No `aws:TagKeys` in the request context. No `aws:RequestTag/environment` in the request context.	No match

Wildcard matching

String condition operators perform a patternless matching that does not enforce a predefined format. ARN and Date condition operators are a subset of string operators that enforce a structure on the condition key value.

We recommend you use condition operators that correspond to the values you're comparing keys to. For example, you should use the section called “String condition operators” when comparing

keys to string values. Similarly, you should use the section called "Amazon Resource Name (ARN) condition operators" when comparing keys to ARN values.

Example

This example shows how you might create a boundary around resources in your organization. The condition in this policy denies access to Amazon S3 actions unless the resource being accessed is in a specific set of organizational units (OUs) in AWS Organizations. An AWS Organizations path is a text representation of the structure of an organization's entity.

The condition requires that `aws:ResourceOrgPaths` contains any of the listed OU paths. Because `aws:ResourceOrgPaths` is a multi-value condition, the policy uses the `ForAllValues:StringNotLike` operator to compare the values of `aws:ResourceOrgPaths` to the list of OUs in the policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyS3AccessOutsideMyBoundary",
      "Effect": "Deny",
      "Action": [
        "s3:*"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringNotLike": {
          "aws:ResourceOrgPaths": [
            "o-acorg/r-acroot/ou-acroot-mediaou/",
            "o-acorg/r-acroot/ou-acroot-sportsou/*"
          ]
        }
      }
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"ForAllValues:StringNotLike": { "aws:ResourceOrgPaths": [ "o-acorg/r-acroot/ou-acroot-mediaou/", "o-acorg/r-acroot/ou-acroot-sportsou/*" ] }`	`aws:ResourceOrgPaths: - o-acorg/r-acroot/ou-acroot-sportsou/costcenter/`	Match
`"ForAllValues:StringNotLike": { "aws:ResourceOrgPaths": [ "o-acorg/r-acroot/ou-acroot-mediaou/", "o-acorg/r-acroot/ou-acroot-sportsou/*" ] }`	`aws:ResourceOrgPaths: - o-acorg/r-acroot/ou-acroot-mediaou/costcenter/`	No match
`"ForAllValues:StringNotLike": { "aws:ResourceOrgPaths": [ "o-acorg/r-acroot/ou-acroot-mediaou/", "o-acorg/r-acroot/ou-acroot-sportsou/*" ] }`	No `aws:ResourceOrgPaths:` in the request.	No match

Numeric condition operators

Numeric condition operators let you construct `Condition` elements that restrict access based on comparing a key to an integer or decimal value.

- **Policy variables** – Not supported
- **Wildcards** – Not supported

Condition operator	Description
`NumericEquals`	Matching
`NumericNotEquals`	Negated matching
`NumericLessThan`	"Less than" matching
`NumericLessThanEquals`	"Less than or equals" matching
`NumericGreaterThan`	"Greater than" matching
`NumericGreaterThanEquals`	"Greater than or equals" matching

For example, the following statement contains a `Condition` element that uses the `NumericLessThanEquals` condition operator with the `s3:max-keys` key to specify that the requester can list *up to* 10 objects in `amzn-s3-demo-bucket` at a time.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
    "Condition": {"NumericLessThanEquals": {"s3:max-keys": "10"}}
  }
```

```
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. In this example, the `s3:max-keys` key is always present in the request when you perform the `ListBucket` operation. If this policy allowed all Amazon S3 operations, then only the operations that include the `max-keys` context key with a value of less than or equal to 10 would be allowed.

Date condition operators

Date condition operators let you construct `Condition` elements that restrict access based on comparing a key to a date/time value. You use these condition operators with `aws:CurrentTime` key or `aws:EpochTime` key. You must specify date/time values with one of the W3C implementations of the ISO 8601 date formats or in epoch (UNIX) time.

- **Policy variables** – Not supported
- **Wildcards** – Not supported

Condition operator	Description
`DateEquals`	Matching a specific date
`DateNotEquals`	Negated matching
`DateLessThan`	Matching before a specific date and time
`DateLessThanEquals`	Matching at or before a specific date and time
`DateGreaterThan`	Matching after a specific a date and time
`DateGreaterThanEqu als`	Matching at or after a specific date and time

For example, the following statement contains a `Condition` element that uses the `DateGreaterThan` condition operator with the `aws:TokenIssueTime` key. This condition specifies that the temporary security credentials used to make the request were issued in 2020.

This policy can be updated programmatically every day to ensure that account members use fresh credentials.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iam:*AccessKey*",
        "Resource": "arn:aws:iam::111122223333:user/*",
        "Condition": {
            "DateGreaterThan": {
                "aws:TokenIssueTime": "2020-01-01T00:00:01Z"
            }
        }
    }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. The `aws:TokenIssueTime` key is present in the request context only when the principal uses temporary credentials to make the request. The key is not present in AWS CLI, AWS API, or AWS SDK requests that are made using access keys. In this example, if an IAM user attempts to view or edit an access key, the request is denied.

Boolean condition operators

Boolean conditions let you construct `Condition` elements that restrict access based on comparing a key to `true` or `false`.

If a key contains multiple values, boolean operators can be qualified with set operators `ForAllValues` and `ForAnyValue`. For more information on the evaluation logic of multiple context keys or values, see Set operators for multivalued context keys.

- **Policy variables** – Supported
- **Wildcards** – Not supported

Condition operator	Description
`Bool`	Boolean matching
`ForAllValues:Bool`	Use with the Array of Bool data type. All of the booleans in the context key values must match the boolean values in your policy. To prevent `ForAllValues` operators from evaluating missing context keys or context keys with empty values as Allowed, you can include the Null condition operator in your policy.
`ForAnyValue:Bool`	Use with the Array of Bool data type. At least one of the booleans in the context key values must match the boolean values in your policy.

Example boolean condition operator

The following identity-based policy uses the `Bool` condition operator with the `aws:SecureTransport` key to deny replicating objects and object tags to the destination bucket and its contents if the request is not over SSL.

> **Important**
>
> This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "BooleanExample",
      "Action": "s3:ReplicateObject",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
```

```
      ],
      "Condition": {
        "Bool": {
          "aws:SecureTransport": "false"
        }
      }
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"Bool": { "aws:SecureTranspo rt": "false" }`	`aws:SecureTransport: - false`	Match
`"Bool": { "aws:SecureTranspo rt": "false" }`	`aws:SecureTransport: - true`	No match
`"Bool": { "aws:SecureTranspo rt": "false" }`	No `aws:SecureTranspor t` in the request context.	No match

Binary condition operators

The `BinaryEquals` condition operator lets you construct `Condition` elements that test key values that are in binary format. It compares the value of the specified key byte for byte against a base-64 encoded representation of the binary value in the policy. If the key that you specify in a policy condition is not present in the request context, the values do not match.

- **Policy variables** – Not supported
- **Wildcards** – Not supported

```
"Condition" : {
  "BinaryEquals": {
    "key" : "QmluYXJ5VmFsdWVJbkJhc2U2NA=="
  }
}
```

Policy condition	Request context	Result
`"BinaryEquals": { "key" : "QmluYXJ5VmFsdWVJbkJhc2U2NA==" }`	`key: - QmluYXJ5VmFsdWVJbkJhc2U2NA==`	Match
`"BinaryEquals": { "key" : "QmluYXJ5VmFsdWVJbkJhc2U2NA==" }`	`key: - ASIAIOSFODNN7EXAMPLE`	No match
`"BinaryEquals": { "key" : "QmluYXJ5VmFsdWVJbkJhc2U2NA==" }`	No `key` in the request context.	No match

IP address condition operators

IP address condition operators let you construct `Condition` elements that restrict access based on comparing a key to an IPv4 or IPv6 address or range of IP addresses. You use these with the `aws:SourceIp` key. The value must be in the standard CIDR format (for example, 203.0.113.0/24 or 2001:DB8:1234:5678::/64). If you specify an IP address without the associated routing prefix, IAM uses the default prefix value of `/32`.

Some AWS services support IPv6, using :: to represent a range of 0s. To learn whether a service supports IPv6, see the documentation for that service.

- **Policy variables** – Not supported
- **Wildcards** – Not supported

Condition operator	Description
`IpAddress`	The specified IP address or range
`NotIpAddress`	All IP addresses except the specified IP address or range

Example IP address condition operator

The following statement uses the `IpAddress` condition operator with the `aws:SourceIp` key to specify that the request must come from the IP range 203.0.113.0 to 203.0.113.255.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iam:*AccessKey*",
        "Resource": "arn:aws:iam::111122223333:user/*",
        "Condition": {
            "IpAddress": {
                "aws:SourceIp": "203.0.113.0/24"
            }
        }
    }
}
```

The `aws:SourceIp` condition key resolves to the IP address that the request originates from. If the requests originates from an Amazon EC2 instance, `aws:SourceIp` evaluates to the instance's public IP address.

If the key that you specify in a policy condition is not present in the request context, the values do not match. The `aws:SourceIp` key is always present in the request context, except when the

requester uses a VPC endpoint to make the request. In this case, the condition returns `false` and the request is implicitly denied by this statement.

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"IpAddress": { "aws:SourceIp": "203.0.113.0/24" }`	`aws:SourceIp: - 203.0.113.1`	Match
`"IpAddress": { "aws:SourceIp": "203.0.113.0/24" }`	`aws:SourceIp: - 198.51.100.1`	No match

The following example shows how to mix IPv4 and IPv6 addresses to cover all of your organization's valid IP addresses. We recommend that you update your organization's policies with your IPv6 address ranges in addition to IPv4 ranges you already have to ensure the policies continue to work as you make the transition to IPv6.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "someservice:*",
    "Resource": "*",
    "Condition": {
      "IpAddress": {
        "aws:SourceIp": [
          "203.0.113.0/24",
          "2001:DB8:1234:5678::/64"
        ]
      }
```

```
    }
  }
}
```

The `aws:SourceIp` condition key works only in a JSON policy if you are calling the tested API directly as a user. If you instead use a service to call the target service on your behalf, the target service sees the IP address of the calling service rather than the IP address of the originating user. This can happen, for example, if you use AWS CloudFormation to call Amazon EC2 to construct instances for you. There is currently no way to pass the originating IP address through a calling service to the target service for evaluation in a JSON policy. For these types of service API calls, do not use the `aws:SourceIp` condition key.

Amazon Resource Name (ARN) condition operators

Amazon Resource Name (ARN) condition operators let you construct `Condition` elements that restrict access based on comparing a key to an ARN. The ARN is considered a string.

- **Policy variables** – Supported
- **Wildcards** – Supported

Condition operator	Description
`ArnEquals` , `ArnLike`	Case-sensitive matching of the ARN. Each of the six colon-delimited components of the ARN is checked separately and each can include multi-character match wildcards (*) or single-character match wildcards (?). The `ArnEquals` and `ArnLike` condition operators behave identically.
`ArnNotEquals` , `ArnNotLike`	Negated matching for ARN. The `ArnNotEquals` and `ArnNotLike` condition operators behave identically.

Example ARN condition operator

The following resource-based policy example shows a policy attached to an Amazon SQS queue to which you want to send SNS messages. It gives Amazon SNS permission to send messages to the queue (or queues) of your choice, but only if the service is sending the messages on behalf of

a particular Amazon SNS topic (or topics). You specify the queue in the `Resource` field, and the Amazon SNS topic as the value for the `SourceArn` key.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {
            "Service": "sns.amazonaws.com"
        },
        "Action": "SQS:SendMessage",
        "Resource": "arn:aws:sqs:us-east-1:123456789012:QUEUE-ID",
        "Condition": {
            "ArnEquals": {
                "aws:SourceArn": "arn:aws:sns:us-east-1:123456789012:TOPIC-ID"
            }
        }
    }
}
```

The `aws:SourceArn` key is present in the request context only if a resource triggers a service to call another service on behalf of the resource owner. If an IAM user attempts to perform this operation directly, the condition returns `false` and the request is implicitly denied by this statement.

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"ArnEquals": { "aws:SourceArn": "arn:aws:sns:us-west-2:123456789012:TOPIC-ID" }`	`aws:SourceArn: - arn:aws:sns:us-west-2:123456789012:TOPIC-ID`	Match

Policy condition	Request context	Result
`"ArnEquals": { "aws:SourceArn": "arn:aws:sns:us-west-2:123456789012:TOPIC-ID" }`	`aws:SourceArn: - arn:aws:sns:us-west-2:777788889999:TOPIC-ID`	No match
`"ArnEquals": { "aws:SourceArn": "arn:aws:sns:us-west-2:123456789012:TOPIC-ID" }`	No `aws:SourceArn` in the request context.	No match

Multivalued ARN condition operators

If a key in the request contains multiple values, ARN operators can be qualified with set operators `ForAllValues` and `ForAnyValue`. For more information on the evaluation logic of multiple context keys or values, see Set operators for multivalued context keys.

Condition operator	Description
`ForAllValues:ArnEquals` `ForAllValues:ArnLike`	All of the ARNs in the request context must match at least one of the ARN patterns in your policy.
`ForAnyValue:ArnEquals` `ForAnyValue:ArnLike`	At least one ARN in the request context must match one of the ARN patterns in your policy.
`ForAllValues:ArnNotEquals` `ForAllValues:ArnNotLike`	Negated matching. None of the ARNs in the request context can match any string ARN patterns in your policy.
`ForAnyValue:ArnNotEquals`	Negated matching.

Condition operator	Description
`ForAnyValue:ArnNotLike`	At least one ARN in the request context must NOT match any of ARN patterns in your policy.

Example using `ForAllValues` with an ARN condition operator

The following example uses `ForAllValues:ArnLike` to create or update a logical delivery source for Amazon CloudWatch Logs logs. The condition block includes the condition key `logs:LogGeneratingResourceArns` to filter the log generating resource ARNs passed in the request. Using this condition operator, all of the ARNs in the request must match at least one ARN in the policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "logs:PutDeliverySource",
            "Resource": "arn:aws:logs:us-east-1:123456789012:delivery-source:*",
            "Condition": {
                "ForAllValues:ArnLike": {
                    "logs:LogGeneratingResourceArns": [
                        "arn:aws:cloudfront::123456789012:distribution/*",
                        "arn:aws:cloudfront::123456789012:distribution/support*"
                    ]
                }
            }
        }
    ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"ForAllValues:ArnLike": { "logs:LogGeneratingResourceArns": [ "arn:aws::cloudfront:123456789012:distribution/*", "arn:aws::cloudfront:123456789012:distribution/support*" ] }`	`logs:LogGeneratingResourceArns: - arn:aws::cloudfront:123456789012:distribution/costcenter`	Match
`"ForAllValues:ArnLike": { "logs:LogGeneratingResourceArns": [ "arn:aws::cloudfront:123456789012:distribution/*", "arn:aws::cloudfront:123456789012:distribution/support*" ] }`	`logs:LogGeneratingResourceArns: - arn:aws::cloudfront:123456789012:distribution/costcenter - arn:aws::cloudfront:123456789012:distribution/support2025`	Match
`"ForAllValues:ArnLike": { "logs:LogGeneratingResourceArns": [ "arn:aws::cloudfront:123456789012:distribution/*", "arn:aws::cloudfront:123456789012:distribution/support*" ] }`	`logs:LogGeneratingResourceArns: - arn:aws::cloudfront:123456789012:distribution/costcenter - arn:aws::cloudfront:123456789012:distribution/admin`	No match

Policy condition	Request context	Result
`"ForAllValues:ArnLike": { "logs:LogGeneratingResourceArns": [ "arn:aws::cloudfront:123456789012:distribution/*", "arn:aws::cloudfront:123456789012:distribution/support*" ] }`	`logs:LogGeneratingResourceArns: - arn:aws::cloudfront:777788889999:distribution/costcenter`	No match
`"ForAllValues:ArnLike": { "logs:LogGeneratingResourceArns": [ "arn:aws::cloudfront:123456789012:distribution/*", "arn:aws::cloudfront:123456789012:distribution/support*" ] }`	No `logs:LogGeneratingResourceArns` in the request context.	Match

The `ForAllValues` qualifier returns true if there are no context keys in the request or if the context key value resolves to a null dataset, such as an empty string. To prevent missing context keys or context keys with empty values from evaluating to true, you can include the Null condition operator in your policy with a `false` value to check if the context key exists and its value is not null.

...IfExists condition operators

You can add `IfExists` to the end of any condition operator name except the `Null` condition —for example, `StringLikeIfExists`. You do this to say "If the condition key is present in the context of the request, process the key as specified in the policy. If the key is not

present, evaluate the condition element as true." Other condition elements in the statement can still result in a nonmatch, but not a missing key when checked with `...IfExists`. If you are using an `"Effect": "Deny"` element with a negated condition operator like `StringNotEqualsIfExists`, the request is still denied even if the condition key is not present.

Example using `IfExists`

Many condition keys describe information about a certain type of resource and only exist when accessing that type of resource. These condition keys are not present on other types of resources. This doesn't cause an issue when the policy statement applies to only one type of resource. However, there are cases where a single statement can apply to multiple types of resources, such as when the policy statement references actions from multiple services or when a given action within a service accesses several different resource types within the same service. In such cases, including a condition key that applies to only one of the resources in the policy statement can cause the `Condition` element in the policy statement to fail such that the statement's `"Effect"` does not apply.

For example, consider the following policy example:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "THISPOLICYDOESNOTWORK",
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": "*",
    "Condition": {"StringLike": {"ec2:InstanceType": [
      "t1.*",
      "t2.*",
      "m3.*"
    ]}}
  }
}
```

The *intent* of the preceding policy is to enable the user to launch any instance that is type `t1`, `t2` or `m3`. However, launching an instance requires accessing many resources in addition to the instance itself; for example, images, key pairs, security groups, and more. The entire statement is evaluated

against every resource that is required to launch the instance. These additional resources do not have the `ec2:InstanceType` condition key, so the `StringLike` check fails, and the user is not granted the ability to launch *any* instance type.

To address this, use the `StringLikeIfExists` condition operator instead. This way, the test only happens if the condition key exists. You could read the following policy as: "If the resource being checked has an "`ec2:InstanceType`" condition key, then allow the action only if the key value begins with `t1.`, `t2.`, or `m3.`. If the resource being checked does not have that condition key, then don't worry about it." The asterisk (*) in the condition key values, when used with the `StringLikeIfExists` condition operator, is interpreted as a wildcard to achieve partial string matches. The `DescribeActions` statement includes the actions required to view the instance in the console.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RunInstance",
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
        "StringLikeIfExists": {
          "ec2:InstanceType": [
            "t1.*",
            "t2.*",
            "m3.*"
          ]
        }
      }
    },
    {
      "Sid": "DescribeActions",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeImages",
        "ec2:DescribeInstances",
        "ec2:DescribeVpcs",
        "ec2:DescribeKeyPairs",
```

```
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
      ],
      "Resource": "*"
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"StringLikeIfExists": { "ec2:InstanceType": [ "t1.*", "t2.*", "m3.*" ] }`	`ec2:InstanceType: - t1.micro`	Match
`"StringLikeIfExists": { "ec2:InstanceType": [ "t1.*", "t2.*", "m3.*" ] }`	`ec2:InstanceType: - m2.micro`	No match
`"StringLikeIfExists": { "ec2:InstanceType": [ "t1.*", "t2.*",`	No `ec2:InstanceType` in the request context.	Match

Policy condition	Request context	Result

`"m3.*"`
`]`
`}`		

Condition operator to check existence of condition keys

Use a `Null` condition operator to check if a condition key is absent at the time of authorization. In the policy statement, use either `true` (the key doesn't exist — it is null) or `false` (the key exists and its value is not null).

You can not use a policy variable with the `Null` condition operator.

For example, you can use this condition operator to determine whether a user is using temporary credentials or their own credentials to make a request. If the user is using temporary credentials, then the key `aws:TokenIssueTime` exists and has a value. The following example shows a condition that states that the user must be using temporary credentials (the key cannot be absent) for the user to use the Amazon EC2 API.

JSON

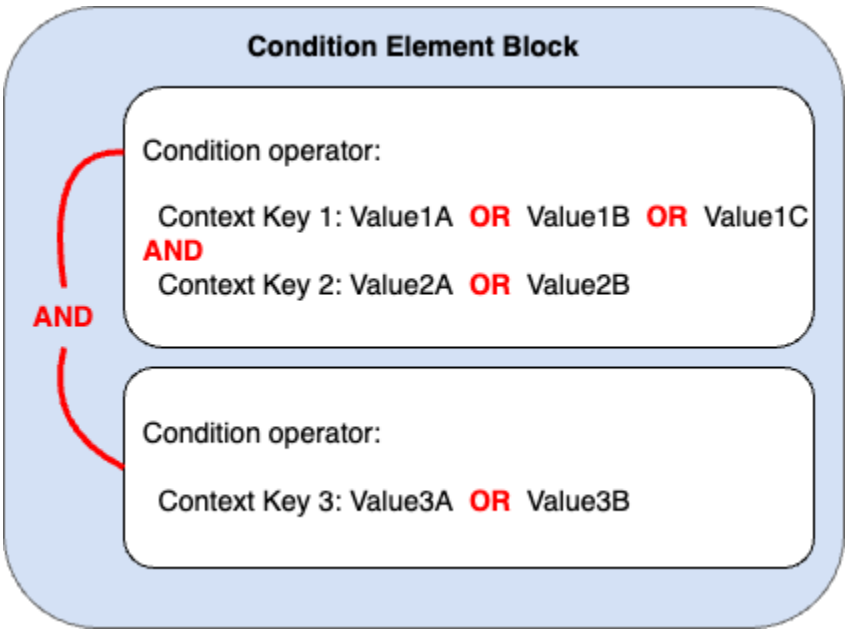
```
{
  "Version": "2012-10-17",
  "Statement":{
      "Action":"ec2:*",
      "Effect":"Allow",
      "Resource":"*",
      "Condition":{"Null":{"aws:TokenIssueTime":"false"}}
  }
}
```

Conditions with multiple context keys or values

You can use the `Condition` element of a policy to test multiple context keys or multiple values for a single context key in a request. When you make a request to AWS, either programmatically or through the AWS Management Console, your request includes information about your principal, operation, tags, and more. You can use context keys to test the values of the matching context keys

in the request, with the context keys specified in the policy condition. To learn about information and data included in a request, see The request context.

Topics



- Evaluation logic for multiple context keys or values
- Evaluation logic for negated matching condition operators

Evaluation logic for multiple context keys or values

A `Condition` element can contain multiple condition operators, and each condition operator can contain multiple context key-value pairs. Most context keys support using multiple values, unless otherwise specified.

- If your policy statement has multiple condition operators, the condition operators are evaluated using a logical `AND`.
- If your policy statement has multiple context keys attached to a single condition operator, the context keys are evaluated using a logical `AND`.
- If a single condition operator includes multiple values for a context key, those values are evaluated using a logical `OR`.
- If a single negated matching condition operator includes multiple values for a context key, those values are evaluated using a logical `NOR`.

All context keys in a condition element block must resolve to true to invoke the desired `Allow` or `Deny` effect. The following figure illustrates the evaluation logic for a condition with multiple condition operators and context key-value pairs.

For example, the following S3 bucket policy illustrates how the previous figure is represented in a policy. The condition block includes condition operators `StringEquals` and `ArnLike`, and context keys `aws:PrincipalTag` and `aws:PrincipalArn`. To invoke the desired `Allow` or `Deny` effect, all context keys in the condition block must resolve to true. The user making the request must have both principal tag keys, *department* and *role*, that include one of the tag key values specified in the policy. Also, the principal ARN of the user making the request must match one of the `aws:PrincipalArn` values specified in the policy to be evaluated as true.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExamplePolicy",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::222222222222:root"
      },
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalTag/department": [
            "finance",
```

```
            "hr",
            "legal"
          ],
          "aws:PrincipalTag/role": [
            "audit",
            "security"
          ]
        },
        "ArnLike": {
          "aws:PrincipalArn": [
            "arn:aws:iam::222222222222:user/Ana",
            "arn:aws:iam::222222222222:user/Mary"
          ]
        }
      }
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy Condition	Request Context	Result
`"StringEquals": { "aws:PrincipalTag/department": [ "finance", "hr", "legal" ], "aws:PrincipalTag/role": [ "audit", "security" ] }, "ArnLike": { "aws:PrincipalArn": [`	`aws:PrincipalTag/department: legal aws:PrincipalTag/role: audit aws:PrincipalArn: arn:aws:iam::222222222222:user/Mary`	**Match**

Evaluation logic for negated matching condition operators

Some condition operators, such as `StringNotEquals` or `ArnNotLike`, use negated matching to compare the context key-value pairs in your policy against the context key-value pairs in a request. When multiple values are specified for a single context key in a policy with negated matching condition operators, the effective permissions work like a logical `NOR`. In negated matching, a logical `NOR` or `NOT OR` returns true only if all values evaluate to false.

The following figure illustrates the evaluation logic for a condition with multiple condition operators and context key-value pairs. The figure includes a negated matching condition operator for context key 3.

For example, the following S3 bucket policy illustrates how the previous figure is represented in a policy. The condition block includes condition operators `StringEquals` and `ArnNotLike`, and context keys `aws:PrincipalTag` and `aws:PrincipalArn`. To invoke the desired `Allow` or `Deny` effect, all context keys in the condition block must resolve to true. The user making the request must have both principal tag keys, *department* and *role*, that include one of the tag key values specified in the policy. Since the `ArnNotLike` condition operator uses negated matching, the principal ARN of the user making the request must not match any of the `aws:PrincipalArn` values specified in the policy to be evaluated as true.

Single-valued vs. multivalued context keys

The difference between single-valued and multivalued context keys lies in the number of values in the request context, not the number of values in the policy condition.

- *Single-valued* condition context keys have at most one value in the request context. For example, when you tag resources in AWS, each resource tag is stored as a key-value pair. Since a resource tag key can have only a single tag value, the section called “ResourceTag” is a single-valued context key. Do not use a condition set operator with a single-valued context key.
- *Multivalued* condition context keys can have multiple values in the request context. For example, when you tag resources in AWS, you can include multiple tag key-value pairs in a single request.

Therefore, the section called "TagKeys" is a multivalued context key. Multivalued context keys require a condition set operator.

For example, a request can originate from at most one VPC endpoint, so the section called "SourceVpce" is a single-valued context key. Since a service can have more than one service principal name that belongs to the service, the section called "PrincipalServiceNamesList" is a multivalued context key.

> **Important**
>
> The difference between single-valued and multivalued context keys depends on the number of values in the request context, not the number of values in the policy condition.

Key points

- The *Single-valued* and *Multivalued* classifications are included in the description of each condition context key as *Value type* in the AWS global condition context keys topic.
- Multivalued context keys in the Service Authorization Reference use an `ArrayOf` prefix followed by the condition operator category type, such as `ArrayOfString` or `ArrayOfARN`, indicating that the request may include multiple values for a condition context key.
- You can use any available single-valued context key as a policy variable, but you cannot use a multivalued context key as a policy variable. For more information about policy variables, see IAM policy elements: Variables and tags.
- When using context keys that include key-value pairs, it's important to note that even though there can be multiple tag-key values, each `tag-key` can have only one value.
  - the section called "PrincipalTag", the section called "RequestTag" and the section called "ResourceTag" are single-valued context keys.
  - the section called "TagKeys" defines what tag-keys are allowed in a request but does not include the tag-key values. Because you can include multiple tag key-value pairs in a request, `aws:TagKeys` is a multivalued context key.
- Multivalued context keys require a condition set operator. Do not use condition set operators `ForAllValues` or `ForAnyValue` with single-valued context keys. Using condition set operators with single-valued context keys can lead to overly permissive policies.

Set operators for multivalued context keys

To compare your condition context key against a request context key with multiple values, you must use the `ForAllValues` or `ForAnyValue` set operators. These set operators are used to compare two sets of values, such as the set of tags in a request and the set of tags in a policy condition.

The `ForAllValues` and `ForAnyValue` qualifiers add set-operation functionality to the condition operator, allowing you to test request context keys with multiple values against multiple context key values in a policy condition. Additionally, if you include a multivalued string context key in your policy with a wildcard or a variable, you must also use the `StringLike` condition operator. Multiple condition key values must be enclosed in brackets like an array, for example, `"Key2": ["Value2A", "Value2B"]`.

ForAllValues

The `ForAllValues` qualifier tests whether the value of every member of the request context matches the condition operator that follows the qualifier. The condition returns `true` if every context key value in the request matches a context key value in the policy. It also returns `true` if there are no context keys in the request.

> **Important**
>
> Use caution if you use `ForAllValues` with an `Allow` effect, as it can be overly permissive if the presence of missing context keys in the request context is unexpected. You should always include the `Null` condition operator in your policy with a `false` value to check if the context key exists and its value is not null. For an example, see Controlling access based on tag keys.

Example ForAllValues set operator

In the following example, ForAllValues is used with aws:TagKeys to allow users to delete specific tags assigned to an EC2 instance. This policy allows users to delete only the `environment` and `cost-center` tags. You can delete them separately or together. The tag-keys in the request must match exactly the specified keys in the policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:DeleteTags",
            "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": [
                        "environment",
                        "cost-center"
                    ]
                },
                "Null": {
                    "aws:TagKeys": "false"
                }
            }
        }
    ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy Condition	Request Context	Result
`"ForAllValues:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }, "Null": { "aws:TagKeys": "false"`	`aws:TagKeys: - environment`	**Match**

Policy Condition	Request Context	Result
`}`		
`"ForAllValues:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }, "Null": { "aws:TagKeys": "false" }`	`aws:TagKeys: - cost-center`	**Match**
`"ForAllValues:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }, "Null": { "aws:TagKeys": "false" }`	`aws:TagKeys: - environment - cost-center`	**Match**
`"ForAllValues:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }, "Null": { "aws:TagKeys": "false" }`	`aws:TagKeys: - environment - dept`	**No match**

Policy Condition	Request Context	Result
`"ForAllValues:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }, "Null": { "aws:TagKeys": "false" }`	No `aws:TagKeys` in the request context.	**No match**

Note that in the last example, the result is "No Match" because the Null condition check prevents matching when the context key is missing. This is a best practice to avoid overly permissive policies.

ForAnyValue

The `ForAnyValue` qualifier tests whether at least one member of the set of request context key values matches at least one member of the set of context key values in your policy condition. The condition returns `true` if any one of the context key values in the request matches any one of the context key values in the policy. For no matching context key or if the key does not exist, the condition returns `false`.

> **Important**
>
> When using `ForAnyValue` with a `Deny` effect, if the context key is not present in the request, the policy evaluates as **No match**. For consistent behavior, add an explicit `Null` condition check in your policy to verify whether the context key exists. For details, see Condition operator to check existence of condition keys .

Example ForAnyValue set operator

In the following example, ForAnyValue is used with aws:TagKeys to allow users to delete specific tags assigned to an EC2 instance. This policy allows users to delete tags for an instance if the tag keys specified in the request include `environment` or `cost-center`. The request can include

additional tag keys beyond those specified in the policy, but must include at least one of the specified keys to match the condition.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:DeleteTags",
            "Resource": "arn:aws:ec2:us-east-1:111122223333:instance/*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:TagKeys": [
                        "environment",
                        "cost-center"
                    ]
                }
            }
        }
    ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy Condition	Request Context	Result
`"ForAnyValue:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }`	`aws:TagKeys: - environment`	**Match**
`"ForAnyValue:StringEquals": {`	`aws:TagKeys:`	**Match**

Policy Condition	Request Context	Result
`"aws:TagKeys": [ "environment", "cost-center" ] }`	`- cost-center`	
`"ForAnyValue:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }`	`aws:TagKeys: - environment - cost-center`	**Match**
`"ForAnyValue:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }`	`aws:TagKeys: - environment - dept`	**Match**
`"ForAnyValue:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }`	`aws:TagKeys: - dept`	**No match**
`"ForAnyValue:StringEquals": { "aws:TagKeys": [ "environment", "cost-center" ] }`	No `aws:TagKeys` in the request context.	**No match**

Condition policy examples

In IAM policies, you can specify multiple values for both single-valued and multivalued context keys for comparison against the request context. The following set of policy examples demonstrates policy conditions with multiple context keys and values.

> **Note**
>
> If you would like to submit a policy to be included in this reference guide, use the **Feedback** button at the bottom of this page. For IAM identity-based policy examples, see Example IAM identity-based policies.

Condition policy examples: Single-valued context keys

- Multiple condition blocks with single-valued context keys. (View this example.)
- One condition block with multiple single-valued context keys and values. (View this example.)

Condition policy examples: Multivalued context keys

- Deny policy with condition set operator `ForAllValues`. (View this example.)
- Deny policy with condition set operator `ForAnyValue`. (View this example.)

Multivalued context key examples

The following set of policy examples demonstrate how to create policy conditions with multivalued context keys.

Example: Deny policy with condition set operator ForAllValues

The following examples show how to use an identity-based policy to deny the use of IAM tagging actions when specific tag key prefixes are included in the request. The values for `aws:TagKeys` include a wildcard (*) for partial string matching. The policy includes the `ForAllValues` set operator with context key `aws:TagKeys` because the request context key can include multiple values. In order for context key `aws:TagKeys` to match, every value in the request context must match at least one value in the policy.

The `ForAllValues` set operator also returns true if there are no context keys in the request.

You can prevent missing context keys or context keys with empty values from evaluating to true by including a `Null` condition operator in your policy with a value of `false` to check if the context key in the request exists and its value is not null. For more information, see Condition operator to check existence of condition keys .

> **Important**
>
> This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

Example Deny a single policy condition value for a multivalued context key

In the following example, the policy denies requests where the values for `aws:TagKeys` in the request do not include the prefix **key1**. The request context can have multiple values, but because of the `ForAllValues` condition set operator, all the tag key values in the request context must start with the prefix **key1**.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyRestrictedTags",
      "Effect": "Deny",
      "Action": [
        "iam:Tag*",
        "iam:UnTag*"
      ],
      "Resource": [
        "*"
      ],
      "Condition": {
        "ForAllValues:StringNotLike": {
          "aws:TagKeys": "key1*"
        }
      }
    }
  ]
```

```
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request. For a Deny statement, Match is Denied and No match is Not denied, so it may be allowed by another statement.

Policy Condition	Request Context	Result
`"ForAllValues:StringNotLike": { "aws:TagKeys": "key1*" }`	`aws:TagKeys: - key1:legal`	**No match** May be allowed by another statement.
`"ForAllValues:StringNotLike": { "aws:TagKeys": "key1*" }`	`aws:TagKeys: - key1:hr - key1:personnel`	**No match** May be allowed by another statement.
`"ForAllValues:StringNotLike": { "aws:TagKeys": "key1*" }`	`aws:TagKeys: - key2:audit`	**Match**
`"ForAllValues:StringNotLike": { "aws:TagKeys": "key1*" }`	No `aws:TagKeys` in the request context.	**Match**

Example Deny multiple policy condition values for a multivalued context key

In the following example, the policy denies requests where the values for `aws:TagKeys` in the request do not include the prefix **key1** or **key2**. The request context can have multiple values, but

because of the `ForAllValues` condition set operator, all the tag key values in the request context must start with the prefix **key1** or **key2**.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyRestrictedTags",
      "Effect": "Deny",
      "Action": [
        "iam:Tag*",
        "iam:UnTag*"
      ],
      "Resource": [
        "*"
      ],
      "Condition": {
        "ForAllValues:StringNotLike": {
          "aws:TagKeys": [
            "key1*",
            "key2*"
          ]
        }
      }
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request. For a Deny statement, Match is Denied and No match is Not denied, so it may be allowed by another statement.

Policy Condition	Request Context	Result
`"ForAllValues:StringNotLike": { "aws:TagKeys": [ "key1*",`	`aws:TagKeys: - key1:legal`	**No match** May be allowed by another statement.

Policy Condition	Request Context	Result

`"key2*"`
`]`
`}`		

`"ForAllValues:StringNotLike": {`
`"aws:TagKeys": [`
`"key1*",`
`"key2*"`
`]`
`}`
	`aws:TagKeys:`
	`- key1:hr`
	`- key1:personnel`
		No match
		May be allowed by another statement.

`"ForAllValues:StringNotLike": {`
`"aws:TagKeys": [`
`"key1*",`
`"key2*"`
`]`
`}`
	`aws:TagKeys:`
	`- key1:hr`
	`- key2:audit`
		No match
		May be allowed by another statement.

`"ForAllValues:StringNotLike": {`
`"aws:TagKeys": [`
`"key1*",`
`"key2*"`
`]`
`}`
	`aws:TagKeys:`
	`- key3:legal`
		Match

`"ForAllValues:StringNotLike": {`
`"aws:TagKeys": [`
`"key1*",`
`"key2*"`
`]`
`}`
	No `aws:TagKeys` in the request context.	**Match**

Example: Deny policy with condition set operator ForAnyValue

The following identity-based policy example denies creating snapshots of EC2 instance volumes if any snapshots are tagged with one of the tag keys specified in the policy, `environment` or `webserver`. The policy includes the `ForAnyValue` set operator with context key `aws:TagKeys` because the request context key can include multiple values. If your tagging request includes any one of the tag key values specified in the policy, the `aws:TagKeys` context key returns true invoking the deny policy effect.

> **Important**
>
> This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ec2:CreateSnapshot",
        "ec2:CreateSnapshots"
      ],
      "Resource": "arn:aws:ec2:us-west-2::snapshot/*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": "webserver"
        }
      }
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request. For a Deny statement, Match is Denied and No match is Not denied, so it may be allowed by another statement.

Policy Condition	Request Context	Result
`"ForAnyValue:StringEquals": { "aws:TagKeys": "webserver" }`	`aws:TagKeys: - webserver`	**Match**
`"ForAnyValue:StringEquals": { "aws:TagKeys": "webserver" }`	`aws:TagKeys: - environment - webserver - test`	**Match**
`"ForAnyValue:StringEquals": { "aws:TagKeys": "webserver" }`	`aws:TagKeys: - environment - test`	**No match** May be allowed by another statement.
`"ForAnyValue:StringEquals": { "aws:TagKeys": "webserver" }`	No `aws:TagKeys` in the request context.	**No match** May be allowed by another statement.

Single-valued context key policy examples

The following set of policy examples demonstrate how to create policy conditions with single-valued context keys.

Example: Multiple condition blocks with single-valued context keys

When a condition block has multiple conditions, each with a single context key, all context keys must resolve to true for the desired `Allow` or `Deny` effect to be invoked. When you use negated matching condition operators, the evaluation logic of the condition value is reversed.

The following example lets users create EC2 volumes and apply tags to the volumes during volume creation. The request context must include a value for context key `aws:RequestTag/project`, and the value for context key `aws:ResourceTag/environment` can be anything except production.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CreateVolume",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "ec2:CreateTags",
      "Resource": "arn:aws:ec2:us-east-1:123456789012:volume/*",
      "Condition": {
        "StringLike": {
          "aws:RequestTag/project": "*"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:CreateTags",
      "Resource": "arn:aws:ec2:us-east-1:123456789012:*/*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceTag/environment": "production"
        }
      }
    }
  ]
}
```

The request context must include a project tag-value and cannot be created for a production resource to invoke the `Allow` effect. The following EC2 volume is successfully created because the project name is `Feature3` with a QA resource tag.

```
aws ec2 create-volume \
    --availability-zone us-east-1a \
    --volume-type gp2 \
    --size 80 \
    --tag-specifications 'ResourceType=volume,Tags=[{Key=project,Value=Feature3},
{Key=environment,Value=QA}]'
```

Example: One condition block with multiple single-valued context keys and values

When a condition block contains multiple context keys and each context key has multiple values, each context key must resolve to true for at least one key value for the desired `Allow` or `Deny` effect to be invoked. When you use negated matching condition operators, the evaluation logic of the context key value is reversed.

The following example allows users to start and run tasks on Amazon Elastic Container Service clusters.

- The request context must include `production` **OR** `prod-backup` for the `aws:RequestTag/environment` context key **AND**.
- The `ecs:cluster` context key makes sure that tasks are run on either the `default1` **OR** `default2` ARN ECS clusters.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:RunTask",
        "ecs:StartTask"
      ],
      "Resource": [
        "*"
      ],
```

```
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/environment": [
            "production",
            "prod-backup"
          ]
        },
        "ArnEquals": {
          "ecs:cluster": [
            "arn:aws:ecs:us-east-1:111122223333:cluster/default1",
            "arn:aws:ecs:us-east-1:111122223333:cluster/default2"
          ]
        }
      }
    }
  ]
}
```

The following table shows how AWS evaluates this policy based on the condition key values in your request.

Policy condition	Request context	Result
`"StringEquals": { "aws:RequestTag/environment": [ "production", "prod-backup" ] }, "ArnEquals": { "ecs:cluster": [ "arn:aws:ecs:us-east-1:111122223333:cluster/default1", "arn:aws:ecs:us-east-1:111122223333:cluster/default2" ] }`	`aws:RequestTag: environment:production ecs:cluster: arn:aws:ecs:us-east-1:111122223333:cluster/default1`	Match

Policy condition	Request context	Result
`"StringEquals": { "aws:RequestTag/environment": [ "production", "prod-backup" ] }, "ArnEquals": { "ecs:cluster": [ "arn:aws:ecs:us-east-1:111122223333:cluster/default1", "arn:aws:ecs:us-east-1:111122223333:cluster/default2" ] }`	`aws:RequestTag: environment:prod-backup ecs:cluster: arn:aws:ecs:us-east-1:111122223333:cluster/default2`	Match
`"StringEquals": { "aws:RequestTag/environment": [ "production", "prod-backup" ] }, "ArnEquals": { "ecs:cluster": [ "arn:aws:ecs:us-east-1:111122223333:cluster/default1", "arn:aws:ecs:us-east-1:111122223333:cluster/default2" ] }`	`aws:RequestTag: webserver:production ecs:cluster: arn:aws:ecs:us-east-1:111122223333:cluster/default2`	No match

Policy condition	Request context	Result
`"StringEquals": { "aws:RequestTag/environment": [ "production", "prod-backup" ] }, "ArnEquals": { "ecs:cluster": [ "arn:aws:ecs:us-east-1:111122223333:cluster/default1", "arn:aws:ecs:us-east-1:111122223333:cluster/default2" ] }`	No `aws:RequestTag` in the request context. `ecs:cluster arn:aws:ecs:us-east-1:111122223333:cluster/default2`	No match

IAM policy elements: Variables and tags

Use AWS Identity and Access Management (IAM) policy variables as placeholders when you don't know the exact value of a resource or condition key when you write the policy.

> **Note**
>
> If AWS cannot resolve a variable this might cause the entire statement to be invalid. For example, if you use the `aws:TokenIssueTime` variable, the variable resolves to a value only when the requester authenticated using temporary credentials (an IAM role). To prevent variables from causing invalid statements, use the ...IfExists condition operator.

Topics

- Introduction
- Using variables in policies
- Tags as policy variables
- Where you can use policy variables

- Policy variables with no value
- Request information that you can use for policy variables
- Specifying default values
- For more information

Introduction

In IAM policies, many actions allow you to provide a name for the specific resources that you want to control access to. For example, the following policy allows users to list, read, and write objects in the S3 bucket `amzn-s3-demo-bucket` for `marketing` projects.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket"],
      "Condition": {"StringLike": {"s3:prefix": ["marketing/*"]}}
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/marketing/*"]
    }
  ]
}
```

In some cases, you might not know the exact name of the resource when you write the policy. You might want to generalize the policy so it works for many users without having to make a unique copy of the policy for each user. Instead of creating a separate policy for each user, we recommend you create a single group policy that works for any user in that group.

Using variables in policies

You can define dynamic values inside policies by using *policy variables* that set placeholders in a policy.

Variables are marked using a **$** prefix followed by a pair of curly braces (**{ }**) that include the variable name of the value from the request.

When the policy is evaluated, the policy variables are replaced with values that come from the conditional context keys passed in the request. Variables can be used in identity-based policies, resource policies, service control policies, session policies, and VPC endpoint policies. Identity-based policies used as permissions boundaries also support policy variables.

Global condition context keys can be used as variables in requests across AWS services. Service specific condition keys can also be used as variables when interacting with AWS resources, but are only available when requests are made against resources which support them. For a list of context keys available for each AWS service and resource, see the *Service Authorization Reference*. Under certain circumstances, you can't populate global condition context keys with a value. To learn more about each key, see AWS global condition context keys.

Important

- Key names are case-insensitive. For example, `aws:CurrentTime` is equivalent to `AWS:currenttime`.
- You can use any single-valued condition key as a variable. You can't use a multivalued condition key as a variable.

The following example shows a policy for an IAM role or user that replaces a specific resource name with a policy variable. You can reuse this policy by taking advantage of the `aws:PrincipalTag` condition key. When this policy is evaluated, `${aws:PrincipalTag/team}` allows the actions only if the bucket name ends with a team name from the `team` principal tag.

JSON

```
{
  "Version": "2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket"],
      "Condition": {"StringLike": {"s3:prefix": ["${aws:PrincipalTag/team}/*"]}}
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/${aws:PrincipalTag/team}/*"]
    }
  ]
}
```

The variable is marked using a $ prefix followed by a pair of curly braces ({ }). Inside the ${ } characters, you can include the name of the value from the request that you want to use in the policy. The values you can use are discussed later on this page.

For details about this global condition key, see aws:PrincipalTag/*tag-key* in the list of global condition keys.

> **Note**
>
> In order to use policy variables, you must include the `Version` element in a statement, and the version must be set to a version that supports policy variables. Variables were introduced in version `2012-10-17`. Earlier versions of the policy language don't support policy variables. If you don't include the `Version` element and set it to an appropriate version date, variables like `${aws:username}` are treated as literal strings in the policy. A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you change a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see the section called “Version”. To learn more about policy versions, see the section called “Versioning IAM policies”.

A policy that allows a principal to get objects from the /David path of an S3 bucket looks like this:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/David/*"
      ]
    }
  ]
}
```

If this policy is attached to user `David`, that user get objects from his own S3 bucket, but you would have to create a separate policy for each user that includes the user's name. You would then attach each policy to the individual users.

By using a policy variable, you can create policies that can be reused. The following policy allows a user to get objects from an Amazon S3 bucket if the tag-key value for `aws:PrincipalTag` matches the tag-key `owner` value passed in the request.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "AllowUnlessOwnedBySomeoneElse",
    "Effect": "Allow",
    "Action": ["s3:GetObject"],
    "Resource": ["*"],
    "Condition": {
        "StringEquals": {
```

```
          "s3:ExistingObjectTag/owner": "${aws:PrincipalTag/owner}"
        }
      }
    }
  ]
}
```

When you use a policy variable in place of a user like this, you don't have to have a separate policy for each individual user. In the following example, the policy is attached to an IAM role that is assumed by Product Managers using temporary security credentials. When a user makes a request to add an Amazon S3 object, IAM substitutes the `dept` tag value from the current request for the `${aws:PrincipalTag}` variable and evaluates the policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowOnlyDeptS3Prefix",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/${aws:PrincipalTag/dept}/*"
            ]
        }
    ]
}
```

Tags as policy variables

In some AWS services you can attach your own custom attributes to resources that are created by those services. For example, you can apply tags to Amazon S3 buckets or to IAM users. These tags are key-value pairs. You define the tag key name and the value that is associated with that key name. For example, you might create a tag with a **`department`** key and a **`Human Resources`** value. For more information about tagging IAM entities, see Tags for AWS Identity and Access Management resources. For information about tagging resources created by other AWS services,

see the documentation for that service. For information about using Tag Editor, see Working with Tag Editor in the *AWS Management Console User Guide*.

You can tag IAM resources to simplify discovering, organizing, and tracking your IAM resources. You can also tag IAM identities to control access to resources or to tagging itself. To learn more about using tags to control access, see Controlling access to and for IAM users and roles using tags.

Where you can use policy variables

You can use policy variables in the `Resource` element and in string comparisons in the `Condition` element.

Resource element

You can use a policy variable in the `Resource` element, but only in the resource portion of the ARN. This portion of the ARN appears after the fifth colon (:). You can't use a variable to replace parts of the ARN before the fifth colon, such as the service or account. For more information about the ARN format, see IAM ARNs.

To replace part of an ARN with a tag value, surround the prefix and key name with `${ }`. For example, the following Resource element refers to only a bucket that is named the same as the value in the requesting user's department tag.

```
"Resource": ["arn:aws::s3:::amzn-s3-demo-bucket/
${aws:PrincipalTag/department}"]
```

Many AWS resources use ARNs that contain a user-created name. The following IAM policy ensures that only intended users with matching access-project, access-application, and access-environment tag values can modify their resources. In addition, using * wildcard matches, they are able to allow for custom resource name suffixes.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessBasedOnArnMatching",
      "Effect": "Allow",
      "Action": [
        "sns:CreateTopic",
```

```
        "sns:DeleteTopic"],
      "Resource": ["arn:aws:sns:*:*:${aws:PrincipalTag/access-project}-
${aws:PrincipalTag/access-application}-${aws:PrincipalTag/access-environment}-*"
      ]
    }
  ]
}
```

Condition element

You can use a policy variable for `Condition` values in any condition that involves the string operators or the ARN operators. String operators include `StringEquals`, `StringLike`, and `StringNotLike`. ARN operators include `ArnEquals` and `ArnLike`. You can't use a policy variable with other operators, such as `Numeric`, `Date`, `Boolean`, `Binary`, `IP Address`, or `Null` operators. For more information about condition operators, see IAM JSON policy elements: Condition operators.

When referencing a tag in a `Condition` element expression, use the relevant prefix and key name as the condition key. Then use the value that you want to test in the condition value.

For example, the following policy example allows full access to users, but only if the tag `costCenter` is attached to the user. The tag must also have a value of either `12345` or `67890`. If the tag has no value, or has any other value, then the request fails.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
          "iam:*user*"
       ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "iam:ResourceTag/costCenter": [ "12345", "67890" ]
        }
      }
```

```
    }
  ]
}
```

Policy variables with no value

When policy variables reference a condition context key that has no value or is not present in an authorization context for a request, the value is effectively null. There is no equal or like value. Condition context keys may not be present in the authorization context when:

- You are using service specific condition context keys in requests to resources that do not support that condition key.
- Tags on IAM principals, sessions, resources, or requests are not present.
- Other circumstances as listed for each global condition context key in AWS global condition context keys.

When you use a variable with no value in the condition element of an IAM policy, IAM JSON policy elements: Condition operators like `StringEquals` or `StringLike` do not match, and the policy statement does not take effect.

Inverted condition operators like `StringNotEquals` or `StringNotLike` do match against a null value, as the value of the condition key they are testing against is not equal to or like the effectively null value.

In the following example, `aws:principaltag/Team` must be equal to `s3:ExistingObjectTag/Team` to allow access. Access is explicitly denied when `aws:principaltag/Team` is not set. If a variable that has no value in the authorization context is used as part of the `Resource` or `NotResource` element of a policy, the resource that includes a policy variable with no value will not match any resource.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
   {
    "Effect": "Deny",
    "Action": "s3:GetObject",
```

```
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "Condition": {
      "StringNotEquals": {
        "s3:ExistingObjectTag/Team": "${aws:PrincipalTag/Team}"
       }
      }
    }
  ]
}
```

Request information that you can use for policy variables

You can use the `Condition` element of a JSON policy to compare keys in the request context with key values that you specify in your policy. When you use a policy variable, AWS substitutes a value from the request context key in place of the variable in your policy.

Principal key values

The values for `aws:username`, `aws:userid`, and `aws:PrincipalType` depend on what type of principal initiated the request. For example, the request could be made using the credentials of an IAM user, an IAM role, or the AWS account root user. The following list shows values for these keys for different types of principals.

- **AWS account root user**
  - `aws:username`: (not present)
  - `aws:userid`: AWS account ID
  - `aws:PrincipalType`: `Account`
- **IAM user**
  - `aws:username`: *`IAM-user-name`*
  - `aws:userid`: unique ID
  - `aws:PrincipalType`: `User`
- **AWS STS federated user principal**
  - `aws:username`: (not present)
  - `aws:userid`: *`account`*:*`caller-specified-name`*
  - `aws:PrincipalType`: `FederatedUser`
- **OIDC and SAML federated principals**

> **Note**
>
> For information about policy keys that are available when you use OIDC federation, see OIDC federation.

  - `aws:username`: (not present)
  - `aws:userid`: (not present)
  - `aws:PrincipalType`: `AssumedRole`
- **Assumed role**
  - `aws:username`: (not present)
  - `aws:userid`: *`role-id`*:*`caller-specified-role-name`*
  - `aws:PrincipalType`: `Assumed role`
- **Role assigned to Amazon EC2 instance**
  - `aws:username`: (not present)
  - `aws:userid`: *`role-id`*:*`ec2-instance-id`*
  - `aws:PrincipalType`: `Assumed role`
- **Anonymous caller** (Amazon SQS Amazon SNS and Amazon S3 only)
  - `aws:username`: (not present)
  - `aws:userid`: (not present)
  - `aws:PrincipalType`: `Anonymous`

For the items in this list, note the following:

- *not present* means that the value is not in the current request information, and any attempt to match it fails and causes the statement to be invalid.
- *`role-id`* is a unique identifier assigned to each role at creation. You can display the role ID with the AWS CLI command: `aws iam get-role --role-name` *`rolename`*
- *`caller-specified-name`* and *`caller-specified-role-name`* are names that are passed by the calling process (such as an application or service) when it makes a call to get temporary credentials.

- *ec2-instance-id* is a value assigned to the instance when it is launched and appears on the **Instances** page of the Amazon EC2 console. You can also display the instance ID by running the AWS CLI command: `aws ec2 describe-instances`

Information available in requests for federated principals

Federated principals are users who are authenticated using a system other than IAM. For example, a company might have an application for use in-house that makes calls to AWS. It might be impractical to give an IAM identity to every corporate user who uses the application. Instead, the company might use a proxy (middle-tier) application that has a single IAM identity, or the company might use a SAML identity provider (IdP). The proxy application or SAML IdP authenticates individual users using the corporate network. A proxy application can then use its IAM identity to get temporary security credentials for individual users. A SAML IdP can in effect exchange identity information for AWS temporary security credentials. The temporary credentials can then be used to access AWS resources.

Similarly, you might create an app for a mobile device in which the app needs to access AWS resources. In that case, you might use *OIDC federation*, where the app authenticates the user using a well-known identity provider like Login with Amazon, Amazon Cognito, Facebook, or Google. The app can then use the user's authentication information from these providers to get temporary security credentials for accessing AWS resources.

The recommended way to use OIDC federation is by taking advantage of Amazon Cognito and the AWS mobile SDKs. For more information, see the following:

- Amazon Cognito User Guide
- Common scenarios for temporary credentials

Special characters

There are a few special predefined policy variables that have fixed values that enable you to represent characters that otherwise have special meaning. If these special characters are part of the string, you are trying to match and you inserted them literally they would be misinterpreted. For example, inserting an * asterisk in the string would be interpreted as a wildcard, matching any characters, instead of as a literal *. In these cases, you can use the following predefined policy variables:

- **${*}** - use where you need an * (asterisk) character.

- **${?}** - use where you need a ? (question mark) character.
- **${$}** - use where you need a $ (dollar sign) character.

These predefined policy variables can be used in any string where you can use regular policy variables.

Specifying default values

To add a default value to a variable, surround the default value with single quotes (`' '`), and separate the variable text and the default value with a comma and space (`, `).

For example, if a principal is tagged with `team=yellow`, they can access `ExampleCorp's` Amazon S3 bucket named `amzn-s3-demo-bucket-yellow`. A policy with this resource allows team members to access their team bucket, but not those of other teams. For users without team tags, it sets a default value of `company-wide` for the bucket name. These users can access only the `amzn-s3-demo-bucket-company-wide` bucket where they can view broad information, such as instructions for joining a team.

```
"Resource":"arn:aws:s3:::amzn-s3-demo-bucket-${aws:PrincipalTag/team, 'company-wide'}"
```

For more information

For more information about policies, see the following:

- Policies and permissions in AWS Identity and Access Management
- Example IAM identity-based policies
- IAM JSON policy element reference
- Policy evaluation logic
- OIDC federation

IAM JSON policy elements: Supported data types

This section lists the data types that are supported when you specify values in JSON policies. The policy language doesn't support all types for each policy element; for information about each element, see the preceding sections.

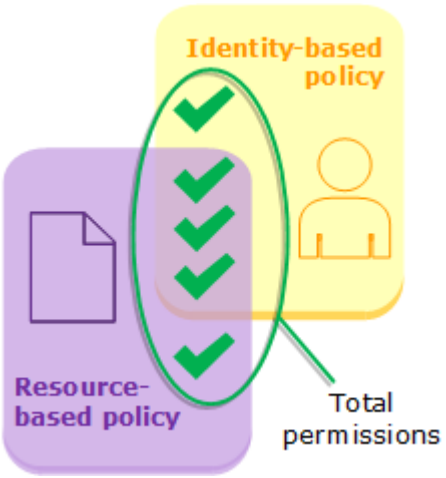
- Strings
- Numbers (Ints and Floats)

- Boolean
- Null
- Lists
- Maps
- Structs (which are just nested Maps)

The following table maps each data type to the serialization. Note that all policies must be in UTF-8. For information about the JSON data types, go to RFC 4627.

Type	JSON
String	String
Integer	Number
Float	Number
Boolean	true false
Null	null
Date	String adhering to the W3C Profile of ISO 8601
IpAddress	String adhering to RFC 4632
List	Array
Object	Object

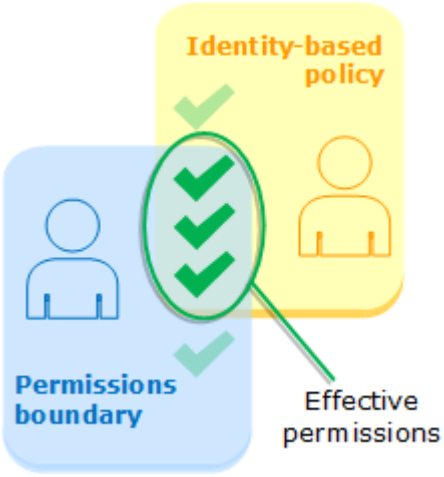
Policy evaluation logic



When a principal tries to use the AWS Management Console, the AWS API, or the AWS CLI, that principal sends a *request* to AWS. When an AWS service receives the request, AWS completes several steps to determine whether to allow or deny the request.

1. **Authentication** – AWS first authenticates the principal that makes the request, if necessary. This step is not necessary for a few services, such as Amazon S3, that allow some requests from anonymous users.

2. **Processing the request context** – AWS processes the information gathered in the request to determine which policies apply to the request.
3. **How AWS enforcement code logic evaluates requests to allow or deny access** – AWS evaluates all of the policy types and the order of the policies affects how they are evaluated. AWS then processes the policies against the request context to determine whether the request is allowed or denied.



Evaluating identity-based policies with resource-based policies

Identity-based policies and resource-based policies grant permissions to the identities or resources to which they are attached. When an IAM entity (user or role) requests access to a resource within the same account, AWS evaluates all the permissions granted by the identity-based and resource-based policies. The resulting permissions are the union of the permissions of the two types. If an action is allowed by an identity-based policy, a resource-based policy, or both, then AWS allows the action. An explicit deny in either of these policies overrides the allow.

Evaluating identity-based policies with permissions boundaries

When AWS evaluates the identity-based policies and permissions boundary for a user, the resulting permissions are the intersection of the two categories. That means that when you add a permissions boundary to a user with existing identity-based policies, you might reduce the actions that the user can perform. Alternatively, when you remove a permissions boundary from a user, you might increase the actions they can perform. An explicit deny in either of these policies overrides the allow. To view information about how other policy types are evaluated with permissions boundaries, see Evaluating effective permissions with boundaries.

Evaluating identity-based policies with AWS Organizations SCPs or RCPs

When a user belongs to an account that is a member of an organization and accesses a resource that doesn't have a resource-based policy configured, the resulting permissions are the intersection of the user's policies, service control policies (SCPs), and resource control policy (RCP). This means that an action must be allowed by all three policy types. An explicit deny in the identity-based policy, an SCP, or an RCP overrides the allow.

You can learn whether your account is a member of an organization in AWS Organizations. Organization members might be affected by an SCP or RCP. To view this data using the AWS CLI command or AWS API operation, you must have permissions for the `organizations:DescribeOrganization` action for your AWS Organizations entity. You must have additional permissions to perform the operation in the AWS Organizations console. To learn whether an SCP or RCP is denying access to a specific request, or to change your effective permissions, contact your AWS Organizations administrator.

Processing the request context

When AWS evaluates and authorizes a request, it assembles the request information into a *request context*. The request context contains any information that can be used in policy evaluation.

- **Principal** – The user, role, or federated user principal that sent the request. Information about the principal includes the policies that are associated with that principal.
- **Actions** – One or more actions that the principal wants to perform.
- **Resources** – One or more AWS resource objects upon which the actions or operations are performed.
- **Resource data** – Data related to the resource that is being requested. This can include information such as a DynamoDB table name or a tag on an Amazon EC2 instance.
- **Environment data** – Information about the IP address, user agent, SSL enabled status, or the time of day.

This information is compared against applicable policies to determine whether to allow or deny the request. You can organize this property information using the **Principal**, **Action**, **Resource**, and **Condition** (PARC) model to better understand how AWS policies are evaluated.

Understanding the PARC model

The PARC model represents the request context based on the four JSON elements in the policy language:

- Principal – The entity making the request. A principal represents a human user or programmatic workload that can be authenticated and then authorized to perform actions in AWS accounts.
- Action – The operation being performed. Often the action will map to an API action.
- Resource – The AWS resource on which the action is being performed.
- Condition – Additional constraints that must be met for the request to be allowed.

The following shows an example of how the PARC model might represent a request context:

```
Principal: AIDA123456789EXAMPLE
Action: s3:CreateBucket
Resource: arn:aws:s3:::amzn-s3-demo-bucket1
Context:
```

```
- aws:UserId=AIDA123456789EXAMPLE:BobsSession
- aws:PrincipalAccount=123456789012
- aws:PrincipalOrgId=o-example

```

Importance of the request context

Understanding the request context and how it interacts with policy evaluation is crucial for:

- Troubleshooting access issues
- Designing effective and secure policies
- Understanding the full scope of permissions granted by a policy
- Predicting the outcome of policy evaluations in different scenarios

By visualizing the request context using the PARC model, you can more easily understand how AWS makes authorization decisions and design your policies more effectively.

How AWS uses the request context

When evaluating policies, AWS compares the information in the request context with the information specified in all applicable policies. This includes identity-based policies, resource-based policies, IAM permissions boundaries, Organizations SCPs, Organizations RCPs, and session policies.

For each policy type, AWS uses the request context to check:

- Whether the policy applies to the request based on the principal.
- Whether the requested action is allowed on the specified resource.
- Whether any conditions specified in the policy are met by the request context.

How AWS evaluates policies depends on the types of policies that apply to the request context. These policy types are available for use within a single AWS account. For more information about

these policy types, see Policies and permissions in AWS Identity and Access Management. To learn how AWS evaluates policies for cross-account access, see Cross-account policy evaluation logic.

- **AWS Organizations resource control policies (RCPs)** – AWS Organizations RCPs specify the maximum available permissions for resources within accounts in an organization or organizational unit (OU). RCPs apply to resources in member accounts and impact the effective permissions for principals, including the AWS account root user, regardless of whether the principals belong to your organization. RCPs don't apply to resources in the organization management account and to calls made by service-linked roles. If an RCP is present, permissions granted by identity-based and resource-based policies to resources in your member accounts are only effective if the RCP allows the action.
- **AWS Organizations service control policies (SCPs)** – AWS Organizations SCPs specify the maximum available permissions for principals within accounts in an organization or organizational unit (OU). SCPs apply to principals in member accounts, including each AWS account root user. If an SCP is present, permissions granted by identity-based and resource-based policies to principals in your member accounts are only effective if the SCP allows the action. The only exceptions are principals in the organization management account and service-linked roles.
- **Resource-based policies** – Resource-based policies grant permissions for principals specified in the policy. The permissions define what the principal can do with the resource to which the policy is attached.
- **Permissions boundaries** – Permissions boundaries are a feature that sets the maximum permissions that an identity-based policy can grant to an IAM entity (user or role). When you set a permissions boundary for an entity, the entity can perform only the actions that are allowed by both its identity-based policies and its permissions boundary. In some cases, an implicit deny in a permissions boundary can limit the permissions granted by a resource-based policy. For more information, see How AWS enforcement code logic evaluates requests to allow or deny access.
- **Identity-based policies** – Identity-based policies are attached to an IAM identity (user, group of users, or role) and grant permissions to IAM entities (users and roles). If only identity-based policies apply to a request, then AWS checks all of those policies for at least one `Allow`.
- **Session policies** – Session policies are policies that you pass as parameters when you programmatically create a temporary session for a role or federated user session. To create a role session programmatically, use one of the `AssumeRole*` API operations. When you do this and pass session policies, the resulting session's permissions are the intersection of the IAM entity's identity-based policy and the session policies. To create a federated user session, you use the IAM

user access keys to programmatically call the `GetFederationToken` API operation. For more information, see Session policies.

Remember, an explicit deny in any of these policies overrides the allow.

> **Note**
>
> **AWS Organizations declarative policies** allow you to centrally declare and enforce your desired configuration for a given AWS service at scale across an organization. Since declarative policies are applied directly at the service level, they don't directly impact policy evaluation requests and aren't included with the request context. For more information, see Declarative policies in the AWS Organizations User Guide.

Example policy evaluation using the PARC model

To illustrate how the request context interacts with policy evaluation, let's consider an example policy:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:CreateBucket",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalTag/dept": "123"
        }
      }
    }
  ]
}
```

In this example, the policy would allow the `CreateBucket` action only when the request context includes an `aws:PrincipalTag/dept` value of "123" and the resource matches the `amzn-s3-`

demo-bucket1 bucket name. The following table shows how AWS uses the request context to evaluate this policy and make authorization decisions.

Policy	Request context	Evaluation result
"StringEquals": { "aws:PrincipalTag/dept": "123" }	Principal: AIDA12345 6789EXAMPLE Action: s3:Create Bucket Resource: arn:aws:s 3:::amzn-s3-demo-b ucket1 Context: - aws:PrincipalTag/ dept=123	**Match**
"StringEquals": { "aws:PrincipalTag/dept": "123" }	Principal: AIDA12345 6789EXAMPLE Action: s3: *DeleteBuc ket* Resource: arn:aws:s 3:::amzn-s3-demo-b ucket1 Context: - aws:PrincipalTag/ dept=123	**No match**
"StringEquals": { "aws:PrincipalTag/dept": "123" }	Principal: AIDA12345 6789EXAMPLE Action: s3:Create Bucket Resource: arn:aws:s 3:::amzn-s3-demo-b ucket1 Context: - aws:PrincipalTag/ dept= *321*	**No match**
"StringEquals": {	Principal: AIDA12345 6789EXAMPLE	**No match**

Policy	Request context	Evaluation result

`"aws:PrincipalTag/dept": "123"`
`}`
	`Action: s3:CreateBucket`
	`Resource: arn:aws:s3:::amzn-s3-demo-bucket1`
	`Context:`
	
	No `aws:PrincipalTag` in the request.	

How AWS enforcement code logic evaluates requests to allow or deny access

The AWS enforcement code decides whether a request sent to AWS should be allowed or denied. AWS evaluates all policies that are applicable to the request context. The following is a summary of the AWS policy evaluation logic.

- By default, all requests are implicitly denied with the exception of the AWS account root user, which has full access.
- Requests must be explicitly allowed by a policy or set of policies following the evaluation logic below to be allowed.
- An explicit deny overrides an explicit allow.

Policy evaluation can differ depending on whether the request is within a single account or a cross-account request. For details about how a policy evaluation decision is made for an IAM role or user within a single account, see Policy evaluation for requests within a single account. For details about how a policy evaluation decision is made for cross-account requests, see Cross-account policy evaluation logic.

- **Deny evaluation** – By default, all requests are denied. This is called an implicit deny. The AWS enforcement code evaluates all policies within the account that apply to the request. These include AWS Organizations SCPs and RCPs, resource-based policies, identity-based policies, IAM permissions boundaries, and session policies. In all those policies, the enforcement code looks for a `Deny` statement that applies to the request. This is called an explicit deny. If the enforcement code finds even one explicit deny that applies, the enforcement code returns a final decision of **Deny**. If there is no explicit deny, the enforcement code evaluation continues.

- **AWS Organizations RCPs** – The enforcement code evaluates AWS Organizations resource control policies (RCPs) that apply to the request. RCPs apply to resources of the account where the RCPs are attached. If the enforcement code does not find any applicable `Allow` statements in the RCPs, the enforcement code returns a final decision of **Deny**. Note that an AWS managed policy called `RCPFullAWSAccess` is automatically created and attached to every entity in your organization including the root, each OU, and AWS account when RCPs are enabled. `RCPFullAWSAccess` can't be detached, so there will always be an `Allow` statement. If there is no RCP, or if the RCP allows the requested action, the enforcement code evaluation continues.
- **AWS Organizations SCPs** – The enforcement code evaluates AWS Organizations service control policies (SCPs) that apply to the request. SCPs apply to principals of the account where the SCPs are attached. If the enforcement code does not find any applicable `Allow` statements in the SCPs, the enforcement code returns a final decision of **Deny**. If there is no SCP, or if the SCP allows the requested action, the enforcement code evaluation continues.
- **Resource-based policies** – Within the same account, resource-based policies impact policy evaluation differently depending on the type of principal accessing the resource, and the principal that is allowed in the resource-based policy. Depending on the type of principal, an `Allow` in a resource-based policy can result in a final decision of `Allow`, even if an implicit deny in an identity-based policy, permissions boundary, or session policy is present.

  For most resources, you only need an explicit `Allow` for the principal in either an identity-based policy or a resource-based policy to grant access. IAM role trust policies and KMS key policies are exceptions to this logic, because they must explicitly allow access for principals. Resource-based policies for services other than IAM and AWS KMS may also require an explicit `Allow` statement within the same account to grant access. For more information, see the documentation for the specific service you're working with.

  For single account policy evaluation requests, resource-based policy logic differs from other policy types if the specified principal is an IAM user, an IAM role, or a session principal. Session principals include IAM role sessions or an AWS STS federated user principals. If a resource-based policy grants permission directly to the IAM user or the session principal that is making the request, then an implicit deny in an identity-based policy, a permissions boundary, or a session policy does not impact the final decision.

  - **IAM role** – Resource-based policies that grant permissions to an IAM role ARN are limited by an implicit deny in a permissions boundary or session policy. You can specify the role ARN in the Principal element or the `aws:PrincipalArn` condition key. In both cases, the principal that makes the request is the **IAM role session**.

Permissions boundaries and session policies do not limit permissions granted using the `aws:PrincipalArn` condition key with a wildcard(*) in the Principal element, unless the identity-based policies contain an explicit deny. For more information, see IAM role principals.

Example role ARN

```
arn:aws:iam::111122223333:role/examplerole
```

- **IAM role session** – Within the same account, resource-based policies that grant permissions to an IAM role session ARN grant permissions directly to the assumed role session. Permissions granted directly to a session are not limited by an implicit deny in an identity-based policy, a permissions boundary, or session policy. When you assume a role and make a request, the principal making the request is the IAM role session ARN and not the ARN of the role itself. For more information, see Role session principals.

  Example role session ARN

  ```
  arn:aws:sts::111122223333:assumed-role/examplerole/examplerolesessionname
  ```

- **IAM user** – Within the same account, resource-based policies that grant permissions to an IAM user ARN (that is not a federated user session) are not limited by an implicit deny in an identity-based policy or permissions boundary.

  Example IAM user ARN

  ```
  arn:aws:iam::111122223333:user/exampleuser
  ```

- **AWS STS federated user principal** – A federated user session is a session created by calling `GetFederationToken`. When a federated user makes a request, the principal making the request is the federated user ARN and not the ARN of the IAM user who federated. Within the same account, resource-based policies that grant permissions to a federated user ARN grant permissions directly to the session. Permissions granted directly to a session are not limited by an implicit deny in an identity-based policy, a permissions boundary, or session policy.

  However, if a resource-based policy grants permission to the ARN of the IAM user who federated, then requests made by the federated user during the session are limited by an implicit deny in a permission boundary or session policy.

  Example federated user session ARN

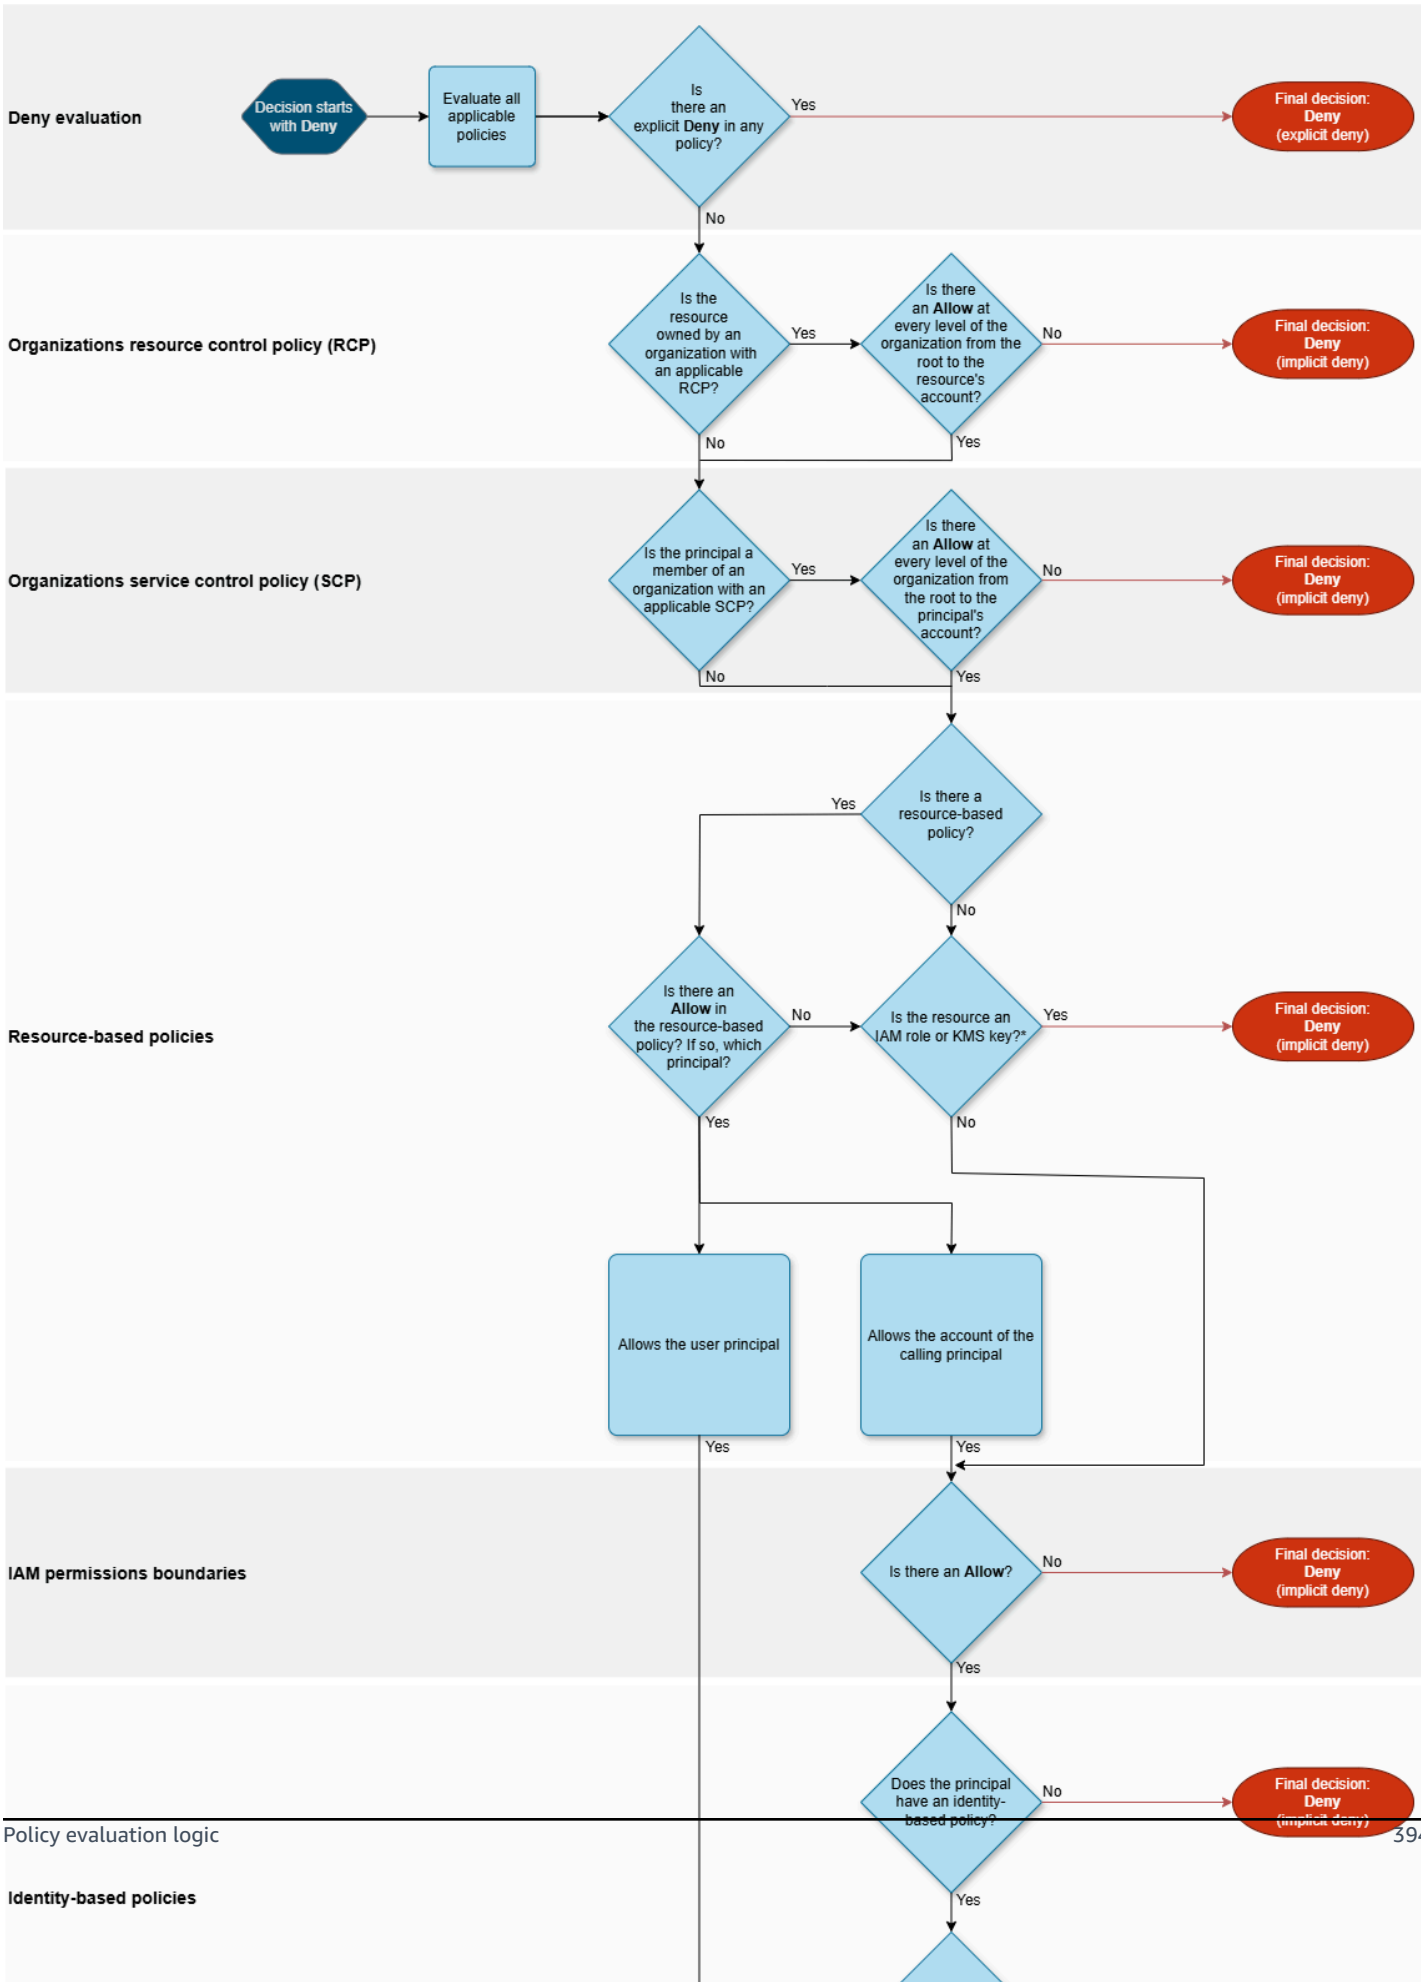
```
arn:aws:sts::111122223333:federated-user/exampleuser
```

- **Identity-based policies** – The enforcement code checks the identity-based policies for the principal. For an IAM user, these include user policies and policies from groups to which the user belongs. If there are no identity-based policies or no statements in identity-based policies that allow the requested action, then the request is implicitly denied and the enforcement code returns a final decision of **Deny**. If any statement in any applicable identity-based policies allows the requested action, the code evaluation continues.
- **IAM permissions boundaries** – The enforcement code checks whether the IAM entity that is used by the principal has a permissions boundary. If the policy that is used to set the permissions boundary does not allow the requested action, then the request is implicitly denied. The enforcement code returns a final decision of **Deny**. If there is no permissions boundary, or if the permissions boundary allows the requested action, the code evaluation continues.
- **Session policies** – The enforcement code checks whether the principal is a session principal. Session principals include an IAM role session or an AWS STS federated user session. If the principal is not a session principal, the enforcement code returns a final decision of **Allow**.

  For session principals, the enforcement code checks whether a session policy was passed in the request. You can pass a session policy while using the AWS CLI or AWS API to get temporary credentials for a role or an AWS STS federated user principal. If you didn't pass a session policy, a default session policy is created and the enforcement code returns a final decision of **Allow**.

  - If a session policy is present and does not allow the requested action, then the request is implicitly denied. The enforcement code returns a final decision of **Deny**.
  - The enforcement code checks whether the principal is a role session. If the principal is a role session, then the request is **Allowed**. Otherwise, the request is implicitly denied and the enforcement code returns a final decision of **Deny**.
  - If a session policy is present and allows the requested action, then the enforcement code returns a final decision of **Allow**.

Policy evaluation for requests within a single account



Policy evaluation for an IAM role

The following flow chart provides details about how a policy evaluation decision is made for an IAM role within a single account.

Deny evaluation
Decision starts with Deny
Evaluate all applicable policies
Is there an explicit Deny in any policy?
Yes
Final decision: Deny (explicit deny)
No
Organizations resource control policy (RCP)
Is the resource owned by an organization with an applicable RCP?
Yes
Is there an Allow at every level of the organization from the root to the resource's account?
No
Final decision: Deny (implicit deny)
No
Yes
Organizations service control policy (SCP)
Is the principal a member of an organization with an applicable SCP?
Yes
Is there an Allow at every level of the organization from the root to the principal's account?
No
Final decision: Deny (implicit deny)
No
Yes
Resource-based policies
Yes
Is there a resource-based policy?
No
Is there an Allow in the resource-based policy? If so, which principal?
No
Is the resource an IAM role or KMS key?*
Yes
Final decision: Deny (implicit deny)
Yes
No
Allows the session of the calling principal
Allows the role of the calling principal
Allows the account of the calling principal
Yes
Yes
Yes
Identity-based policies
Does the principal have an identity-based policy?
No
Final decision: Deny (implicit deny)
Yes
Yes
Is there an Allow?
No
Final decision: Deny (implicit deny)
IAM permissions boundaries
Does the principal have a permissions
Yes
Is there an Allow?
No
Final decision: Deny

Policy evaluation for an IAM user

The following flow chart provides details about how a policy evaluation decision is made for an IAM user within a single account.

Deny evaluation
Decision starts with Deny
Evaluate all applicable policies
Is there an explicit Deny in any policy?
Yes
Final decision: Deny (explicit deny)
No
Organizations resource control policy (RCP)
Is the resource owned by an organization with an applicable RCP?
Yes
Is there an Allow at every level of the organization from the root to the resource's account?
No
Final decision: Deny (implicit deny)
No
Yes
Organizations service control policy (SCP)
Is the principal a member of an organization with an applicable SCP?
Yes
Is there an Allow at every level of the organization from the root to the principal's account?
No
Final decision: Deny (implicit deny)
No
Yes
Resource-based policies
Is there a resource-based policy?
Yes
No
Is there an Allow in the resource-based policy? If so, which principal?
No
Is the resource an IAM role or KMS key?*
Yes
Final decision: Deny (implicit deny)
Yes
No
Allows the user principal
Allows the account of the calling principal
Yes
IAM permissions boundaries
Is there an Allow?
No
Final decision: Deny (implicit deny)
Yes
Identity-based policies
Does the principal have an identity-based policy?
No
Final decision: Deny (implicit deny)
Yes

Example identity-based and resource-based policy evaluation

The most common types of policies are identity-based policies and resource-based policies. When access to a resource is requested, AWS evaluates all the permissions granted by the policies for **at least one Allow** within the same account. An explicit deny in any of the policies overrides the allow.

> **Important**
>
> If either the identity-based policy or the resource-based policy within the same account allows the request and the other doesn't, the request is still allowed.

Assume that Carlos has the user name `carlossalazar` and he tries to save a file to the `amzn-s3-demo-bucket-carlossalazar-logs` Amazon S3 bucket.

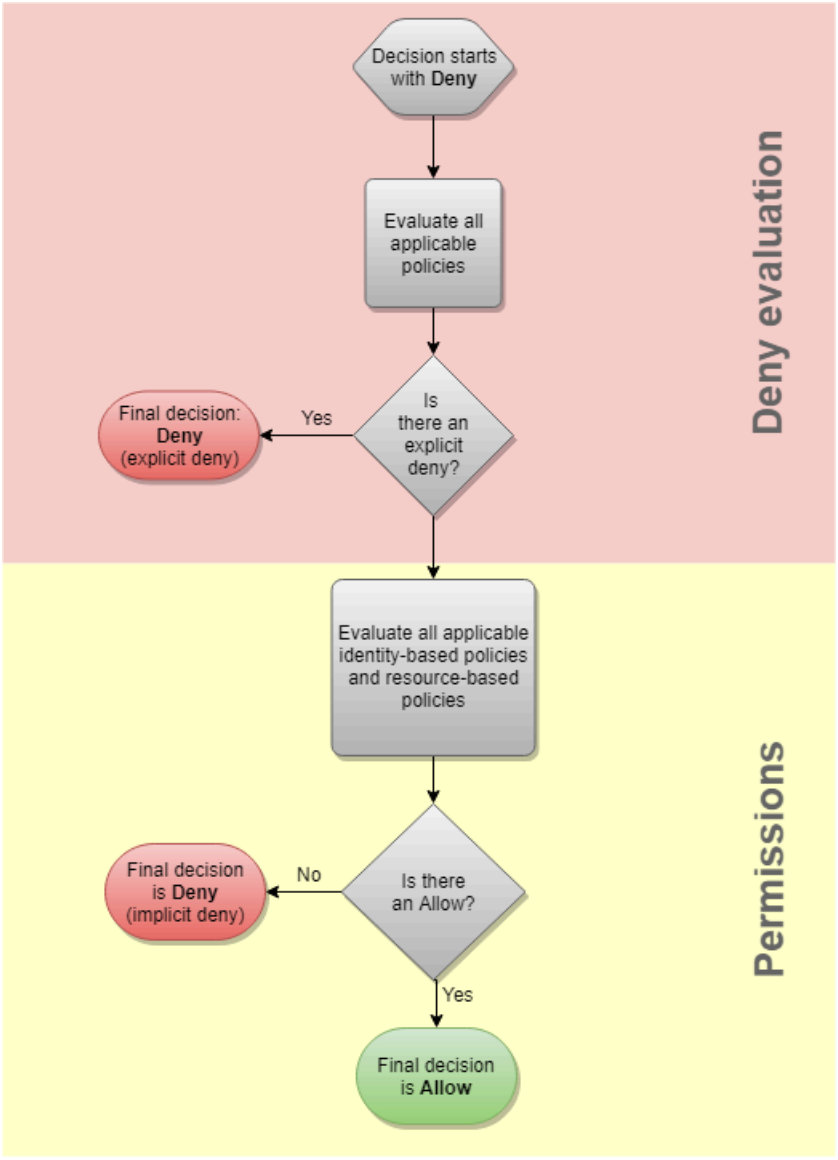
Also assume that the following policy is attached to the `carlossalazar` IAM user.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3ListRead",
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketLocation",
                "s3:GetAccountPublicAccessBlock",
                "s3:ListAccessPoints",
                "s3:ListAllMyBuckets"
            ],
            "Resource": "arn:aws:s3:::*"
        },
        {
            "Sid": "AllowS3Self",
            "Effect": "Allow",
            "Action": "s3:*",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket-carlossalazar/*",
                "arn:aws:s3:::amzn-s3-demo-bucket-carlossalazar"
            ]
```

```
        },
        {
            "Sid": "DenyS3Logs",
            "Effect": "Deny",
            "Action": "s3:*",
            "Resource": "arn:aws:s3:::*log*"
        }
    ]
}
```

The `AllowS3ListRead` statement in this policy allows Carlos to view a list of all of the buckets in the account. The `AllowS3Self` statement allows Carlos full access to the bucket with the same name as his user name. The `DenyS3Logs` statement denies Carlos access to any S3 bucket with `log` in its name.



Additionally, the following resource-based policy (called a bucket policy) is attached to the `amzn-s3-demo-bucket-carlossalazar` bucket.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/carlossalazar"
            },
            "Action": "s3:*",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket-carlossalazar/*",
                "arn:aws:s3:::amzn-s3-demo-bucket-carlossalazar"
            ]
        }
    ]
}
```

This policy specifies that only the `carlossalazar` user can access the `amzn-s3-demo-bucket-carlossalazar` bucket.

When Carlos makes his request to save a file to the `amzn-s3-demo-bucket-carlossalazar-logs` bucket, AWS determines what policies apply to the request. In this case, only the identity-based policy and the resource-based policy apply. These are both permissions policies. Because no permissions boundaries apply, the evaluation logic is reduced to the following logic.

AWS first checks for a `Deny` statement that applies to the context of the request. It finds one, because the identity-based policy explicitly denies Carlos access to any S3 buckets used for logging. Carlos is denied access.

Assume that he then realizes his mistake and tries to save the file to the `amzn-s3-demo-bucket-carlossalazar` bucket. AWS checks for a `Deny` statement and does not find one. It then checks the permissions policies. Both the identity-based policy and the resource-based policy allow the request. Therefore, AWS allows the request. If either of them explicitly denied the statement,

the request would have been denied. If one of the policy types allows the request and the other doesn't, the request is still allowed.

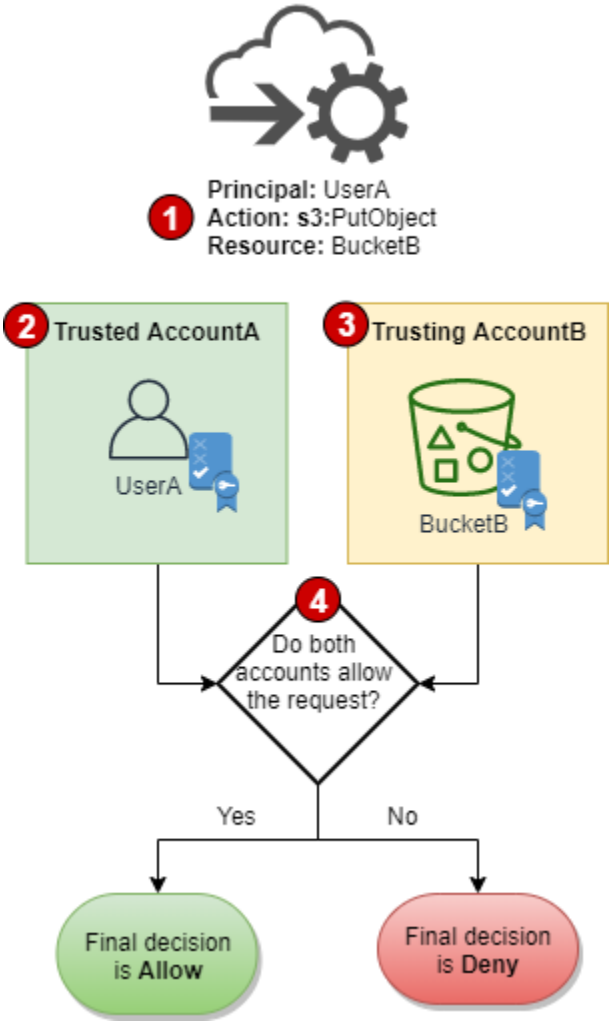
Cross-account policy evaluation logic

You can allow a principal in one account to access resources in a second account. This is called cross-account access. When you allow cross-account access, the account where the principal exists is called the *trusted* account. The account where the resource exists is the *trusting* account.

To allow cross-account access, you attach a resource-based policy to the resource that you want to share. You must also attach an identity-based policy to the identity that acts as the principal in the request. The resource-based policy in the trusting account must specify the principal of the trusted account that will have access to the resource. You can specify the entire account or its IAM users, AWS STS federated user principals, IAM roles, or assumed-role sessions. You can also specify an AWS service as a principal. For more information, see How to specify a principal.

The principal's identity-based policy must allow the requested access to the resource in the trusting service. You can do this by specifying the ARN of the resource.

In IAM, you can attach a resource-based policy to an IAM role to allow principals in other accounts to assume that role. The role's resource-based policy is called a role trust policy. After assuming that role, the allowed principals can use the resulting temporary credentials to access multiple resources in your account. This access is defined in the role's identity-based permissions policy. To learn how allowing cross-account access using roles is different from allowing cross-account access using other resource-based policies, see Cross account resource access in IAM.

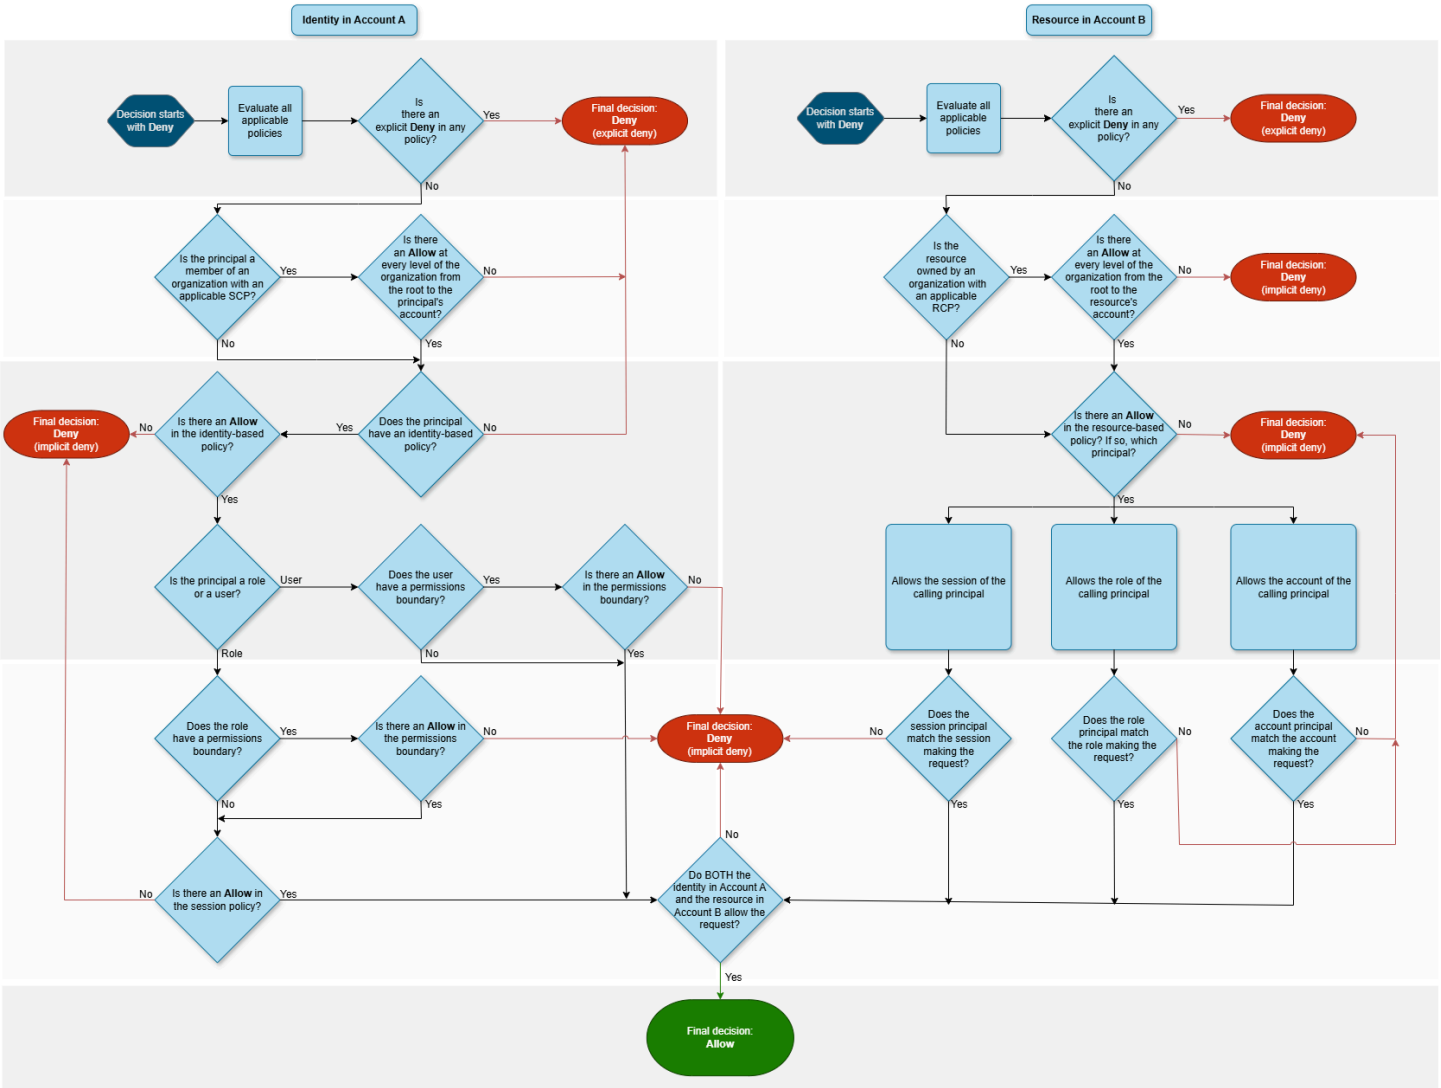


> **Important**
>
> Other services can affect the policy evaluation logic. For example, AWS Organizations supports service control policies and resource control policies that can be applied to principals and resources in one or more accounts. AWS Resource Access Manager supports policy fragments that control which actions that principals are allowed to perform on resources that are shared with them.

Determining whether a cross-account request is allowed

For cross-account requests, the requester in the trusted `AccountA` must have an identity-based policy. That policy must allow them to make a request to the resource in the trusting `AccountB`.

Additionally, the resource-based policy in `AccountB` must allow the requester in `AccountA` to access the resource.



When you make a cross-account request, AWS performs two evaluations. AWS evaluates the request in the trusting account and the trusted account. For more information about how a request is evaluated within a single account, see [How AWS enforcement code logic evaluates requests to allow or deny access]. The request is allowed only if both evaluations return a decision of `Allow`.

1. When a principal in one account makes a request to access a resource in another account, this is a cross-account request.
2. The requesting principal exists in the trusted account (`AccountA`). When AWS evaluates this account, it checks the identity-based policy and any policies that can limit an identity-based policy. For more information, see [Evaluating identity-based policies with permissions boundaries].

3. The requested resource exists in the trusting account (`AccountB`). When AWS evaluates this account, it checks the resource-based policy that is attached to the requested resource and any policies that can limit a resource-based policy. For more information, see [Evaluating identity-based policies with resource-based policies].
4. AWS allows the request only if both account policy evaluations allow the request.

The following flow chart provides a more detailed illustration of how a policy evaluation decision is made for a cross-account request. Again, AWS allows the request only if both account policy evaluations allow the request.

Example cross-account policy evaluation

The following example demonstrates a scenario where a role in one account is granted permissions by a resource-based policy in a second account.

Assume that Carlos is a developer with an IAM role named Demo in account 111111111111. He wants to save a file to the amzn-s3-demo-bucket-production-logs Amazon S3 bucket in account 222222222222.

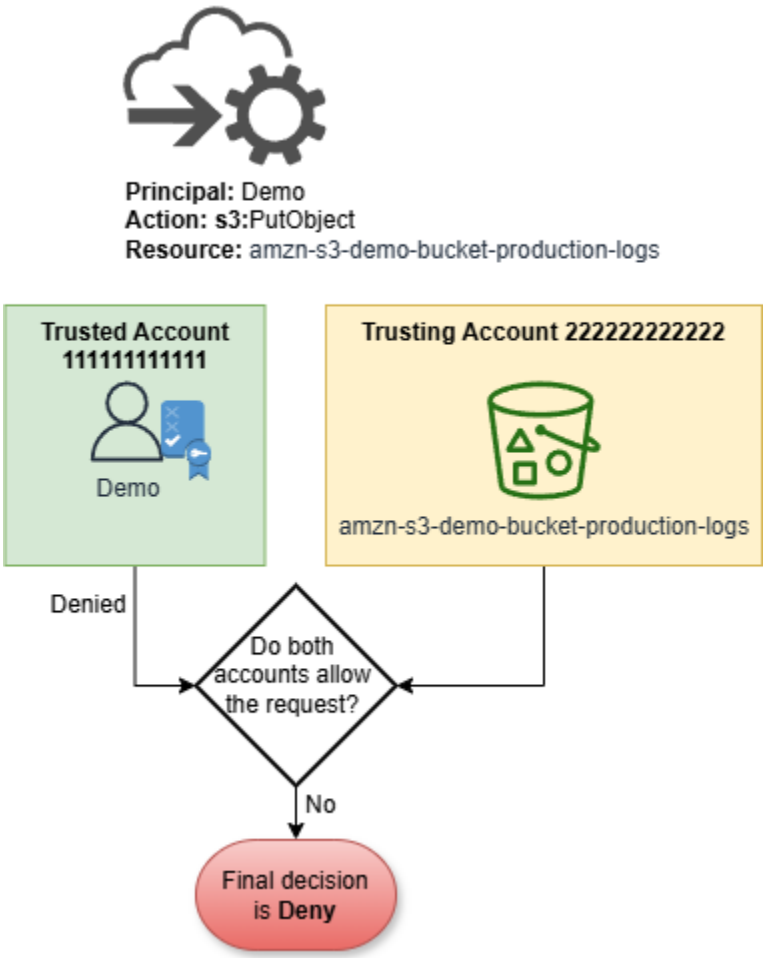
Also assume that the following policy is attached to the Demo IAM role.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3ListRead",
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Sid": "AllowS3ProductionObjectActions",
            "Effect": "Allow",
            "Action": "s3:*Object*",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket-production/*"
        },
        {
            "Sid": "DenyS3Logs",
            "Effect": "Deny",
            "Action": "s3:*",
            "Resource": [
                "arn:aws:s3:::*log*",
                "arn:aws:s3:::*log*/*"
            ]
        }
    ]
}
```

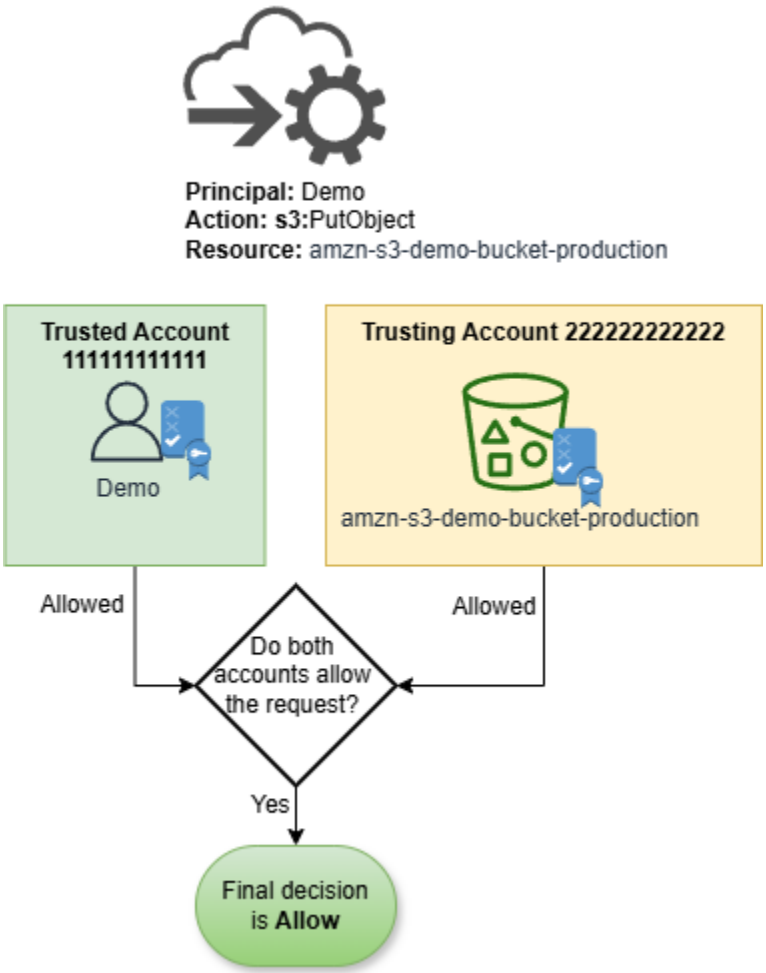
The AllowS3ListRead statement in this policy allows Carlos to view a list of all of the buckets in Amazon S3. The AllowS3ProductionObjectActions statement allows Carlos full access to objects in the amzn-s3-demo-bucket-production bucket.

Additionally, the following resource-based policy (called a bucket policy) is attached to the amzn-s3-demo-bucket-production bucket in account 222222222222.



JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject*",
                "s3:PutObject*",
                "s3:ReplicateObject",
                "s3:RestoreObject"
            ],
            "Principal": { "AWS": "arn:aws:iam::111111111111:role/Demo" },
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket-production/*"
        }
    ]
}
```



This policy allows the Demo role to access objects in the amzn-s3-demo-bucket-production bucket. The role can create and edit, but not delete the objects in the bucket. The role can't manage the bucket itself.

When Carlos makes his request to save a file to the amzn-s3-demo-bucket-production-logs bucket, AWS determines what policies apply to the request. In this case, the identity-based policy attached to the Demo role is the only policy that applies in account 111111111111. In account 222222222222, there is no resource-based policy attached to the amzn-s3-demo-bucket-production-logs bucket. When AWS evaluates account 111111111111, it returns a decision of Deny. This is because the DenyS3Logs statement in the identity-based policy explicitly denies access to any log buckets. For more information about how a request is evaluated within a single account, see How AWS enforcement code logic evaluates requests to allow or deny access.

Because the request is explicitly denied within one of the accounts, the final decision is to deny the request.

Assume that Carlos then realizes his mistake and tries to save the file to the `Production` bucket. AWS first checks account 111111111111 to determine if the request is allowed. Only the identity-based policy applies, and it allows the request. AWS then checks account 222222222222. Only the resource-based policy attached to the `Production` bucket applies, and it allows the request. Because both accounts allow the request, the final decision is to allow the request.

The difference between explicit and implicit denies

A request results in an explicit deny if an applicable policy includes a `Deny` statement. If policies that apply to a request include an `Allow` statement and a `Deny` statement, the `Deny` statement trumps the `Allow` statement. The request is explicitly denied.

An implicit denial occurs when there is no applicable `Deny` statement but also no applicable `Allow` statement. Because an IAM principal is denied access by default, they must be explicitly allowed to perform an action. Otherwise, they are implicitly denied access.

When you design your authorization strategy, you must create policies with `Allow` statements to allow your principals to successfully make requests. However, you can choose any combination of explicit and implicit denies.

For example, you can create the following policy that includes allowed actions, implicitly denied actions, and explicitly denied actions. The `AllowGetList` statement **allows** read-only access

to IAM actions that begin with the prefixes `Get` and `List`. All other actions in IAM, such as `iam:CreatePolicy` are **implicitly denied**. The `DenyReports` statement **explicitly denies** access to IAM reports by denying access to actions that include the `Report` suffix, such as `iam:GetOrganizationsAccessReport`. If someone adds another policy to this principal to grant them access to IAM reports, such as `iam:GenerateCredentialReport`, report-related requests are still denied because of this explicit deny.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowGetList",
            "Effect": "Allow",
            "Action": [
                "iam:Get*",
                "iam:List*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "DenyReports",
            "Effect": "Deny",
            "Action": "iam:*Report",
            "Resource": "*"
        }
    ]
}
```

Grammar of the IAM JSON policy language

This page presents a formal grammar for the language used to create JSON policies in IAM. We present this grammar so that you can understand how to construct and validate policies.

For examples of policies, see the following topics:

- Policies and permissions in AWS Identity and Access Management
- Example IAM identity-based policies

- Example Policies for Working in the Amazon EC2 Console and Example Policies for Working With the AWS CLI, the Amazon EC2 CLI, or an AWS SDK in the *Amazon EC2 User Guide*.
- Bucket Policy Examples and User Policy Examples in the *Amazon Simple Storage Service User Guide*.

For examples of policies used in other AWS services, go to the documentation for those services.

Topics

- The policy language and JSON
- Conventions used in this grammar
- Grammar
- Policy grammar notes

The policy language and JSON

Policies are expressed in JSON. When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see IAM policy validation. To learn more about IAM Access Analyzer policy checks and actionable recommendations, see IAM Access Analyzer policy validation.

In this document, we do not provide a complete description of what constitutes valid JSON. However, here are some basic JSON rules:

- White space between individual entities is allowed.
- Values are enclosed in quotation marks. Quotation marks are optional for numeric and Boolean values.
- Many elements (for example, `action_string_list` and `resource_string_list`) can take a JSON array as a value. Arrays can take one or more values. If more than one value is included, the array is in square brackets ([and]) and comma-delimited, as in the following example:

```
"Action" : ["ec2:Describe*","ec2:List*"]
```

- Basic JSON data types (Boolean, number, and string) are defined in RFC 7159.

Conventions used in this grammar

The following conventions are used in this grammar:

- The following characters are JSON tokens and *are* included in policies:

  ```
  { } [ ] " , :
  ```

- The following characters are special characters in the grammar and are *not* included in policies:

  ```
  = < > ( ) |
  ```

- If an element allows multiple values, it is indicated using repeated values, a comma delimiter, and an ellipsis (`...`). Examples:

  ```
  [<action_string>, <action_string>, ...]
  ```

  ```
  <principal_map> = { <principal_map_entry>, <principal_map_entry>, ... }
  ```

  If multiple values are allowed, it is also valid to include only one value. For only one value, the trailing comma must be omitted. If the element takes an array (marked with [and]) but only one value is included, the brackets are optional. Examples:

  ```
  "Action": [<action_string>]
  ```

  ```
  "Action": <action_string>
  ```

- A question mark (?) following an element indicates that the element is optional. Example:

  ```
  <version_block?>
  ```

  However, be sure to refer to the notes that follow the grammar listing for details about optional elements.

- A vertical line (`|`) between elements indicates alternatives. In the grammar, parentheses define the scope of the alternatives. Example:

  ```
  ("Principal" | "NotPrincipal")
  ```

- Elements that must be literal strings are enclosed in double quotation marks ("). Example:

  ```
  <version_block> = "Version" : ("2008-10-17" | "2012-10-17")
  ```

For additional notes, see Policy grammar notes following the grammar listing.

Grammar

The following listing describes the policy language grammar. For conventions used in the listing, see the preceding section. For additional information, see the notes that follow.

> **Note**
>
> This grammar describes policies marked with a version of `2008-10-17` and `2012-10-17`. A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you make changes to a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see IAM JSON policy elements: Version. To learn more about policy versions, see the section called "Versioning IAM policies".

```
policy  = {
     <version_block?>,
     <id_block?>,
     <statement_block>
}

<version_block> = "Version" : ("2008-10-17" | "2012-10-17")

<id_block> = "Id" : <policy_id_string>

<statement_block> = "Statement" : [ <statement>, <statement>, ... ]

<statement> = {
    <sid_block?>,
    <principal_block?>,
    <effect_block>,
    <action_block>,
    <resource_block>,
    <condition_block?>
}

<sid_block> = "Sid" : <sid_string>

<effect_block> = "Effect" : ("Allow" | "Deny")
```

```
<principal_block> = ("Principal" | "NotPrincipal") : ("*" | <principal_map>)

<principal_map> = { <principal_map_entry>, <principal_map_entry>, ... }

<principal_map_entry> = ("AWS" | "Federated" | "Service" | "CanonicalUser") :
    [<principal_id_string>, <principal_id_string>, ...]

<action_block> = ("Action" | "NotAction") :
    ("*" | <action_string> | [<action_string>, <action_string>, ...])

<resource_block> = ("Resource" | "NotResource") :
    : ("*" | <resource_string> | [<resource_string>, <resource_string>, ...])

<condition_block> = "Condition" : { <condition_map> }
<condition_map> = {
  <condition_type_string> : { <condition_key_string> : <condition_value_list> },
  <condition_type_string> : { <condition_key_string> : <condition_value_list> }, ...
}
<condition_value_list> = [<condition_value>, <condition_value>, ...]
<condition_value> = (<condition_value_string> | <condition_value_string> |
 <condition_value_string>)
```

Policy grammar notes

- A single policy can contain an array of statements.
- Policies have a maximum size between 2048 characters and 10,240 characters, depending on what entity the policy is attached to. For more information, see IAM and AWS STS quotas. Policy size calculations do not include white space characters.
- Individual elements must not contain multiple instances of the same key. For example, you cannot include the `Effect` block twice in the same statement.
- Blocks can appear in any order. For example, `version_block` can follow `id_block` in a policy. Similarly, `effect_block`, `principal_block`, `action_block` can appear in any order within a statement.
- The `id_block` is optional in resource-based policies. It must *not* be included in identity-based policies.
- The `principal_block` element is required in resource-based policies (for example, in Amazon S3 bucket policies) and in trust policies for IAM roles. It must *not* be included in identity-based policies.

- The `principal_map` element in Amazon S3 bucket policies can include the `CanonicalUser` ID. Most resource-based policies do not support this mapping. To learn more about using the canonical user ID in a bucket policy, see Specifying a Principal in a Policy in the *Amazon Simple Storage Service User Guide*.
- Each string value (`policy_id_string`, `sid_string`, `principal_id_string`, `action_string`, `resource_string`, `condition_type_string`, `condition_key_string`, and the string version of `condition_value`) can have its own minimum and maximum length restrictions, specific allowed values, or required internal format.

Notes about string values

This section provides additional information about string values that are used in different elements in a policy.

`action_string`

Consists of a service namespace, a colon, and the name of an action. Action names can include wildcards. Examples:

```
"Action":"ec2:StartInstances"

"Action":[
  "ec2:StartInstances",
  "ec2:StopInstances"
]

"Action":"cloudformation:*"

"Action":"*"

"Action":[
  "s3:Get*",
  "s3:List*"
]
```

`policy_id_string`

Provides a way to include information about the policy as a whole. Some services, such as Amazon SQS and Amazon SNS, use the `Id` element in reserved ways. Unless otherwise

restricted by an individual service, policy_id_string can include spaces. Some services require this value to be unique within an AWS account.

> **Note**
>
> The `id_block` is allowed in resource-based policies, but not in identity-based policies.

There is no limit to the length, although this string contributes to the overall length of the policy, which is limited.

```
"Id":"Admin_Policy"

"Id":"cd3ad3d9-2776-4ef1-a904-4c229d1642ee"
```

`sid_string`

Provides a way to include information about an individual statement. For IAM policies, basic alphanumeric characters (A-Z,a-z,0-9) are the only allowed characters in the `Sid` value. Other AWS services that support resource policies may have other requirements for the `Sid` value. For example, some services require this value to be unique within an AWS account, and some services allow additional characters such as spaces in the `Sid` value.

```
"Sid":"1"

"Sid": "ThisStatementProvidesPermissionsForConsoleAccess"
```

`principal_id_string`

Provides a way to specify a principal using the *Amazon Resource Name* (ARN) of the AWS account, IAM user, IAM role, federated user, or assumed-role user. For an AWS account, you can also use the short form `AWS:accountnumber` instead of the full ARN. For all of the options including AWS services, assumed roles, and so on, see How to specify a principal.

Note that you can use * only to specify "everyone/anonymous." You cannot use it to specify part of a name or ARN.

`resource_string`

In most cases, consists of an Amazon Resource Name (ARN). You can use wildcards (* and ?) in the resource portion of the ARN. For more information about using wildcards in ARNs, see Using wildcards in paths.

> **Note**
>
> When you specify an incomplete ARN (one with fewer than the standard six fields) in an identity-based policy, AWS automatically completes the ARN by adding wildcard characters (*) to all missing fields. For example, specifying `arn:aws:sqs` is equivalent to `arn:aws:sqs:*:*:*`, which grants access to all Amazon SQS resources across all regions and accounts.

```
"Resource":"arn:aws:iam::123456789012:user/Bob"

"Resource":"arn:aws:s3:::amzn-s3-demo-bucket/*"
```

`condition_type_string`

Identifies the type of condition being tested, such as `StringEquals`, `StringLike`, `NumericLessThan`, `DateGreaterThanEquals`, `Bool`, `BinaryEquals`, `IpAddress`, `ArnEquals`, etc. For a complete list of condition types, see IAM JSON policy elements: Condition operators.

```
"Condition": {
  "NumericLessThanEquals": {
    "s3:max-keys": "10"
  }
}

"Condition": {
  "Bool": {
    "aws:SecureTransport": "true"
  }
}

"Condition": {
  "StringEquals": {
```

```
      "s3:x-amz-server-side-encryption": "AES256"
   }
}
```

condition_key_string

Identifies the condition key whose value will be tested to determine whether the condition is met. AWS defines a set of condition keys that are available in all AWS services, including `aws:PrincipalType`, `aws:SecureTransport`, and `aws:userid`.

For a list of AWS condition keys, see AWS global condition context keys. For condition keys that are specific to a service, see the documentation for that service such as the following:

- Specifying Conditions in a Policy in the *Amazon Simple Storage Service User Guide*
- IAM Policies for Amazon EC2 in the *Amazon EC2 User Guide*.

```
"Condition":{
  "Bool": {
      "aws:SecureTransport": "true"
   }
}

"Condition": {
  "StringNotEquals": {
      "s3:x-amz-server-side-encryption": "AES256"
   }
}

"Condition": {
  "StringEquals": {
    "aws:ResourceTag/purpose": "test"
  }
}
```

condition_value_string

Identifies the value of the condition_key_string that determines whether the condition is met. For a complete list of valid values for a condition type, see IAM JSON policy elements: Condition operators.

```
"Condition":{
  "ForAnyValue:StringEquals": {
```

```
  "dynamodb:Attributes": [
   "ID",
   "PostDateTime"
         ]
  }
}
```

AWS managed policies for job functions

We recommend using policies that grant least privilege, or granting only the permissions required to perform a task. The most secure way to grant least privilege is to write a custom policy with only the permissions needed by your team. You must create a process to allow your team to request more permissions when necessary. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need.

To get started adding permissions to your IAM identities (users, groups of users, and roles), you can use AWS managed policies. AWS managed policies cover common use cases and are available in your AWS account. AWS managed policies don't grant least privilege permissions. You must consider the security risk of granting your principals more permissions than they need to do their job.

You can attach AWS managed policies, including job functions, to any IAM identity. To switch to least privilege permissions, you can run AWS Identity and Access Management and Access Analyzer to monitor principals with AWS managed policies. After learning which permissions they are using, then you can write a custom policy or generate a policy with only the required permissions for your team. This is less secure, but provides more flexibility as you learn how your team is using AWS.

AWS managed policies for job functions are designed to closely align to common job functions in the IT industry. You can use these policies to grant the permissions needed to carry out the tasks expected of someone in a specific job function. These policies consolidate permissions for many services into a single policy that's easier to work with than having permissions scattered across many policies.

Use Roles to Combine Services

Some of the policies use IAM service roles to help you take advantage of features found in other AWS services. These policies grant access to `iam:passrole`, which allows a user with the policy to pass a role to an AWS service. This role delegates IAM permissions to the AWS service to carry out actions on your behalf.

You must create the roles according to your needs. For example, the Network Administrator policy allows a user with the policy to pass a role named "flow-logs-vpc" to the Amazon CloudWatch service. CloudWatch uses that role to log and capture IP traffic for VPCs created by the user.

To follow security best practices, the policies for job functions include filters that limit the names of valid roles that can be passed. This helps avoid granting unnecessary permissions. If your users do require the optional service roles, you must create a role that follows the naming convention specified in the policy. You then grant permissions to the role. Once that is done, the user can configure the service to use the role, granting it whatever permissions the role provides.

In the following sections, each policy's name is a link to the policy details page in the AWS Management Console. There you can see the policy document and review the permissions it grants.

Administrator job function

AWS managed policy name: AdministratorAccess

Use case: This user has full access and can delegate permissions to every service and resource in AWS.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants all actions for all AWS services and for all resources in the account. For more information about the managed policy, see AdministratorAccess in *AWS Managed Policy Reference Guide*.

> **Note**
>
> Before an IAM user or role can access the AWS Billing and Cost Management console with the permissions in this policy, you must first activate IAM user and role access. To do this, follow the instructions in Grant access to the billing console to delegate access to the billing console.

Billing job function

AWS managed policy name: Billing

Use case: This user needs to view billing information, set up payments, and authorize payments. The user can monitor the costs accumulated for the entire AWS service.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants full permissions for managing billing, costs, payment methods, budgets, and reports. For additional cost management policy examples, see AWS Billing policy examples in the *AWS Billing and Cost Management User Guide*. For more information about the managed policy, see Billing in *AWS Managed Policy Reference Guide*.

> **Note**
>
> Before an IAM user or role can access the AWS Billing and Cost Management console with the permissions in this policy, you must first activate IAM user and role access. To do this, follow the instructions in Grant access to the billing console to delegate access to the billing console.

Database administrator job function

AWS managed policy name: DatabaseAdministrator

Use case: This user sets up, configures, and maintains databases in the AWS Cloud.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to create, configure, and maintain databases. It includes access to AWS database services, such as Amazon DynamoDB, Amazon Relational Database Service (RDS), and Amazon Redshift. View the policy for the full list of database services that this policy supports. For more information about the managed policy, see DatabaseAdministrator in *AWS Managed Policy Reference Guide*.

This job function policy supports the ability to pass roles to AWS services. The policy allows the `iam:PassRole` action for only those roles named in the following table. For more information, see Creating roles and attaching policies (console) later in this topic.

Use case	Role name (* is a wildcard)	Service role type to select	Select this AWS managed policy
Allow the user to monitor RDS databases	rds-monitoring-role	Amazon RDS Role for Enhanced Monitoring	AmazonRDSEnhancedMonitoringRole
Allow AWS Lambda to monitor your database and access external databases	rdbms-lambda-access	Amazon EC2	AWSLambda_FullAccess
Allow Lambda to upload files to Amazon S3 and to Amazon Redshift clusters with DynamoDB	lambda_exec_role	AWS Lambda	Create a new managed policy as defined in the AWS Big Data Blog
Allow Lambda functions to act as triggers for your DynamoDB tables	lambda-dynamodb-*	AWS Lambda	AWSLambda DynamoDBExecutionRole
Allow Lambda functions to access Amazon RDS in a VPC	lambda-vpc-execution-role	Create a role with a trust policy as defined in the AWS Lambda Developer Guide	AWSLambdaVPCAccessExecutionRole
Allow AWS Data Pipeline to access your AWS resources	DataPipelineDefaultRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	The AWS Data Pipeline documentation lists the required permissions for this use case. See IAM roles for AWS Data Pipeline
Allow your applications running on Amazon EC2	DataPipelineDefaultResourceRole	Create a role with a trust	AmazonEC2RoleforDataPipelineRole

Use case	Role name (* is a wildcard)	Service role type to select	Select this AWS managed policy
instances to access your AWS resources		policy as defined in the AWS Data Pipeline Developer Guide	

Data scientist job function

AWS managed policy name: DataScientist

Use case: This user runs Hadoop jobs and queries. The user also accesses and analyzes information for data analytics and business intelligence.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to create, manage, and run queries on an Amazon EMR cluster and perform data analytics with tools such as Amazon QuickSight. The policy includes access to additional data scientist services, such as AWS Data Pipeline, Amazon EC2, Amazon Kinesis, Amazon Machine Learning, and SageMaker AI. View the policy for the full list of data scientist services that this policy supports. For more information about the managed policy, see DataScientist in *AWS Managed Policy Reference Guide*.

This job function policy supports the ability to pass roles to AWS services. One statement allows passing any role to SageMaker AI. Another statement allows the `iam:PassRole` action for only those roles named in the following table. For more information, see Creating roles and attaching policies (console) later in this topic.

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allow Amazon EC2 instances access to services and resources suitable for clusters	EMR-EC2_DefaultRole	Amazon EMR for EC2	AmazonElasticMapReduceforEC2Role

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allow Amazon EMR access to access the Amazon EC2 service and resources for clusters	EMR_DefaultRole	Amazon EMR	AmazonEMR ServicePolicy_v2
Allow Kinesis Managed Service for Apache Flink to access streaming data sources	kinesis-*	Create a role with a trust policy as defined in the AWS Big Data Blog.	See the AWS Big Data Blog, which outlines four possible options depending on your use case
Allow AWS Data Pipeline to access your AWS resources	DataPipelineDefaultRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	The AWS Data Pipeline documentation lists the required permissions for this use case. See IAM roles for AWS Data Pipeline
Allow your applications running on Amazon EC2 instances to access your AWS resources	DataPipelineDefaultResourceRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	AmazonEC2 RoleforDataPipelineRole

Developer power user job function

AWS managed policy name: PowerUserAccess

Use case: This user performs application development tasks and can create and configure resources and services that support AWS aware application development.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: The first statement of this policy uses the `NotAction` element to allow all actions for all AWS services and for all resources except AWS Identity and Access Management, AWS Organizations, and AWS Account Management. The second statement grants IAM permissions to create a service-linked role. This is required by some services that must access resources in another service, such as an Amazon S3 bucket. It also grants AWS Organizations permissions to view information about the user's organization, including the management account email and organization limitations. Although this policy limits IAM, AWS Organizations, it allows the user to perform all IAM Identity Center actions if IAM Identity Center is enabled. It also grants Account Management permissions to view which AWS Regions are enabled or disabled for the account.

Network administrator job function

AWS managed policy name: NetworkAdministrator

Use case: This user is tasked with setting up and maintaining AWS network resources.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to create and maintain network resources in Auto Scaling, Amazon EC2, AWS Direct Connect, Route 53, Amazon CloudFront, Elastic Load Balancing, AWS Elastic Beanstalk, Amazon SNS, CloudWatch, CloudWatch Logs, Amazon S3, IAM, and Amazon Virtual Private Cloud. For more information about the managed policy, see NetworkAdministrator in *AWS Managed Policy Reference Guide*.

This job function requires the ability to pass roles to AWS services. The policy grants `iam:GetRole` and `iam:PassRole` for only those roles named in the following table. For more information, see Creating roles and attaching policies (console) later in this topic.

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allows Amazon VPC to create and manage logs in	flow-logs-*	Create a role with a trust policy as	This use case does not have

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
CloudWatch Logs on the user's behalf to monitor IP traffic going in and out of your VPC		defined in the Amazon VPC User Guide	an existing AWS managed policy, but the documentation lists the required permissions. See Amazon VPC User Guide.

Read-only access

AWS managed policy name: ReadOnlyAccess

Use case: This user requires read-only access to every resource in an AWS account.

> **Important**
>
> This user will also have access to read data in storage services like Amazon S3 buckets and Amazon DynamoDB tables.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to list, get, describe, and otherwise view resources and their attributes. It does not include mutating functions like create or delete. This policy does include read-only access to security-related AWS services, such as AWS Identity and Access Management and AWS Billing and Cost Management. View the policy for the full list of services and actions that this policy supports. For more information about the managed policy, see ReadOnlyAccess in *AWS Managed Policy Reference Guide*. If you need a similar policy that does not grant access to read data in storage services, see View-only user job function.

Security auditor job function

AWS managed policy name: SecurityAudit

Use case: This user monitors accounts for compliance with security requirements. This user can access logs and events to investigate potential security breaches or potential malicious activity.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to view configuration data for many AWS services and to review their logs. For more information about the managed policy, see SecurityAudit in *AWS Managed Policy Reference Guide*.

Support user job function

AWS managed policy name: AWSSupportAccess

Use case: This user contacts AWS Support, creates support cases, and views the status of existing cases.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to create and update Support cases. For more information about the managed policy, see AWSSupportAccess in *AWS Managed Policy Reference Guide*.

System administrator job function

AWS managed policy name: SystemAdministrator

Use case: This user sets up and maintains resources for development operations.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants permissions to create and maintain resources across a large variety of AWS services, including AWS CloudTrail, Amazon CloudWatch, AWS CodeCommit, AWS CodeDeploy, AWS Config, AWS Directory Service, Amazon EC2, AWS Identity and Access Management, AWS Key Management Service, AWS Lambda, Amazon RDS, Route 53, Amazon S3, Amazon SES, Amazon SQS, AWS Trusted Advisor, and Amazon VPC. For more information about the managed policy, see SystemAdministrator in *AWS Managed Policy Reference Guide*.

This job function requires the ability to pass roles to AWS services. The policy grants `iam:GetRole` and `iam:PassRole` for only those roles named in the following table. For more information, see Creating roles and attaching policies (console) later in this topic. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allow apps running in EC2 instances in an Amazon ECS cluster to access Amazon ECS	ecr-sysadmin-*	Amazon EC2 Role for EC2 Container Service	AmazonEC2ContainerServiceforEC2Role
Allow a user to monitor databases	rds-monitoring-role	Amazon RDS Role for Enhanced Monitoring	AmazonRDSEnhancedMonitoringRole
Allow apps running in EC2 instances to access AWS resources.	ec2-sysadmin-*	Amazon EC2	Sample policy for role that grants access to an S3 bucket as shown in the Amazon EC2 User Guide; customize as needed
Allow Lambda to read DynamoDB streams and write to CloudWatch Logs	lambda-sysadmin-*	AWS Lambda	AWSLambdaDynamoDBExecutionRole

View-only user job function

AWS managed policy name: ViewOnlyAccess

Use case: This user can view a list of AWS resources and basic metadata in the account across services. The user cannot read resource content or metadata that goes beyond the quota and list information for resources.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see Updates to AWS managed policies for job functions.

Policy description: This policy grants `List*`, `Describe*`, `Get*`, `View*`, and `Lookup*` access to resources for AWS services. To see what actions this policy includes for each service, see ViewOnlyAccess. For more information about the managed policy, see ViewOnlyAccess in *AWS Managed Policy Reference Guide*.

Updates to AWS managed policies for job functions

These policies are all maintained by AWS and are kept up to date to include support for new services and new capabilities as they are added by AWS services. These policies cannot be modified by customers. You can make a copy of the policy and then modify the copy, but that copy is not automatically updated as AWS introduces new services and API operations.

For a job function policy, you can view the version history and the time and date of each update in the IAM console. To do this, use the links on this page to view the policy details. Then choose the **Policy versions** tab to view the versions. This page shows the last 25 versions of a policy. To view all of the versions for a policy, call the get-policy-version AWS CLI command or the GetPolicyVersion API operation.

> **Note**
>
> You can have up to five versions of a customer managed policy, but AWS retains the full version history of AWS managed policies.

Creating roles and attaching policies (console)

Several of the previously listed policies grant the ability to configure AWS services with roles that enable those services to perform operations on your behalf. The job function policies either specify exact role names that you must use or at least include a prefix that specifies the first part of the name that can be used. To create one of these roles, perform the steps in the following procedure.

To create a role for an AWS service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.

3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose a service, and then choose the use case. Use cases are defined by the service to include the trust policy that the service requires.
5. Choose **Next**.
6. For **Permissions policies**, the options depend on the use case that you selected:
   - If the service defines the permissions for the role, you can't select permissions policies.
   - Select from a limited set of permission polices.
   - Select from all permission policies.
   - Select no permissions policies, create the policies after the role is created, and then attach the policies to the role.
7. (Optional) Set a permissions boundary. This is an advanced feature that is available for service roles, but not service-linked roles.
   a. Open the **Set permissions boundary** section, and then choose **Use a permissions boundary to control the maximum role permissions**.

      IAM includes a list of the AWS managed and customer-managed policies in your account.
   b. Select the policy to use for the permissions boundary.
8. Choose **Next**.
9. For **Role name**, the options depend on the service:
   - If the service defines the role name, you can't edit the role name.
   - If the service defines a prefix for the role name, you can enter an optional suffix.
   - If the service doesn't define the role name, you can name the role.

> **Important**
>
> When you name a role, note the following:
>
> - Role names must be unique within your AWS account, and can't be made unique by case.
>
>   For example, don't create roles named both **`PRODROLE`** and **`prodrole`**. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

- You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.
11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.
12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see Tags for AWS Identity and Access Management resources in the *IAM User Guide*.
13. Review the role, and then choose **Create role**.

Example 1: Configuring a user as a database administrator (console)

This example shows the steps required to configure Alice, an IAM user, as a Database Administrator. You use the information in first row of the table in that section and allow the user to enable Amazon RDS monitoring. You attach the DatabaseAdministrator policy to Alice's IAM user so that they can manage the Amazon database services. That policy also allows Alice to pass a role called `rds-monitoring-role` to the Amazon RDS service that allows the service to monitor the Amazon RDS databases on their behalf.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Policies**, type **`database`** in the search box, and then press enter.
3. Select the radio button for the **DatabaseAdministrator** policy, choose **Actions**, and then choose **Attach**.
4. In the list of entities, select **Alice** and then choose **Attach policy**. Alice now can administer AWS databases. However, to allow Alice to monitor those databases, you must configure the service role.
5. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
6. Choose the **AWS Service** role type, and then choose **Amazon RDS**.
7. Choose the **Amazon RDS Role for Enhanced Monitoring** use case.
8. Amazon RDS defines the permissions for your role. Choose **Next: Review** to continue.
9. The role name must be one of those specified by the DatabaseAdministrator policy that Alice now has. One of those is **`rds-monitoring-role`**. Enter that for the **Role name**.

10. (Optional) For **Role description**, enter a description for the new role.
11. After you review the details, choose **Create role**.
12. Alice can now enable **RDS Enhanced Monitoring** in the **Monitoring** section of the Amazon RDS console. For example, they might do this when they create a DB instance, create a read replica, or modify a DB instance. They must enter the role name they created (rds-monitoring-role) in the **Monitoring Role** box when they set **Enable Enhanced Monitoring** to **Yes**.

Example 2: Configuring a user as a network administrator (console)

This example shows the steps required to configure Jorge, an IAM user, as a Network Administrator. It uses the information in the table in that section to allow Jorge to monitor IP traffic going to and from a VPC. It also allows Jorge to capture that information in the logs in CloudWatch Logs. You attach the NetworkAdministrator policy to Jorge's IAM user so that they can configure AWS network resources. That policy also allows Jorge to pass a role whose name begins with `flow-logs*` to Amazon EC2 when you create a flow log. In this scenario, unlike Example 1, there isn't a predefined service role type, so you must perform a few steps differently.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies** and then enter **`network`** in the search box, and then press enter.
3. Select the radio button next to **NetworkAdministrator** policy, choose **Actions**, and then choose **Attach**.
4. In the list of users, select the checkbox next to **Jorge** and then choose **Attach policy**. Jorge can now administer AWS network resources. However, to enable monitoring of IP traffic in your VPC, you must configure the service role.
5. Because the service role you need to create doesn't have a predefined managed policy, you must first create it. In the navigation pane, choose **Policies**, then choose **Create policy**.
6. In the **Policy editor** section, choose the **JSON** option and copy the text from the following JSON policy document. Paste this text into the **JSON** text box.

   JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
    {
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:DescribeLogGroups",
        "logs:DescribeLogStreams"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

7. Resolve any security warnings, errors, or general warnings generated during policy validation, and then choose **Next**.

> **Note**
>
> You can switch between the **Visual** and **JSON** editor options any time. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see Policy restructuring.

8. On the **Review and create** page, type **`vpc-flow-logs-policy-for-service-role`** for the policy name. Review the **Permissions defined in this policy** to see the permissions granted by your policy, and then choose **Create policy** to save your work.

   The new policy appears in the list of managed policies and is ready to attach.

9. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
10. Choose the **AWS Service** role type, and then choose **Amazon EC2**.
11. Choose the **Amazon EC2** use case.
12. On the **Attach permissions policies** page, choose the policy you created earlier, **vpc-flow-logs-policy-for-service-role**, and then choose **Next: Review**.
13. The role name must be permitted by the NetworkAdministrator policy that Jorge now has. Any name that begins with `flow-logs-` is allowed. For this example, enter **`flow-logs-for-jorge`** for the **Role name**.
14. (Optional) For **Role description**, enter a description for the new role.
15. After you review the details, choose **Create role**.

16. Now you can configure the trust policy required for this scenario. On the **Roles** page, choose the **flow-logs-for-jorge** role (the name, not the checkbox). On the details page for your new role, choose the **Trust relationships** tab, and then choose **Edit trust relationship**.
17. Change the "Service" line to read as follows, replacing the entry for `ec2.amazonaws.com`:

```
        "Service": "vpc-flow-logs.amazonaws.com"
```

18. Jorge can now create flow logs for a VPC or subnet in the Amazon EC2 console. When you create the flow log, specify the **flow-logs-for-jorge** role. That role has the permissions to create the log and write data to it.

AWS global condition context keys

When a principal makes a request to AWS, AWS gathers the request information into a request context. You can use the `Condition` element of a JSON policy to compare keys in the request context with key values that you specify in your policy. Request information is provided by different sources, including the principal making the request, the resource the request is made against, and the metadata about the request itself.

Global condition keys can be used across all AWS services. While these condition keys can be used in all policies, the key is not available in every request context. For example, the `aws:SourceAccount` condition key is only available when the call to your resource is made directly by an AWS service principal. To learn more about the circumstances under which a global key is included in the request context, see the **Availability** information for each key.

Some individual services create their own condition keys that are available in the request context for other services. **Cross-service condition keys** are a type of global condition key that include a prefix matching the name of the service, such as `ec2:` or `lambda:`, but are available across other services.

Service-specific condition keys are defined for use with an individual AWS service. For example, Amazon S3 lets you write a policy with the `s3:VersionId` condition key to limit access to a specific version of an Amazon S3 object. This condition key is unique to the service, meaning it only works with requests to the Amazon S3 service. For condition keys that are service-specific, see Actions, Resources, and Condition Keys for AWS Services and choose the service whose keys you want to view.

Note

If you use condition keys that are available only in some circumstances, you can use the IfExists versions of the condition operators. If the condition keys are missing from a request context, the policy can fail the evaluation. For example, use the following condition block with `...IfExists` operators to match when a request comes from a specific IP range or from a specific VPC. If either or both keys are not included in the request context, the condition still returns `true`. The values are only checked if the specified key is included in the request context. For more information about how a policy is evaluated when a key is not present for other operators, see Condition operators.

```
"Condition": {
    "IpAddressIfExists": {"aws:SourceIp" : ["xxx"] },
    "StringEqualsIfExists" : {"aws:SourceVpc" : ["yyy"]}
}
```

Important

To compare your condition against a request context with multiple key values, you must use the `ForAllValues` or `ForAnyValue` set operators. Use set operators only with multivalued condition keys. Do not use set operators with single-valued condition keys. For more information, see Set operators for multivalued context keys.

Properties of the principal	Properties of a role session	Properties of the network	Properties of the resource	Properties of the request

	uingServi ce lambda:So urceFunct ionArn ssm:Sourc eInstance Arn identitys tore:User Id			

Sensitive condition keys

The following condition keys are considered sensitive. The use of wildcards in these condition keys does not have any valid use cases, even with a substring of the key value with a wildcard. This is because the wildcard may match the condition key to any value, which could pose a security risk.

- aws:PrincipalAccount
- aws:PrincipalOrgID
- aws:ResourceAccount
- aws:ResourceOrgID
- aws:SourceAccount
- aws:SourceOrgID
- aws:SourceVpc
- aws:SourceVpce
- aws:VpceAccount
- aws:VpceOrgID

Properties of the principal

Use the following condition keys to compare details about the principal making the request with the principal properties that you specify in the policy. For a list of principals that can make requests, see How to specify a principal.

aws:PrincipalArn

Use this key to compare the Amazon Resource Name (ARN) of the principal that made the request with the ARN that you specify in the policy. For IAM roles, the request context returns the ARN of the role, not the ARN of the user that assumed the role.

- **Availability** – This key is included in the request context for all signed requests. Anonymous requests do not include this key. You can specify the following types of principals in this condition key:
  - IAM role
  - IAM user
  - AWS STS federated user principal
  - AWS account root user
- **Data type** – ARN

  AWS recommends that you use ARN operators instead of string operators when comparing ARNs.
- **Value type** – Single-valued
- **Example values** The following list shows the request context value returned for different types of principals that you can specify in the `aws:PrincipalArn` condition key:
  - **IAM role** – The request context contains the following value for condition key `aws:PrincipalArn`. Do not specify the assumed role session ARN as a value for this condition key. For more information about the assumed role session principal, see Role session principals.

    ```
    arn:aws:iam::123456789012:role/role-name
    ```
  - **IAM user** – The request context contains the following value for condition key `aws:PrincipalArn`.

    ```
    arn:aws:iam::123456789012:user/user-name
    ```

- **AWS STS federated user principals** – The request context contains the following value for condition key `aws:PrincipalArn`.

```
arn:aws:sts::123456789012:federated-user/user-name
```

- **AWS account root user** – The request context contains the following value for condition key `aws:PrincipalArn`. When you specify the root user ARN as the value for the `aws:PrincipalArn` condition key, it limits permissions only for the root user of the AWS account. This is different from specifying the root user ARN in the principal element of a resource-based policy, which delegates authority to the AWS account. For more information about specifying the root user ARN in the principal element of a resource-based policy, see AWS account principals.

```
arn:aws:iam::123456789012:root
```

You can specify the root user ARN as a value for condition key `aws:PrincipalArn` in AWS Organizations service control policies (SCPs). SCPs are a type of organization policy used to manage permissions in your organization and affect only member accounts in the organization. An SCP restricts permissions for IAM users and roles in member accounts, including the member account's root user. For more information about the effect of SCPs on permissions, see SCP effects on permissions in the *AWS Organizations User Guide*.

aws:PrincipalAccount

Use this key to compare the account to which the requesting principal belongs with the account identifier that you specify in the policy. For anonymous requests, the request context returns `anonymous`.

- **Availability** – This key is included in the request context for all requests, including anonymous requests.
- **Data type** – String
- **Value type** – Single-valued

In the following example, access is denied except to principals with the account number `123456789012`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyAccessFromPrincipalNotInSpecificAccount",
      "Action": "service:*",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:service:us-east-1:111122223333:resource"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:PrincipalAccount": [
            "123456789012"
          ]
        }
      }
    }
  ]
}
```

aws:PrincipalOrgPaths

Use this key to compare the AWS Organizations path for the principal who is making the request to the path in the policy. That principal can be an IAM user, IAM role, AWS STS federated user principal, or AWS account root user. In a policy, this condition key ensures that the requester is an account member within the specified organization root or organizational units (OUs) in AWS Organizations. An AWS Organizations path is a text representation of the structure of an AWS Organizations entity. For more information about using and understanding paths, see Understand the AWS Organizations entity path.

- **Availability** – This key is included in the request context only if the principal is a member of an organization. Anonymous requests do not include this key.
- **Data type** – String (list)
- **Value type** – Multivalued

> **Note**
>
> Organization IDs are globally unique but OU IDs and root IDs are unique only within an organization. This means that no two organizations share the same organization ID. However, another organization might have an OU or root with the same ID as yours. We recommend that you always include the organization ID when you specify an OU or root.

For example, the following condition returns `true` for principals in accounts that are attached directly to the `ou-ab12-22222222` OU, but not in its child OUs.

```
"Condition" : { "ForAnyValue:StringEquals" : {
     "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/"]
}}
```

The following condition returns `true` for principals in an account that is attached directly to the OU or any of its child OUs. When you include a wildcard, you must use the `StringLike` condition operator.

```
"Condition" : { "ForAnyValue:StringLike" : {
     "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/
*"]
}}
```

The following condition returns `true` for principals in an account that is attached directly to any of the child OUs, but not directly to the parent OU. The previous condition is for the OU or any children. The following condition is for only the children (and any children of those children).

```
"Condition" : { "ForAnyValue:StringLike" : {
     "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/
ou-*"]
}}
```

The following condition allows access for every principal in the `o-a1b2c3d4e5` organization, regardless of their parent OU.

```
"Condition" : { "ForAnyValue:StringLike" : {
     "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/*"]
}}
```

`aws:PrincipalOrgPaths` is a multivalued condition key. Multivalued keys can have multiple values in the request context. When you use multiple values with the `ForAnyValue` condition operator, the principal's path must match one of the paths listed in the policy. For more information about multivalued condition keys, see Set operators for multivalued context keys.

```
    "Condition": {
        "ForAnyValue:StringLike": {
            "aws:PrincipalOrgPaths": [
                "o-a1b2c3d4e5/r-ab12/ou-ab12-33333333/*",
                "o-a1b2c3d4e5/r-ab12/ou-ab12-22222222/*"
            ]
        }
    }
```

aws:PrincipalOrgID

Use this key to compare the identifier of the organization in AWS Organizations to which the requesting principal belongs with the identifier specified in the policy.

- **Availability** – This key is included in the request context only if the principal is a member of an organization. Anonymous requests do not include this key.
- **Data type** – String
- **Value type** – Single-valued

This global key provides an alternative to listing all the account IDs for all AWS accounts in an organization. You can use this condition key to simplify specifying the `Principal` element in a resource-based policy. You can specify the organization ID in the condition element. When you add and remove accounts, policies that include the `aws:PrincipalOrgID` key automatically include the correct accounts and don't require manual updating.

For example, the following Amazon S3 bucket policy allows members of any account in the `o-xxxxxxxxxxx` organization to add an object into the `amzn-s3-demo-bucket` bucket.

JSON

```
{
 "Version": "2012-10-17",
 "Statement": {
```

```
    "Sid": "AllowPutObject",
    "Effect": "Allow",
    "Principal": "*",
    "Action": "s3:PutObject",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "Condition": {"StringEquals":
      {"aws:PrincipalOrgID":"o-xxxxxxxxxxx"}
    }
  }
}
```

Note

This global condition also applies to the management account of an AWS organization. This policy prevents all principals outside of the specified organization from accessing the Amazon S3 bucket. This includes any AWS services that interact with your internal resources, such as AWS CloudTrail sending log data to your Amazon S3 buckets. To learn how you can safely grant access for AWS services, see aws:PrincipalIsAWSService.

For more information about AWS Organizations, see What Is AWS Organizations? in the *AWS Organizations User Guide*.

aws:PrincipalTag/*tag-key*

Use this key to compare the tag attached to the principal making the request with the tag that you specify in the policy. If the principal has more than one tag attached, the request context includes one `aws:PrincipalTag` key for each attached tag key.

- **Availability** – This key is included in the request context if the principal is using an IAM user with attached tags. It is included for a principal using an IAM role with attached tags or session tags. Anonymous requests do not include this key.
- **Data type** – String
- **Value type** – Single-valued

You can add custom attributes to a user or role in the form of a key-value pair. For more information about IAM tags, see Tags for AWS Identity and Access Management resources. You can use `aws:PrincipalTag` to control access for AWS principals.

This example shows how you might create an identity-based policy that allows users with the **`department=hr`** tag to manage IAM users, groups, or roles. To use this policy, replace the *`italicized placeholder text`* in the example policy with your own information. Then, follow the directions in create a policy or edit a policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:Get*",
        "iam:List*",
        "iam:Generate*"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalTag/department": "hr"
        }
      }
    }
  ]
}
```

aws:PrincipalIsAWSService

Use this key to check whether the call to your resource is being made directly by an AWS service principal. For example, AWS CloudTrail uses the service principal `cloudtrail.amazonaws.com` to write logs to your Amazon S3 bucket. The request context key is set to true when a service uses a service principal to perform a direct action on your resources. The context key is set to false if the service uses the credentials of an IAM principal to make a request on the principal's behalf. It is also set to false if the service uses a service role or service-linked role to make a call on the principal's behalf.

- **Availability** – This key is present in the request context for all signed API requests that use AWS credentials. Anonymous requests do not include this key.

- **Data type** – Boolean
- **Value type** – Single-valued

You can use this condition key to limit access to your trusted identities and expected network locations while safely granting access to AWS services.

In the following Amazon S3 bucket policy example, access to the bucket is restricted unless the request originates from `vpc-111bbb22` or is from a service principal, such as CloudTrail.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExpectedNetworkServicePrincipal",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/AWSLogs/AccountNumber/*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceVpc": "vpc-111bbb22"
        },
        "BoolIfExists": {
          "aws:PrincipalIsAWSService": "false"
        }
      }
    }
  ]
}
```

In the following video, learn more about how you might use the `aws:PrincipalIsAWSService` condition key in a policy.

Safely grant access to your authorized users, expected network locations, and AWS services together.

aws:PrincipalServiceName

Use this key to compare the service principal name in the policy with the service principal that is making requests to your resources. You can use this key to check whether this call is made by a specific service principal. When a service principal makes a direct request to your resource, the `aws:PrincipalServiceName` key contains the name of the service principal. For example, the AWS CloudTrail service principal name is `cloudtrail.amazonaws.com`.

- **Availability** – This key is present in the request when the call is made by an AWS service principal. This key is not present in any other situation, including the following:
  - If the service uses a service role or service-linked role to make a call on the principal's behalf.
  - If the service uses the credentials of an IAM principal to make a request on the principal's behalf.
  - If the call is made directly by an IAM principal.
  - If the call is made by an anonymous requester.
- **Data type** – String
- **Value type** – Single-valued

You can use this condition key to limit access to your trusted identities and expected network locations while safely granting access to an AWS service.

In the following Amazon S3 bucket policy example, access to the bucket is restricted unless the request originates from `vpc-111bbb22` or is from a service principal, such as CloudTrail.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExpectedNetworkServicePrincipal",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/AWSLogs/AccountNumber/*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceVpc": "vpc-111bbb22",
```

```
          "aws:PrincipalServiceName": "cloudtrail.amazonaws.com"
        }
      }
    }
  ]
}
```

aws:PrincipalServiceNamesList

This key provides a list of all service principal names that belong to the service. This is an advanced condition key. You can use it to restrict the service from accessing your resource from a specific Region only. Some services may create Regional service principals to indicate a particular instance of the service within a specific Region. You can limit access to a resource to a particular instance of the service. When a service principal makes a direct request to your resource, the `aws:PrincipalServiceNamesList` contains an unordered list of all service principal names associated with the Regional instance of the service.

- **Availability** – This key is present in the request when the call is made by an AWS service principal. This key is not present in any other situation, including the following:
  - If the service uses a service role or service-linked role to make a call on the principal's behalf.
  - If the service uses the credentials of an IAM principal to make a request on the principal's behalf.
  - If the call is made directly by an IAM principal.
  - If the call is made by an anonymous requester.
- **Data type** – String (list)
- **Value type** – Multivalued

`aws:PrincipalServiceNamesList` is a multivalued condition key. Multivalued keys can have multiple values in the request context. You must use the `ForAnyValue` or `ForAllValues` set operators with string condition operators for this key. For more information about multivalued condition keys, see Set operators for multivalued context keys.

aws:PrincipalType

Use this key to compare the type of principal making the request with the principal type that you specify in the policy. For more information, see How to specify a principal. For specific examples of `principal` key values, see Principal key values.

- **Availability** – This key is included in the request context for all requests, including anonymous requests.
- **Data type** – String
- **Value type** – Single-valued

aws:userid

Use this key to compare the requester's principal identifier with the ID that you specify in the policy. For IAM users, the request context value is the user ID. For IAM roles, this value format can vary. For details about how the information appears for different principals, see How to specify a principal. For specific examples of `principal` key values, see Principal key values.

- **Availability** – This key is included in the request context for all requests, including anonymous requests.
- **Data type** – String
- **Value type** – Single-valued

aws:username

Use this key to compare the requester's user name with the user name that you specify in the policy. For details about how the information appears for different principals, see How to specify a principal. For specific examples of `principal` key values, see Principal key values.

- **Availability** – This key is always included in the request context for IAM users. Anonymous requests and requests that are made using the AWS account root user or IAM roles do not include this key. Requests made using IAM Identity Center credentials do not include this key in the context.
- **Data type** – String
- **Value type** – Single-valued

Properties of a role session

Use the following condition keys to compare properties of the role session at the time the session was generated. These condition keys are only available when a request is made by a principal with role session or federated user principal credentials. The values for these condition keys are embedded in the role's session token.

A role is a type of principal. You can also use the condition keys from the Properties of the principal section to evaluate the properties of a role when a role is making a request.

aws:AssumedRoot

Use this key to check whether the request was made using AssumeRoot. `AssumeRoot` returns short term credentials for a privileged root user session you can use to take privileged actions on member accounts in your organization. For more information, see Centrally manage root access for member accounts.

- **Availability** – This key is included in the request context only when the principal uses credentials from AssumeRoot to make the request.
- **Data type** – Boolean
- **Value type** – Single-valued

In the following example, when used as a service control policy, denies the usage of the long term credentials of a root user in an AWS Organizations member account. The policy does not deny `AssumeRoot` sessions from taking the actions allowed by an `AssumeRoot` session.

JSON

```
{
    "Version":"2012-10-17",
    "Statement":[
       {
          "Effect":"Deny",
          "Action":"*",
          "Resource": "*",
          "Condition":{
             "ArnLike":{
                "aws:PrincipalArn":[
                   "arn:aws:iam::*:root"
```

```
                ]
            },
            "Null":{
                "aws:AssumedRoot":"true"
            }
        }
    }
  ]
}
```

aws:FederatedProvider

Use this key to compare the principal's issuing identity provider (IdP) with the IdP that you specify in the policy. This means that an IAM role assumed using the `AssumeRoleWithWebIdentity` AWS STS operation. When the resulting role session's temporary credentials are used to make a request, the request context identifies the IdP that authenticated the original federated identity.

- **Availability** – This key is present in the role-session of a role that was assumed using OpenID Connect (OIDC) provider, and in the role-trust policy when an OIDC provider is used to call `AssumeRoleWithWebIdentity`.
- **Data type** – String*
- **Value type** – Single-valued

* The data type depends on your IdP:

- If you're using a built-in AWS IdP, like Amazon Cognito, the key value will be a **string**. The key value may look like: `cognito-identity.amazonaws.com`.
- If you're using an IdP that is not built-in to AWS, like GitHub or Amazon EKS, the key value will be **ARN**. The key value may look like: `arn:aws:iam::`*`111122223333`*`:oidc-provider/oidc.eks.`*`region`*`.amazonaws.com/id/`*`OIDC_Provider_ID`*.

For more information on external IdPs and `AssumeRoleWithWebIDentity`, see Common scenarios. For more information, see Role session principals.

aws:TokenIssueTime

Use this key to compare the date and time that temporary security credentials were issued with the date and time that you specify in the policy.

- **Availability** – This key is included in the request context only when the principal uses temporary credentials to make the request. The key is not present in AWS CLI, AWS API, or AWS SDK requests that are made using access keys.
- **Data type** – Date
- **Value type** – Single-valued

To learn which services support using temporary credentials, see AWS services that work with IAM.

aws:MultiFactorAuthAge

Use this key to compare the number of seconds since the requesting principal was authorized using MFA with the number that you specify in the policy. For more information about MFA, see AWS Multi-factor authentication in IAM.

> **Important**
>
> This condition key is not present for federated identities or requests made using access keys to sign AWS CLI, AWS API, or AWS SDK requests. To learn more about adding MFA protection to API operations with temporary security credentials, see Secure API access with MFA.
>
> To check whether MFA is used to validate IAM federated identities, you can pass the authentication method from your identity provider to AWS as a session tag. For details, see Pass session tags in AWS STS. To enforce MFA for IAM Identity Center identities, you can enable attributes for access control to pass a SAML assertion claim with the authentication method from your identity provider to IAM Identity Center.

- **Availability** – This key is included in the request context only when the principal uses temporary security credentials to make the request. Policies with MFA conditions can be attached to:
  - An IAM user or group
  - A resource such as an Amazon S3 bucket, Amazon SQS queue, or Amazon SNS topic
  - The trust policy of an IAM role that can be assumed by a user
- **Data type** – Numeric
- **Value type** – Single-valued

aws:MultiFactorAuthPresent

Use this key to check whether multi-factor authentication (MFA) was used to validate the temporary security credentials that made the request.

> **Important**
>
> This condition key is not present for federated identities or requests made using access keys to sign AWS CLI, AWS API, or AWS SDK requests. To learn more about adding MFA protection to API operations with temporary security credentials, see Secure API access with MFA.
>
> To check whether MFA is used to validate IAM federated identities, you can pass the authentication method from your identity provider to AWS as a session tag. For details, see Pass session tags in AWS STS. To enforce MFA for IAM Identity Center identities, you can enable attributes for access control to pass a SAML assertion claim with the authentication method from your identity provider to IAM Identity Center.

- **Availability** – This key is included in the request context only when the principal uses temporary credentials to make the request. Policies with MFA conditions can be attached to:
  - An IAM user or group
  - A resource such as an Amazon S3 bucket, Amazon SQS queue, or Amazon SNS topic
  - The trust policy of an IAM role that can be assumed by a user
- **Data type** – Boolean
- **Value type** – Single-valued

Temporary credentials are used to authenticate IAM roles and IAM users with temporary tokens from AssumeRole or GetSessionToken, and users of the AWS Management Console.

IAM user access keys are long-term credentials, but in some cases, AWS creates temporary credentials on behalf of IAM users to perform operations. In these cases, the `aws:MultiFactorAuthPresent` key is present in the request and set to a value of `false`. There are two common cases where this can happen:

- IAM users in the AWS Management Console unknowingly use temporary credentials. Users sign into the console using their user name and password, which are long-term credentials. However, in the background, the console generates temporary credentials on behalf of the user.

- If an IAM user makes a call to an AWS service, the service re-uses the user's credentials to make another request to a different service. For example, when calling Athena to access an Amazon S3 bucket, or when using AWS CloudFormation to create an Amazon EC2 instance. For the subsequent request, AWS uses temporary credentials.

To learn which services support using temporary credentials, see AWS services that work with IAM.

The `aws:MultiFactorAuthPresent` key is not present when an API or CLI command is called with long-term credentials, such as user access key pairs. Therefore we recommend that when you check for this key that you use the `...IfExists` versions of the condition operators.

It is important to understand that the following `Condition` element is ***not*** a reliable way to check whether a request is authenticated using MFA.

```
#####   WARNING: NOT RECOMMENDED   #####
"Effect" : "Deny",
"Condition" : { "Bool" : { "aws:MultiFactorAuthPresent" : "false" } }
```

This combination of the `Deny` effect, `Bool` element, and `false` value denies requests that can be authenticated using MFA, but were not. This applies only to temporary credentials that support using MFA. This statement does not deny access to requests that are made using long-term credentials, or to requests that are authenticated using MFA. Use this example with caution because its logic is complicated and it does not test whether MFA-authentication was actually used.

Also do not use the combination of the `Deny` effect, `Null` element, and `true` because it behaves the same way and the logic is even more complicated.

Recommended Combination

We recommend that you use the `BoolIfExists` operator to check whether a request is authenticated using MFA.

```
"Effect" : "Deny",
"Condition" : { "BoolIfExists" : { "aws:MultiFactorAuthPresent" : "false" } }
```

This combination of `Deny`, `BoolIfExists`, and `false` denies requests that are not authenticated using MFA. Specifically, it denies requests from temporary credentials that do not include MFA. It also denies requests that are made using long-term credentials, such as AWS CLI or AWS API

operations made using access keys. The `*IfExists` operator checks for the presence of the `aws:MultiFactorAuthPresent` key and whether or not it could be present, as indicated by its existence. Use this when you want to deny any request that is not authenticated using MFA. This is more secure, but can break any code or scripts that use access keys to access the AWS CLI or AWS API.

Alternative Combinations

You can also use the `BoolIfExists` operator to allow MFA-authenticated requests and AWS CLI or AWS API requests that are made using long-term credentials.

```
"Effect" : "Allow",
"Condition" : { "BoolIfExists" : { "aws:MultiFactorAuthPresent" : "true" } }
```

This condition matches either if the key exists and is present **or** if the key does not exist. This combination of `Allow`, `BoolIfExists`, and `true` allows requests that are authenticated using MFA, or requests that cannot be authenticated using MFA. This means that AWS CLI, AWS API, and AWS SDK operations are allowed when the requester uses their long-term access keys. This combination does not allow requests from temporary credentials that could, but do not include MFA.

When you create a policy using the IAM console visual editor and choose **MFA required**, this combination is applied. This setting requires MFA for console access, but allows programmatic access with no MFA.

Alternatively, you can use the `Bool` operator to allow programmatic and console requests only when authenticated using MFA.

```
"Effect" : "Allow",
"Condition" : { "Bool" : { "aws:MultiFactorAuthPresent" : "true" } }
```

This combination of the `Allow`, `Bool`, and `true` allows only MFA-authenticated requests. This applies only to temporary credentials that support using MFA. This statement does not allow access to requests that were made using long-term access keys, or to requests made using temporary credentials without MFA.

Do not use a policy construct similar to the following to check whether the MFA key is present:

```
#####   WARNING: USE WITH CAUTION   #####
```

```
"Effect" : "Allow",
"Condition" : { "Null" : { "aws:MultiFactorAuthPresent" : "false" } }
```

This combination of the `Allow` effect, `Null` element, and `false` value allows only requests that can be authenticated using MFA, regardless of whether the request is actually authenticated. This allows all requests that are made using temporary credentials, and denies access for long-term credentials. Use this example with caution because it does not test whether MFA-authentication was actually used.

aws:ChatbotSourceArn

Use this key to compare the source chat configuration ARN set by the principal to the chat configuration ARN you specify in the policy of the IAM role associated with your channel configuration. You can authorize requests based on the assume role session initiated by Amazon Q Developer in chat applications.

- **Availability** – This key is included in the request context by the Amazon Q Developer in chat applications service whenever a role session is assumed. The key value is the chat configuration ARN, such as when you run an AWS CLI command from a chat channel.
- **Data type** – ARN
- **Value type** – Single-valued
- **Example value** – `arn:aws::chatbot::123456789021:chat-configuration/slack-channel/private_channel`

The following policy denies Amazon S3 put requests on the specified bucket for all requests originating from a Slack channel.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ExampleS3Deny",
            "Effect": "Deny",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
```

```
            "Condition": {
                "ArnLike": {
                      "aws:ChatbotSourceArn": "arn:aws:chatbot::*:chat-
configuration/slack-channel/*"
                }
            }
        }
    ]
}
```

aws:Ec2InstanceSourceVpc

This key identifies the VPC to which Amazon EC2 IAM role credentials were delivered to. You can use this key in a policy with the `aws:SourceVPC` global key to check if a call is made from a VPC (`aws:SourceVPC`) that matches the VPC where a credential was delivered to (`aws:Ec2InstanceSourceVpc`).

- **Availability** – This key is included in the request context whenever the requester is signing requests with an Amazon EC2 role credential. It can be used in IAM policies, service control policies, VPC endpoint policies, and resource policies.
- **Data type** – String
- **Value type** – Single-valued

This key can be used with VPC identifier values, but is most useful when used as a variable combined with the `aws:SourceVpc` context key. The `aws:SourceVpc` context key is included in the request context only if the requester uses a VPC endpoint to make the request. Using `aws:Ec2InstanceSourceVpc` with `aws:SourceVpc` allows you to use `aws:Ec2InstanceSourceVpc` more broadly since it compares values that typically change together.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RequireSameVPC",
      "Effect": "Deny",
```

```
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
            "aws:SourceVpc": "${aws:Ec2InstanceSourceVpc}"
        },
        "Null": {
          "ec2:SourceInstanceARN": "false"
        },
        "BoolIfExists": {
          "aws:ViaAWSService": "false"
        }
      }
    }
  ]
}
```

In the example above, access is denied if the `aws:SourceVpc` value isn't equal to the `aws:Ec2InstanceSourceVpc` value. The policy statement is limited to only roles used as Amazon EC2 instance roles by testing for the existence of the `ec2:SourceInstanceARN` condition key.

The policy uses `aws:ViaAWSService` to allow AWS to authorize requests when requests are made on behalf of your Amazon EC2 instance roles. For example, when you make a request from an Amazon EC2 instance to an encrypted Amazon S3 bucket, Amazon S3 makes a call to AWS KMS on your behalf. Some of the keys are not present when the request is made to AWS KMS.

aws:Ec2InstanceSourcePrivateIPv4

This key identifies the private IPv4 address of the primary elastic network interface to which Amazon EC2 IAM role credentials were delivered. You must use this condition key with its companion key `aws:Ec2InstanceSourceVpc` to ensure that you have a globally unique combination of VPC ID and source private IP. Use this key with `aws:Ec2InstanceSourceVpc` to ensure that a request was made from the same private IP address that the credentials were delivered to.

- **Availability** – This key is included in the request context whenever the requester is signing requests with an Amazon EC2 role credential. It can be used in IAM policies, service control policies, VPC endpoint policies, and resource policies.
- **Data type** – IP address

- **Value type** – Single-valued

> **Important**
>
> This key should not be used alone in an `Allow` statement. Private IP addresses are by definition not globally unique. You should use the `aws:Ec2InstanceSourceVpc` key every time you use the `aws:Ec2InstanceSourcePrivateIPv4` key to specify the VPC your Amazon EC2 instance credentials can be used from.

The following example is a service control policy (SCP) that denies access to all resources unless the request arrives via a VPC Endpoint in the same VPC as the as the role credentals. In this example, `aws:Ec2InstanceSourcePrivateIPv4` limits the credential source to a particular instance based on the source IP.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action":  "*",
            "Resource": "*",
            "Condition": {
                "StringNotEquals": {
                    "aws:Ec2InstanceSourceVpc": "${aws:SourceVpc}"
                },
                "Null": {
                    "ec2:SourceInstanceARN": "false"
                },
                "BoolIfExists": {
                    "aws:ViaAWSService": "false"
                }
            }
        },
        {
            "Effect": "Deny",
            "Action":  "*",
            "Resource": "*",
```

```
            "Condition": {
                "StringNotEquals": {
                    "aws:Ec2InstanceSourcePrivateIPv4": "${aws:VpcSourceIp}"
                },
                "Null": {
                    "ec2:SourceInstanceARN": "false"
                },
                "BoolIfExists": {
                    "aws:ViaAWSService": "false"
                }
            }
        }
    ]
}
```

aws:SourceIdentity

Use this key to compare the source identity that was set by the principal with the source identity that you specify in the policy.

- **Availability** – This key is included in the request context after a source identity has been set when a role is assumed using any AWS STS assume-role CLI command, or AWS STS `AssumeRole` API operation.
- **Data type** – String
- **Value type** – Single-valued

You can use this key in a policy to allow actions in AWS by principals that have set a source identity when assuming a role. Activity for the role's specified source identity appears in AWS CloudTrail. This makes it easier for administrators to determine who or what performed actions with a role in AWS.

Unlike `sts:RoleSessionName`, after the source identity is set, the value cannot be changed. It is present in the request context for all actions taken by the role. The value persists into subsequent role sessions when you use the session credentials to assume another role. Assuming one role from another is called role chaining.

The `sts:SourceIdentity` key is present in the request when the principal initially sets a source identity while assuming a role using any AWS STS assume-role CLI command, or AWS STS

`AssumeRole` API operation. The `aws:SourceIdentity` key is present in the request for any actions that are taken with a role session that has a source identity set.

The following role trust policy for `CriticalRole` in account `111122223333` contains a condition for `aws:SourceIdentity` that prevents a principal without a source identity that is set to Saanvi or Diego from assuming the role.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AssumeRoleIfSourceIdentity",
            "Effect": "Allow",
            "Principal": {"AWS": "arn:aws:iam::123456789012:role/CriticalRole"},
            "Action": [
                "sts:AssumeRole",
                "sts:SetSourceIdentity"
            ],
            "Condition": {
                "StringLike": {
                    "aws:SourceIdentity": ["Saanvi","Diego"]
                }
            }
        }
    ]
}
```

To learn more about using source identity information, see Monitor and control actions taken with assumed roles.

ec2:RoleDelivery

Use this key to compare the version of the instance metadata service in the signed request with the IAM role credentials for Amazon EC2. The instance metadata service distinguishes between IMDSv1 and IMDSv2 requests based on whether, for any given request, either the PUT or GET headers, which are unique to IMDSv2, are present in that request.

- **Availability** – This key is included in the request context whenever the role session is created by an Amazon EC2 instance.
- **Data type** – Numeric
- **Value type** – Single-valued
- **Example values** – 1.0, 2.0

You can configure the Instance Metadata Service (IMDS) on each instance so that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works.

- Instance Metadata Service Version 1 (IMDSv1) – A request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

For information about how to configure your instance to use IMDSv2, see Configure the instance metadata options.

In the following example, access is denied if the ec2:RoleDelivery value in the request context is 1.0 (IMDSv1). This policy statement can be applied generally because, if the request is not signed by Amazon EC2 role credentials, it has no effect.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
                {
            "Sid": "RequireAllEc2RolesToUseV2",
            "Effect": "Deny",
            "Action": "*",
            "Resource": "*",
            "Condition": {
                "NumericLessThan": {
                    "ec2:RoleDelivery": "2.0"
                }
            }
        }
    ]
}
```

For more information, see Example policies for working with instance metadata.

ec2:SourceInstanceArn

Use this key to compare the ARN of the instance from which the role's session was generated.

- **Availability** – This key is included in the request context whenever the role session is created by an Amazon EC2 instance.
- **Data type** – ARN
- **Value type** – Single-valued
- **Example value** – arn:aws::ec2:us-west-2:111111111111:instance/instance-id

For policy examples, see Allow a specific instance to view resources in other AWS services.

glue:RoleAssumedBy

The AWS Glue service sets this condition key for each AWS API request where AWS Glue makes a request using a service role on the customer's behalf (not by a job or developer endpoint, but directly by the AWS Glue service). Use this key to verify whether a call to an AWS resource came from the AWS Glue service.

- **Availability** – This key is included in the request context when AWS Glue makes a request using a service role on the customer's behalf.
- **Data type** – String
- **Value type** – Single-valued
- **Example value** – This key is always set to `glue.amazonaws.com`.

The following example adds a condition to allow the AWS Glue service to get an object from an Amazon S3 bucket.

```
{
    "Effect": "Allow",
    "Action": "s3:GetObject",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "Condition": {
        "StringEquals": {
            "glue:RoleAssumedBy": "glue.amazonaws.com"
        }
    }
```

```
}
```

glue:CredentialIssuingService

The AWS Glue service sets this key for each AWS API request using a service role that comes from a job or developer endpoint. Use this key to verify whether a call to an AWS resource came from an AWS Glue job or developer endpoint.

- **Availability** – This key is included in the request context when AWS Glue makes a request that comes from a job or developer endpoint.
- **Data type** – String
- **Value type** – Single-valued
- **Example value** – This key is always set to `glue.amazonaws.com`.

The following example adds a condition that is attached to an IAM role that is used by an AWS Glue job. This ensures certain actions are allowed/denied based on whether the role session is used for an AWS Glue job runtime environment.

```
{
    "Effect": "Allow",
    "Action": "s3:GetObject",
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
    "Condition": {
        "StringEquals": {
            "glue:CredentialIssuingService": "glue.amazonaws.com"
        }
    }
}
```

lambda:SourceFunctionArn

Use this key to identify the Lambda function ARN that IAM role credentials were delivered to. The Lambda service sets this key for each AWS API request that comes from your function's execution environment. Use this key to verify whether a call to an AWS resource came from a specific Lambda function's code. Lambda also sets this key for some requests that come from outside the execution environment, such as writing logs to CloudWatch and sending traces to X-Ray.

- **Availability** – This key is included in the request context whenever Lambda function code is invoked.

- **Data type** – ARN
- **Value type** – Single-valued
- **Example value** – arn:aws:lambda:us-east-1:123456789012:function:TestFunction

The following example allows one specific Lambda function to have `s3:PutObject` access the specified bucket.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ExampleSourceFunctionArn",
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*",
            "Condition": {
                "ArnEquals": {
                    "lambda:SourceFunctionArn": "arn:aws:lambda:us-
east-1:123456789012:function:source_lambda"
                }
            }
        }
    ]
}
```

For more information, see Working with Lambda execution environment credentials in the *AWS Lambda Developer Guide*.

ssm:SourceInstanceArn

Use this key to identify the AWS Systems Manager managed instance ARN that IAM role credentials were delivered to. This condition key is not present when the request comes from a managed instance with an IAM role associated with an Amazon EC2 instance profile.

- **Availability** – This key is included in the request context whenever role credentials are delivered to an AWS Systems Manager managed instance.
- **Data type** – ARN

- **Value type** – Single-valued
- **Example value** – arn:aws::ec2:us-west-2:111111111111:instance/instance-id

identitystore:UserId

Use this key to compare IAM Identity Center workforce identity in the signed request with the identity specified in the policy.

- **Availability** – This key is included when the caller of the request is a user in IAM Identity Center.
- **Data type** – String
- **Value type** – Single-valued
- **Example value** – 94482488-3041-7026-18f3-be45837cd0e4

You can find the UserId of a user in IAM Identity Center by making a request to the GetUserId API using the AWS CLI, AWS API, or AWS SDK.

Properties of the network

Use the following condition keys to compare details about the network that the request originated from or passed through with the network properties that you specify in the policy.

aws:SourceIp

Use this key to compare the requester's IP address with the IP address that you specify in the policy. The `aws:SourceIp` condition key can only be used for public IP address ranges.

- **Availability** – This key is included in the request context, except when the requester uses a VPC endpoint to make the request.
- **Data type** – IP address
- **Value type** – Single-valued

The `aws:SourceIp` condition key can be used in a policy to allow principals to make requests only from within a specified IP range.

> **Note**
>
> `aws:SourceIp` supports both IPv4 and IPv6 address or range of IP addresses. For a list of AWS services that support IPv6, see AWS services that support IPv6 in the *Amazon VPC User Guide*.

For example, you can attach the following identity-based policy to an IAM role. This policy allows the user to put objects into the `amzn-s3-demo-bucket3` Amazon S3 bucket if they make the call from the specified IPv4 address range. This policy also allows an AWS service that uses Forward access sessions to perform this operation on your behalf.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PrincipalPutObjectIfIpAddress",
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket3/*",
            "Condition": {
                "IpAddress": {
                    "aws:SourceIp": "203.0.113.0/24"
                }
            }
        }
    ]
}
```

If you need to restrict access from networks that support both IPv4 and IPv6 addressing, you can include the IPv4 and IPv6 address or ranges of IP addresses in the IAM policy condition. The following identity-based policy will allow the user to put objects into the `amzn-s3-demo-bucket3` Amazon S3 bucket if the user makes the call from either specified IPv4 or IPv6 address ranges. Before you include IPv6 address ranges in your IAM policy, verify that the AWS service you are working with supports IPv6. For a list of AWS services that support IPv6, see AWS services that support IPv6 in the *Amazon VPC User Guide*.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PrincipalPutObjectIfIpAddress",
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket3/*",
            "Condition": {
                "IpAddress": {
                    "aws:SourceIp": [
                        "203.0.113.0/24",
                        "2001:DB8:1234:5678::/64"
                    ]
                }
            }
        }
    ]
}
```

If the request comes from a host that uses an Amazon VPC endpoint, then the `aws:SourceIp` key is not available. You should instead use a VPC-specific key such as aws:VpcSourceIp. For more information about using VPC endpoints, see Identity and access management for VPC endpoints and VPC endpoint services in the *AWS PrivateLink Guide*.

> **Note**
>
> When AWS services make calls to other AWS services on your behalf (service-to-service calls), certain network-specific authorization context is redacted. If your policy uses this condition key with `Deny` statements, AWS service principals might be unintentionally blocked. To allow AWS services to work properly while maintaining your security requirements, exclude service principals from your `Deny` statements by adding the `aws:PrincipalIsAWSService` condition key with a value of `false`.

aws:SourceVpc

Use this key to check whether the request travels through the VPC that the VPC endpoint is attached to. In a policy, you can use this key to allow access to only a specific VPC. For more information, see Restricting Access to a Specific VPC in the *Amazon Simple Storage Service User Guide*.

- **Availability** – This key is included in the request context only if the requester uses a VPC endpoint to make the request.
- **Data type** – String
- **Value type** – Single-valued

In a policy, you can use this key to allow or restrict access to a specific VPC.

For example, you can attach the following identity-based policy to an IAM role to deny `PutObject` to the `amzn-s3-demo-bucket3` Amazon S3 bucket, unless the request is made from the specified VPC ID or by AWS services that use forward access sessions (FAS) to make requests on behalf of the role. Unlike with aws:SourceIp, you must use aws:ViaAWSService or aws:CalledVia to allow FAS requests, because the source VPC of the initial request is not preserved.

> **Note**
>
> This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PutObjectIfNotVPCID",
      "Effect": "Deny",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket3/*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceVpc": "vpc-1234567890abcdef0"
```

```
        },
        "Bool": {
          "aws:ViaAWSService": "false"
        }
      }
    }
  ]
}
```

For an example of how to apply this key in a resource-based policy, see Restricting access to a specific VPC in the *Amazon Simple Storage Service User Guide*.

aws:SourceVpce

Use this key to compare the VPC endpoint identifier of the request with the endpoint ID that you specify in the policy.

- **Availability** – This key is included in the request context only if the requester uses a VPC endpoint to make the request.
- **Data type** – String
- **Value type** – Single-valued

In a policy, you can use this key to restrict access to a specific VPC endpoint. For more information, see Restricting access to a specific VPC in the *Amazon Simple Storage Service User Guide*. Similarly to using aws:SourceVpc, you must use aws:ViaAWSService or aws:CalledVia to allow requests made by AWS services using forward access sessions (FAS). This is because the source VPC endpoint of the initial request is not preserved.

aws:VpceAccount

Use this key to compare the AWS account ID that owns the VPC endpoint through which the request was made with the account ID that you specify in the policy. This condition key helps you establish network perimeter controls by ensuring requests come through VPC endpoints owned by specific accounts.

- **Availability** – This key is included in the request context when a request is made through a VPC endpoint. The key is not included for requests made through public service endpoints.

  The following services support this key:

- AWS App Runner (prefix: `apprunner`)
- AWS Application Discovery Service (prefix: `discovery`)
- Amazon Athena (prefix: `athena`)
- AWS Cloud Map (prefix: `servicediscovery`)
- Amazon CloudWatch Application Insights (prefix: `applicationinsights`)
- AWS CloudFormation (prefix: `cloudformation`)
- Amazon Comprehend Medical (prefix: `comprehendmedical`)
- AWS Compute Optimizer (prefix: `compute-optimizer`)
- AWS DataSync (prefix: `datasync`)
- Amazon Elastic Block Store (prefix: `ebs`)
- Amazon EventBridge Scheduler (prefix: `scheduler`)
- Amazon Data Firehose (prefix: `firehose`)
- AWS HealthImaging (prefix: `medical-imaging`)
- AWS HealthLake (prefix: `healthlake`)
- AWS HealthOmics (prefix: `omics`)
- AWS Identity and Access Management (except for the `iam:PassRole` action) (prefix: `iam`)
- AWS IoT FleetWise (prefix: `iotfleetwise`)
- AWS IoT Wireless (prefix: `iotwireless`)
- AWS Key Management Service (prefix: `kms`)
- AWS Lambda (prefix: `lambda`)
- AWS Payment Cryptography (prefix: `payment-cryptography`)
- Amazon Polly (prefix: `polly`)
- AWS Private Certificate Authority (prefix: `acm-pca`)
- AWS Recycle Bin (prefix: `rbin`)
- Amazon Rekognition (prefix: `rekognition`)
- Service Quotas (prefix: `servicequotas`)
- Amazon Simple Storage Service (prefix: `s3`)
- AWS Storage Gateway (prefix: `storagegateway`)
- AWS Systems Manager Incident Manager Contacts (prefix: `ssm-contacts`)
- Amazon Textract (prefix: `textract`)

- Amazon Transcribe (prefix: `transcribe`)
- AWS Transfer Family (prefix: `transfer`)

- **Data type** – String
- **Value type** – Single-valued
- **Example value** – `123456789012`

You can use this condition key to restrict access to resources so that requests must come through VPC endpoints owned by your account. The following Amazon S3 bucket policy example allows access when the request comes through a VPC endpoint owned by the specified account:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToSpecificVpceAccountOnly",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/RoleName"
      },
      "Action": "s3:GetObject",
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
      "Condition": {
        "StringEquals": {
          "aws:VpceAccount": "111122223333"
        }
      }
    }
  ]
}
```

Note

This condition key is currently supported for a select set of AWS services. Using this key with unsupported services can lead to unintended authorization results. Always scope the condition key to supported services in your policies.

Some AWS services access your resources from their networks when they act on your behalf. If you use such services, you will need to edit the above policy example to allow AWS services access

your resources from outside your network. For more information on access patterns that need to be accounted for when enforcing access controls based on the request origin, see Establish permissions guardrails using data perimeters.

aws:VpceOrgID

Use this key to compare the identifier of the organization in AWS Organizations that owns the VPC endpoint from which the request was made with the identifier that you specify in the policy. This condition key provides the most scalable approach to network perimeter controls, automatically including all VPC endpoints owned by accounts within your organization.

- **Availability** – This key is included in the request context when a request is made through a VPC endpoint and the VPC endpoint owner account is a member of an AWS organization. The key is not included for requests made through other network paths or when the VPC endpoint owner account is not part of an organization.

  The following services support this key:

  - AWS App Runner (prefix: `apprunner`)
  - AWS Application Discovery Service (prefix: `discovery`)
  - Amazon Athena (prefix: `athena`)
  - AWS Cloud Map (prefix: `servicediscovery`)
  - Amazon CloudWatch Application Insights (prefix: `applicationinsights`)
  - AWS CloudFormation (prefix: `cloudformation`)
  - Amazon Comprehend Medical (prefix: `comprehendmedical`)
  - AWS Compute Optimizer (prefix: `compute-optimizer`)
  - AWS DataSync (prefix: `datasync`)
  - Amazon Elastic Block Store (prefix: `ebs`)
  - Amazon EventBridge Scheduler (prefix: `scheduler`)
  - Amazon Data Firehose (prefix: `firehose`)
  - AWS HealthImaging (prefix: `medical-imaging`)
  - AWS HealthLake (prefix: `healthlake`)
  - AWS HealthOmics (prefix: `omics`)
  - AWS Identity and Access Management (except for the `iam:PassRole` action) (prefix: `iam`)
  - AWS IoT FleetWise (prefix: `iotfleetwise`)

- AWS IoT Wireless (prefix: `iotwireless`)
- AWS Key Management Service (prefix: `kms`)
- AWS Lambda (prefix: `lambda`)
- AWS Payment Cryptography (prefix: `payment-cryptography`)
- Amazon Polly (prefix: `polly`)
- AWS Private Certificate Authority (prefix: `acm-pca`)
- AWS Recycle Bin (prefix: `rbin`)
- Amazon Rekognition (prefix: `rekognition`)
- Service Quotas (prefix: `servicequotas`)
- Amazon Simple Storage Service (prefix: `s3`)
- AWS Storage Gateway (prefix: `storagegateway`)
- AWS Systems Manager Incident Manager Contacts (prefix: `ssm-contacts`)
- Amazon Textract (prefix: `textract`)
- Amazon Transcribe (prefix: `transcribe`)
- AWS Transfer Family (prefix: `transfer`)

- **Data type** – String
- **Value type** – Single-valued
- **Example values** – `o-a1b2c3d4e5`

The following resource control policy example denies access to your Amazon S3 and AWS Key Management Service resources unless the request comes through VPC endpoints owned by the specified organization or from networks of AWS services that act on your behalf. Some organizations may need to further edit this policy to meet the needs of their organization, for example, allow third-party partner access. For more information on access patterns that need to be accounted for when enforcing access controls based on the request origin, see Establish permissions guardrails using data perimeters.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceNetworkPerimeterVpceOrgID",
      "Effect": "Deny",
      "Principal": "*",
```

```
      "Action": [
        "s3:*",
        "kms:*"
      ],
      "Resource": "*",
      "Condition": {
        "BoolIfExists": {
          "aws:PrincipalIsAWSService": "false",
          "aws:ViaAWSService": "false"
        },
        "StringNotEqualsIfExists": {
          "aws:VpceOrgID": "o-abcdef0123",
          "aws:PrincipalTag/network-perimeter-exception": "true"
        }
      }
    }
  ]
}
```

> **Note**
>
> This condition key is currently supported for a select set of AWS services. Using this key with unsupported services can lead to unintended authorization results. Always scope the condition key to supported services in your policies.

aws:VpceOrgPaths

Use this key to compare the AWS Organizations path for the VPC endpoint from which the request was made with the path that you specify in the policy. This condition key enables you to implement network perimeter controls at the organizational unit (OU) level, automatically scaling with your VPC endpoint usage as you add new endpoints within the specified OUs.

- **Availability** – This key is included in the request context when a request is made through a VPC endpoint and the VPC endpoint owner account is a member of an organization. The key is not included for requests made through other network paths or when the VPC endpoint owner account is not part of an organization.

  The following services support this key:

  - AWS App Runner (prefix: `apprunner`)

- AWS Application Discovery Service (prefix: `discovery`)
- Amazon Athena (prefix: `athena`)
- AWS Cloud Map (prefix: `servicediscovery`)
- Amazon CloudWatch Application Insights (prefix: `applicationinsights`)
- AWS CloudFormation (prefix: `cloudformation`)
- Amazon Comprehend Medical (prefix: `comprehendmedical`)
- AWS Compute Optimizer (prefix: `compute-optimizer`)
- AWS DataSync (prefix: `datasync`)
- Amazon Elastic Block Store (prefix: `ebs`)
- Amazon EventBridge Scheduler (prefix: `scheduler`)
- Amazon Data Firehose (prefix: `firehose`)
- AWS HealthImaging (prefix: `medical-imaging`)
- AWS HealthLake (prefix: `healthlake`)
- AWS HealthOmics (prefix: `omics`)
- AWS Identity and Access Management (except for the `iam:PassRole` action) (prefix: `iam`)
- AWS IoT FleetWise (prefix: `iotfleetwise`)
- AWS IoT Wireless (prefix: `iotwireless`)
- AWS Key Management Service (prefix: `kms`)
- AWS Lambda (prefix: `lambda`)
- AWS Payment Cryptography (prefix: `payment-cryptography`)
- Amazon Polly (prefix: `polly`)
- AWS Private Certificate Authority (prefix: `acm-pca`)
- AWS Recycle Bin (prefix: `rbin`)
- Amazon Rekognition (prefix: `rekognition`)
- Service Quotas (prefix: `servicequotas`)
- Amazon Simple Storage Service (prefix: `s3`)
- AWS Storage Gateway (prefix: `storagegateway`)
- AWS Systems Manager Incident Manager Contacts (prefix: `ssm-contacts`)
- Amazon Textract (prefix: `textract`)
- Amazon Transcribe (prefix: `transcribe`)

  - AWS Transfer Family (prefix: `transfer`)
- **Data type** – String (list)
- **Value type** – Multivalued
- **Example values** – `o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/`

Since `aws:VpceOrgPaths` is a multivalued condition key, you must use the `ForAnyValue` or `ForAllValues` set operators with string condition operators for this key. The following Amazon S3 bucket policy example allows access only when requests come through VPC endpoints owned by accounts in specific organizational units:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessFromSpecificOrgPaths",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/RoleName"
      },
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket1/*",
      "Condition": {
        "ForAnyValue:StringLike": {
          "aws:VpceOrgPaths": [
            "o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/*",
            "o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-33333333/*"
          ]
        }
      }
    }
  ]
}
```

Note

This condition key is currently supported for a select set of AWS services. Using this key with unsupported services can lead to unintended authorization results. Always scope the condition key to supported services in your policies.

Some AWS services access your resources from their networks when they act on your behalf. If you use such services, you will need to edit the above policy example to allow AWS services access your resources from outside your network. For more information on access patterns that need to be accounted for when enforcing access controls based on the request origin, see Establish permissions guardrails using data perimeters.

aws:VpcSourceIp

Use this key to compare the IP address from which a request was made with the IP address that you specify in the policy. In a policy, the key matches only if the request originates from the specified IP address and it goes through a VPC endpoint.

- **Availability** – This key is included in the request context only if the request is made using a VPC endpoint.
- **Data type** – IP address
- **Value type** – Single-valued

For more information, see Control access to VPC endpoints using endpoint policies in the *Amazon VPC User Guide*. Similarly to using aws:SourceVpc, you must use aws:ViaAWSService or aws:CalledVia to allow requests made by AWS services using forward access sessions (FAS). This is because the source IP of the initial request made using a VPC endpoint is not preserved in FAS requests.

Note

`aws:VpcSourceIp` supports both IPv4 and IPv6 address or range of IP addresses. For a list of AWS services that support IPv6, see AWS services that support IPv6 in the *Amazon VPC User Guide*.

The `aws:VpcSourceIp` condition key should always be used in conjunction with either the `aws:SourceVpc` or the `aws:SourceVpce` condition keys. Otherwise, it is possible for API calls from an unexpected VPC that uses the same or overlapping IP CIDR to be permitted by a policy. This can occur because the IP CIDRs from the two unrelated VPCs can be the same or overlap. Instead, VPC IDs or VPC Endpoints IDs should be used in the policy as they have globally unique identifiers. These unique identifiers ensure that unexpected results will not occur.

Note

When AWS services make calls to other AWS services on your behalf (service-to-service calls), certain network-specific authorization context is redacted. If your policy uses this condition key with `Deny` statements, AWS service principals might be unintentionally blocked. To allow AWS services to work properly while maintaining your security requirements, exclude service principals from your `Deny` statements by adding the `aws:PrincipalIsAWSService` condition key with a value of `false`.

Properties of the resource

Use the following condition keys to compare details about the resource that is the target of the request with the resource properties that you specify in the policy.

aws:ResourceAccount

Use this key to compare the requested resource owner's AWS account ID with the resource account in the policy. You can then allow or deny access to that resource based on the account that owns the resource.

- **Availability** – This key is always included in the request context for most service actions. The following actions don't support this key:
  - AWS Audit Manager
    - `auditmanager:UpdateAssessmentFrameworkShare`
  - Amazon Detective
    - `detective:AcceptInvitation`
  - AWS Directory Service
    - `ds:AcceptSharedDirectory`
  - Amazon Elastic Block Store – All actions
  - Amazon EC2
    - `ec2:AcceptTransitGatewayPeeringAttachment`
    - `ec2:AcceptVpcEndpointConnections`
    - `ec2:AcceptVpcPeeringConnection`
    - `ec2:CopySnapshot`

    - `ec2:CreateTransitGatewayPeeringAttachment`
    - `ec2:CreateVpcEndpoint`
    - `ec2:CreateVpcPeeringConnection`
    - `ec2:DeleteTransitGatewayPeeringAttachment`
    - `ec2:DeleteVpcPeeringConnection`
    - `ec2:RejectTransitGatewayPeeringAttachment`
    - `ec2:RejectVpcEndpointConnections`
    - `ec2:RejectVpcPeeringConnection`
- Amazon EventBridge
    - `events:PutEvents` – EventBridge `PutEvents` calls on an event bus in another account, if that event bus was configured as a cross-account EventBridge target before March 2, 2023. For more information, see Grant permissions to allow events from other AWS accounts in the *Amazon EventBridge User Guide*.
- Amazon GuardDuty
    - `guardduty:AcceptAdministratorInvitation`
- Amazon Macie
    - `macie2:AcceptInvitation`
- Amazon OpenSearch Service
    - `es:AcceptInboundConnection`
- Amazon Route 53
    - `route53:AssociateVpcWithHostedZone`
    - `route53:CreateVPCAssociationAuthorization`
    - `route53:DeleteVPCAssociationAuthorization`
    - `route53:DisassociateVPCFromHostedZone`
    - `route53:ListHostedZonesByVPC`
- AWS Security Hub
    - `securityhub:AcceptAdministratorInvitation`
- **Data type** – String
- **Value type** – Single-valued

Note

For additional considerations for the above unsupported actions, see the Data Perimeter Policy Examples repository.

This key is equal to the AWS account ID for the account with the resources evaluated in the request.

For most resources in your account, the ARN contains the owner account ID for that resource. For certain resources, such as Amazon S3 buckets, the resource ARN does not include the account ID. The following two examples show the difference between a resource with an account ID in the ARN, and an Amazon S3 ARN without an account ID:

- `arn:aws:iam::123456789012:role/AWSExampleRole` – IAM role created and owned within the account 123456789012.
- `arn:aws:s3:::amzn-s3-demo-bucket2` – Amazon S3 bucket created and owned within the account `111122223333`, not displayed in the ARN.

Use the AWS console, or API, or CLI, to find all of your resources and corresponding ARNs.

You write a policy that denies permissions to resources based on the resource owner's account ID. For example, the following identity-based policy denies access to the *specified resource* if the resource does not belong to the *specified account*.

To use this policy, replace the *italicized placeholder text* with your account information.

Important

This policy does not allow any actions. Instead, it uses the `Deny` effect which explicitly denies access to all of the resources listed in the statement that do not belong to the listed account. Use this policy in combination with other policies that allow access to specific resources.

JSON

```
{
```

```
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyInteractionWithResourcesNotInSpecificAccount",
      "Action": "service:*",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:service:us-east-1:111122223333:*"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
            "111122223333"
          ]
        }
      }
    }
  ]
}
```

This policy denies access to all resources for a specific AWS service unless the specified AWS account owns the resource.

> **Note**
>
> Some AWS services require access to AWS owned resources that are hosted in another AWS account. Using `aws:ResourceAccount` in your identity-based policies might impact your identity's ability to access these resources.

Certain AWS services, such as AWS Data Exchange, rely on access to resources outside of your AWS accounts for normal operations. If you use the element `aws:ResourceAccount` in your policies, include additional statements to create exemptions for those services. The example policy AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange demonstrates how to deny access based on the resource account while defining exceptions for service-owned resources.

Use this policy example as a template for creating your own custom policies. Refer to your service documentation for more information.

aws:ResourceOrgPaths

Use this key to compare the AWS Organizations path for the accessed resource to the path in the policy. In a policy, this condition key ensures that the resource belongs to an account member within the specified organization root or organizational units (OUs) in AWS Organizations. An AWS Organizations path is a text representation of the structure of an Organizations entity. For more information about using and understanding paths, see Understand the AWS Organizations entity path

- **Availability** – This key is included in the request context only if the account that owns the resource is a member of an organization. This global condition key does not support the following actions:
  - AWS Audit Manager
    - `auditmanager:UpdateAssessmentFrameworkShare`
  - Amazon Detective
    - `detective:AcceptInvitation`
  - AWS Directory Service
    - `ds:AcceptSharedDirectory`
  - Amazon Elastic Block Store – All actions
  - Amazon EC2
    - `ec2:AcceptTransitGatewayPeeringAttachment`
    - `ec2:AcceptVpcEndpointConnections`
    - `ec2:AcceptVpcPeeringConnection`
    - `ec2:CopySnapshot`
    - `ec2:CreateTransitGatewayPeeringAttachment`
    - `ec2:CreateVpcEndpoint`
    - `ec2:CreateVpcPeeringConnection`
    - `ec2:DeleteTransitGatewayPeeringAttachment`
    - `ec2:DeleteVpcPeeringConnection`
    - `ec2:RejectTransitGatewayPeeringAttachment`
    - `ec2:RejectVpcEndpointConnections`
    - `ec2:RejectVpcPeeringConnection`
  - Amazon EventBridge

    - `events:PutEvents` – EventBridge `PutEvents` calls on an event bus in another account, if that event bus was configured as a cross-account EventBridge target before March 2, 2023. For more information, see Grant permissions to allow events from other AWS accounts in the *Amazon EventBridge User Guide*.
- Amazon GuardDuty
    - `guardduty:AcceptAdministratorInvitation`
- Amazon Macie
    - `macie2:AcceptInvitation`
- Amazon OpenSearch Service
    - `es:AcceptInboundConnection`
- Amazon Route 53
    - `route53:AssociateVpcWithHostedZone`
    - `route53:CreateVPCAssociationAuthorization`
    - `route53:DeleteVPCAssociationAuthorization`
    - `route53:DisassociateVPCFromHostedZone`
    - `route53:ListHostedZonesByVPC`
- AWS Security Hub
    - `securityhub:AcceptAdministratorInvitation`

- **Data type** – String (list)
- **Value type** – Multivalued

> **Note**
>
> For additional considerations for the above unsupported actions, see the Data Perimeter Policy Examples repository.

`aws:ResourceOrgPaths` is a multivalued condition key. Multivalued keys can have multiple values in the request context. You must use the `ForAnyValue` or `ForAllValues` set operators with string condition operators for this key. For more information about multivalued condition keys, see Set operators for multivalued context keys.

For example, the following condition returns `True` for resources that belong to the organization `o-a1b2c3d4e5`. When you include a wildcard, you must use the StringLike condition operator.

```
"Condition": {
      "ForAnyValue:StringLike": {
            "aws:ResourceOrgPaths":["o-a1b2c3d4e5/*"]
   }
}
```

The following condition returns `True` for resources with the OU ID `ou-ab12-11111111`. It will match resources owned by accounts attached to the OU ou-ab12-11111111 or any of the child OUs.

```
"Condition": { "ForAnyValue:StringLike" : {
     "aws:ResourceOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/*"]
}}
```

The following condition returns `True` for resources owned by accounts attached directly to the OU ID `ou-ab12-22222222`, but not the child OUs. The following example uses the StringEquals condition operator to specify the exact match requirement for the OU ID and not a wildcard match.

```
"Condition": { "ForAnyValue:StringEquals" : {
     "aws:ResourceOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/"]
}}
```

Note

Some AWS services require access to AWS owned resources that are hosted in another AWS account. Using `aws:ResourceOrgPaths` in your identity-based policies might impact your identity's ability to access these resources.

Certain AWS services, such as AWS Data Exchange, rely on access to resources outside of your AWS accounts for normal operations. If you use the `aws:ResourceOrgPaths` key in your policies, include additional statements to create exemptions for those services. The example policy AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange demonstrates how to deny access based on the resource account while defining exceptions for service-owned resources. You can create a similar policy to restrict access to resources within an

organizational unit (OU) using the `aws:ResourceOrgPaths` key, while accounting for service-owned resources.

Use this policy example as a template for creating your own custom policies. Refer to your service documentation for more information.

aws:ResourceOrgID

Use this key to compare the identifier of the organization in AWS Organizations to which the requested resource belongs with the identifier specified in the policy.

- **Availability** – This key is included in the request context only if the account that owns the resource is a member of an organization. This global condition key does not support the following actions:
  - AWS Audit Manager
    - `auditmanager:UpdateAssessmentFrameworkShare`
  - Amazon Detective
    - `detective:AcceptInvitation`
  - AWS Directory Service
    - `ds:AcceptSharedDirectory`
  - Amazon Elastic Block Store – All actions
  - Amazon EC2
    - `ec2:AcceptTransitGatewayPeeringAttachment`
    - `ec2:AcceptVpcEndpointConnections`
    - `ec2:AcceptVpcPeeringConnection`
    - `ec2:CopySnapshot`
    - `ec2:CreateTransitGatewayPeeringAttachment`
    - `ec2:CreateVpcEndpoint`
    - `ec2:CreateVpcPeeringConnection`
    - `ec2:DeleteTransitGatewayPeeringAttachment`
    - `ec2:DeleteVpcPeeringConnection`
    - `ec2:RejectTransitGatewayPeeringAttachment`
    - `ec2:RejectVpcEndpointConnections`
    - `ec2:RejectVpcPeeringConnection`

- Amazon EventBridge
  - `events:PutEvents` – EventBridge `PutEvents` calls on an event bus in another account, if that event bus was configured as a cross-account EventBridge target before March 2, 2023. For more information, see Grant permissions to allow events from other AWS accounts in the *Amazon EventBridge User Guide*.
- Amazon GuardDuty
  - `guardduty:AcceptAdministratorInvitation`
- Amazon Macie
  - `macie2:AcceptInvitation`
- Amazon OpenSearch Service
  - `es:AcceptInboundConnection`
- Amazon Route 53
  - `route53:AssociateVpcWithHostedZone`
  - `route53:CreateVPCAssociationAuthorization`
  - `route53:DeleteVPCAssociationAuthorization`
  - `route53:DisassociateVPCFromHostedZone`
  - `route53:ListHostedZonesByVPC`
- AWS Security Hub
  - `securityhub:AcceptAdministratorInvitation`
- **Data type** – String
- **Value type** – Single-valued

> **Note**
>
> For additional considerations for the above unsupported actions, see the Data Perimeter Policy Examples repository.

This global key returns the resource organization ID for a given request. It allows you to create rules that apply to all resources in an organization that are specified in the `Resource` element of an identity-based policy. You can specify the organization ID in the condition element. When you add and remove accounts, policies that include the `aws:ResourceOrgID` key automatically include the correct accounts and you don't have to manually update it.

For example, the following policy prevents the principal from adding objects to the `policy-genius-dev` resource unless the Amazon S3 resource belongs to the same organization as the principal making the request.

> **Important**
>
> This policy does not allow any actions. Instead, it uses the `Deny` effect which explicitly denies access to all of the resources listed in the statement that do not belong to the listed account. Use this policy in combination with other policies that allow access to specific resources.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Sid": "DenyPutObjectToS3ResourcesOutsideMyOrganization",
        "Effect": "Deny",
        "Action": "s3:PutObject",
        "Resource": "arn:aws:s3:::policy-genius-dev/*",
        "Condition": {
            "StringNotEquals": {
                "aws:ResourceOrgID": "${aws:PrincipalOrgID}"
            }
        }
    }
}
```

> **Note**
>
> Some AWS services require access to AWS owned resources that are hosted in another AWS account. Using `aws:ResourceOrgID` in your identity-based policies might impact your identity's ability to access these resources.

Certain AWS services, such as AWS Data Exchange, rely on access to resources outside of your AWS accounts for normal operations. If you use the `aws:ResourceOrgID` key in your policies, include

additional statements to create exemptions for those services. The example policy AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange demonstrates how to deny access based on the resource account while defining exceptions for service-owned resources. You can create a similar policy to restrict access to resources within your organization using the `aws:ResourceOrgID` key, while accounting for service-owned resources.

Use this policy example as a template for creating your own custom policies. Refer to your service documentation for more information.

In the following video, learn more about how you might use the `aws:ResourceOrgID` condition key in a policy.

Ensure identities and networks can only be used to access trusted resources.

aws:ResourceTag/*tag-key*

Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key `"Dept"` with the value `"Marketing"`. For more information, see Controlling access to AWS resources.

- **Availability** – This key is included in the request context when the requested resource already has attached tags or in requests that create a resource with an attached tag. This key is returned only for resources that support authorization based on tags. There is one context key for each tag key-value pair.
- **Data type** – String
- **Value type** – Single-valued

This context key is formatted `"aws:ResourceTag/`*`tag-key`*`":"`*`tag-value`*`"` where *`tag-key`* and *`tag-value`* are a tag key and value pair. Tag keys are not case-sensitive. This means that if you specify `"aws:ResourceTag/TagKey1": "Value1"` in the condition element of your policy, then the condition matches a resource tag key named either `TagKey1` or `tagkey1`, but not both. Values in these tag key/value pairs are case-sensitive. This means that if you specify `"aws:ResourceTag/TagKey1": "Production"` in the condition element of your policy, then the condition matches a resource tag value named `Production` but it would not match `production` or `PRODUCTION`.

For examples of using the `aws:ResourceTag` key to control access to IAM resources, see Controlling access to AWS resources.

For examples of using the `aws:ResourceTag` key to control access to other AWS resources, see Controlling access to AWS resources using tags.

For a tutorial on using the `aws:ResourceTag` condition key for attribute based access control (ABAC), see IAM tutorial: Define permissions to access AWS resources based on tags.

Properties of the request

Use the following condition keys to compare details about the request itself and the contents of the request with the request properties that you specify in the policy.

aws:CalledVia

Use this key to compare the services in the policy with the services that made requests on behalf of the IAM principal (user or role). When a principal makes a request to an AWS service, that service might use the principal's credentials to make subsequent requests to other services. When the request is made using forward access sessions (FAS), this key is set with the value of the service principal. The `aws:CalledVia` key contains an ordered list of each service in the chain that made requests on the principal's behalf.

For more information, see Forward access sessions.

- **Availability** – This key is present in the request when a service that supports `aws:CalledVia` uses the credentials of an IAM principal to make a request to another service. This key is not present if the service uses a service role or service-linked role to make a call on the principal's behalf. This key is also not present when the principal makes the call directly.
- **Data type** – String (list)
- **Value type** – Multivalued

To use the `aws:CalledVia` condition key in a policy, you must provide the service principals to allow or deny AWS service requests. For example, you can use AWS CloudFormation to read and write from an Amazon DynamoDB table. DynamoDB then uses encryption supplied by AWS Key Management Service (AWS KMS).

To allow or deny access when *any* service makes a request using the principal's credentials, use the `aws:ViaAWSService` condition key. That condition key supports AWS services.

The `aws:CalledVia` key is a multivalued key. However, you can't enforce order using this key in a condition. Using the example above, **User 1** makes a request to AWS CloudFormation, which calls

DynamoDB, which calls AWS KMS. These are three separate requests. The final call to AWS KMS is performed by User 1 *via* AWS CloudFormation and then DynamoDB.

In this case, the `aws:CalledVia` key in the request context includes `cloudformation.amazonaws.com` and `dynamodb.amazonaws.com`, in that order. If you care only that the call was made via DynamoDB somewhere in the chain of requests, you can use this condition key in your policy.

For example, the following policy allows managing the AWS KMS key named `my-example-key`, but only if DynamoDB is one of the requesting services. The `ForAnyValue:StringEquals` condition operator ensures that DynamoDB is one of the calling services. If the principal makes the call to AWS KMS directly, the condition returns `false` and the request is not allowed by this policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "KmsActionsIfCalledViaDynamodb",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey",
                "kms:DescribeKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/my-example-key",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:CalledVia": [
                        "dynamodb.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

If you want to enforce which service makes the first or last call in the chain, you can use the aws:CalledViaFirst and aws:CalledViaLast keys. For example, the following policy allows managing the key named my-example-key in AWS KMS. These AWS KMS operations are allowed only if multiple requests were included in the chain. The first request must be made via AWS CloudFormation and the last via DynamoDB. If other services make requests in the middle of the chain, the operation is still allowed.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "KmsActionsIfCalledViaChain",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey",
                "kms:DescribeKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/my-example-key",
            "Condition": {
                "StringEquals": {
                    "aws:CalledViaFirst": "cloudformation.amazonaws.com",
                    "aws:CalledViaLast": "dynamodb.amazonaws.com"
                }
            }
        }
    ]
}
```

The aws:CalledViaFirst and aws:CalledViaLast keys are present in the request when a service uses an IAM principal's credentials to call another service. They indicate the first and last services that made calls in the chain of requests. For example, assume that AWS CloudFormation calls another service named X Service, which calls DynamoDB, which then calls AWS KMS. The final call to AWS KMS is performed by User 1 *via* AWS CloudFormation, then X Service, and then DynamoDB. It was first called via AWS CloudFormation and last called via DynamoDB.

aws:CalledViaFirst

Use this key to compare the services in the policy with the ***first service*** that made a request on behalf of the IAM principal (user or role). For more information, see `aws:CalledVia`.

- **Availability** – This key is present in the request when a service uses the credentials of an IAM principal to make at least one other request to a different service. This key is not present if the service uses a service role or service-linked role to make a call on the principal's behalf. This key is also not present when the principal makes the call directly.
- **Data type** – String
- **Value type** – Single-valued

aws:CalledViaLast

Use this key to compare the services in the policy with the *last service* that made a request on behalf of the IAM principal (user or role). For more information, see `aws:CalledVia`.

- **Availability** – This key is present in the request when a service uses the credentials of an IAM principal to make at least one other request to a different service. This key is not present if the service uses a service role or service-linked role to make a call on the principal's behalf. This key is also not present when the principal makes the call directly.
- **Data type** – String
- **Value type** – Single-valued

aws:ViaAWSService

Use this key to check whether an AWS service makes a request to another service on your behalf using forward access sessions (FAS).

The request context key returns `true` when a service uses forward access sessions to make a request on behalf of the original IAM principal. The request context key also returns `false` when the principal makes the call directly.

- **Availability** – This key is always included in the request context.
- **Data type** – Boolean
- **Value type** – Single-valued

aws:CurrentTime

Use this key to compare the date and time of the request with the date and time that you specify in the policy. To view an example policy that uses this condition key, see AWS: Allows access based on date and time.

- **Availability** – This key is always included in the request context.
- **Data type** – Date
- **Value type** – Single-valued

aws:EpochTime

Use this key to compare the date and time of the request in epoch or Unix time with the value that you specify in the policy. This key also accepts the number of seconds since January 1, 1970.

- **Availability** – This key is always included in the request context.
- **Data type** – Date, Numeric
- **Value type** – Single-valued

aws:referer

Use this key to compare who referred the request in the client browser with the referer that you specify in the policy. The `aws:referer` request context value is provided by the caller in an HTTP header. The `Referer` header is included in a web browser request when you select a link on a web page. The `Referer` header contains the URL of the web page where the link was selected.

- **Availability** – This key is included in the request context only if the request to the AWS resource was invoked by linking from a web page URL in the browser. This key is not included for programmatic requests because it doesn't use a browser link to access the AWS resource.
- **Data type** – String
- **Value type** – Single-valued

For example, you can access an Amazon S3 object directly using a URL or using direct API invocation. For more information, see Amazon S3 API operations directly using a web browser. When you access an Amazon S3 object from a URL that exists in a webpage, the URL of the source web page is in used in `aws:referer`. When you access an Amazon S3 object by typing the URL

into your browser, `aws:referer` is not present. When you invoke the API directly, `aws:referer` is also not present. You can use the `aws:referer` condition key in a policy to allow requests made from a specific referer, such as a link on a web page in your company's domain.

> **Warning**
>
> This key should be used carefully. It is dangerous to include a publicly known referer header value. Unauthorized parties can use modified or custom browsers to provide any `aws:referer` value that they choose. As a result, `aws:referer` should not be used to prevent unauthorized parties from making direct AWS requests. It is offered only to allow customers to protect their digital content, such as content stored in Amazon S3, from being referenced on unauthorized third-party sites.

aws:RequestedRegion

Use this key to compare the AWS Region that was called in the request with the Region that you specify in the policy. You can use this global condition key to control which Regions can be requested. To view the AWS Regions for each service, see Service endpoints and quotas in the *Amazon Web Services General Reference*.

- **Availability** – This key is always included in the request context.
- **Data type** – String
- **Value type** – Single-valued

Some global services, such as IAM, have a single endpoint. Because this endpoint is physically located in the US East (N. Virginia) Region, IAM calls are always made to the us-east-1 Region. For example, if you create a policy that denies access to all services if the requested Region is not us-west-2, then IAM calls always fail. To view an example of how to work around this, see NotAction with Deny.

> **Note**
>
> The `aws:RequestedRegion` condition key allows you to control which endpoint of a service is invoked but does not control the impact of the operation. Some services have cross-Region impacts.
> For example, Amazon S3 has API operations that extend across regions.

- You can invoke `s3:PutBucketReplication` in one Region (which is affected by the `aws:RequestedRegion` condition key), but other Regions are affected based on the replications configuration settings.
- You can invoke `s3:CreateBucket` to create a bucket in another region, and use the `s3:LocationConstraint` condition key to control the applicable regions.

You can use this context key to limit access to AWS services within a given set of Regions. For example, the following policy allows a user to view all of the Amazon EC2 instances in the AWS Management Console. However it only allows them to make changes to instances in Ireland (eu-west-1), London (eu-west-2), or Paris (eu-west-3).

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "InstanceConsoleReadOnly",
            "Effect": "Allow",
            "Action": [
                "ec2:Describe*",
                "ec2:Export*",
                "ec2:Get*",
                "ec2:Search*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "InstanceWriteRegionRestricted",
            "Effect": "Allow",
            "Action": [
                "ec2:Associate*",
                "ec2:Import*",
                "ec2:Modify*",
                "ec2:Monitor*",
                "ec2:Reset*",
                "ec2:Run*",
                "ec2:Start*",
                "ec2:Stop*",
```

```
                "ec2:Terminate*"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestedRegion": [
                        "eu-west-1",
                        "eu-west-2",
                        "eu-west-3"
                    ]
                }
            }
        }
    ]
}
```

aws:RequestTag/*tag-key*

Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key `"Dept"` and that it has the value `"Accounting"`. For more information, see Controlling access during AWS requests.

- **Availability** – This key is included in the request context when tag key-value pairs are passed in the request. When multiple tags are passed in the request, there is one context key for each tag key-value pair.
- **Data type** – String
- **Value type** – Single-valued

This context key is formatted `"aws:RequestTag/`*`tag-key`*`":"`*`tag-value`*`"` where *`tag-key`* and *`tag-value`* are a tag key and value pair. Tag keys are not case-sensitive. This means that if you specify `"aws:RequestTag/TagKey1": "Value1"` in the condition element of your policy, then the condition matches a request tag key named either `TagKey1` or `tagkey1`, but not both. Values in these tag key/value pairs are case-sensitive. This means that if you specify `"aws:RequestTag/TagKey1": "Production"` in the condition element of your policy, then the condition matches a request tag value named `Production` but it would not match `production` or `PRODUCTION`.

This example shows that while the key is single-valued, you can still use multiple key-value pairs in a request if the keys are different.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "ec2:CreateTags",
    "Resource": "arn:aws:ec2::111122223333:instance/*",
    "Condition": {
      "StringEquals": {
        "aws:RequestTag/environment": [
          "preprod",
          "production"
        ],
        "aws:RequestTag/team": [
          "engineering"
        ]
      }
    }
  }
}
```

aws:TagKeys

Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see the section called “Controlling access based on tag keys”.

- **Availability** – This key is included in the request context if the operation supports passing tags in the request.
- **Data type** – String (list)
- **Value type** – Multivalued

This context key is formatted `"aws:TagKeys":"`*`tag-key`*`"` where *`tag-key`* is a list of tag keys without values (for example, `["Dept","Cost-Center"]`).

Because you can include multiple tag key-value pairs in a request, the request content could be a multivalued request. In this case, you must use the `ForAllValues` or `ForAnyValue` set operators. For more information, see Set operators for multivalued context keys.

Some services support tagging with resource operations, such as creating, modifying, or deleting a resource. To allow tagging and operations as a single call, you must create a policy that includes both the tagging action and the resource-modifying action. You can then use the `aws:TagKeys` condition key to enforce using specific tag keys in the request. For example, to limit tags when someone creates an Amazon EC2 snapshot, you must include the `ec2:CreateSnapshot` creation action ***and*** the `ec2:CreateTags` tagging action in the policy. To view a policy for this scenario that uses `aws:TagKeys`, see Creating a Snapshot with Tags in the *Amazon EC2 User Guide*.

aws:SecureTransport

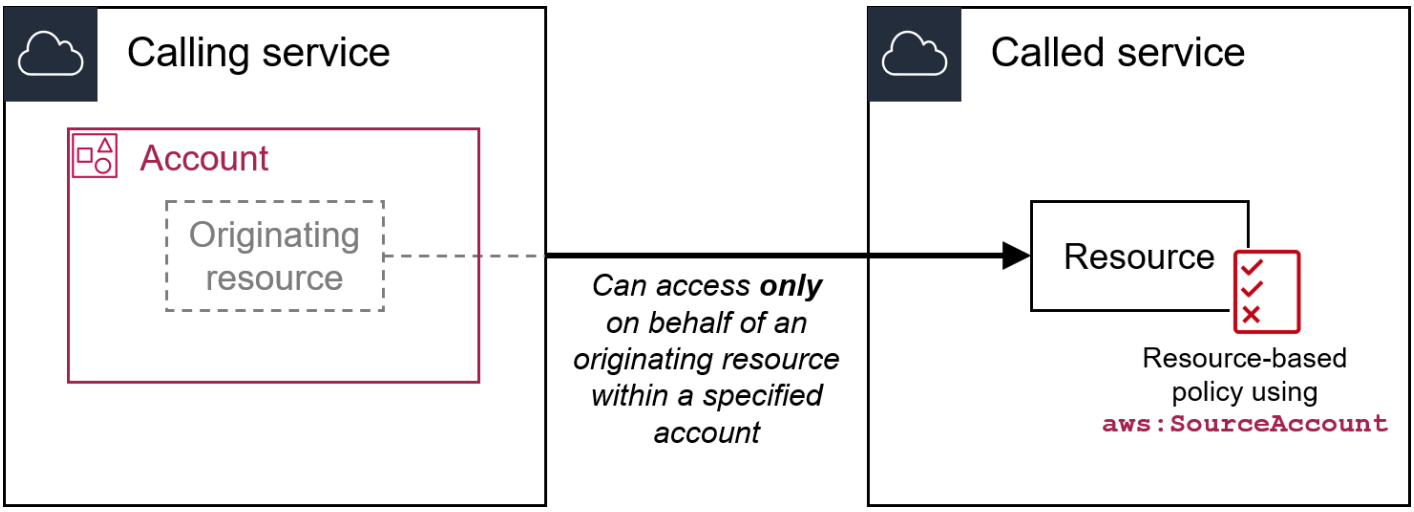
Use this key to check whether the request was sent using TLS. The request context returns `true` or `false`. In a policy, you can allow specific actions only if the request is sent using TLS.

- **Availability** – This key is always included in the request context.
- **Data type** – Boolean
- **Value type** – Single-valued

> **Note**
>
> When AWS services make calls to other AWS services on your behalf (service-to-service calls), certain network-specific authorization context is redacted. If your policy uses this condition key with `Deny` statements, AWS service principals might be unintentionally blocked. To allow AWS services to work properly while maintaining your security requirements, exclude service principals from your `Deny` statements by adding the `aws:PrincipalIsAWSService` condition key with a value of `false`. For example:

```
{
  "Effect": "Deny",
  "Action": "s3:*",
  "Resource": "*",
  "Condition": {
    "Bool": {
      "aws:SecureTransport": "false",
      "aws:PrincipalIsAWSService": "false"
    }
```

```
  }
}
```



This policy denies access to Amazon S3 operations when HTTPS is not used (`aws:SecureTransport` is false), but only for non-AWS service principals. This ensures your conditional restrictions apply to all principals except AWS service principals.

aws:SourceAccount

Use this key to compare the account ID of the resource making a service-to-service request with the account ID that you specify in the policy, but only when the request is made by an AWS service principal.

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an AWS service principal on behalf of a resource for which the configuration triggered the service-to-service request. The calling service passes the account ID of the original resource to the called service.

> **Note**
>
> This key provides a uniform mechanism for enforcing cross-service confused deputy control across AWS services. However, not all service integrations require the use of this global condition key. See the documentation of the AWS services you use for more information about service-specific mechanisms for mitigating cross-service confused deputy risks.

- **Data type** – String
- **Value type** – Single-valued

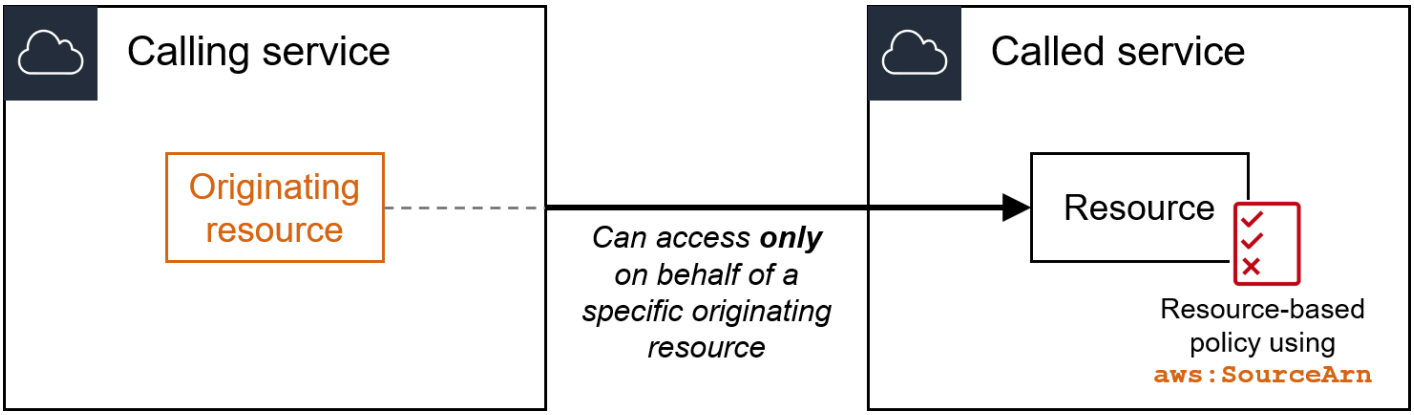
You can use this condition key to help ensure that a calling service can access your resource only when the request originates from a specific account. For example, you can attach the following resource control policy (RCP) to deny requests by service principals against Amazon S3 buckets, unless they were triggered by a resource in the specified account. This policy applies the control only on requests by service principals (`"Bool": {"aws:PrincipalIsAWSService": "true"}`) that have the `aws:SourceAccount` key present (`"Null": {"aws:SourceAccount": "false"}`), so that service integrations that don't require the use of this key and calls by your principals aren't impacted. If the `aws:SourceAccount` key is present in the request context, the `Null` condition will evaluate to `true`, causing the `aws:SourceAccount` key to be enforced.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RCPEnforceConfusedDeputyProtection",
      "Effect": "Deny",
      "Principal": "*",
      "Action": [
        "s3:*"
      ],
```

```
      "Resource": "*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceAccount": "111122223333"
        },
        "Null": {
          "aws:SourceAccount": "false"
        },
        "Bool": {
          "aws:PrincipalIsAWSService": "true"
        }
      }
    }
  ]
}
```

In resource-based policies where the principal is an AWS service principal, use the key to limit permissions granted to the service. For example, when an Amazon S3 bucket is configured to send notifications to an Amazon SNS topic, the Amazon S3 service invokes the `sns:Publish` API operation for all configured events. In the topic policy that allows the `sns:Publish` operation, set the value of the condition key to the account ID of the Amazon S3 bucket.



aws:SourceArn

Use this key to compare the Amazon Resource Name (ARN) of the resource making a service-to-service request with the ARN that you specify in the policy, but only when the request is made by an AWS service principal. When the source's ARN includes the account ID, it is not necessary to use `aws:SourceAccount` with `aws:SourceArn`.

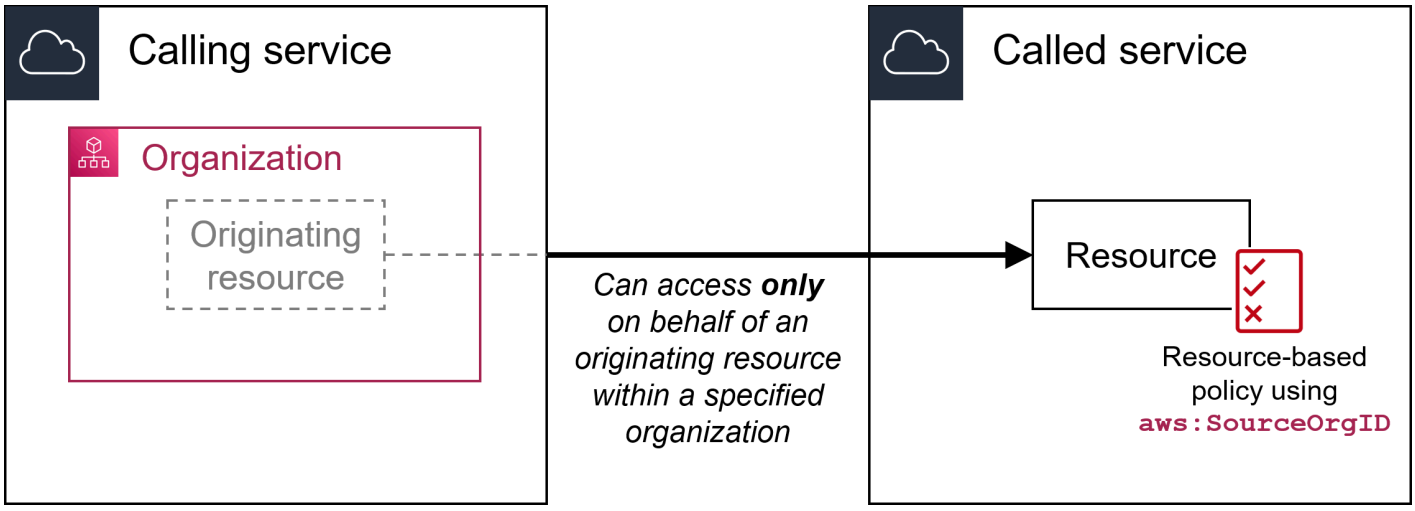
This key does not work with the ARN of the principal making the request. Instead, use `aws:PrincipalArn`.

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an AWS service principal on behalf of a resource for which the configuration triggered the service-to-service request. The calling service passes the ARN of the original resource to the called service.

> **Note**
>
> This key provides a uniform mechanism for enforcing cross-service confused deputy control across AWS services. However, not all service integrations require the use of this global condition key. See the documentation of the AWS services you use for more information about service-specific mechanisms for mitigating cross-service confused deputy risks.

- **Data type** – ARN

  AWS recommends that you use ARN operators instead of string operators when comparing ARNs.
- **Value type** – Single-valued



You can use this condition key to help ensure that a calling service can access your resource only when the request originates from a specific resource. When using a resource-based policy with an AWS service principal as the `Principal`, set this condition key's value to the ARN of the resource you want to restrict access to. For example, when an Amazon S3 bucket is configured to send notifications to an Amazon SNS topic, the Amazon S3 service invokes the `sns:Publish` API operation for all configured events. In the topic policy that allows the `sns:Publish` operation, set the value of the condition key to the ARN of the Amazon S3 bucket. For recommendations on when to use this condition key in resource-based policies, see the documentation for the AWS services you are using.

aws:SourceOrgID

Use this key to compare the organization ID of the resource making a service-to-service request with the organization ID that you specify in the policy, but only when the request is made by an AWS service principal. When you add and remove accounts to an organization in AWS Organizations, policies that include the `aws:SourceOrgID` key automatically include the correct accounts and you don't have to manually update the policies.

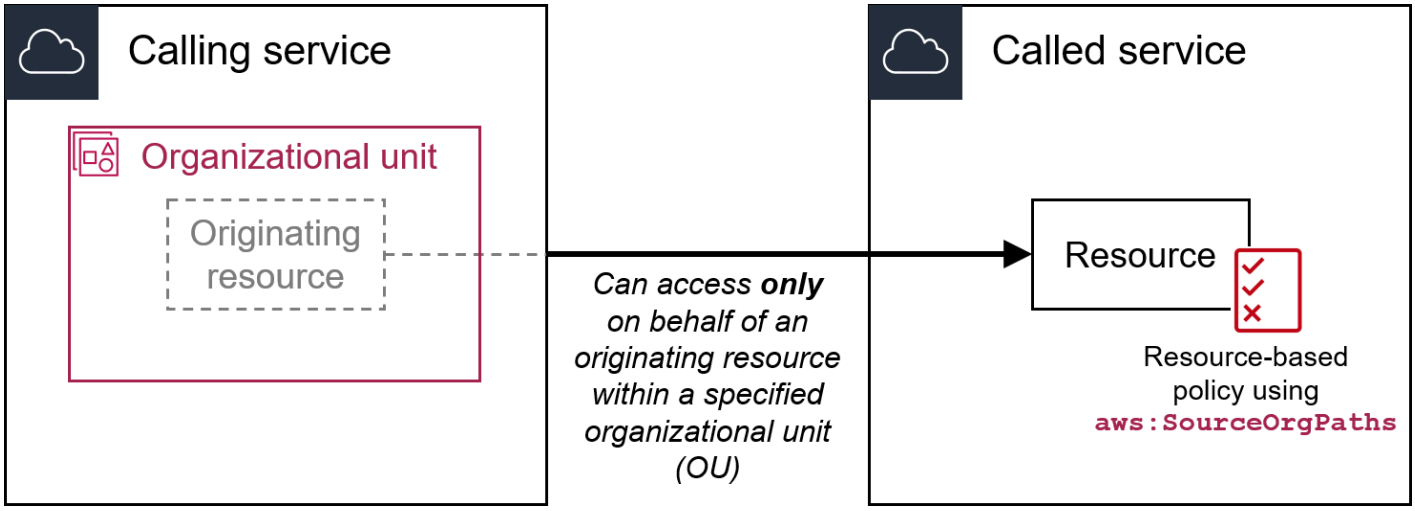
- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an AWS service principal on behalf of a resource owned by an account which is a member of an organization. The calling service passes the organization ID of the original resource to the called service.

> **Note**
>
> This key provides a uniform mechanism for enforcing cross-service confused deputy control across AWS services. However, not all service integrations require the use of this global condition key. See the documentation of the AWS services you use for more information about service-specific mechanisms for mitigating cross-service confused deputy risks.

- **Data type** – String
- **Value type** – Single-valued

You can use this condition key to help ensure that a calling service can access your resource only when the request originates from a specific organization. For example, you can attach the following resource control policy (RCP) to deny requests by service principals against Amazon S3 buckets, unless they were triggered by a resource in the specified AWS organization. This policy applies the control only on requests by service principals (`"Bool": {"aws:PrincipalIsAWSService": "true"}`) that have the `aws:SourceAccount` key present (`"Null": {"aws:SourceAccount": "false"}`), so that service integrations that don't require the use of the key and calls by your principals aren't impacted. If the `aws:SourceAccount` key is present in the request context, the `Null` condition will evaluate to `true`, causing the `aws:SourceOrgID` key to be enforced. We use `aws:SourceAccount` instead of `aws:SourceOrgID` in the `Null` condition operator so that the control still applies if the request originates from an account that doesn't belong to an organization.

JSON



```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RCPEnforceConfusedDeputyProtection",
      "Effect": "Deny",
      "Principal": "*",
      "Action": [
        "s3:*"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceOrgID": "o-xxxxxxxxxx"
        },
        "Null": {
          "aws:SourceAccount": "false"
        },
        "Bool": {
          "aws:PrincipalIsAWSService": "true"
        }
      }
    }
  ]
}
```

aws:SourceOrgPaths

Use this key to compare the AWS Organizations path of the resource making a service-to-service request with the organizations path that you specify in the policy, but only when the request is made by an AWS service principal. An AWS Organizations path is a text representation of the structure of an AWS Organizations entity. For more information about using and understanding paths, see Understand the AWS Organizations entity path.

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an AWS service principal on behalf of a resource owned by an account which is a member of an organization. The calling service passes the organization path of the original resource to the called service.

> **Note**
>
> This key provides a uniform mechanism for enforcing cross-service confused deputy control across AWS services. However, not all service integrations require the use of this global condition key. See the documentation of the AWS services you use for more information about service-specific mechanisms for mitigating cross-service confused deputy risks.

- **Data type** – String (list)
- **Value type** – Multivalued

Use this condition key to help ensure that a calling service can access your resource only when the request originates from a specific organizational unit (OU) in AWS Organizations.

Similarly to `aws:SourceOrgID`, to help prevent impact on service integrations that don't require the use of this key, use the `Null` condition operator with the `aws:SourceAccount` condition key so that the control still applies if the request originates from an account that doesn't belong to an organization.

```
{
      "Condition": {
        "ForAllValues:StringNotLikeIfExists": {
            "aws:SourceOrgPaths": "o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-
ab12-22222222/"
        },
        "Null": {
          "aws:SourceAccount": "false"
        },
        "Bool": {
          "aws:PrincipalIsAWSService": "true"
        }
      }
}
```

`aws:SourceOrgPaths` is a multivalued condition key. Multivalued keys can have multiple values in the request context. You must use the `ForAnyValue` or `ForAllValues` set operators with string condition operators for this key. For more information about multivalued condition keys, see Set operators for multivalued context keys.

aws:UserAgent

Use this key to compare the requester's client application with the application that you specify in the policy.

- **Availability** – This key is always included in the request context.
- **Data type** – String
- **Value type** – Single-valued

Warning

This key should be used carefully. Since the `aws:UserAgent` value is provided by the caller in an HTTP header, unauthorized parties can use modified or custom browsers to provide any `aws:UserAgent` value that they choose. As a result, `aws:UserAgent` should not be used to prevent unauthorized parties from making direct AWS requests. You can use it to allow only specific client applications, and only after testing your policy.

Other cross-service condition keys

AWS STS supports SAML-based federation condition keys and cross-service condition keys for OIDC federation. These keys are available when a user who was federated using OIDC or SAML performs AWS operations in other services.

IAM and AWS STS condition context keys

You can use the `Condition` element in a JSON policy to test the value of keys that are included in the request context of all AWS requests. These keys provide information about the request itself or the resources that the request references. You can check that keys have specified values before allowing the action requested by the user. This gives you granular control over when your JSON policy statements match or don't match an incoming request. For information about how to use the `Condition` element in a JSON policy, see IAM JSON policy elements: Condition.

This topic describes the keys defined and provided by the IAM service (with an `iam:` prefix) and the AWS Security Token Service (AWS STS) service (with an `sts:` prefix). Several other AWS services also provide service-specific keys that are relevant to the actions and resources defined by that service. For more information, see Actions, Resources, and Condition Keys for AWS Services. The documentation for a service that supports condition keys often has additional information. For example, for information about keys that you can use in policies for Amazon S3 resources, see Amazon S3 Policy Keys in the *Amazon Simple Storage Service User Guide*.

Topics

- Available keys for IAM
- Available keys for AWS OIDC federation
- Available keys for SAML-based AWS STS federation
- Cross-service SAML-based AWS STS federation context keys

- Available keys for AWS STS

Available keys for IAM

You can use the following condition keys in policies that control access to IAM resources:

iam:AssociatedResourceArn

Works with ARN operators.

Specifies the ARN of the resource to which this role will be associated at the destination service. The resource usually belongs to the service to which the principal is passing the role. Sometimes, the resource might belong to a third service. For example, you might pass a role to Amazon EC2 Auto Scaling that they use on an Amazon EC2 instance. In this case, the condition would match the ARN of the Amazon EC2 instance.

This condition key applies to only the PassRole action in a policy. It can't be used to limit any other action.

> **Important**
>
> When using the `iam:AssociatedResourceArn` condition in a policy to restrict the PassRole action, special considerations apply if the policy is intended to define access for the AddRoleToInstanceProfile action. In this case, you cannot specify a Region or instance ID in the EC2 instance ARN. The ARN value must be `arn:aws:ec2:*:CallerAccountId:instance/*`. Using any other ARN value may lead to unexpected evaluation results.

Use this condition key in an identity-based policy to allow an entity to pass a role, but only if that role is associated with the specified resource. For example, you can allow an IAM user or role to pass any role to the Amazon EC2 service to be used with instances in the AWS account. The IAM user or role would not be allowed to pass roles to other services.

```
{
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "*",
    "Condition": {
```

```
        "StringEquals": {
            "iam:PassedToService": "ec2.amazonaws.com"
        },
        "ArnLike": {
            "iam:AssociatedResourceARN": [
                "arn:aws:ec2:*:111122223333:instance/*"
            ]
        }
    }
}
```

> **Note**
>
> AWS services that support iam:PassedToService also support this condition key.

iam:AWSServiceName

Works with string operators.

Specifies the AWS service to which this role is attached.

This condition key is supported by the `CreateServiceLinkedRole` API operation.

> **Tip**
>
> For information about which services support using service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

In this example, you allow an entity to create a service-linked role using the `CreateServiceLinkedRole` API operation if the service name is *access-analyzer.amazonaws.com.*

JSON

```
{
   "Version": "2012-10-17",
```

```
   "Statement": [{
       "Effect": "Allow",
       "Action": "iam:CreateServiceLinkedRole",
       "Resource": "*",
       "Condition": {
         "StringLike": {
           "iam:AWSServiceName": "access-analyzer.amazonaws.com"
         }
       }
     }]
 }
```

iam:FIDO-certification

Works with string operators.

Checks the MFA device FIDO certification level at the time of registration of a FIDO security key. The device certification is retrieved from the FIDO Alliance Metadata Service (MDS). If the certification status or level of your FIDO security key changes, it will not be updated unless the device is unregistered and registered again to fetch the updated certification information.

Possible values of L1, L1plus, L2, L2plus, L3, L3plus

In this example, you register a security key and retrieve the FIDO Level 1 plus certification for your device.

JSON

```
{
      "Version": "2012-10-17",
      "Statement": [{
            "Effect": "Allow",
            "Action": "iam:EnableMFADevice",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:RegisterSecurityKey" : "Create"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "iam:EnableMFADevice",
```

```
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:RegisterSecurityKey" : "Activate",
                    "iam:FIDO-certification": "L1plus"
                }
            }
        }
    ]

}
```

iam:FIDO-FIPS-140-2-certification

Works with string operators.

Checks the MFA device FIPS-140-2 validation certification level at the time of registration of a FIDO security key. The device certification is retrieved from the FIDO Alliance Metadata Service (MDS). If the certification status or level of your FIDO security key changes, it will not be updated unless the device is unregistered and registered again to fetch the updated certification information.

Possible values of L1, L2, L3, L4

In this example, you register a security key and retrieve the FIPS-140-2 Level 2 certification for your device.

JSON

```
{
      "Version": "2012-10-17",
      "Statement": [{
            "Effect": "Allow",
            "Action": "iam:EnableMFADevice",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:RegisterSecurityKey" : "Create"
                }
            }
        },
        {
            "Effect": "Allow",
```

```
            "Action": "iam:EnableMFADevice",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:RegisterSecurityKey" : "Activate",
                    "iam:FIDO-FIPS-140-2-certification": "L2"
                }
            }
        }
    ]

}
```

iam:FIDO-FIPS-140-3-certification

Works with string operators.

Checks the MFA device FIPS-140-3 validation certification level at the time of registration of a FIDO security key. The device certification is retrieved from the FIDO Alliance Metadata Service (MDS). If the certification status or level of your FIDO security key changes, it will not be updated unless the device is unregistered and registered again to fetch the updated certification information.

Possible values of L1, L2, L3, L4

In this example, you register a security key and retrieve the FIPS-140-3 Level 3 certification for your device.

JSON

```
{
      "Version": "2012-10-17",
      "Statement": [{
            "Effect": "Allow",
            "Action": "iam:EnableMFADevice",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:RegisterSecurityKey" : "Create"
                }
            }
        },
        {
```

```
            "Effect": "Allow",
            "Action": "iam:EnableMFADevice",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:RegisterSecurityKey" : "Activate",
                    "iam:FIDO-FIPS-140-3-certification": "L3"
                }
            }
        }
    ]

}
```

iam:OrganizationsPolicyId

Works with string operators.

Checks that the policy with the specified AWS Organizations ID matches the policy used in the request. To view an example IAM policy that uses this condition key, see IAM: View service last accessed information for an AWS Organizations policy.

iam:PassedToService

Works with string operators.

Specifies the service principal of the service to which a role can be passed. This condition key applies to only the PassRole action in a policy. It can't be used to limit any other action.

When you use this condition key in a policy, specify the service using a service principal. A service principal is the name of a service that can be specified in the `Principal` element of a policy. This is the usual format: `SERVICE_NAME_URL.amazonaws.com`.

You can use `iam:PassedToService` to restrict your users so that they can pass roles only to specific services. For example, a user might create a service role that trusts CloudWatch to write log data to an Amazon S3 bucket on their behalf. Then the user must attach a permissions policy and a trust policy to the new service role. In this case, the trust policy must specify `cloudwatch.amazonaws.com` in the `Principal` element. To view a policy that allows the user to pass the role to CloudWatch, see IAM: Pass an IAM role to a specific AWS service.

By using this condition key, you can ensure that users create service roles only for the services that you specify. For example, if a user with the preceding policy attempts to create a service

role for Amazon EC2, the operation will fail. The failure occurs because the user does not have permission to pass the role to Amazon EC2.

Sometimes you pass a role to a service that then passes the role to a different service. `iam:PassedToService` includes only the final service that assumes the role, not the intermediate service that passes the role.

> **Note**
>
> Some services do not support this condition key.

iam:PermissionsBoundary

Works with ARN operators.

Checks that the specified policy is attached as permissions boundary on the IAM principal resource. For more information, see Permissions boundaries for IAM entities

iam:PolicyARN

Works with ARN operators.

Checks the Amazon Resource Name (ARN) of a managed policy in requests that involve a managed policy. For more information, see Controlling access to policies.

iam:RegisterSecurityKey

Works with string operators.

Checks the current state of MFA device enablement.

Possible values of `Create` or `Activate`.

In this example, you register a security key and retrieve the FIPS-140-3 Level 1 certification for your device.

JSON

```
{
      "Version": "2012-10-17",
```

```
    "Statement": [{
          "Effect": "Allow",
          "Action": "iam:EnableMFADevice",
          "Resource": "*",
          "Condition": {
              "StringEquals": {
                  "iam:RegisterSecurityKey" : "Create"
              }
          }
      },
      {
          "Effect": "Allow",
          "Action": "iam:EnableMFADevice",
          "Resource": "*",
          "Condition": {
              "StringEquals": {
                  "iam:RegisterSecurityKey" : "Activate",
                  "iam:FIDO-FIPS-140-3-certification": "L1"
              }
          }
      }
  ]

}
```

iam:ResourceTag/*key-name*

Works with string operators.

Checks that the tag attached to the identity resource (user or role) matches the specified key name and value.

> **Note**
>
> IAM and AWS STS support both the `iam:ResourceTag` IAM condition key and the `aws:ResourceTag` global condition key.

You can add custom attributes to IAM resources in the form of a key-value pair. For more information about tags for IAM resources, see the section called “Tags for IAM resources”. You can use `ResourceTag` to control access to AWS resources, including IAM resources. However, because IAM does not support tags for groups, you cannot use tags to control access to groups.

This example shows how you might create an identity-based policy that allows deleting users with the **`status=terminated`** tag. To use this policy, replace the *`italicized placeholder text`* in the example policy with your own information. Then, follow the directions in create a policy or edit a policy.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "iam:DeleteUser",
        "Resource": "*",
        "Condition": {"StringEquals": {"iam:ResourceTag/status":
 "terminated"}}
    }]
}
```

iam:ServiceSpecificCredentialAgeDays

Works with numeric operators.

This condition key limits the creation of service-specific credentials based on their expiration settings. It allows you to control the maximum age, in days, of service-specific credentials that can be created.

The valid range for days is 1 to 36600 (minimum 1 day, maximum 36600 days).

This condition key is supported by the `CreateServiceSpecificCredential` API operation.

In this example, you allow a user to create service-specific credentials for the Amazon Bedrock service only if they expire within 90 days.

```
{
   "Version": "2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": "iam:CreateServiceSpecificCredential",
           "Resource": "arn:aws:iam::111122223333:user/username",
           "Condition": {
               "StringEquals": {
```

```
                    "iam:ServiceSpecificCredentialServiceName":
 "bedrock.amazonaws.com"
                },
                "NumericLessThanEquals": {
                    "iam:ServiceSpecificCredentialAgeDays": "90"
                }
            }
        }
    ]
}
```

iam:ServiceSpecificCredentialServiceName

Works with string operators.

Specifies which AWS services can be used when managing service-specific credentials. This condition key allows you to restrict which AWS services are permitted when managing service-specific credentials.

This condition key is supported by the following API operations:

- CreateServiceSpecificCredential
- DeleteServiceSpecificCredential
- ResetServiceSpecificCredential
- UpdateServiceSpecificCredential

The following services are supported for service-specific credentials with their exact value formatting:

- `bedrock.amazonaws.com`
- `cassandra.amazonaws.com`
- `codecommit.amazonaws.com`

In this example, you allow a user to create service-specific credentials using the CreateServiceSpecificCredential API operation only for the Amazon Bedrock service.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Action": "iam:CreateServiceSpecificCredential",
            "Resource": "arn:aws:iam::111122223333:user/username",
            "Condition": {
                "StringEquals": {
                    "iam:ServiceSpecificCredentialServiceName":
 "bedrock.amazonaws.com"
                }
            }
        }
    ]
}
```

Available keys for AWS OIDC federation

You can use OIDC federation to give temporary security credentials to users who have been authenticated through an OpenID Connect compatible identity provider (IdP) to an IAM OpenID Connect (OIDC) identity provider in your AWS account. Examples of such providers include GitHub, Amazon Cognito, Login with Amazon, and Google. Identity tokens and access tokens from your own IdP may be used, as well as service account tokens granted to Amazon Elastic Kubernetes Service workloads.

You can use AWS OIDC condition context keys to write policies that limit the access of federated principals to resources that are associated with a specific provider, app, or user. These keys are typically used in the trust policy for a role. Define condition keys using the name of the OIDC provider (`token.actions.githubusercontent.com`) followed by a claim (`:aud`): **`token.actions.githubusercontent.com:aud`**.

Some OIDC federation condition keys can be used in the role session to authorize resource access. If the value is **Yes** in the **Available in session** column, you can use these condition keys in policies to define what users are allowed to access in other AWS services. When a claim is not available in session, the OIDC condition context key can only be used in a role trust policy for the initial AssumeRoleWithWebIdentity authentication.

Select your IdP to see how claims from your IdP map to IAM condition context keys in AWS. More information on keys for GitHub and Google can be found under the **Default** tab.

Default

Default lists the standard OIDC claims and how they map to AWS STS condition context keys in AWS. You can use these keys to control access to a role. To do that, compare the **AWS STS**

condition keys to the values in the **IdP JWT claim** column. Use this mapping if your IdP is not listed in the tab options.

GitHub Actions workflows and Google are some examples of IdPs that use the default implementation in their OIDC JWT ID token.

AWS STS condition key	IdP JWT claim	Available in session
amr	amr	Yes
aud	azp If no value is set for `azp`, the `aud` condition key maps to the `aud` claim.	Yes
email	email	No
oaud	aud	No
sub	sub	Yes

For more information about using OIDC condition context keys with GitHub, see Configuring a role for GitHub OIDC identity provider. For more information about Google `aud` and `azp` fields, see the Google Identity Platform OpenID Connect Guide.

amr

Works with string operators. The key is multivalued, meaning that you test it in a policy using condition set operators.

Example: `token.actions.githubusercontent.com:amr`

Authentication Methods Reference includes login information about the user. The key can contain the following values:

- If the user is unauthenticated, the key contains only `unauthenticated`.
- If the user is authenticated, the key contains the value `authenticated` and the name of the login provider used in the call (`accounts.google.com`).

aud

Works with string operators.

Examples:

- `accounts.google.com:aud`
- `token.actions.githubusercontent.com:aud`

Use the aud condition key to verify that the audience matches the one you specify in the policy. You can use the aud key with the sub key for the same identity provider.

This condition key is set from the following token fields:

- aud for OAuth 2.0 Google client IDs of your application, when the azp field is not set. When the azp field is set, the aud field matches the `accounts.google.com:oaud` condition key.
- azp when the azp field is set. This can happen for hybrid apps where a web application and Android app have a different OAuth 2.0 Google client ID but share the same Google APIs project.

When you write a policy using the `accounts.google.com:aud` condition key, you must know whether the app is a hybrid app that sets the azp field.

azp Field Not Set

The following example policy works for non-hybrid apps that do not set the azp field. In this case the Google ID Token aud field value matches both the `accounts.google.com:aud` and the `accounts.google.com:oaud` condition key values.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {"Federated": "accounts.google.com"},
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringEquals": {
                    "accounts.google.com:aud": "aud-value",
                    "accounts.google.com:oaud": "aud-value",
```

```
                    "accounts.google.com:sub": "sub-value"
                }
            }
        }
    ]
}
```

`azp` Field Set

The following example policy works for hybrid apps that do set the `azp` field. In this case, the Google ID Token `aud` field value matches only the `accounts.google.com:oaud` condition key value. The `azp` field value matches the `accounts.google.com:aud` condition key value.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {"Federated": "accounts.google.com"},
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringEquals": {
                    "accounts.google.com:aud": "azp-value",
                    "accounts.google.com:oaud": "aud-value",
                    "accounts.google.com:sub": "sub-value"
                }
            }
        }
    ]
}
```

email

Works with string operators.

Example: `accounts.google.com:email`

This condition key validates the user's email address. The value of this claim may not be unique to this account and could change over time, therefore you should not use this value as the primary identifier to verify your user record.

oaud

Works with string operators.

Example: `accounts.google.com:oaud`

This key specifies the other audience (aud) that this ID token is intended for. It must be one of the OAuth 2.0 client IDs of your application.

sub

Works with string operators.

Examples:

- `accounts.google.com:sub`
- token.actions.githubusercontent.com:sub

Use these keys to verify that the subject matches the one that you specify in the policy. You can use the sub key with the aud key for the same identity provider.

In the following role trust policy, the sub condition key limits the role to the GitHib branch named demo.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:oidc-provider/
token.actions.githubusercontent.com"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "token.actions.githubusercontent.com:aud": "sts.amazonaws.com",
          "token.actions.githubusercontent.com:sub": "repo:org-name/repo-
name:ref:refs/heads/demo"
        }
      }
    }
```

```
  ]
}
```

Amazon Cognito

This tab explains how Amazon Cognito maps OIDC claims to AWS STS condition context keys in AWS. You can use these keys to control access to a role. To do that, compare the **AWS STS condition keys** to the values in the **IdP JWT claim** column.

For roles used by Amazon Cognito, keys are defined using `cognito-identity.amazonaws.com` followed by the claim.

For more information about identity pool claim mapping, see Default provider mappings in the *Amazon Cognito Developer Guide*. For more information about user pool claim mapping see Using the ID token in the *Amazon Cognito Developer Guide*.

AWS STS condition key	IdP JWT claim	Available in session
amr	amr	Yes
aud	aud	Yes
oaud	aud	No
sub	sub	Yes

amr

Works with string operators. The key is multivalued, meaning that you test it in a policy using condition set operators.

Example – `cognito-identity.amazonaws.com:amr`

Authentication Methods Reference includes login information about the user. The key can contain the following values:

- If the user is unauthenticated, the key contains only `unauthenticated`.
- If the user is authenticated, the key contains the value `authenticated` and the name of the login provider used in the call (`cognito-identity.amazonaws.com`).

As an example, the following condition in the trust policy for an Amazon Cognito role tests whether the user is unauthenticated.

```
"Condition": {
  "StringEquals":
    { "cognito-identity.amazonaws.com:aud": "us-east-2:identity-pool-id" },
  "ForAnyValue:StringLike":
    { "cognito-identity.amazonaws.com:amr": "unauthenticated" }
}
```

aud

Works with string operators.

Example – `cognito-identity.amazonaws.com:aud`

The user pool app client that authenticated your user. Amazon Cognito renders the same value in the access token `client_id` claim.

oaud

Works with string operators.

Example – `cognito-identity.amazonaws.com:oaud`

The user pool app client that authenticated your user. Amazon Cognito renders the same value in the access token `client_id` claim.

sub

Works with string operators.

Example – `cognito-identity.amazonaws.com:sub`

A unique identifier (UUID), or subject, for the authenticated user. The username might not be unique in your user pool. The sub claim is the best way to identify a given user. You can use the sub key with the aud key for the same identity provider.

```
"Condition": {
        "StringEquals": {
           "cognito-identity.amazonaws.com:aud": "us-east-1:12345678-abcd-abcd-
abcd-123456790ab",
           "cognito-identity.amazonaws.com:sub": [
```

```
            "us-east-1:12345678-1234-1234-1234-123456790ab",
            "us-east-1:98765432-1234-1234-1243-123456790ab"
         ]
      }
   }
```

Login with Amazon

This tab explains how Login with Amazon maps OIDC claims to AWS STS condition context keys in AWS. You can use these keys to control access to a role. To do that, compare the **AWS STS condition keys** to the values in the **IdP JWT claim** column.

AWS STS condition key	IdP JWT claim	Available in session
app_id	Application ID	Yes
sub	User ID	Yes
user_id	User ID	Yes

app_id

Works with string operators.

Example – `www.amazon.com:app_id`

This key specifies the audience context that matches the aud field used by other identity providers.

sub

Works with string operators.

Example – `www.amazon.com:sub`

This key verifies that the user ID matches the one that you specify in the policy. You can use the `sub` key with the aud key for the same identity provider.

user_id

Works with string operators.

Example – `www.amazon.com:user_id`

This key specifies the audience context that matches the aud field used by other identity providers.You can use the `user_id` key with the `id` key for the same identity provider.

Facebook

This tab explains how Facebook maps OIDC claims to AWS STS condition context keys in AWS. You can use these keys to control access to a role. To do that, compare the **AWS STS condition keys** to the values in the **IdP JWT claim** column.

AWS STS condition key	IdP JWT claim	Available in session
app_id	Application ID	Yes
id	id	Yes

app_id

Works with string operators.

Example – `graph.facebook.com:app_id`

This key verifies that the audience context matches the aud field used by other identity providers.

id

Works with string operators.

Example – `graph.facebook.com:id`

This key verified that the application (or site) ID matches the one that you specify in the policy.

More information about OIDC federation

- Amazon Cognito User Guide
- OIDC federation

Available keys for SAML-based AWS STS federation

If you are working with SAML-based federation using AWS Security Token Service (AWS STS), you can include additional condition keys in the policy.

SAML role trust policies

In the trust policy of a role, you can include the following keys, which help you establish whether the caller is allowed to assume the role. Except for `saml:doc`, all the values are derived from the SAML assertion. All items in the list are available in the IAM console visual editor when you create or edit a policy with conditions. Items marked with `[]` *can* have a value that is a list of the specified type.

saml:aud

Works with string operators.

An endpoint URL to which SAML assertions are presented. The value for this key comes from the `SAML Recipient` field in the assertion, *not* the `Audience` field.

saml:commonName[]

Works with string operators.

This is a `commonName` attribute.

saml:cn[]

Works with string operators.

This is an `eduOrg` attribute.

saml:doc

Works with string operators.

This represents the principal that was used to assume the role. The format is *`account-ID`*`/`*`provider-friendly-name`*, such as `123456789012/SAMLProviderName`. The *account-ID* value refers to the account that owns the SAML provider.

saml:edupersonaffiliation[]

Works with string operators.

This is an `eduPerson` attribute.

saml:edupersonassurance[]

Works with string operators.

This is an eduPerson attribute.

saml:edupersonentitlement[]

Works with string operators.

This is an eduPerson attribute.

saml:edupersonnickname[]

Works with string operators.

This is an eduPerson attribute.

saml:edupersonorgdn

Works with string operators.

This is an eduPerson attribute.

saml:edupersonorgunitdn[]

Works with string operators.

This is an eduPerson attribute.

saml:edupersonprimaryaffiliation

Works with string operators.

This is an eduPerson attribute.

saml:edupersonprimaryorgunitdn

Works with string operators.

This is an eduPerson attribute.

saml:edupersonprincipalname

Works with string operators.

This is an eduPerson attribute.

saml:edupersonscopedaffiliation[]

Works with string operators.

This is an `eduPerson` attribute.

saml:edupersontargetedid[]

Works with string operators.

This is an `eduPerson` attribute.

saml:eduorghomepageuri[]

Works with string operators.

This is an `eduOrg` attribute.

saml:eduorgidentityauthnpolicyuri[]

Works with string operators.

This is an `eduOrg` attribute.

saml:eduorglegalname[]

Works with string operators.

This is an `eduOrg` attribute.

saml:eduorgsuperioruri[]

Works with string operators.

This is an `eduOrg` attribute.

saml:eduorgwhitepagesuri[]

Works with string operators.

This is an `eduOrg` attribute.

saml:givenName[]

Works with string operators.

This is a `givenName` attribute.

saml:iss

Works with string operators.

The issuer, which is represented by a URN.

saml:mail[]

Works with string operators.

This is a `mail` attribute.

saml:name[]

Works with string operators.

This is a `name` attribute.

saml:namequalifier

Works with string operators.

A hash value based on the friendly name of the SAML provider. The value is the concatenation of the following values, in order and separated by a '/' character:

1. The `Issuer` response value (`saml:iss`)
2. The AWS account ID
3. The friendly name (the last part of the ARN) of the SAML provider in IAM

The concatenation of the account ID and friendly name of the SAML provider is available to IAM policies as the key `saml:doc`. For more information, see Uniquely identifying users in SAML-based federation.

saml:organizationStatus[]

Works with string operators.

This is an `organizationStatus` attribute.

saml:primaryGroupSID[]

Works with string operators.

This is a `primaryGroupSID` attribute.

saml:sub

Works with string operators.

This is the subject of the claim, which includes a value that uniquely identifies an individual user within an organization (for example, `_cbb88bf52c2510eabe00c1642d4643f41430fe25e3`).

saml:sub_type

Works with string operators.

This key can have the value `persistent`, `transient`, or consist of the full `Format` URI from the `Subject` and `NameID` elements used in your SAML assertion. A value of `persistent` indicates that the value in `saml:sub` is the same for a user between sessions. If the value is `transient`, the user has a different `saml:sub` value for each session. For information about the `NameID` element's `Format` attribute, see Configure SAML assertions for the authentication response.

saml:surname[]

Works with string operators.

This is a `surnameuid` attribute.

saml:uid[]

Works with string operators.

This is a `uid` attribute.

saml:x500UniqueIdentifier[]

Works with string operators.

This is an `x500UniqueIdentifier` attribute.

For general information about `eduPerson` and `eduOrg` attributes, see the REFEDS Wiki website. For a list of `eduPerson` attributes, see eduPerson Object Class Specification (201602).

Condition keys whose type is a list can include multiple values. To create conditions in the policy for list values, you can use set operators (`ForAllValues`, `ForAnyValue`). For example, to allow any user whose affiliation is "faculty" or "staff" (but not "student"), you might use a condition like the following:

```
"Condition": {
   "ForAllValues:StringLike": {
     "saml:edupersonaffiliation":[ "faculty", "staff"]
   }
```

```
}
```

Cross-service SAML-based AWS STS federation context keys

Some SAML-based federation condition keys can be used in subsequent requests to authorize AWS operations in other services and `AssumeRole` calls. These are the following condition keys that can be used in role trust policies when federated principals assume another role, and in resource policies from other AWS services to authorize resource access by federated principals. For more information about using these keys, see About SAML 2.0-based federation.

Select a condition key to see the description.

- saml:namequalifier
- saml:sub
- saml:sub_type

> **Note**
>
> No other SAML-based federation condition keys are available for use after the initial external identity provider (IdP) authentication response.

Available keys for AWS STS

You can use the following condition keys in IAM role trust policies for roles that are assumed using AWS Security Token Service (AWS STS) operations.

saml:sub

Works with string operators.

This is the subject of the claim, which includes a value that uniquely identifies an individual user within an organization (for example, `_cbb88bf52c2510eabe00c1642d4643f41430fe25e3`).

sts:AWSServiceName

Works with string operators.

Use this key to specify a service where a bearer token can be used. When you use this condition key in a policy, specify the service using a service principal. A service principal is the name

of a service that can be specified in the `Principal` element of a policy. For example, `codeartifact.amazonaws.com` is the AWS CodeArtifact service principal.

Availability – This key is present in requests that get a bearer token. You cannot make a direct call to AWS STS to get a bearer token. When you perform some operations in other services, the service requests the bearer token on your behalf.

Some AWS services require that you have permission to get an AWS STS service bearer token before you can access their resources programmatically. For example, AWS CodeArtifact requires principals to use bearer tokens to perform some operations. The `aws codeartifact get-authorization-token` command returns a bearer token. You can then use the bearer token to perform AWS CodeArtifact operations. For more information about bearer tokens, see Service bearer tokens.

You can use this condition key to allow principals to get a bearer token for use with a specific service.

sts:DurationSeconds

Works with numeric operators.

Use this key to specify the duration (in seconds) that a principal can use when getting an AWS STS bearer token.

Availability – This key is present in requests that get a bearer token. You cannot make a direct call to AWS STS to get a bearer token. When you perform some operations in other services, the service requests the bearer token on your behalf. The key is not present for AWS STS assume-role operations.

Some AWS services require that you have permission to get an AWS STS service bearer token before you can access their resources programmatically. For example, AWS CodeArtifact requires principals to use bearer tokens to perform some operations. The `aws codeartifact get-authorization-token` command returns a bearer token. You can then use the bearer token to perform AWS CodeArtifact operations. For more information about bearer tokens, see Service bearer tokens.

sts:ExternalId

Works with string operators.

Use this key to require that a principal provide a specific identifier when assuming an IAM role.

Availability – This key is present in the request when the principal provides an external ID while assuming a role using the AWS CLI or AWS API.

A unique identifier that might be required when you assume a role in another account. If the administrator of the account to which the role belongs provided you with an external ID, then provide that value in the `ExternalId` parameter. This value can be any string, such as a passphrase or account number. The primary function of the external ID is to address and prevent the confused deputy problem. For more information about the external ID and the confused deputy problem, see Access to AWS accounts owned by third parties.

The `ExternalId` value must have a minimum of 2 characters and a maximum of 1,224 characters. The value must be alphanumeric without white space. It can also include the following symbols: plus (+), equal (=), comma (,), period (.), at (@), colon (:), forward slash (/), and hyphen (-).

sts:RequestContext/*context-key*

Works with string operators.

Use this key to compare the session context key-value pairs that are embedded in the trusted token issuer signed context assertion passed in the request with the context key-values specified in the role trust policy.

Availability – This key is present in the request when a context assertion is provided in the `ProvidedContexts` request parameter while assuming a role using the AWS STS AssumeRole API operation.

This context key is formatted as `"sts:RequestContext/context-key":"context-value"` where `context-key` and `context-value` are a context key-value pair. When multiple context keys are embedded in the signed context assertion passed in the request, there is one context key for each key-value pair. You must grant permission for the `sts:SetContext` action in the role trust policy to allow a principal to set context keys within the resulting session token. To learn more about the supported IAM Identity Center context keys that can be used with this key, see AWS STS condition keys for IAM Identity Center in the *AWS IAM Identity Center User Guide*.

You can use this key in a role trust policy to enforce fine-grained access control based on the user or their attributes when they assume a role. After the role is assumed, activity appears in the AWS CloudTrail logs within the `AdditionalEventData` attribute, containing the session context key-value pairs that were set by the context provider in the assume role request. This makes it easier for administrators to differentiate between role sessions when a role is used by

different principals. The key-value pairs are set by the specified context provider, not by AWS CloudTrail or AWS STS. This gives the context provider control over what context is included in the CloudTrail logs and session information.

sts:RequestContextProviders

Works with ARN operators.

Use this key to compare the context provider ARN in the request with the context provider ARN specified in the role trust policy.

Availability – This key is present in the request when a context assertion is provided in the `ProvidedContexts` request parameter while assuming a role using the AWS STS AssumeRole API operation.

The following example condition checks that the context provider ARN passed in the request matches the ARN specified in the role trust policy condition. We recommend you add a null check with `ForAllValues` to prevent missing context keys or context keys with empty values from evaluating to true. For details, see Condition operator to check existence of condition keys .

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Action": "sts:SetContext",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
      "ForAllValues:ArnEquals": {
        "sts:RequestContextProviders": [
          "arn:aws:iam::aws:contextProvider/IdentityCenter"
        ]
      },
      "Null": {
        "sts:RequestContextProviders": "false"
      }
    }
  }
}
```

sts:RoleSessionName

Works with string operators.

Use this key to compare the session name that a principal specifies when assuming a role with the value that is specified in the policy.

Availability – This key is present in the request when the principal assumes the role using the AWS Management Console, any assume-role CLI command, or any AWS STS `AssumeRole` API operation.

You can use this key in a role trust policy to require that your users provide a specific session name when they assume a role. For example, you can require that IAM users specify their own user name as their session name. After the IAM user assumes the role, activity appears in AWS CloudTrail logs with the session name that matches their user name. This makes it easier for administrators to differentiate between role sessions when a role is used by different principals.

The following role trust policy requires that IAM users in account 111122223333 provide their IAM user name as the session name when they assume the role. This requirement is enforced using the `aws:username` condition variable in the condition key. This policy allows IAM users to assume the role to which the policy is attached. This policy does not allow anyone using temporary credentials to assume the role because the `username` variable is present for only IAM users.

> **Important**
>
> You can use any single-valued condition key as a variable. You can't use a multivalued condition key as a variable.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RoleTrustPolicyRequireUsernameForSessionName",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Principal": {"AWS": "arn:aws:iam::111122223333:root"},
```

```
            "Condition": {
                "StringLike": {"sts:RoleSessionName": "prefix-
${aws:username}"}
            }
        }
    ]
}
```

When an administrator views the AWS CloudTrail log for an action, they can compare the session name to the user names in their account. In the following example, the user named `matjac` performed the operation using the role named `MateoRole`. The administrator can then contact Mateo Jackson, who has the user named `matjac`.

```
"assumedRoleUser": {
    "assumedRoleId": "AROACQRSTUVWRAOEXAMPLE:matjac",
    "arn": "arn:aws:sts::111122223333:assumed-role/MateoRole/matjac"
}
```

If you allow cross-account access using roles, then users in one account can assume a role in another account. The ARN of the assumed role user listed in CloudTrail includes the account *where the role exists*. It does not include the account of the user that assumed the role. Users are unique only within an account. Therefore, we recommend that you use this method for checking CloudTrail logs only for roles that are assumed by users in accounts that you administer. Your users might use the same user name in multiple accounts.

sts:SourceIdentity

Works with string operators.

Use this key to compare the source identity that a principal specifies when assuming a role with the value that is specified in the policy.

Availability – This key is present in the request when the principal provides a source identity while assuming a role using any AWS STS assume-role CLI command, or AWS STS `AssumeRole` API operation.

You can use this key in a role trust policy to require that your users set a specific source identity when they assume a role. For example, you can require your workforce or federated identities to specify a value for source identity. You can configure your identity provider (IdP) to use one of the attributes that are associated with your users, like a user name or email as the source

identity. The IdP then passes the source identity as an attribute in the assertions or claims that it sends to AWS. The value of the source identity attribute identifies the user or application who is assuming the role.

After the user assumes the role, activity appears in AWS CloudTrail logs with the source identity value that was set. This makes it easier for administrators to determine who or what performed actions with a role in AWS. You must grant permissions for the `sts:SetSourceIdentity` action to allow an identity to set a source identity.

Unlike `sts:RoleSessionName`, after the source identity is set, the value cannot be changed. It is present in the request context for all actions taken with the role by the source identity. The value persists into subsequent role sessions when you use the session credentials to assume another role. Assuming one role from another is called role chaining.

You can use the `aws:SourceIdentity` global condition key to further control access to AWS resources based on the value of source identity in subsequent requests.

The following role trust policy allows the IAM user `AdminUser` to assume a role in account `111122223333`. It also grants permission to the `AdminUser` to set a source identity, as long as the source identity set is `DiegoRamirez`.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAdminUserAssumeRole",
            "Effect": "Allow",
            "Principal": {"AWS": " arn:aws:iam::111122223333:user/AdminUser"},
            "Action": [
                "sts:AssumeRole",
                "sts:SetSourceIdentity"
            ],
            "Condition": {
                "StringEquals": {"sts:SourceIdentity": "DiegoRamirez"}
            }
        }
    ]
}
```

To learn more about using source identity information, see Monitor and control actions taken with assumed roles.

sts:TaskPolicyArn

Works with ARN operators.

Use this key to compare the policy ARN in an sts:AssumeRoot request with the policy ARN specified in the policy.

Availability – This key is present in the request when you make a request using sts:AssumeRoot.

Administrators can use this condition key in IAM policies to restrict specific roles or users within the management account or delegated administrator account from performing certain actions when assuming root credentials. For more information, see Perform a privileged task on an AWS Organizations member account.

sts:TransitiveTagKeys

Works with string operators.

Use this key to compare the transitive session tag keys in the request with those specified in the policy.

Availability – This key is present in the request when you make a request using temporary security credentials. These include credentials created using any assume-role operation, or the `GetFederationToken` operation.

When you make a request using temporary security credentials, the request context includes the `aws:PrincipalTag` context key. This key includes a list of session tags, transitive session tags, and role tags. Transitive session tags are tags that persist into all subsequent sessions when you use the session credentials to assume another role. Assuming one role from another is called role chaining.

You can use this condition key in a policy to require setting specific session tags as transitive when assuming a role or federating a user.

Actions, resources, and condition keys for AWS services

Each AWS service can define actions, resources, and condition context keys for use in IAM policies. For a list of AWS services and their actions, resources, and condition context keys, see Actions, resources, and condition keys in the *Service Authorization Reference.*

Resources to learn more about IAM

IAM is a rich product, and you'll find many resources to help you learn more about how IAM can help you secure your AWS account and resources.

Topics

- Identities
- Credentials (passwords, access keys, and MFA devices)
- Permissions and policies
- Federation and delegation
- IAM and other AWS products
- General security practices
- General resources

Identities

Consult these resources for creating, managing, and using identities.

- Manage identities in IAM Identity Center – Procedural information about creating users and group in IAM Identity Center.
- **IAM Identities** – An in-depth discussion of users, groups, and roles.

Credentials (passwords, access keys, and MFA devices)

Review the following guides to manage passwords, access keys, and MFA devices for your AWS account and for IAM users.

- **User passwords in AWS** – Describes options for managing passwords for IAM users in your account.
- **Manage access keys for IAM users** – Describes how *access keys* work and how you can use them to make programmatic calls to AWS. There are other more secure alternatives to access keys that we recommend you consider first. For more information, see Considerations and alternatives for long-term access keys in the *AWS General Reference guide*.

- **AWS Multi-factor authentication in IAM** – Describes how to configure your account and IAM users to require both a password and a one-time use code that is generated on a device before sign-in is allowed. (This is sometimes called two-factor authentication.)

For general information about the types of credentials you use to access Amazon Web Services, see **AWS Security Credentials** in the *AWS General Reference guide*..

Permissions and policies

Learn the inner workings of IAM policies and find tips on the best ways to confer permissions:

- **Policies and permissions in AWS Identity and Access Management** – Introduces the policy language that is used to define permissions. Describes how permissions can be attached to users or groups or, for some AWS products, to resources themselves.
- **IAM JSON policy element reference** – Provides descriptions and examples of each policy language element.
- **IAM policy validation** – Find resources for JSON policy validation.
- **Example IAM identity-based policies** – Shows examples of policies for common tasks in various AWS products.
- **AWS Policy Generator** – Create custom policies by choosing products and actions from a list.
- **IAM Policy Simulator** – Test whether a policy would allow or deny a specific request to AWS.

Federation and delegation

You can grant access to resources in your AWS account for users who are authenticated (signed in) elsewhere. These can be IAM users in another AWS account (known as *delegation*), users who are authenticated with your organization's sign-in process, or users from an Internet identity provider like Login with Amazon, Facebook, Google, or any other OpenID Connect (OIDC) compatible identity provider. In these cases, the users get temporary security credentials to access AWS resources.

- **IAM tutorial: Delegate access across AWS accounts using IAM roles** – Guides you through granting cross-account access to an IAM user in another AWS account.
- **Common scenarios for temporary credentials** – Describes ways in which users can be federated into AWS after being authenticated outside of AWS.

IAM and other AWS products

Most AWS products are integrated with IAM so that you can use IAM features to help protect access to the resources in those products. The following resources discuss IAM and security for some of the most popular AWS products. For a complete list of products that work with IAM, including links to more information on each, see AWS services that work with IAM.

Using IAM with Amazon EC2

- Controlling Access to Amazon EC2 Resources – Describes how to use IAM features to permit users to administer Amazon EC2 instances, volumes, and more.
- Use instance profiles – Describes how to use IAM roles to securely provide credentials for applications that run on Amazon EC2 instances and that need access to other AWS products.

Using IAM with Amazon S3

- Managing Access Permissions to Your Amazon S3 Resources – Discusses the Amazon S3 security model for buckets and objects, which includes IAM policies.
- Writing IAM Policies: Grant Access to User-Specific Folders in an Amazon S3 Bucket – Discusses how to let users protect their own folders in Amazon S3. (For more posts about Amazon S3 and IAM, choose the **S3** tag below the title of the blog post.)

Using IAM with Amazon RDS

- Using AWS Identity and Access Management (IAM) to Manage Access to Amazon RDS Resources – Describes how to use IAM to control access to database instances, database snapshots, and more.
- A Primer on RDS Resource-Level Permissions – Describes how to use IAM to control access to specific Amazon RDS instances.

Using IAM with Amazon DynamoDB

- Using IAM to Control Access to DynamoDB Resources – Describes how to use IAM to permit users to administer DynamoDB tables and indexes.
- The following video (8:55) explains how to provide access control for individual DynamoDB database items or attributes (or both).

Getting Started with Fine-Grained Access Control for DynamoDB

General security practices

Find expert tips and guidance on the best ways to secure your AWS account and resources:

- **Best Practices for Security, Identity, &, Compliance** – Find resources for how to manage security across AWS accounts and products, including suggestions for security architecture, use of IAM, encryption and data security, and more.
- **Identity and Access Management** – The AWS Well-Architected Framework helps you understand key concepts, design principles, and architectural best practices for designing and running workloads in the cloud.
- **Security best practices in IAM** – Offers recommendations for ways to use IAM to help secure your AWS account and resources.
- **AWS CloudTrail User Guide** – Use AWS CloudTrail to track a history of API calls made to AWS and store that information in log files. This helps you determine which users and accounts accessed resources in your account, when the calls were made, what actions were requested, and more.

General resources

Explore the following resources to learn more about IAM and AWS.

- **Product Information for IAM** – General information about the AWS Identity and Access Management product.
- **AWS re:Post for AWS Identity and Access Management** – Visit AWS re:Post to discuss technical questions related to IAM with the AWS community.

- Classes & Workshops – Links to role-based and specialty courses, in addition to self-paced labs to help sharpen your AWS skills and gain practical experience.
- AWS Developer Center – Explore tutorials, download tools, and learn about AWS developer events.
- AWS Developer Tools – Links to developer tools, SDKs, IDE toolkits, and command line tools for developing and managing AWS applications.

- Getting Started Resource Center – Learn how to set up your AWS account, join the AWS community, and launch your first application.
- Hands-On Tutorials – Follow step-by-step tutorials to launch your first application on AWS.
- AWS Whitepapers – Links to a comprehensive list of technical AWS whitepapers, covering topics such as architecture, security, and economics and authored by AWS Solutions Architects or other technical experts.
- AWS Support Center – The hub for creating and managing your AWS Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and AWS Trusted Advisor.
- Support – The primary webpage for information about Support, a one-on-one, fast-response support channel to help you build and run applications in the cloud.
- Contact Us – A central contact point for inquiries concerning AWS billing, account, events, abuse, and other issues.
- AWS Site Terms – Detailed information about our copyright and trademark; your account, license, and site access; and other topics.

Calling the IAM API using HTTP query requests

Contents

- Endpoints
- HTTPS required
- Signing IAM API requests

You can access the IAM and AWS STS services programmatically using the Query API. Query API requests are HTTPS requests that must contain an `Action` parameter to indicate the action to be performed. IAM and AWS STS support GET and POST requests for all actions. That is, the API does not require you to use GET for some actions and POST for others. However, GET requests are subject to the limitation size of a URL; although this limit is browser dependent, a typical limit is 2048 bytes. Therefore, for Query API requests that require larger sizes, you must use a POST request.

The response is an XML document. For details about the response, see the individual action pages in the IAM API Reference or the AWS Security Token Service API Reference.

> **Tip**
>
> Instead of making direct calls to the IAM or AWS STS API operations, you can use one of the AWS SDKs. The AWS SDKs consist of libraries and sample code for various programming languages and platforms (Java, Ruby, .NET, iOS, Android, etc.). The SDKs provide a convenient way to create programmatic access to IAM and AWS. For example, the SDKs take care of tasks such as cryptographically signing requests (see below), managing errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see the Tools for Amazon Web Services page.

For details about the API actions and errors, see the IAM API Reference or the AWS Security Token Service API Reference.

Endpoints

IAM and AWS STS each have a single global endpoint:

- (IAM) https://iam.amazonaws.com
- (AWS STS) https://sts.amazonaws.com

> **Important**
>
> AWS STS also supports sending requests to regional endpoints in addition to the global endpoint. AWS recommends using regional endpoints instead of global endpoints to reduce latency, build in redundancy, and increase session token validity. Before you can use AWS STS in a Region, you must first activate STS in that Region for your AWS account. For more information about activating additional Regions for AWS STS, see Manage AWS STS in an AWS Region.

For more information about AWS endpoints and Regions for all services, see Service endpoints and quotas in the *AWS General Reference*.

HTTPS required

Because the Query API returns sensitive information such as security credentials, you must use HTTPS with all API requests.

Signing IAM API requests

Requests must be signed using an access key ID and a secret access key. We strongly recommend that you do not use your AWS account root user credentials for everyday work with IAM. You can use the credentials for an IAM user or you can use AWS STS to generate temporary security credentials.

To sign your API requests, we recommend using AWS Signature Version 4. For information about using Signature Version 4, go to Signature Version 4 Signing Process in the *AWS General Reference*.

If you need to use Signature Version 2, information about using Signature Version 2 is available in the AWS General Reference.

For more information, see the following:

- AWS Security Credentials. Provides general information about the types of credentials used for accessing AWS.

- Security best practices in IAM. Presents a list of suggestions for using IAM service to help secure your AWS resources.
- Temporary security credentials in IAM. Describes how to create and use temporary security credentials.

Document history for IAM

The following table describes major documentation updates for IAM.

Change	Description	Date
IAM condition context keys for service-specific credential APIs	IAM now supports two new condition context keys for controlling access to service-specific credential APIs: `iam:ServiceSpecificCredentialAgeDays` and `iam:ServiceSpecificCredentialServiceName` . These keys allow you to restrict the creation and management of service-specific credentials based on expiration settings and permitted AWS services. • `iam:ServiceSpecificCredentialAgeDays` • `iam:ServiceSpecificCredentialServiceName`	September 4, 2025
VPC endpoint condition keys for network perimeter controls	IAM now supports three new AWS global condition context keys for implementing scalable network perimeter controls: `aws:VpceAccount` , `aws:VpceOrgID` , and `aws:VpceOrgPaths` . These keys help ensure requests come through	August 28, 2025

	VPC endpoints owned by specific accounts, organizations, or organizational units, automatically scaling with your VPC endpoint usage without requiring policy updates when you create new endpoints. For more information, see Establish permissions guardrails using data perimeters.	
IAM SAML federation AWS CloudFormation tutorials	IAM added new tutorials for creating SAML identity providers (IdPs) and federated roles using AWS CloudFormation. • Create SAML IdP with AWS CloudFormation • Create SAML federated role with AWS CloudFormation • Create SAML IdP and federated role with AWS CloudFormation	August 25, 2025
Additional shared OIDC provider controls for shared OIDC providers	IAM now includes Amazon Cognito, Azure Sentinel, Pulumi Cloud, and Vercel global endpoint in the list of shared OIDC identity providers that require explicit evaluation of specific claims in JSON Web Tokens (JWTs).	August 1, 2025

IAM Access Analyzer added internal access analyzers	IAM Access Analyzer helps you identify which principals within your organization or account have access to selected business-critical resources. Internal access analyzers support implementing the principle of least privilege by ensuring that your specified resources can only be accessed by the intended principals within your AWS organization or account.	June 16, 2025
Identity provider controls for shared OIDC providers	IAM now requires explicit evaluation of specific claims in JSON Web Tokens (JWTs) for recognized shared OIDC identity providers. This security control ensures that only authorized identities from the intended organization can assume roles and access AWS resources.	June 6, 2025
`IAMUserChangePassword` – Added permissions	IAM added permissions to IAMUserChangePassword to allow users specified within a path.	May 28, 2025
`AccessAnalyzerServiceRolePolicy` – Added permissions	IAM Access Analyzer added `iam:GetAccountAuthorizationDetails` to the service-level permissions of AccessAnalyzerServiceRolePolicy.	May 12, 2025

AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added Amazon S3 directory bucket access points to the service-level permissions of AccessAnalyzerServiceRolePolicy.	March 31, 2025
IAM dual-stack endpoint support	IAM now provides improved dual-stack endpoint support that enables clients to communicate with IAM using either IPv4 or IPv6 addresses.	March 20, 2025
Updates to policy evaluation logic	Enhanced documentation for policy evaluation logic, including improved flow charts and clearer explanations of how AWS evaluates policies to determine whether to allow or deny a request.	January 30, 2025
IAMDeleteRootUserCredentials – Removed permissions	IAM removed the `iam:DeleteVirtualMFADevice` permission from the managed policy.	January 7, 2025
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for permission to retrieve information about Amazon ECR account settings and registry policies to the service-level permissions of AccessAnalyzerServiceRolePolicy.	December 10, 2024

IAM Access Analyzer added access configuration	IAM Access Analyzer added support to configure analyzers to change the scope of which AWS accounts, IAM users, and roles generate findings.	November 14, 2024
Centrally manage root access for member accounts	You can now manage privileged root user credentia ls across member accounts in AWS Organizations with centralized root access. Centrally secure the root user credentials of your AWS accounts managed using AWS Organizations to remove and prevent root user credential recovery and access at scale. • Root user best practices	November 14, 2024

AWS managed policy update - New policies	IAM added two new policies to scope permissions for privileged root user sessions that you can initiate after you centralize root user access for member accounts in your organization. • IAMAuditRootUserCredentials • IAMCreateRootUserPassword • IAMDeleteRootUserCredentials • S3UnlockBucketPolicy • SQSUnlockQueuePolicy	November 14, 2024
Support for AWS Organizations resource control policies (RCPs)	Use an AWS Organizations resource control policy (RCP) to define the maximum permissions for resources within accounts in your organization or organizational unit (OU). RCPs limit permissions that identity-based and resource-based policies can grant to resources in accounts within your organization.	November 13, 2024

AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for permission to retrieve information about IAM user and role tags to the service-level permissions of AccessAnalyzerServiceRolePolicy.	October 29, 2024
SAML encryption support enhancements	Enhanced documentation for SAML encryption support in IAM SAML providers, including improved troubleshooting guidance and clarification on service compatibility.	June 5, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for permission to retrieve information about IAM user and role policies to the service-level permissions of AccessAnalyzerServiceRolePolicy.	May 30, 2024
Encryption support for SAML identity providers	IAM SAML providers now support encrypted assertions in the SAML response from your external IdP. To understand how encryption works with IAM SAML federation, see Using SAML-based federation for API access.	February 4, 2024

AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for permission to retrieve the current state of the block public access for Amazon EC2 snapshots to the service-level permissions of AccessAnalyzerServiceRolePolicy.	January 23, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added DynamoDB streams and tables to the service-level permissions of AccessAnalyzerServiceRolePolicy.	January 11, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added Amazon S3 directory buckets to the service-level permissions of AccessAnalyzerServiceRolePolicy.	December 1, 2023
IAMAccessAnalyzerReadOnlyAccess – Added permissions	IAM Access Analyzer added permissions to IAMAccessAnalyzerReadOnlyAccess to allow you to check whether updates to your policies grant additional access. This permission is required by IAM Access Analyzer to perform policy checks on your policies.	November 26, 2023

IAM Access Analyzer added unused access analyzers	IAM Access Analyzer simplifies inspecting unused access to guide you toward least privilege. IAM Access Analyzer continuously analyzes your accounts to identify unused access and creates a centralized dashboard with findings.	November 26, 2023
IAM Access Analyzer added custom policy checks	IAM Access Analyzer now provides custom policy checks to validate that IAM policies adhere to your security standards ahead of deployments.	November 26, 2023
`AccessAnalyzerServiceRolePolicy` – Added permissions	IAM Access Analyzer added IAM actions to the service-level permissions of AccessAnalyzerServiceRolePolicy to support the following actions: • Listing entities for a policy • Generating service last accessed details • Listing access key information	November 26, 2023
Action last accessed information and policy generation support for over 60 additional services and actions	IAM now supports action last accessed information and generates policies with action-level information for over 60 additional services, along with a list of the actions for which action last accessed information is available.	November 1, 2023

Action last accessed information support for over 140 services	IAM now provides action last accessed information for more than 140 services, along with a list of the actions for which action last accessed information is available.	September 14, 2023
Support for multiple multi-factor authentication (MFA) devices for root users and IAM users	Now you can to add up to eight MFA devices per user, including FIDO security keys, software time-based one-time password (TOTP) with virtual authenticator applications, or hardware TOTP tokens.	November 16, 2022
IAM Access Analyzer support for new resource types	IAM Access Analyzer added support for the following resource types: • Amazon EBS volume snapshots • Amazon ECR repositories • Amazon EFS file systems • Amazon RDS DB snapshots • Amazon RDS DB cluster snapshots • Amazon SNS topics	October 25, 2022
U2F deprecation and WebAuthn/FIDO update	Removed mentions of U2F as an MFA option and added information about WebAuthn, FIDO2, and FIDO security keys.	May 31, 2022

Updates to resilience in IAM	Added information about maintaining access to IAM credentials when an event disrupts communication between AWS Regions.	May 16, 2022
New global condition keys for resources	You can now control access to resources based on the account, Organizational Unit (OU), or organization in AWS Organizations that contains your resources. You can use the `aws:ResourceAccount` , `aws:ResourceOrgID` , and `aws:ResourceOrgPaths` global condition keys in an IAM policy.	April 27, 2022
Code examples for IAM using AWS SDKs	Added code examples that show how to use IAM with an AWS software development kit (SDK). The examples are divided into code excerpts that show you how to call individual service functions and examples that show you how to accomplish a specific task by calling multiple functions within the same service.	April 7, 2022
Updates to policy evaluation logic flow chart	Updates to the policy evaluation logic flow chart and related text in the Determining whether a request is allowed or denied within an account section.	November 17, 2021

Updates to security best practices	Added information about creating administrative users instead of using root user credentials, removed the best practice of using IAM groups to assign permissions to IAM users, and clarified when to use managed policies instead of inline policies.	October 5, 2021
Updates to policy evaluation logic topic for resource-based policies	Added information about the impact of resource-based policies and different principal types in the same account.	October 5, 2021
Updates to single-valued and multivalued condition keys	The differences between single-valued and multivalued condition keys are now explained in more detail. The value type was added to each AWS global condition context key.	September 30, 2021
IAM Access Analyzer supports Amazon S3 Multi-Region Access Points	IAM Access Analyzer identifies Amazon S3 buckets that allow public and cross-account access, including those that use Amazon S3 Multi-Region Access Points.	September 2, 2021
AWS managed policy updates - Update to an existing policy	IAM Access Analyzer updated an existing AWS managed policy.	September 2, 2021

More services supported for action-level policy generation	IAM Access Analyzer can generate IAM policies with action-level access activity information for additional AWS services.	August 24, 2021
Generate IAM policies for cross-account trails	You can now use IAM Access Analyzer to generate fine-grai ned policies based on your access activity using a AWS CloudTrail trail in a different account, for example, a centralized AWS Organizat ions trail.	August 18, 2021

Additional IAM Access Analyzer policy checks	IAM Access Analyzer extended policy validation by adding new policy checks that validate conditions included in IAM policies. These checks analyze the condition block in your policy statement and report security warnings, errors, and suggestions along with actionable recommend ations. IAM Access Analyzer added the following policy checks: • Error – Invalid service principal format • Error – Missing tag key in condition • Security Warning – Deny NotAction with unsupport ed tag condition key for service • Security Warning – Deny with unsupported tag condition key for service • Security Warning – Missing paired condition keys • Suggestion – Allow NotAction with unsupport ed tag condition key for service • Suggestion – Allow with unsupported tag condition key for service	June 29, 2021

Action last accessed support for more services	You can now view action last accessed information in the IAM console about the last time an IAM principal used an action for the following services: Amazon EC2, IAM, Lambda, and Amazon S3 management actions. You can also use the AWS CLI or AWS API to retrieve a data report. You can use this informati on to identify unnecessary permissions so that you can refine your IAM policies to better adhere to the principle of least privilege.	April 19, 2021
Monitor and control actions taken with assumed roles	Administrators can configure IAM roles to require that identities pass a source identity, which is logged in AWS CloudTrail. Reviewing source identity informati on helps administrators determine who or what performed actions with assumed role sessions.	April 13, 2021
Generate IAM policies based on access activity	You can now use IAM Access Analyzer to generate fine-grai ned policies based on your access activity found in your AWS CloudTrail.	April 7, 2021

IAM Access Analyzer policy checks	IAM Access Analyzer now provides over 100 policy checks with actionable recommendations during policy authoring.	March 16, 2021
Expanded policy validation options	Expanded policy validation available in the IAM console, AWS API, and AWS CLI using policy checks in IAM Access Analyzer to help you author secure and functional JSON policies.	March 15, 2021
Tagging IAM resources	You can now tag additional IAM resources using a tag key-value pair.	February 11, 2021
Default password policy for IAM users	If you do not set a custom password policy for your AWS account, IAM user passwords must now meet the default AWS password policy.	November 18, 2020
The actions, resources, and condition keys pages for AWS services have moved	Each AWS service can define actions, resources, and condition context keys for use in IAM policies. You can now find the list of AWS services and their actions, resources , and condition context keys in the *Service Authorization Reference.*	November 16, 2020

IAM users longer role session duration	IAM users can now have a longer role session duration when switching roles in the AWS Management Console, reducing interruptions due to session expiration. Users are granted the maximum session duration set for the role, or the remaining time in the IAM user's session, whichever is less.	July 24, 2020
Use Service Quotas to request quick increases for IAM entities	You can request quota increases for adjustable IAM quotas using the Service Quotas console. Now, some increases are automatically approved in Service Quotas and available in your account within a few minutes. Larger requests are submitted to AWS Support.	June 25, 2020

Last accessed information in IAM now includes Amazon S3 management actions	In addition to service last accessed information, you can now view information in the IAM console about the last time an IAM principal used an Amazon S3 action. You can also use the AWS CLI or AWS API to retrieve the data report. The report includes information about the allowed services and actions that principals last attempted to access and when. You can use this information to identify unnecessary permissions so that you can refine your IAM policies to better adhere to the principle of least privilege.	June 3, 2020
Security chapter addition	The security chapter helps you understand how to configure IAM and AWS STS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your IAM resources.	April 29, 2020
sts:RoleSessionName	You can now write a policy that grants permissions based on the session name that a principal specifies when assuming a role.	April 21, 2020

AWS sign-in page update	When you sign in on the main AWS sign-in page, you can no choose to sign in as the AWS account root user or an IAM user. When you do, the label on the page indicates whether you should provide your root user email address or your IAM user information. This documentation includes updated screen captures to help you understand the AWS sign-in pages.	March 4, 2020
aws:ViaAWSService and aws:CalledVia condition keys	You can now write a policy to limit whether services can make requests on behalf of an IAM principal (user or role). When a principal makes a request to an AWS service, that service might use the principal's credentials to make subsequent requests to other services. Use the `aws:ViaAWSService` condition key to match if any service makes a request using a principal's credentia ls. Use the `aws:CalledVia` condition keys to match if specific services make a request using a principal's credentials.	February 20, 2020

Policy simulator adds support for permissions boundaries	You can now test the effect of permissions boundaries on IAM entities with the IAM policy simulator.	January 23, 2020
Cross-account policy evaluation	You can now learn how AWS evaluates policies for cross-account access. This occurs when a resource in a trusting account includes a resource-based policy that allows a principal in another account to access the resource. The request must be allowed in both accounts.	January 2, 2020
Session tags	You can now include tags when you assume a role or federate a user in AWS STS. When you perform the `AssumeRole` or `GetFederationToken` operation, you can pass the session tags as attributes. When you perform the `AssumeRoleWithSAML` or `AssumeRoleWithWebIdentity` operations, you can pass attributes from your corporate identities to AWS.	November 22, 2019

Control access for groups of AWS accounts in AWS Organizations	You can now reference organizational units (OUs) from AWS Organizations in IAM policies. If you use AWS Organizations to organize your accounts into OUs, you can require that principal s belong to a specific OU before granting access to your resources. Principals include AWS account root user, IAM users and IAM roles. To do this, specify the OU path in the `aws:PrincipalOrgPaths` condition key in your policies.	November 20, 2019
Role last used	You can now view the date, time, and Region where a role was last used. This information also helps you identify unused roles in your account. You can use the AWS Management Console, AWS CLI and AWS API to view information about when a role was last used.	November 19, 2019

Update to the global condition context keys page	You can now learn when each of the global condition keys is included in the context of a request. You can also navigate to each key more easily using the page table of contents (TOC). The information on the page helps you to write more accurate policies. For example, if your employees use federation with IAM roles, you should use the `aws:userId` key and not the `aws:userName` key. The `aws:userName` key applies only to IAM users and not roles.	October 6, 2019
ABAC in AWS	Learn how attribute-based access control (ABAC) works in AWS using tags, and how it compares to the tradition al AWS authorization model. Use the ABAC tutorial to learn how to create and test a policy that allows IAM roles with principal tags to access resources with matching tags. This strategy allows individua ls to view or edit only the AWS resources required for their jobs.	October 3, 2019

AWS STS GetAccessKeyInfo operation	You can review the AWS access keys in your code to determine whether the keys are from an account that you own. You can pass an access key ID using the `aws sts get-access-key-info` AWS CLI command or the `GetAccessKeyInfo` AWS API operation.	July 24, 2019
Viewing AWS Organizations service last accessed information in IAM	You can now view service last accessed information for an AWS Organizations entity or policy in the **AWS Organizations** section of the IAM console. You can also use the AWS CLI or AWS API to retrieve the data report. This data includes information about the allowed services that principals in an AWS Organizations account last attempted to access and when. You can use this information to identify unnecessary permissions so that you can refine your AWS Organizations policies to better adhere to the principle of least privilege.	June 20, 2019

Using a managed policy as a session policy	You can now pass up to 10 managed policy ARNs when you assume a role. This allows you to limit the permissio ns of the role's temporary credentials.	May 7, 2019
AWS STS Region compatibi lity of session tokens for the global endpoint	You can now choose whether to use version 1 or version 2 global endpoint tokens. Version 1 tokens are valid only in AWS Regions that are available by default. These tokens will not work in manually enabled Regions, such as Asia Pacific (Hong Kong). Version 2 tokens are valid in all Regions. However, version 2 tokens are longer and might affect systems where you temporarily store tokens.	April 26, 2019
Allow enabling and disabling AWS regions	You can now create a policy that allows an administrator to enable and disable the Asia Pacific (Hong Kong) Region (ap-east-1).	April 24, 2019

IAM user my security credentials page	IAM users can now manage all of their own credentials on the **My Security Credentials** page. This AWS Managemen t Console page displays account information such as the account ID and canonical user ID. Users can also view and edit their own passwords, access keys, X.509 certificates, SSH keys, and Git credentials.	January 24, 2019
Access Analyzer API	You can now use the AWS CLI and AWS API to view service last accessed information.	December 7, 2018
Tagging IAM users and roles	You can now use IAM tags to add custom attributes to an identity (IAM user or role) using a tag key-value pair. You can also use tags to control an identity's access to resources or to control what tags can be attached to an identity.	November 14, 2018
U2F security keys	You can now use U2F security keys as a multi-factor authentication (MFA) option when signing in to the AWS Management Console.	September 25, 2018
Support for Amazon VPC endpoints	You can now establish a private connection between your VPC and AWS STS in the US West (Oregon) Region.	July 31, 2018

Permissions boundaries	New feature makes it easier to grant trusted employees the ability to manage IAM permissions without also granting full IAM administr ative access.	July 12, 2018
aws:PrincipalOrgID	New condition key provides an easier way to control access to AWS resources by specifying the AWS organizat ion of IAM principals.	May 17, 2018
aws:RequestedRegion	New condition key provides an easier way to use IAM policies to control access to AWS Regions.	April 25, 2018
Increased session duration for IAM roles	An IAM role can now have a session duration of 12 hours.	March 28, 2018
Updated role-creation workflow	New workflow improves the process of creating trust relationships and attaching permissions to roles.	September 8, 2017
AWS account sign-in process	Updated AWS sign-in experience allows both the root user and IAM users to use the **Sign In to the Console** link on the AWS Management Console's home page.	August 25, 2017
Example IAM policies	Documentation update features more than 30 example policies.	August 2, 2017

IAM best practices	Information added to the **Users** section of the IAM console makes it easier to follow IAM best practices.	July 5, 2017
Auto Scaling resources	Resource-level permissions can control access to and permissions for Auto Scaling resources.	May 16, 2017
Amazon RDS for MySQL and Amazon Aurora databases	Database administrators can associate database users with IAM users and roles and thus manage user access to all AWS resources from a single location.	April 24, 2017
Service-linked roles	Service-linked roles provide an easier and more secure way to delegate permissions to AWS services.	April 19, 2017
Policy summaries	New policy summaries make it easier to understand permissions in IAM policies.	March 23, 2017
