Amazon DynamoDB Developer Guide

API Version 2012-08-10

v
What Is Amazon DynamoDB?

Welcome to the Amazon DynamoDB Developer Guide.

Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. DynamoDB lets you offload the administrative burdens of operating and scaling a distributed database so that you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling. DynamoDB also offers encryption at rest, which eliminates the operational burden and complexity involved in protecting sensitive data. For more information, see DynamoDB Encryption at Rest (p. 816).

With DynamoDB, you can create database tables that can store and retrieve any amount of data and serve any level of request traffic. You can scale up or scale down your tables' throughput capacity without downtime or performance degradation. You can use the AWS Management Console to monitor resource utilization and performance metrics.

DynamoDB provides on-demand backup capability. It allows you to create full backups of your tables for long-term retention and archival for regulatory compliance needs. For more information, see On-Demand Backup and Restore for DynamoDB (p. 604).

You can create on-demand backups and enable point-in-time recovery for your Amazon DynamoDB tables. Point-in-time recovery helps protect your tables from accidental write or delete operations. With point-in-time recovery, you can restore that table to any point in time during the last 35 days. For more information, see Point-in-Time Recovery: How It Works (p. 619).

DynamoDB allows you to delete expired items from tables automatically to help you reduce storage usage and the cost of storing data that is no longer relevant. For more information, see Expiring Items By Using DynamoDB Time to Live (TTL) (p. 409).

High Availability and Durability

DynamoDB automatically spreads the data and traffic for your tables over a sufficient number of servers to handle your throughput and storage requirements, while maintaining consistent and fast performance. All of your data is stored on solid-state disks (SSDs) and is automatically replicated across multiple Availability Zones in an AWS Region, providing built-in high availability and data durability. You can use global tables to keep DynamoDB tables in sync across AWS Regions. For more information, see Global Tables: Multi-Region Replication with DynamoDB (p. 625).

Getting Started with DynamoDB

We recommend that you begin by reading the following sections:

- Amazon DynamoDB: How It Works (p. 2)—To learn essential DynamoDB concepts.
- Setting Up DynamoDB (p. 46)—To learn how to set up DynamoDB (the downloadable version or the web service).
- Accessing DynamoDB (p. 55)—To learn how to access DynamoDB using the console, AWS CLI, or API.
Amazon DynamoDB: How It Works

The following sections provide an overview of Amazon DynamoDB service components and how they interact.

After you read this introduction, try working through the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section, which walks you through the process of creating sample tables, uploading data, and performing some basic database operations.

For language-specific tutorials with sample code, see Getting Started with DynamoDB and AWS SDKs (p. 77).

Core Components of Amazon DynamoDB

In DynamoDB, tables, items, and attributes are the core components that you work with. A table is a collection of items, and each item is a collection of attributes. DynamoDB uses primary keys to uniquely identify each item in a table and secondary indexes to provide more querying flexibility. You can use DynamoDB Streams to capture data modification events in DynamoDB tables.

There are limits in DynamoDB. For more information, see Service, Account, and Table Limits in Amazon DynamoDB (p. 961).
Tables, Items, and Attributes

The following are the basic DynamoDB components:

- **Tables** – Similar to other database systems, DynamoDB stores data in tables. A *table* is a collection of data. For example, see the example table called *People* that you could use to store personal contact information about friends, family, or anyone else of interest. You could also have a *Cars* table to store information about vehicles that people drive.

- **Items** – Each table contains zero or more items. An *item* is a group of attributes that is uniquely identifiable among all of the other items. In a *People* table, each item represents a person. For a *Cars* table, each item represents one vehicle. Items in DynamoDB are similar in many ways to rows, records, or tuples in other database systems. In DynamoDB, there is no limit to the number of items you can store in a table.

- **Attributes** – Each item is composed of one or more attributes. An *attribute* is a fundamental data element, something that does not need to be broken down any further. For example, an item in a *People* table contains attributes called *PersonID*, *LastName*, *FirstName*, and so on. For a *Department* table, an item might have attributes such as *DepartmentID*, *Name*, *Manager*, and so on. Attributes in DynamoDB are similar in many ways to fields or columns in other database systems.

The following diagram shows a table named *People* with some example items and attributes.
Note the following about the People table:

- Each item in the table has a unique identifier, or primary key, that distinguishes the item from all of the others in the table. In the People table, the primary key consists of one attribute (PersonID).
- Other than the primary key, the People table is schemaless, which means that neither the attributes nor their data types need to be defined beforehand. Each item can have its own distinct attributes.
- Most of the attributes are scalar, which means that they can have only one value. Strings and numbers are common examples of scalars.
• Some of the items have a nested attribute (*Address*). DynamoDB supports nested attributes up to 32 levels deep.

The following is another example table named *Music* that you could use to keep track of your music collection.

**Music**

```
{
    "Artist": "No One You Know",
    "SongTitle": "My Dog Spot",
    "AlbumTitle": "Hey Now",
    "Price": 1.98,
    "Genre": "Country",
    "CriticRating": 8.4
}
```

```
{
    "Artist": "No One You Know",
    "SongTitle": "Somewhere Down The Road",
    "AlbumTitle": "Somewhat Famous",
    "Genre": "Country",
    "CriticRating": 8.4,
    "Year": 1984
}
```

```
{
    "Artist": "The Acme Band",
    "SongTitle": "Still in Love",
    "AlbumTitle": "The Buck Starts Here",
    "Price": 2.47,
    "Genre": "Rock",
    "PromotionInfo": {
        "RadioStationsPlaying": {
            "KHOV",
            "KQBX",
            "WTNR",
            "WJHJ"
        },
        "TourDates": {
            "Seattle": "20150625",
            "Cleveland": "20150630"
        },
        "Rotation": "Heavy"
    }
}
```

```
{
    "Artist": "The Acme Band",
    "SongTitle": "Look Out, World",
    "AlbumTitle": "The Buck Starts Here",
    "Price": 0.99,
    "Genre": "Rock"
}
```

Note the following about the *Music* table:

• The primary key for *Music* consists of two attributes (*Artist* and *SongTitle*). Each item in the table must have these two attributes. The combination of *Artist* and *SongTitle* distinguishes each item in the table from all of the others.
• Other than the primary key, the Music table is schemaless, which means that neither the attributes nor their data types need to be defined beforehand. Each item can have its own distinct attributes.

• One of the items has a nested attribute (PromotionInfo), which contains other nested attributes. DynamoDB supports nested attributes up to 32 levels deep.

For more information, see Working with Tables and Data in DynamoDB (p. 336).

Primary Key

When you create a table, in addition to the table name, you must specify the primary key of the table. The primary key uniquely identifies each item in the table, so that no two items can have the same key.

DynamoDB supports two different kinds of primary keys:

• **Partition key** – A simple primary key, composed of one attribute known as the *partition key*.

  DynamoDB uses the partition key's value as input to an internal hash function. The output from the hash function determines the partition (physical storage internal to DynamoDB) in which the item will be stored.

  In a table that has only a partition key, no two items can have the same partition key value.

  The People table described in Tables, Items, and Attributes (p. 3) is an example of a table with a simple primary key (PersonID). You can access any item in the People table directly by providing the PersonId value for that item.

• **Partition key and sort key** – Referred to as a *composite primary key*, this type of key is composed of two attributes. The first attribute is the *partition key*, and the second attribute is the *sort key*.

  DynamoDB uses the partition key value as input to an internal hash function. The output from the hash function determines the partition (physical storage internal to DynamoDB) in which the item will be stored. All items with the same partition key value are stored together, in sorted order by sort key value.

  In a table that has a partition key and a sort key, it's possible for two items to have the same partition key value. However, those two items must have different sort key values.

  The Music table described in Tables, Items, and Attributes (p. 3) is an example of a table with a composite primary key (Artist and SongTitle). You can access any item in the Music table directly, if you provide the Artist and SongTitle values for that item.

A composite primary key gives you additional flexibility when querying data. For example, if you provide only the value for Artist, DynamoDB retrieves all of the songs by that artist. To retrieve only a subset of songs by a particular artist, you can provide a value for Artist along with a range of values for SongTitle.

**Note**

The partition key of an item is also known as its *hash attribute*. The term *hash attribute* derives from the use of an internal hash function in DynamoDB that evenly distributes data items across partitions, based on their partition key values.

The sort key of an item is also known as its *range attribute*. The term *range attribute* derives from the way DynamoDB stores items with the same partition key physically close together, in sorted order by the sort key value.

Each primary key attribute must be a scalar (meaning that it can hold only a single value). The only data types allowed for primary key attributes are string, number, or binary. There are no such restrictions for other, non-key attributes.
Secondary Indexes

You can create one or more secondary indexes on a table. A secondary index lets you query the data in the table using an alternate key, in addition to queries against the primary key. DynamoDB doesn't require that you use indexes, but they give your applications more flexibility when querying your data. After you create a secondary index on a table, you can read data from the index in much the same way as you do from the table.

DynamoDB supports two kinds of indexes:

- Global secondary index – An index with a partition key and sort key that can be different from those on the table.
- Local secondary index – An index that has the same partition key as the table, but a different sort key.

Each table in DynamoDB has a limit of 20 global secondary indexes (default limit) and 5 local secondary indexes per table.

In the example Music table shown previously, you can query data items by Artist (partition key) or by Artist and SongTitle (partition key and sort key). What if you also wanted to query the data by Genre and AlbumTitle? To do this, you could create an index on Genre and AlbumTitle, and then query the index in much the same way as you'd query the Music table.

The following diagram shows the example Music table, with a new index called GenreAlbumTitle. In the index, Genre is the partition key and AlbumTitle is the sort key.
Note the following about the **GenreAlbumTitle** index:

- Every index belongs to a table, which is called the base table for the index. In the preceding example, **Music** is the base table for the **GenreAlbumTitle** index.
- DynamoDB maintains indexes automatically. When you add, update, or delete an item in the base table, DynamoDB adds, updates, or deletes the corresponding item in any indexes that belong to that table.
- When you create an index, you specify which attributes will be copied, or projected, from the base table to the index. At a minimum, DynamoDB projects the key attributes from the base table into the index. This is the case with **GenreAlbumTitle**, where only the key attributes from the **Music** table are projected into the index.
You can query the `GenreAlbumTitle` index to find all albums of a particular genre (for example, all Rock albums). You can also query the index to find all albums within a particular genre that have certain album titles (for example, all Country albums with titles that start with the letter H).

For more information, see Improving Data Access with Secondary Indexes (p. 497).

**DynamoDB Streams**

DynamoDB Streams is an optional feature that captures data modification events in DynamoDB tables. The data about these events appear in the stream in near-real time, and in the order that the events occurred.

Each event is represented by a stream record. If you enable a stream on a table, DynamoDB Streams writes a stream record whenever one of the following events occurs:

- A new item is added to the table: The stream captures an image of the entire item, including all of its attributes.
- An item is updated: The stream captures the "before" and "after" image of any attributes that were modified in the item.
- An item is deleted from the table: The stream captures an image of the entire item before it was deleted.

Each stream record also contains the name of the table, the event timestamp, and other metadata. Stream records have a lifetime of 24 hours; after that, they are automatically removed from the stream.

You can use DynamoDB Streams together with AWS Lambda to create a trigger—code that executes automatically whenever an event of interest appears in a stream. For example, consider a Customers table that contains customer information for a company. Suppose that you want to send a "welcome" email to each new customer. You could enable a stream on that table, and then associate the stream with a Lambda function. The Lambda function would execute whenever a new stream record appears, but only process new items added to the Customers table. For any item that has an EmailAddress attribute, the Lambda function would invoke Amazon Simple Email Service (Amazon SES) to send an email to that address.
In this example, the last customer, Craig Roe, will not receive an email because he doesn’t have an EmailAddress.

In addition to triggers, DynamoDB Streams enables powerful solutions such as data replication within and across AWS Regions, materialized views of data in DynamoDB tables, data analysis using Kinesis materialized views, and much more.

For more information, see Capturing Table Activity with DynamoDB Streams (p. 574).

**DynamoDB API**

To work with Amazon DynamoDB, your application must use a few simple API operations. The following is a summary of these operations, organized by category.

**Topics**
- Control Plane (p. 10)
- Data Plane (p. 11)
- DynamoDB Streams (p. 12)
- Transactions (p. 12)

**Control Plane**

*Control plane* operations let you create and manage DynamoDB tables. They also let you work with indexes, streams, and other objects that are dependent on tables.

- **CreateTable** – Creates a new table. Optionally, you can create one or more secondary indexes, and enable DynamoDB Streams for the table.
• **DescribeTable**—Returns information about a table, such as its primary key schema, throughput settings, and index information.

• **ListTables**—Returns the names of all of your tables in a list.

• **UpdateTable**—Modifies the settings of a table or its indexes, creates or removes new indexes on a table, or modifies DynamoDB Streams settings for a table.

• **DeleteTable**—Removes a table and all of its dependent objects from DynamoDB.

## Data Plane

*Data plane* operations let you perform create, read, update, and delete (also called **CRUD**) actions on data in a table. Some of the data plane operations also let you read data from a secondary index.

### Creating Data

• **PutItem**—Writes a single item to a table. You must specify the primary key attributes, but you don't have to specify other attributes.

• **BatchWriteItem**—Writes up to 25 items to a table. This is more efficient than calling **PutItem** multiple times because your application only needs a single network round trip to write the items. You can also use **BatchWriteItem** for deleting multiple items from one or more tables.

### Reading Data

• **GetItem**—Retrieves a single item from a table. You must specify the primary key for the item that you want. You can retrieve the entire item, or just a subset of its attributes.

• **BatchGetItem**—Retrieves up to 100 items from one or more tables. This is more efficient than calling **GetItem** multiple times because your application only needs a single network round trip to read the items.

• **Query**—Retrieves all items that have a specific partition key. You must specify the partition key value. You can retrieve entire items, or just a subset of their attributes. Optionally, you can apply a condition to the sort key values so that you only retrieve a subset of the data that has the same partition key. You can use this operation on a table, provided that the table has both a partition key and a sort key. You can also use this operation on an index, provided that the index has both a partition key and a sort key.

• **Scan**—Retrieves all items in the specified table or index. You can retrieve entire items, or just a subset of their attributes. Optionally, you can apply a filtering condition to return only the values that you are interested in and discard the rest.

### Updating Data

• **UpdateItem**—Modifies one or more attributes in an item. You must specify the primary key for the item that you want to modify. You can add new attributes and modify or remove existing attributes. You can also perform conditional updates, so that the update is only successful when a user-defined condition is met. Optionally, you can implement an atomic counter, which increments or decrements a numeric attribute without interfering with other write requests.

### Deleting Data

• **DeleteItem**—Deletes a single item from a table. You must specify the primary key for the item that you want to delete.

• **BatchWriteItem**—Deletes up to 25 items from one or more tables. This is more efficient than calling **DeleteItem** multiple times because your application only needs a single network round trip to delete the items. You can also use **BatchWriteItem** for adding multiple items to one or more tables.
DynamoDB Streams

*DynamoDB Streams* operations let you enable or disable a stream on a table, and allow access to the data modification records contained in a stream.

- **ListStreams** – Returns a list of all your streams, or just the stream for a specific table.
- **DescribeStream** – Returns information about a stream, such as its Amazon Resource Name (ARN) and where your application can begin reading the first few stream records.
- **GetShardIterator** – Returns a **shard iterator**, which is a data structure that your application uses to retrieve the records from the stream.
- **GetRecords** – Retrieves one or more stream records, using a given shard iterator.

Transactions

*Transactions* provide atomicity, consistency, isolation, and durability (ACID) enabling you to maintain data correctness in your applications more easily.

- **TransactWriteItems** – A batch operation that allows **Put**, **Update**, and **Delete** operations to multiple items both within and across tables with a guaranteed all-or-nothing result.
- **TransactGetItems** – A batch operation that allows **Get** operations to retrieve multiple items from one or more tables.

Naming Rules and Data Types

This section describes the Amazon DynamoDB naming rules and the various data types that DynamoDB supports. There are limits that apply to data types. For more information, see *Data Types* (p. 965).

**Topics**

- Naming Rules (p. 12)
- Data Types (p. 13)

Naming Rules

Tables, attributes, and other objects in DynamoDB must have names. Names should be meaningful and concise—for example, names such as *Products*, *Books*, and *Authors* are self-explanatory.

The following are the naming rules for DynamoDB:

- All names must be encoded using UTF-8, and are case-sensitive.
- Table names and index names must be between 3 and 255 characters long, and can contain only the following characters:
  - a–z
  - A–Z
  - 0–9
  - _ (underscore)
  - – (dash)
  - . (dot)
- Attribute names must be between 1 and 255 characters long.
Reserved Words and Special Characters

DynamoDB has a list of reserved words and special characters. For a complete list of reserved words in DynamoDB, see Reserved Words in DynamoDB (p. 1027). Also, the following characters have special meaning in DynamoDB: # (hash) and : (colon).

Although DynamoDB allows you to use these reserved words and special characters for names, we recommend that you avoid doing so because you have to define placeholder variables whenever you use these names in an expression. For more information, see Expression Attribute Names in DynamoDB (p. 390).

Data Types

DynamoDB supports many different data types for attributes within a table. They can be categorized as follows:

- **Scalar Types** – A scalar type can represent exactly one value. The scalar types are number, string, binary, Boolean, and null.
- **Document Types** – A document type can represent a complex structure with nested attributes, such as you would find in a JSON document. The document types are list and map.
- **Set Types** – A set type can represent multiple scalar values. The set types are string set, number set, and binary set.

When you create a table or a secondary index, you must specify the names and data types of each primary key attribute (partition key and sort key). Furthermore, each primary key attribute must be defined as type string, number, or binary.

DynamoDB is a NoSQL database and is schemaless. This means that, other than the primary key attributes, you don't have to define any attributes or data types when you create tables. By comparison, relational databases require you to define the names and data types of each column when you create a table.

The following are descriptions of each data type, along with examples in JSON format.

Scalar Types

The scalar types are number, string, binary, Boolean, and null.

**Number**

Numbers can be positive, negative, or zero. Numbers can have up to 38 digits of precision. Exceeding this results in an exception.

- Positive range: 1E-130 to 9.9999999999999999999999999999999999999E+125
- Negative range: -9.9999999999999999999999999999999999999E+125 to -1E-130

In DynamoDB, numbers are represented as variable length. Leading and trailing zeroes are trimmed.

All numbers are sent across the network to DynamoDB as strings, to maximize compatibility across languages and libraries. However, DynamoDB treats them as number type attributes for mathematical operations.

**Note**

If number precision is important, you should pass numbers to DynamoDB using strings that you convert from the number type.
You can use the number data type to represent a date or a timestamp. One way to do this is by using epoch time—the number of seconds since 00:00:00 UTC on 1 January 1970. For example, the epoch time 1437136300 represents 12:31:40 PM UTC on 17 July 2015.

For more information, see http://en.wikipedia.org/wiki/Unix_time.

**String**

Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, if the attribute is not used as a key for an index or table, and is constrained by the maximum DynamoDB item size limit of 400 KB.

The following additional constraints apply to primary key attributes that are defined as type string:

- For a simple primary key, the maximum length of the first attribute value (the partition key) is 2048 bytes.
- For a composite primary key, the maximum length of the second attribute value (the sort key) is 1024 bytes.

DynamoDB collates and compares strings using the bytes of the underlying UTF-8 string encoding. For example, "a" (0x61) is greater than "A" (0x41), and "¿" (0xC2BF) is greater than "z" (0x7A).

You can use the string data type to represent a date or a timestamp. One way to do this is by using ISO 8601 strings, as shown in these examples:

- 2016-02-15
- 2015-12-21T17:42:34Z
- 20150311T122706Z

For more information, see http://en.wikipedia.org/wiki/ISO_8601.

**Binary**

Binary type attributes can store any binary data, such as compressed text, encrypted data, or images. Whenever DynamoDB compares binary values, it treats each byte of the binary data as unsigned.

The length of a binary attribute can be zero, if the attribute is not used as a key for an index or table, and is constrained by the maximum DynamoDB item size limit of 400 KB.

If you define a primary key attribute as a binary type attribute, the following additional constraints apply:

- For a simple primary key, the maximum length of the first attribute value (the partition key) is 2048 bytes.
- For a composite primary key, the maximum length of the second attribute value (the sort key) is 1024 bytes.

Your applications must encode binary values in base64-encoded format before sending them to DynamoDB. Upon receipt of these values, DynamoDB decodes the data into an unsigned byte array and uses that as the length of the binary attribute.

The following example is a binary attribute, using base64-encoded text.

dGhpcyB0ZXh0IGlzIGJhc2U2NC1lbmNvZGVk
**Boolean**

A Boolean type attribute can store either `true` or `false`.

**Null**

Null represents an attribute with an unknown or undefined state.

**Document Types**

The document types are list and map. These data types can be nested within each other, to represent complex data structures up to 32 levels deep.

There is no limit on the number of values in a list or a map, as long as the item containing the values fits within the DynamoDB item size limit (400 KB).

An attribute value can be an empty string or empty binary value if the attribute is not used for a table or index key. An attribute value cannot be an empty set (string set, number set, or binary set), however, empty lists and maps are allowed. Empty string and binary values are allowed within lists and maps. For more information, see Attributes (p. 966).

**List**

A list type attribute can store an ordered collection of values. Lists are enclosed in square brackets: `[ ... ]`

A list is similar to a JSON array. There are no restrictions on the data types that can be stored in a list element, and the elements in a list element do not have to be of the same type.

The following example shows a list that contains two strings and a number.

```
FavoriteThings: ["Cookies", "Coffee", 3.14159]
```

**Note**

DynamoDB lets you work with individual elements within lists, even if those elements are deeply nested. For more information, see Using Expressions in DynamoDB (p. 386).

**Map**

A map type attribute can store an unordered collection of name-value pairs. Maps are enclosed in curly braces: `{ ... }`

A map is similar to a JSON object. There are no restrictions on the data types that can be stored in a map element, and the elements in a map do not have to be of the same type.

Maps are ideal for storing JSON documents in DynamoDB. The following example shows a map that contains a string, a number, and a nested list that contains another map.

```
{
    Day: "Monday",
    UnreadEmails: 42,
    ItemsOnMyDesk: [
        "Coffee Cup",
        "Telephone",
        {
            Pens: { Quantity : 3},
            Pencils: { Quantity : 2},
            Erasers: { Quantity : 1}
        }
    ]
}
```
Note
DynamoDB lets you work with individual elements within maps, even if those elements are deeply nested. For more information, see Using Expressions in DynamoDB (p. 386).

Sets
DynamoDB supports types that represent sets of number, string, or binary values. All the elements within a set must be of the same type. For example, an attribute of type Number Set can only contain numbers; String Set can only contain strings; and so on.

There is no limit on the number of values in a set, as long as the item containing the values fits within the DynamoDB item size limit (400 KB).

Each value within a set must be unique. The order of the values within a set is not preserved. Therefore, your applications must not rely on any particular order of elements within the set. DynamoDB does not support empty sets, however, empty string and binary values are allowed within a set.

The following example shows a string set, a number set, and a binary set:

```
["Black", "Green", "Red"]
[42.2, -19, 7.5, 3.14]
["U3Vubnke", "UmPbunk=", "U25vd3k="]
```

Read Consistency
Amazon DynamoDB is available in multiple AWS Regions around the world. Each Region is independent and isolated from other AWS Regions. For example, if you have a table called People in the us-east-2 Region and another table named People in the us-west-2 Region, these are considered two entirely separate tables. For a list of all the AWS Regions in which DynamoDB is available, see AWS Regions and Endpoints in the Amazon Web Services General Reference.

Every AWS Region consists of multiple distinct locations called Availability Zones. Each Availability Zone is isolated from failures in other Availability Zones, and provides inexpensive, low-latency network connectivity to other Availability Zones in the same Region. This allows rapid replication of your data among multiple Availability Zones in a Region.

When your application writes data to a DynamoDB table and receives an HTTP 200 response (OK), the write has occurred and is durable. The data is eventually consistent across all storage locations, usually within one second or less.

DynamoDB supports eventually consistent and strongly consistent reads.

Eventually Consistent Reads
When you read data from a DynamoDB table, the response might not reflect the results of a recently completed write operation. The response might include some stale data. If you repeat your read request after a short time, the response should return the latest data.

Strongly Consistent Reads
When you request a strongly consistent read, DynamoDB returns a response with the most up-to-date data, reflecting the updates from all prior write operations that were successful. However, this consistency comes with some disadvantages:
• A strongly consistent read might not be available if there is a network delay or outage. In this case, DynamoDB may return a server error (HTTP 500).

• Strongly consistent reads may have higher latency than eventually consistent reads.

• Strongly consistent reads are not supported on global secondary indexes.

• Strongly consistent reads use more throughput capacity than eventually consistent reads. For details, see Read/Write Capacity Mode (p. 17)

**Note**
DynamoDB uses eventually consistent reads, unless you specify otherwise. Read operations (such as GetItem, Query, and Scan) provide a ConsistentRead parameter. If you set this parameter to true, DynamoDB uses strongly consistent reads during the operation.

### Read/Write Capacity Mode

Amazon DynamoDB has two read/write capacity modes for processing reads and writes on your tables:

- On-demand
- Provisioned (default, free-tier eligible)

The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity. You can set the read/write capacity mode when creating a table or you can change it later.

Global secondary indexes inherit the read/write capacity mode from the base table. For more information, see Considerations When Changing Read/Write Capacity Mode (p. 341).

**Topics**

- On-Demand Mode (p. 17)
- Provisioned Mode (p. 19)

### On-Demand Mode

Amazon DynamoDB on-demand is a flexible billing option capable of serving thousands of requests per second without capacity planning. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use.

When you choose on-demand mode, DynamoDB instantly accommodates your workloads as they ramp up or down to any previously reached traffic level. If a workload’s traffic level hits a new peak, DynamoDB adapts rapidly to accommodate the workload. Tables that use on-demand mode deliver the same single-digit millisecond latency, service-level agreement (SLA) commitment, and security that DynamoDB already offers. You can choose on-demand for both new and existing tables and you can continue using the existing DynamoDB APIs without changing code.

On-demand mode is a good option if any of the following are true:

- You create new tables with unknown workloads.
- You have unpredictable application traffic.
- You prefer the ease of paying for only what you use.

The request rate is only limited by the DynamoDB throughput default table limits, but it can be raised upon request. For more information, see Throughput Default Limits (p. 962).
To get started with on-demand, you can create or update a table to use on-demand mode. For more information, see Basic Operations on DynamoDB Tables (p. 336).

You can switch between read/write capacity modes once every 24 hours. For issues you should consider when switching read/write capacity modes, see Considerations When Changing Read/Write Capacity Mode (p. 341).

**Note**
On-demand is currently not supported by the DynamoDB import/export tool.

**Topics**
- Read Request Units and Write Request Units (p. 18)
- Peak Traffic and Scaling Properties (p. 18)
- Initial Throughput for On-Demand Capacity Mode (p. 19)
- Table Behavior while Switching Read/Write Capacity Mode (p. 19)

**Read Request Units and Write Request Units**

For on-demand mode tables, you don't need to specify how much read and write throughput you expect your application to perform. DynamoDB charges you for the reads and writes that your application performs on your tables in terms of read request units and write request units.

- One *read request unit* represents one strongly consistent read request, or two eventually consistent read requests, for an item up to 4 KB in size. Transactional read requests require 2 read request units to perform one read for items up to 4 KB. If you need to read an item that is larger than 4 KB, DynamoDB needs additional read request units. The total number of read request units required depends on the item size, and whether you want an eventually consistent or strongly consistent read. For example, if your item size is 8 KB, you require 2 read request units to sustain one strongly consistent read, 1 read request unit if you choose eventually consistent reads, or 4 read request units for a transactional read request.

  **Note**
  To learn more about DynamoDB read consistency models, see Read Consistency (p. 16).

- One *write request unit* represents one write for an item up to 1 KB in size. If you need to write an item that is larger than 1 KB, DynamoDB needs to consume additional write request units. Transactional write requests require 2 write request units to perform one write for items up to 1 KB. The total number of write request units required depends on the item size. For example, if your item size is 2 KB, you require 2 write request units to sustain one write request or 4 write request units for a transactional write request.

For a list of AWS Regions where DynamoDB on-demand is available, see Amazon DynamoDB Pricing.

**Peak Traffic and Scaling Properties**

DynamoDB tables using on-demand capacity mode automatically adapt to your application's traffic volume. On-demand capacity mode instantly accommodates up to double the previous peak traffic on a table. For example, if your application's traffic pattern varies between 25,000 and 50,000 strongly consistent reads per second where 50,000 reads per second is the previous traffic peak, on-demand capacity mode instantly accommodates sustained traffic of up to 100,000 reads per second. If your application sustains traffic of 100,000 reads per second, that peak becomes your new previous peak, enabling subsequent traffic to reach up to 200,000 reads per second.

If you need more than double your previous peak on table, DynamoDB automatically allocates more capacity as your traffic volume increases to help ensure that your workload does not experience throttling. However, throttling can occur if you exceed double your previous peak within 30 minutes. For example, if your application's traffic pattern varies between 25,000 and 50,000 strongly consistent reads per second where 50,000 reads per second is the previously reached traffic peak, DynamoDB
Initial Throughput for On-Demand Capacity Mode

If you recently switched an existing table to on-demand capacity mode for the first time, or if you created a new table with on-demand capacity mode enabled, the table has the following previous peak settings, even though the table has not served traffic previously using on-demand capacity mode:

- **Newly created table with on-demand capacity mode**: The previous peak is 2,000 write request units or 6,000 read request units. You can drive up to double the previous peak immediately, which enables newly created on-demand tables to serve up to 4,000 write request units or 12,000 read request units, or any linear combination of the two.
- **Existing table switched to on-demand capacity mode**: The previous peak is half the maximum write capacity units and read capacity units provisioned since the table was created, or the settings for a newly created table with on-demand capacity mode, whichever is higher. In other words, your table will deliver at least as much throughput as it did prior to switching to on-demand capacity mode.

Table Behavior while Switching Read/Write Capacity Mode

When you switch a table from provisioned capacity mode to on-demand capacity mode, DynamoDB makes several changes to the structure of your table and partitions. This process can take several minutes. During the switching period, your table delivers throughput that is consistent with the previously provisioned write capacity unit and read capacity unit amounts. When switching from on-demand capacity mode back to provisioned capacity mode, your table delivers throughput consistent with the previous peak reached when the table was set to on-demand capacity mode.

Provisioned Mode

If you choose provisioned mode, you specify the number of reads and writes per second that you require for your application. You can use auto scaling to adjust your table’s provisioned capacity automatically in response to traffic changes. This helps you govern your DynamoDB use to stay at or below a defined request rate in order to obtain cost predictability.

Provisioned mode is a good option if any of the following are true:

- You have predictable application traffic.
- You run applications whose traffic is consistent or ramps gradually.
- You can forecast capacity requirements to control costs.

Read Capacity Units and Write Capacity Units

For provisioned mode tables, you specify throughput capacity in terms of read capacity units (RCUs) and write capacity units (WCUs):

- One read capacity unit represents one strongly consistent read per second, or two eventually consistent reads per second, for an item up to 4 KB in size. Transactional read requests require two read capacity units to perform one read per second for items up to 4 KB. If you need to read an item that is larger than 4 KB, DynamoDB must consume additional read capacity units. The total number of read capacity units required depends on the item size, and whether you want an eventually consistent or strongly consistent read. For example, if your item size is 8 KB, you require 2 read capacity units to sustain one strongly consistent read per second, 1 read capacity unit if you choose eventually consistent reads, or 4 read capacity units for a transactional read request. For more information, see Capacity Unit Consumption for Reads (p. 343).

  **Note**
  To learn more about DynamoDB read consistency models, see Read Consistency (p. 16).
• One write capacity unit represents one write per second for an item up to 1 KB in size. If you need to write an item that is larger than 1 KB, DynamoDB must consume additional write capacity units. Transactional write requests require 2 write capacity units to perform one write per second for items up to 1 KB. The total number of write capacity units required depends on the item size. For example, if your item size is 2 KB, you require 2 write capacity units to sustain one write request per second or 4 write capacity units for a transactional write request. For more information, see Capacity Unit Consumption for Writes (p. 343).

Important
When calling DescribeTable on an on-demand table, read capacity units and write capacity units are set to 0.

If your application reads or writes larger items (up to the DynamoDB maximum item size of 400 KB), it will consume more capacity units.

For example, suppose that you create a provisioned table with 6 read capacity units and 6 write capacity units. With these settings, your application could do the following:

• Perform strongly consistent reads of up to 24 KB per second (4 KB × 6 read capacity units).
• Perform eventually consistent reads of up to 48 KB per second (twice as much read throughput).
• Perform transactional read requests of up to 12 KB per second.
• Write up to 6 KB per second (1 KB × 6 write capacity units).
• Perform transactional write requests of up to 3 KB per second.

For more information, see Managing Settings on DynamoDB Provisioned Capacity Tables (p. 342).

Provisioned throughput is the maximum amount of capacity that an application can consume from a table or index. If your application exceeds your provisioned throughput capacity on a table or index, it is subject to request throttling.

Throttling prevents your application from consuming too many capacity units. When a request is throttled, it fails with an HTTP 400 code (Bad Request) and a ProvisionedThroughputExceeded Exception. The AWS SDKs have built-in support for retrying throttled requests (see Error Retries and Exponential Backoff (p. 225)), so you do not need to write this logic yourself.

You can use the AWS Management Console to monitor your provisioned and actual throughput, and to modify your throughput settings if necessary.

DynamoDB Auto Scaling

DynamoDB auto scaling actively manages throughput capacity for tables and global secondary indexes. With auto scaling, you define a range (upper and lower limits) for read and write capacity units. You also define a target utilization percentage within that range. DynamoDB auto scaling seeks to maintain your target utilization, even as your application workload increases or decreases.

With DynamoDB auto scaling, a table or a global secondary index can increase its provisioned read and write capacity to handle sudden increases in traffic, without request throttling. When the workload decreases, DynamoDB auto scaling can decrease the throughput so that you don't pay for unused provisioned capacity.

Note
If you use the AWS Management Console to create a table or a global secondary index, DynamoDB auto scaling is enabled by default.

You can manage auto scaling settings at any time by using the console, the AWS CLI, or one of the AWS SDKs.
For more information, see Managing Throughput Capacity Automatically with DynamoDB Auto Scaling (p. 346).

Reserved Capacity

As a DynamoDB customer, you can purchase *reserved capacity* in advance, as described at Amazon DynamoDB Pricing. With reserved capacity, you pay a one-time upfront fee and commit to a minimum provisioned usage level over a period of time. Your reserved capacity is billed at the hourly reserved capacity rate. By reserving your read and write capacity units ahead of time, you realize significant cost savings compared to on-demand provisioned throughput settings. Any capacity that you provision in excess of your reserved capacity is billed at standard provisioned capacity rates.

*Note*
Reserved capacity is not available in on-demand mode.

To manage reserved capacity, go to the DynamoDB console and choose **Reserved Capacity**.

*Note*
You can prevent users from viewing or purchasing reserved capacity, while still allowing them to access the rest of the console. For more information, see "Grant Permissions to Prevent Purchasing of Reserved Capacity Offerings" in Identity and Access Management in Amazon DynamoDB (p. 825).

Partitions and Data Distribution

Amazon DynamoDB stores data in partitions. A *partition* is an allocation of storage for a table, backed by solid state drives (SSDs) and automatically replicated across multiple Availability Zones within an AWS Region. Partition management is handled entirely by DynamoDB—you never have to manage partitions yourself.

When you create a table, the initial status of the table is **CREATING**. During this phase, DynamoDB allocates sufficient partitions to the table so that it can handle your provisioned throughput requirements. You can begin writing and reading table data after the table status changes to **ACTIVE**.

DynamoDB allocates additional partitions to a table in the following situations:

- If you increase the table's provisioned throughput settings beyond what the existing partitions can support.
- If an existing partition fills to capacity and more storage space is required.

Partition management occurs automatically in the background and is transparent to your applications. Your table remains available throughout and fully supports your provisioned throughput requirements.

For more details, see Partition Key Design (p. 901).

Global secondary indexes in DynamoDB are also composed of partitions. The data in a global secondary index is stored separately from the data in its base table, but index partitions behave in much the same way as table partitions.

**Data Distribution: Partition Key**

If your table has a simple primary key (partition key only), DynamoDB stores and retrieves each item based on its partition key value.

To write an item to the table, DynamoDB uses the value of the partition key as input to an internal hash function. The output value from the hash function determines the partition in which the item will be stored.

To read an item from the table, you must specify the partition key value for the item. DynamoDB uses this value as input to its hash function, yielding the partition in which the item can be found.
The following diagram shows a table named *Pets*, which spans multiple partitions. The table's primary key is *AnimalType* (only this key attribute is shown). DynamoDB uses its hash function to determine where to store a new item, in this case based on the hash value of the string *Dog*. Note that the items are not stored in sorted order. Each item's location is determined by the hash value of its partition key.

DynamoDB is optimized for uniform distribution of items across a table's partitions, no matter how many partitions there may be. We recommend that you choose a partition key that can have a large number of distinct values relative to the number of items in the table.

**Data Distribution: Partition Key and Sort Key**

If the table has a composite primary key (partition key and sort key), DynamoDB calculates the hash value of the partition key in the same way as described in Data Distribution: Partition Key (p. 21). However, it stores all the items with the same partition key value physically close together, ordered by sort key value.

To write an item to the table, DynamoDB calculates the hash value of the partition key to determine which partition should contain the item. In that partition, several items could have the same partition key value. So DynamoDB stores the item among the others with the same partition key, in ascending order by sort key.

To read an item from the table, you must specify its partition key value and sort key value. DynamoDB calculates the partition key's hash value, yielding the partition in which the item can be found.

You can read multiple items from the table in a single operation (*query*) if the items you want have the same partition key value. DynamoDB returns all of the items with that partition key value. Optionally, you can apply a condition to the sort key so that it returns only the items within a certain range of values.
Suppose that the *Pets* table has a composite primary key consisting of *AnimalType* (partition key) and *Name* (sort key). The following diagram shows DynamoDB writing an item with a partition key value of *Dog* and a sort key value of *Fido*.

To read that same item from the *Pets* table, DynamoDB calculates the hash value of *Dog*, yielding the partition in which these items are stored. DynamoDB then scans the sort key attribute values until it finds *Fido*.

To read all of the items with an *AnimalType* of *Dog*, you can issue a *Query* operation without specifying a sort key condition. By default, the items are returned in the order that they are stored (that is, in ascending order by sort key). Optionally, you can request descending order instead.

To query only some of the *Dog* items, you can apply a condition to the sort key (for example, only the *Dog* items where *Name* begins with a letter that is within the range A through K).

**Note**

In a DynamoDB table, there is no upper limit on the number of distinct sort key values per partition key value. If you needed to store many billions of *Dog* items in the *Pets* table, DynamoDB would allocate enough storage to handle this requirement automatically.

**From SQL to NoSQL**

If you are an application developer, you might have some experience using a relational database management system (RDBMS) and Structured Query Language (SQL). As you begin working with Amazon DynamoDB, you will encounter many similarities, but also many things that are different. This section describes common database tasks, comparing and contrasting SQL statements with their equivalent DynamoDB operations.
NoSQL is a term used to describe nonrelational database systems that are highly available, scalable, and optimized for high performance. Instead of the relational model, NoSQL databases (like DynamoDB) use alternate models for data management, such as key-value pairs or document storage. For more information, see http://aws.amazon.com/nosql.

**Note**
The SQL examples in this section are compatible with the MySQL RDBMS.
The DynamoDB examples in this section show the name of the DynamoDB operation, along with the parameters for that operation in JSON format. For code examples that use these operations, see Getting Started with DynamoDB and AWS SDKs (p. 77).

**Relational (SQL) or NoSQL?**

Today's applications have more demanding requirements than ever before. For example, an online game might start out with just a few users and a very small amount of data. However, if the game becomes successful, it can easily outstrip the resources of the underlying database management system. It is common for web-based applications to have hundreds, thousands, or millions of concurrent users, with terabytes or more of new data generated per day. Databases for such applications must handle tens (or hundreds) of thousands of reads and writes per second.

Amazon DynamoDB is well-suited for these kinds of workloads. As a developer, you can start small and gradually increase your utilization as your application becomes more popular. DynamoDB scales seamlessly to handle very large amounts of data and very large numbers of users.

The following table shows some high-level differences between an RDBMS and DynamoDB.

## Characteristics of Databases

Before your application can access a database, it must be authenticated to ensure that the application is allowed to use the database. It must be authorized so that the application can perform only the actions for which it has permissions.

The following diagram shows a client's interaction with a relational database and with Amazon DynamoDB.
The following table has more details about client interaction tasks.

### Creating a Table

Tables are the fundamental data structures in relational databases and in Amazon DynamoDB. A relational database management system (RDBMS) requires you to define the table's schema when you create it. In contrast, DynamoDB tables are schemaless—other than the primary key, you do not need to define any extra attributes or data types when you create a table.

**Topics**
- SQL (p. 27)
- DynamoDB (p. 28)

### SQL

Use the `CREATE TABLE` statement to create a table, as shown in the following example.

```sql
CREATE TABLE Music (    Artist VARCHAR(20) NOT NULL,    SongTitle VARCHAR(30) NOT NULL,    AlbumTitle VARCHAR(25),)
```
Year INT,  
Price FLOAT,  
Genre VARCHAR(10),  
Tags TEXT,  
PRIMARY KEY(Artist, SongTitle)
);

The primary key for this table consists of Artist and SongTitle.

You must define all of the table’s columns and data types, and the table’s primary key. (You can use the ALTER TABLE statement to change these definitions later, if necessary.)

Many SQL implementations let you define storage specifications for your table, as part of the CREATE TABLE statement. Unless you indicate otherwise, the table is created with default storage settings. In a production environment, a database administrator can help determine the optimal storage parameters.

DynamoDB

Use the CreateTable action to create a provisioned mode table, specifying parameters as shown following:

```
{
  TableName : "Music",
  KeySchema: [  
    {   
      AttributeName: "Artist",
      KeyType: "HASH", //Partition key
    },
    {   
      AttributeName: "SongTitle",
      KeyType: "RANGE" //Sort key
    }
  ],  
  AttributeDefinitions: [  
    {  
      AttributeName: "Artist",
      AttributeType: "S"
    },
    {  
      AttributeName: "SongTitle",
      AttributeType: "S"
    }
  ],
  ProvisionedThroughput: {   // Only specified if using provisioned mode
    ReadCapacityUnits: 1,
    WriteCapacityUnits: 1
  }
}
```

The primary key for this table consists of Artist (partition key) and SongTitle (sort key).

You must provide the following parameters to CreateTable:

- **TableName** – Name of the table.
- **KeySchema** – Attributes that are used for the primary key. For more information, see Tables, Items, and Attributes (p. 3) and Primary Key (p. 6).
- **AttributeDefinitions** – Data types for the key schema attributes.
- **ProvisionedThroughput (for provisioned tables)** – Number of reads and writes per second that you need for this table. DynamoDB reserves sufficient storage and system resources so that your throughput requirements are always met. You can use the UpdateTable action to change these later,
if necessary. You do not need to specify a table’s storage requirements because storage allocation is managed entirely by DynamoDB.

**Note**
For code examples that use `CreateTable`, see Getting Started with DynamoDB and AWS SDKs (p. 77).

### Getting Information About a Table

You can verify that a table has been created according to your specifications. In a relational database, all of the table’s schema is shown. Amazon DynamoDB tables are schemaless, so only the primary key attributes are shown.

**Topics**
- **SQL** (p. 29)
- **DynamoDB** (p. 29)

#### SQL

Most relational database management systems (RDBMS) allow you to describe a table’s structure—columns, data types, primary key definition, and so on. There is no standard way to do this in SQL. However, many database systems provide a `DESCRIBE` command. The following is an example from MySQL.

```
DESCRIBE Music;
```

This returns the structure of your table, with all of the column names, data types, and sizes.

```
+------------+-------------+------+-----+---------+-------+
| Field      | Type        | Null | Key | Default | Extra |
|------------+-------------+------+-----+---------+-------+
| Artist     | varchar(20) | NO   | PRI | NULL    |       |
| SongTitle  | varchar(30) | NO   | PRI | NULL    |       |
| AlbumTitle | varchar(25) | YES  |     | NULL    |       |
| Year       | int(11)     | YES  |     | NULL    |       |
| Price      | float       | YES  |     | NULL    |       |
| Genre      | varchar(10) | YES  |     | NULL    |       |
| Tags       | text        | YES  |     | NULL    |       |
```

The primary key for this table consists of **Artist** and **SongTitle**.

#### DynamoDB

DynamoDB has a `DescribeTable` action, which is similar. The only parameter is the table name.

```
{
  TableName : "Music"
}
```

The reply from `DescribeTable` looks like the following.

```
{
  "Table": {
    "AttributeDefinitions": [
      
```
DescribeTable also returns information about indexes on the table, provisioned throughput settings, an approximate item count, and other metadata.

Writing Data to a Table

Relational database tables contain rows of data. Rows are composed of columns. Amazon DynamoDB tables contain items. Items are composed of attributes.

This section describes how to write one row (or item) to a table.

Topics
- SQL (p. 30)
- DynamoDB (p. 31)

SQL

A table in a relational database is a two-dimensional data structure composed of rows and columns. Some database management systems also provide support for semistructured data, usually with native JSON or XML data types. However, the implementation details vary among vendors.

In SQL, you use the INSERT statement to add a row to a table.

```
INSERT INTO Music
    (Artist, SongTitle, AlbumTitle, Year, Price, Genre, Tags)
VALUES(
    'No One You Know', 'Call Me Today', 'Somewhat Famous', 2015, 2.14, 'Country',
    '{"Composers": ["Smith", "Jones", "Davis"],"LengthInSeconds": 214}');
```

The primary key for this table consists of Artist and SongTitle. You must specify values for these columns.

Note

This example uses the Tags column to store semistructured data about the songs in the Music table. The Tags column is defined as type TEXT, which can store up to 65,535 characters in MySQL.
DynamoDB

In Amazon DynamoDB, you use the `PutItem` action to add an item to a table.

```json
{
   TableName: "Music",
   Item: {
      "Artist": "No One You Know",
      "SongTitle": "Call Me Today",
      "AlbumTitle": "Somewhat Famous",
      "Year": 2015,
      "Price": 2.14,
      "Genre": "Country",
      "Tags": {
         "Composers": ["Smith", "Jones", "Davis"],
         "LengthInSeconds": 214
      }
   }
}
```

The primary key for this table consists of `Artist` and `SongTitle`. You must specify values for these attributes.

Here are some key things to know about this `PutItem` example:

- DynamoDB provides native support for documents, using JSON. This makes DynamoDB ideal for storing semistructured data, such as `Tags`. You can also retrieve and manipulate data from within JSON documents.
- The `Music` table does not have any predefined attributes, other than the primary key (`Artist` and `SongTitle`).
- Most SQL databases are transaction oriented. When you issue an `INSERT` statement, the data modifications are not permanent until you issue a `COMMIT` statement. With Amazon DynamoDB, the effects of a `PutItem` action are permanent when DynamoDB replies with an HTTP 200 status code (OK).

**Note**

For code examples using `PutItem`, see Getting Started with DynamoDB and AWS SDKs (p. 77).

The following are some other `PutItem` examples.

```json
{
   TableName: "Music",
   Item: {
      "Artist": "No One You Know",
      "SongTitle": "My Dog Spot",
      "AlbumTitle": "Hey Now",
      "Price": 1.98,
      "Genre": "Country",
      "CriticRating": 8.4
   }
}
```

```json
{
   TableName: "Music",
}
```

### Key Differences When Reading Data from a Table

With SQL, you use the `SELECT` statement to retrieve one or more rows from a table. You use the `WHERE` clause to determine the data that is returned to you.

Amazon DynamoDB provides the following operations for reading data:

- **GetItem** – Retrieves a single item from a table. This is the most efficient way to read a single item because it provides direct access to the physical location of the item. (DynamoDB also provides the `BatchGetItem` operation, allowing you to perform up to 100 `GetItem` calls in a single operation.)
- **Query** – Retrieves all of the items that have a specific partition key. Within those items, you can apply a condition to the sort key and retrieve only a subset of the data. `query` provides quick, efficient access to the partitions where the data is stored. (For more information, see `Partitions and Data Distribution (p. 21)`.)

---

**Note**

In addition to `PutItem`, DynamoDB supports a `BatchWriteItem` action for writing multiple items at the same time.

---

**Item:**

```
"Artist": "No One You Know",
"SongTitle": "Somewhere Down The Road",
"AlbumTitle": "Somewhat Famous",
"Genre": "Country",
"CriticRating": 8.4,
"Year": 1984
```

---

**Item:**

```
"Artist": "The Acme Band",
"SongTitle": "Still In Love",
"AlbumTitle": "The Buck Starts Here",
"Price": 2.47,
"Genre": "Rock",
"PromotionInfo": {
  "RadioStationsPlaying": [
    "KHCR", "KBQX", "WTNR", "WJJH"
  ],
  "TourDates": {
    "Seattle": "20150625",
    "Cleveland": "20150630"
  },
  "Rotation": "Heavy"
}
```

---

**Item:**

```
"Artist": "The Acme Band",
"SongTitle": "Look Out, World",
"AlbumTitle": "The Buck Starts Here",
"Price": 0.99,
"Genre": "Rock"
```
• Scan – Retrieves all of the items in the specified table. (This operation should not be used with large tables because it can consume large amounts of system resources.)

Note
With a relational database, you can use the SELECT statement to join data from multiple tables and return the results. Joins are fundamental to the relational model. To ensure that joins execute efficiently, the database and its applications should be performance-tuned on an ongoing basis. DynamoDB is a non-relational NoSQL database that does not support table joins. Instead, applications read data from one table at a time.

The following sections describe different use cases for reading data, and how to perform these tasks with a relational database and with DynamoDB.

Topics
• Reading an Item Using Its Primary Key (p. 33)
• Querying a Table (p. 34)
• Scanning a Table (p. 36)

Reading an Item Using Its Primary Key

One common access pattern for databases is to read a single item from a table. You have to specify the primary key of the item you want.

Topics
• SQL (p. 33)
• DynamoDB (p. 33)

SQL

In SQL, you use the SELECT statement to retrieve data from a table. You can request one or more columns in the result (or all of them, if you use the * operator). The WHERE clause determines which rows to return.

The following is a SELECT statement to retrieve a single row from the Music table. The WHERE clause specifies the primary key values.

```sql
SELECT *
FROM Music
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today'
```

You can modify this query to retrieve only a subset of the columns.

```sql
SELECT AlbumTitle, Year, Price
FROM Music
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today'
```

Note that the primary key for this table consists of Artist and SongTitle.

DynamoDB

DynamoDB provides the GetItem action for retrieving an item by its primary key. GetItem is highly efficient because it provides direct access to the physical location of the item. (For more information, see Partitions and Data Distribution (p. 21).)
By default, GetItem returns the entire item with all of its attributes.

```
{
   TableName: "Music",
   Key: {
      "Artist": "No One You Know",
      "SongTitle": "Call Me Today"
   }
}
```

You can add a ProjectionExpression parameter to return only some of the attributes.

```
{
   TableName: "Music",
   Key: {
      "Artist": "No One You Know",
      "SongTitle": "Call Me Today"
   },
   "ProjectionExpression": "AlbumTitle, Year, Price"
}
```

Note that the primary key for this table consists of Artist and SongTitle.

The DynamoDB GetItem action is very efficient: It uses the primary key values to determine the exact storage location of the item in question, and retrieves it directly from there. The SQL SELECT statement is similarly efficient, in the case of retrieving items by primary key values.

The SQL SELECT statement supports many kinds of queries and table scans. DynamoDB provides similar functionality with its Query and Scan actions, which are described in Querying a Table (p. 34) and Scanning a Table (p. 36).

The SQL SELECT statement can perform table joins, allowing you to retrieve data from multiple tables at the same time. Joins are most effective where the database tables are normalized and the relationships among the tables are clear. However, if you join too many tables in one SELECT statement application performance can be affected. You can work around such issues by using database replication, materialized views, or query rewrites.

DynamoDB is a nonrelational database and doesn't support table joins. If you are migrating an existing application from a relational database to DynamoDB, you need to denormalize your data model to eliminate the need for joins.

**Note**
For code examples that use GetItem, see Getting Started with DynamoDB and AWS SDKs (p. 77).

**Querying a Table**

Another common access pattern is reading multiple items from a table, based on your query criteria.

**Topics**
- SQL (p. 34)
- DynamoDB (p. 35)

**SQL**

The SQL SELECT statement lets you query on key columns, non-key columns, or any combination. The WHERE clause determines which rows are returned, as shown in the following examples.

```sql
/* Return a single song, by primary key */
```
SELECT * FROM Music
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today';

/* Return all of the songs by an artist */
SELECT * FROM Music
WHERE Artist='No One You Know';

/* Return all of the songs by an artist, matching first part of title */
SELECT * FROM Music
WHERE Artist='No One You Know' AND SongTitle LIKE 'Call%';

/* Return all of the songs by an artist, with a particular word in the title... ...but only if the price is less than 1.00 */
SELECT * FROM Music
WHERE Artist='No One You Know' AND SongTitle LIKE '%Today%'
AND Price < 1.00;

Note that the primary key for this table consists of Artist and SongTitle.

DynamoDB

The Amazon DynamoDB Query action lets you retrieve data in a similar fashion. The Query action provides quick, efficient access to the physical locations where the data is stored. For more information, see Partitions and Data Distribution (p. 21).

You can use Query with any table that has a composite primary key (partition key and sort key). You must specify an equality condition for the partition key, and you can optionally provide another condition for the sort key.

The KeyConditionExpression parameter specifies the key values that you want to query. You can use an optional FilterExpression to remove certain items from the results before they are returned to you.

In DynamoDB, you must use ExpressionAttributeValues as placeholders in expression parameters (such as KeyConditionExpression and FilterExpression). This is analogous to the use of bind variables in relational databases, where you substitute the actual values into the SELECT statement at runtime.

Note that the primary key for this table consists of Artist and SongTitle.

The following are some DynamoDB Query examples.

// Return a single song, by primary key
{
  TableName: "Music",
  KeyConditionExpression: "Artist = :a and SongTitle = :t",
  ExpressionAttributeValues: {
    ":a": "No One You Know",
    ":t": "Call Me Today"
  }
}

// Return all of the songs by an artist
Reading Data from a Table

```json
{
  TableName: "Music",
  KeyConditionExpression: "Artist = :a",
  ExpressionAttributeValues: {
    ":a": "No One You Know"
  }
}
```

```javascript
// Return all of the songs by an artist, matching first part of title
{
  TableName: "Music",
  KeyConditionExpression: "Artist = :a and begins_with(SongTitle, :t)",
  ExpressionAttributeValues: {
    ":a": "No One You Know",
    ":t": "Call"
  }
}
```

**Note**

For code examples that use `Query`, see Getting Started with DynamoDB and AWS SDKs (p. 77).

### Scanning a Table

In SQL, a `SELECT` statement without a `WHERE` clause will return every row in a table. In Amazon DynamoDB, the `Scan` operation does the same thing. In both cases, you can retrieve all of the items or just some of them.

Whether you are using a SQL or a NoSQL database, scans should be used sparingly because they can consume large amounts of system resources. Sometimes a scan is appropriate (such as scanning a small table) or unavoidable (such as performing a bulk export of data). However, as a general rule, you should design your applications to avoid performing scans.

**Topics**

- SQL (p. 36)
- DynamoDB (p. 36)

### SQL

In SQL, you can scan a table and retrieve all of its data by using a `SELECT` statement without specifying a `WHERE` clause. You can request one or more columns in the result. Or you can request all of them if you use the wildcard character (`*`).

The following are examples of using a `SELECT` statement.

```sql
/* Return all of the data in the table */
SELECT * FROM Music;
```

```sql
/* Return all of the values for Artist and Title */
SELECT Artist, Title FROM Music;
```

### DynamoDB

DynamoDB provides a `Scan` action that works in a similar way. The following are some examples.
// Return all of the data in the table
{
    TableName: "Music"
}

// Return all of the values for Artist and Title
{
    TableName: "Music",
    ProjectionExpression: "Artist, Title"
}

The Scan action also provides a FilterExpression parameter, which you can use to discard items that you do not want to appear in the results. A FilterExpression is applied after the entire table is scanned, but before the results are returned to you. (This is not recommended with large tables. You are still charged for the entire Scan, even if only a few matching items are returned.)

Note
For code examples that use Scan, see Getting Started with DynamoDB and AWS SDKs (p. 77).

Managing Indexes

Indexes give you access to alternate query patterns, and can speed up queries. This section compares and contrasts index creation and usage in SQL and Amazon DynamoDB.

Whether you are using a relational database or DynamoDB, you should be judicious with index creation. Whenever a write occurs on a table, all of the table's indexes must be updated. In a write-heavy environment with large tables, this can consume large amounts of system resources. In a read-only or read-mostly environment, this is not as much of a concern. However, you should ensure that the indexes are actually being used by your application, and not simply taking up space.

Topics
• Creating an Index (p. 37)
• Querying and Scanning an Index (p. 39)

Creating an Index

Compare the CREATE INDEX statement in SQL with the UpdateTable operation in Amazon DynamoDB.

Topics
• SQL (p. 37)
• DynamoDB (p. 38)

SQL

In a relational database, an index is a data structure that lets you perform fast queries on different columns in a table. You can use the CREATE INDEX SQL statement to add an index to an existing table, specifying the columns to be indexed. After the index has been created, you can query the data in the table as usual, but now the database can use the index to quickly find the specified rows in the table instead of scanning the entire table.

After you create an index, the database maintains it for you. Whenever you modify data in the table, the index is automatically modified to reflect changes in the table.

In MySQL, you can create an index like the following.
DynamoDB

In DynamoDB, you can create and use a secondary index for similar purposes.

Indexes in DynamoDB are different from their relational counterparts. When you create a secondary index, you must specify its key attributes—a partition key and a sort key. After you create the secondary index, you can Query it or Scan it just as you would with a table. DynamoDB does not have a query optimizer, so a secondary index is only used when you Query it or Scan it.

DynamoDB supports two different kinds of indexes:

- **Global secondary indexes** – The primary key of the index can be any two attributes from its table.
- **Local secondary indexes** – The partition key of the index must be the same as the partition key of its table. However, the sort key can be any other attribute.

DynamoDB ensures that the data in a secondary index is eventually consistent with its table. You can request strongly consistent Query or Scan actions on a table or a local secondary index. However, global secondary indexes support only eventual consistency.

You can add a global secondary index to an existing table, using the UpdateTable action and specifying GlobalSecondaryIndexUpdates.

```json
{
  TableName: "Music",
  AttributeDefinitions:[
    {AttributeName: "Genre", AttributeType: "S"},
    {AttributeName: "Price", AttributeType: "N"}
  ],
  GlobalSecondaryIndexUpdates: [
    {
      Create: {
        IndexName: "GenreAndPriceIndex",
        KeySchema: [
          {AttributeName: "Genre", KeyType: "HASH"}, //Partition key
          {AttributeName: "Price", KeyType: "RANGE"}, //Sort key
        ],
        Projection: {
          "ProjectionType": "ALL"
        },
        ProvisionedThroughput: { // Only specified if using provisioned mode
          "ReadCapacityUnits": 1,"WriteCapacityUnits": 1
        }
      }
    }
  ]
}
```

You must provide the following parameters to UpdateTable:

- **TableName** – The table that the index will be associated with.
- **AttributeDefinitions** – The data types for the key schema attributes of the index.
- **GlobalSecondaryIndexUpdates** – Details about the index you want to create:
  - **IndexName** – A name for the index.
  - **KeySchema** – The attributes that are used for the index's primary key.
• **Projection** – Attributes from the table that are copied to the index. In this case, **ALL** means that all of the attributes are copied.

• **ProvisionedThroughput (for provisioned tables)** – The number of reads and writes per second that you need for this index. (This is separate from the provisioned throughput settings of the table.)

Part of this operation involves backfilling data from the table into the new index. During backfilling, the table remains available. However, the index is not ready until its **Backfilling** attribute changes from true to false. You can use the **DescribeTable** action to view this attribute.

**Note**
For code examples that use UpdateTable, see Getting Started with DynamoDB and AWS SDKs (p. 77).

### Querying and Scanning an Index

Compare querying and scanning an index using the SELECT statement in SQL with the **Query** and **Scan** operations in Amazon DynamoDB.

**Topics**
- SQL (p. 39)
- DynamoDB (p. 39)

**SQL**

In a relational database, you do not work directly with indexes. Instead, you query tables by issuing **SELECT** statements, and the query optimizer can make use of any indexes.

A **query optimizer** is a relational database management system (RDBMS) component that evaluates the available indexes and determines whether they can be used to speed up a query. If the indexes can be used to speed up a query, the RDBMS accesses the index first and then uses it to locate the data in the table.

Here are some SQL statements that can use **GenreAndPriceIndex** to improve performance. We assume that the **Music** table has enough data in it that the query optimizer decides to use this index, rather than simply scanning the entire table.

```sql
/* All of the rock songs */
SELECT * FROM Music
WHERE Genre = 'Rock';

/* All of the cheap country songs */
SELECT Artist, SongTitle, Price FROM Music
WHERE Genre = 'Country' AND Price < 0.50;
```

**DynamoDB**

In DynamoDB, you perform **query** operations directly on the index, in the same way that you would on a table. You must specify both **TableName** and **IndexName**.

The following are some queries on **GenreAndPriceIndex** in DynamoDB. (The key schema for this index consists of **Genre** and **Price**.)
// All of the rock songs
{
  TableName: "Music",
  IndexName: "GenreAndPriceIndex",
  KeyConditionExpression: "Genre = :genre",
  ExpressionAttributeValues: {
    ":genre": "Rock"
  },
}

// All of the cheap country songs
{
  TableName: "Music",
  IndexName: "GenreAndPriceIndex",
  KeyConditionExpression: "Genre = :genre and Price < :price",
  ExpressionAttributeValues: {
    ":genre": "Country",
    ":price": 0.50
  },
  ProjectionExpression: "Artist, SongTitle, Price"
}

This example uses a ProjectionExpression to indicate that you only want some of the attributes, rather than all of them, to appear in the results.

You can also perform Scan operations on a secondary index, in the same way that you would on a table. The following is a scan on GenreAndPriceIndex.

// Return all of the data in the index
{
  TableName: "Music",
  IndexName: "GenreAndPriceIndex"
}

Modifying Data in a Table

The SQL language provides the UPDATE statement for modifying data. Amazon DynamoDB uses the UpdateItem operation to accomplish similar tasks.

Topics
- SQL (p. 40)
- DynamoDB (p. 41)

SQL

In SQL, you use the UPDATE statement to modify one or more rows. The SET clause specifies new values for one or more columns, and the WHERE clause determines which rows are modified. The following is an example.

```
UPDATE Music
SET RecordLabel = 'Global Records'
WHERE Artist = 'No One You Know' AND SongTitle = 'Call Me Today';
```
If no rows match the `WHERE` clause, the `UPDATE` statement has no effect.

**DynamoDB**

In DynamoDB, you use the `UpdateItem` action to modify a single item. (If you want to modify multiple items, you must use multiple `UpdateItem` operations.)

The following is an example.

```
{  
  TableName: "Music",
  Key: {
    "Artist":"No One You Know",
    "SongTitle":"Call Me Today"
  },
  UpdateExpression: "SET RecordLabel = :label",
  ExpressionAttributeValues: {
    ":label": "Global Records"
  }
}
```

You must specify the `Key` attributes of the item to be modified and an `UpdateExpression` to specify attribute values. `UpdateItem` behaves like an "upsert" operation: The item is updated if it exists in the table, but if not, a new item is added (inserted).

`UpdateItem` supports *conditional writes*, where the operation succeeds only if a specific `ConditionExpression` evaluates to true. For example, the following `UpdateItem` action does not perform the update unless the price of the song is greater than or equal to 2.00.

```
{  
  TableName: "Music",
  Key: {
    "Artist":"No One You Know",
    "SongTitle":"Call Me Today"
  },
  UpdateExpression: "SET RecordLabel = :label",
  ConditionExpression: "Price >= :p",
  ExpressionAttributeValues: {
    ":label": "Global Records",
    ":p": 2.00
  }
}
```

`UpdateItem` also supports *atomic counters*, or attributes of type `Number` that can be incremented or decremented. Atomic counters are similar in many ways to sequence generators, identity columns, or autoincrement fields in SQL databases.

The following is an example of an `UpdateItem` action to initialize a new attribute (`Plays`) to keep track of the number of times a song has been played.

```
{  
  TableName: "Music",
  Key: {
    "Artist":"No One You Know",
    "SongTitle":"Call Me Today"
  },
  UpdateExpression: "SET Plays = :val",
  ExpressionAttributeValues: {
    ":val": 0
  }
}
```
ReturnValues: "UPDATED_NEW"
}

The ReturnValues parameter is set to UPDATED_NEW, which returns the new values of any attributes that were updated. In this case, it returns 0 (zero).

Whenever someone plays this song, we can use the following UpdateItem action to increment Plays by one.

```
{
    TableName: "Music",
    Key: {
        "Artist":"No One You Know",
        "SongTitle":"Call Me Today"
    },
    UpdateExpression: "SET Plays = Plays + :incr",
    ExpressionAttributeValues: {
        ":incr": 1
    },
    ReturnValues: "UPDATED_NEW"
}
```

Note
For code examples that use UpdateItem, see Getting Started with DynamoDB and AWS SDKs (p. 77).

Deleting Data from a Table

In SQL, the DELETE statement removes one or more rows from a table. Amazon DynamoDB uses the DeleteItem operation to delete one item at a time.

Topics
- SQL (p. 42)
- DynamoDB (p. 42)

SQL

In SQL, you use the DELETE statement to delete one or more rows. The WHERE clause determines the rows that you want to modify. The following is an example.

```
DELETE FROM Music
WHERE Artist = 'The Acme Band' AND SongTitle = 'Look Out, World';
```

You can modify the WHERE clause to delete multiple rows. For example, you could delete all of the songs by a particular artist, as shown in the following example.

```
DELETE FROM Music WHERE Artist = 'The Acme Band'
```

Note
If you omit the WHERE clause, the database attempts to delete all of the rows from the table.

DynamoDB

In DynamoDB, you use the DeleteItem action to delete data from a table, one item at a time. You must specify the item's primary key values.
Note
In addition to DeleteItem, Amazon DynamoDB supports a BatchWriteItem action for deleting multiple items at the same time.

DeleteItem supports **conditional writes**, where the operation succeeds only if a specific ConditionExpression evaluates to true. For example, the following DeleteItem action deletes the item only if it has a **RecordLabel** attribute.

```
{
  TableName: "Music",
  Key: {
    Artist: "The Acme Band",
    SongTitle: "Look Out, World"
  },
  ConditionExpression: "attribute_exists(RecordLabel)"
}
```

Note
For code examples that use DeleteItem, see Getting Started with DynamoDB and AWS SDKs (p. 77).

**Removing a Table**

In SQL, you use the **DROP TABLE** statement to remove a table. In Amazon DynamoDB, you use the **DeleteTable** operation.

**Topics**
- SQL (p. 43)
- DynamoDB (p. 43)

**SQL**

When you no longer need a table and want to discard it permanently, you use the **DROP TABLE** statement in SQL.

```
DROP TABLE Music;
```

After a table is dropped, it cannot be recovered. (Some relational databases do allow you to undo a **DROP TABLE** operation, but this is vendor-specific functionality and it is not widely implemented.)

**DynamoDB**

DynamoDB has a similar action: **DeleteTable**. In the following example, the table is permanently deleted.

```
{
  TableName: "Music",
```
Note
For code examples that use DeleteTable, see Getting Started with DynamoDB and AWS SDKs (p. 77).

Setting Up DynamoDB

In addition to the Amazon DynamoDB web service, AWS provides a downloadable version of DynamoDB that you can run on your computer and is perfect for development and testing of your code. The downloadable version lets you write and test applications locally without accessing the DynamoDB web service.

The topics in this section describe how to set up DynamoDB (downloadable version) and the DynamoDB web service.

Topics
- Setting Up DynamoDB Local (Downloadable Version) (p. 46)
- Setting Up DynamoDB (Web Service) (p. 53)

Setting Up DynamoDB Local (Downloadable Version)

With the downloadable version of Amazon DynamoDB, you can develop and test applications without accessing the DynamoDB web service. Instead, the database is self-contained on your computer. When you're ready to deploy your application in production, you remove the local endpoint in the code, and then it points to the DynamoDB web service.

Having this local version helps you save on throughput, data storage, and data transfer fees. In addition, you don't need an internet connection while you develop your application.

DynamoDB Local is available as a download (requires JRE), as an Apache Maven dependency, or as a Docker image.

If you prefer to use the Amazon DynamoDB web service instead, see Setting Up DynamoDB (Web Service) (p. 53).

- Deploying DynamoDB Locally on Your Computer (p. 46)
- Deploying DynamoDB by adding an Apache Maven Repository (p. 48)
- Install the DynamoDB Docker Image (p. 48)

Deploying DynamoDB Locally on Your Computer

The downloadable version of Amazon DynamoDB is provided as an executable .jar file. The application runs on Windows, Linux, macOS, and other platforms that support Java.

Follow these steps to set up and run DynamoDB on your computer.

To set up DynamoDB on your computer

1. Download DynamoDB for free using one of the following links.

Downloadable DynamoDB is available on Apache Maven. For more information, see Deploying DynamoDB by adding an Apache Maven Repository (p. 48). DynamoDB is also available as part of the AWS Toolkit for Eclipse. For more information, see AWS Toolkit For Eclipse.

**Important**
To run DynamoDB on your computer, you must have the Java Runtime Environment (JRE) version 6.x or newer. The application doesn't run on earlier JRE versions.

2. After you download the archive, extract the contents and copy the extracted directory to a location of your choice.
3. To start DynamoDB on your computer, open a command prompt window, navigate to the directory where you extracted DynamoDBLocal.jar, and enter the following command.

```
java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar -sharedDb
```

**Note**
If you're using Windows PowerShell, be sure to enclose the parameter name or the entire name and value like this:
```
java -D"java.library.path=./DynamoDBLocal_lib" -jar DynamoDBLocal.jar
```
DynamoDB processes incoming requests until you stop it. To stop DynamoDB, press Ctrl+C at the command prompt. DynamoDB uses port 8000 by default. If port 8000 is unavailable, this command throws an exception. For a complete list of DynamoDB runtime options, including `-port`, enter this command.
```
java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar -help
```

4. Before you can access DynamoDB programmatically or through the AWS Command Line Interface (AWS CLI), you must configure your credentials to enable authorization for your applications. Downloadable DynamoDB requires any credentials to work, as shown in the following example.

```
AWS Access Key ID: "fakeMyKeyId"
AWS Secret Access Key: "fakeSecretAccessKey"
```

You can use the `aws configure` command of the AWS CLI to set up credentials. For more information, see Using the AWS CLI (p. 57).

5. Start writing applications. To access DynamoDB running locally with the AWS CLI, use the `--endpoint-url` parameter. For example, use the following command to list DynamoDB tables.

```
aws dynamodb list-tables --endpoint-url http://localhost:8000
```
Deploying DynamoDB by adding an Apache Maven Repository

Follow these steps to use Amazon DynamoDB in your application as a dependency.

To deploy DynamoDB as an Apache Maven repository

1. Download and install Apache Maven. For more information, see Downloading Apache Maven and Installing Apache Maven.
2. Add the DynamoDB Maven repository to your application's Project Object Model (POM) file.

```xml
<dependencies>
    <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>DynamoDBLocal</artifactId>
        <version>[1.12,2.0)</version>
    </dependency>
</dependencies>

<repositories>
    <repository>
        <id>dynamodb-local-oregon</id>
        <name>DynamoDB Local Release Repository</name>
        <url>https://s3-us-west-2.amazonaws.com/dynamodb-local/release</url>
    </repository>
</repositories>
```

Note
You can also use one of the following repository URLs, depending on your AWS Region.

<table>
<thead>
<tr>
<th>id</th>
<th>Repository URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>dynamodb-local-mumbai</td>
<td><a href="https://s3.ap-south-1.amazonaws.com/dynamodb-local-mumbai/release">https://s3.ap-south-1.amazonaws.com/dynamodb-local-mumbai/release</a></td>
</tr>
<tr>
<td>dynamodb-local-tokyo</td>
<td><a href="https://s3.ap-northeast-1.amazonaws.com/dynamodb-local-tokyo/release">https://s3.ap-northeast-1.amazonaws.com/dynamodb-local-tokyo/release</a></td>
</tr>
</tbody>
</table>

The aws-dynamodb-examples repository in GitHub contains examples for starting and stopping DynamoDB local inside a Java program and using DynamoDB local in JUnit tests.

Install the DynamoDB Docker Image

The downloadable version of Amazon DynamoDB is available as a Docker image. For more information, see dynamodb-local.
For an example of using DynamoDB local as part of a REST application built on the AWS Serverless Application Model (AWS SAM), see SAM DynamoDB application for managing orders. This sample application demonstrates how to use DynamoDB local for testing.

Using Docker Compose

If you want to run a multi-container application that also uses the DynamoDB local container, use Docker Compose to define and run all the services in your application, including DynamoDB local.

To install and run DynamoDB local with Docker Compose:

1. Download and install Docker Desktop.
2. Copy the following code to a file and save it as docker-compose.yml

```yaml
version: '3.7'
services:
dynamodb-local:
  image: amazon/dynamodb-local:latest
  container_name: dynamodb-local
  ports:
    - "8000:8000"
app-node:
  depends_on:
    - dynamodb-local
  image: banst/awscli
  container_name: app-node
  ports:
    - "8080:8080"
  environment:
    AWS_ACCESS_KEY_ID: 'DUMMYIDEXAMPLE'
    AWS_SECRET_ACCESS_KEY: 'DUMMYEXAMPLEKEY'
  command:
```

If you want to have your application and DynamoDB local be in separate containers use the following yaml file:

```yaml
version: '3.7'
services:
dynamodb-local:
  image: amazon/dynamodb-local
  container_name: dynamodb-local
  ports:
    - "8000:8000"
app-node:
  depends_on:
    - dynamodb-local
  image: location-of-your-dynamodb-demo-app:latest
  container_name: app-node
  ports:
    - "8080:8080"
```

This docker-compose.yml script creates an app-node container and a dynamodb-local container. The script runs a command in the app-node container that uses the AWS CLI to connect to the dynamodb-local container and describes the account and table limits.

To use with your own application image, replace the image value in the example below with that of your application's:
depends_on:
- "dynamodb-local"
links:
- "dynamodb-local"
environment:
- AWS_ACCESS_KEY_ID='DUMMYIDEXAMPLE'
- AWS_SECRET_ACCESS_KEY='DUMMYEXAMPLEKEY'
- REGION='eu-west-1'
dynamodb-local:
  image: amazon/dynamodb-local:latest
  container_name: dynamodb-local
  ports:
  - "8000:8000"

Note
The yaml scripts require that you specify an AWS access key and an AWS secret key, but they are not required to be valid AWS keys for you to access DynamoDB local.

3. Run the following command-line:

   ```
docker-compose up
   ```

DynamoDB Usage Notes

Except for the endpoint, applications that run with the downloadable version of Amazon DynamoDB should also work with the DynamoDB web service. However, when using DynamoDB locally, you should be aware of the following:

- If you use the `-sharedDb` option, DynamoDB creates a single database file named `shared-local-instance.db`. Every program that connects to DynamoDB accesses this file. If you delete the file, you lose any data that you have stored in it.

- If you omit `-sharedDb`, the database file is named `myaccesskeyid_region.db`, with the AWS access key ID and AWS Region as they appear in your application configuration. If you delete the file, you lose any data that you have stored in it.

- If you use the `-inMemory` option, DynamoDB doesn't write any database files at all. Instead, all data is written to memory, and the data is not saved when you terminate DynamoDB.

- If you use the `-optimizeDbBeforeStartup` option, you must also specify the `-dbPath` parameter so that DynamoDB can find its database file.

- The AWS SDKs for DynamoDB require that your application configuration specify an access key value and an AWS Region value. Unless you're using the `-sharedDb` or the `-inMemory` option, DynamoDB uses these values to name the local database file. These values don't have to be valid AWS values to run locally. However, you might find it convenient to use valid values so that you can run your code in the cloud later by changing the endpoint you're using.

Topics

- Command Line Options (p. 50)
- Setting the Local Endpoint (p. 51)
- Differences Between Downloadable DynamoDB and the DynamoDB Web Service (p. 52)

Command Line Options

You can use the following command line options with the downloadable version of DynamoDB:
• **-cors value** — Enables support for cross-origin resource sharing (CORS) for JavaScript. You must provide a comma-separated "allow" list of specific domains. The default setting for -cors is an asterisk (*), which allows public access.

• **-dbPath value** — The directory where DynamoDB writes its database file. If you don't specify this option, the file is written to the current directory. You can't specify both -dbPath and -inMemory at once.

• **-delayTransientStatuses** — Causes DynamoDB to introduce delays for certain operations. DynamoDB (downloadable version) can perform some tasks almost instantaneously, such as create/update/delete operations on tables and indexes. However, the DynamoDB service requires more time for these tasks. Setting this parameter helps DynamoDB running on your computer simulate the behavior of the DynamoDB web service more closely. (Currently, this parameter introduces delays only for global secondary indexes that are in either CREATING or DELETING status.)

• **-help** — Prints a usage summary and options.

• **-inMemory** — DynamoDB runs in memory instead of using a database file. When you stop DynamoDB, none of the data is saved. You can't specify both -dbPath and -inMemory at once.

• **-optimizeDbBeforeStartup** — Optimizes the underlying database tables before starting DynamoDB on your computer. You also must specify -dbPath when you use this parameter.

• **-port value** — The port number that DynamoDB uses to communicate with your application. If you don't specify this option, the default port is 8000.

  **Note**
  DynamoDB uses port 8000 by default. If port 8000 is unavailable, this command throws an exception. You can use the -port option to specify a different port number. For a complete list of DynamoDB runtime options, including -port, type this command:
  ```
  java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar -help
  ```

• **-sharedDb** — If you specify -sharedDb, DynamoDB uses a single database file instead of separate files for each credential and Region.

### Setting the Local Endpoint

By default, the AWS SDKs and tools use endpoints for the Amazon DynamoDB web service. To use the SDKs and tools with the downloadable version of DynamoDB, you must specify the local endpoint:

http://localhost:8000

### AWS Command Line Interface

You can use the AWS Command Line Interface (AWS CLI) to interact with downloadable DynamoDB. For example, you can use it to perform all the steps in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

To access DynamoDB running locally, use the **--endpoint-url** parameter. The following is an example of using the AWS CLI to list the tables in DynamoDB on your computer.

```bash
aws dynamodb list-tables --endpoint-url http://localhost:8000
```

  **Note**
  The AWS CLI can't use the downloadable version of DynamoDB as a default endpoint. Therefore, you must specify --endpoint-url with each AWS CLI command.

### AWS SDKs

The way you specify an endpoint depends on the programming language and AWS SDK you're using. The following sections describe how to do this:
Differences Between Downloadable DynamoDB and the DynamoDB Web Service

The downloadable version of DynamoDB is intended for development and testing purposes only. By comparison, the DynamoDB web service is a managed service with scalability, availability, and durability features that make it ideal for production use.

The downloadable version of DynamoDB differs from the web service in the following ways:

- AWS Regions and distinct AWS accounts are not supported at the client level.
- Provisioned throughput settings are ignored in downloadable DynamoDB, even though the `CreateTable` operation requires them. For `CreateTable`, you can specify any numbers you want for provisioned read and write throughput, even though these numbers are not used. You can call `UpdateTable` as many times as you want per day. However, any changes to provisioned throughput values are ignored.
- `Scan` operations are performed sequentially. Parallel scans are not supported. The `Segment` and `TotalSegments` parameters of the `Scan` operation are ignored.
- The speed of read and write operations on table data is limited only by the speed of your computer. `CreateTable`, `UpdateTable`, and `DeleteTable` operations occur immediately, and table state is always ACTIVE. `UpdateTable` operations that change only the provisioned throughput settings on tables or global secondary indexes occur immediately. If an `UpdateTable` operation creates or deletes any global secondary indexes, then those indexes transition through normal states (such as CREATING and DELETING, respectively) before they become an ACTIVE state. The table remains ACTIVE during this time.
- Read operations are eventually consistent. However, due to the speed of DynamoDB running on your computer, most reads appear to be strongly consistent.
- Item collection metrics and item collection sizes are not tracked. In operation responses, nulls are returned instead of item collection metrics.
- In DynamoDB, there is a 1 MB limit on data returned per result set. Both the DynamoDB web service and the downloadable version enforce this limit. However, when querying an index, the DynamoDB service calculates only the size of the projected key and attributes. By contrast, the downloadable version of DynamoDB calculates the size of the entire item.
- If you're using DynamoDB Streams, the rate at which shards are created might differ. In the DynamoDB web service, shard-creation behavior is partially influenced by table partition activity. When you run DynamoDB locally, there is no table partitioning. In either case, shards are ephemeral, so your application should not be dependent on shard behavior.
- `TransactionConflictExceptions` are not thrown by downloadable DynamoDB for transactional APIs. We recommend that you use a Java mocking framework to simulate `TransactionConflictExceptions` in the DynamoDB handler to test how your application responds to conflicting transactions.
- In the DynamoDB web service, table names are case sensitive. A table named `Authors` and one named `authors` can both exist as separate tables. In the downloadable version, table names are case insensitive, and attempting to create these two tables would result in an error.
Setting Up DynamoDB (Web Service)

To use the Amazon DynamoDB web service:

1. Sign up for AWS. (p. 53)
2. Get an AWS access key (p. 53) (used to access DynamoDB programmatically).
   
   **Note**
   
   If you plan to interact with DynamoDB only through the AWS Management Console, you don't need an AWS access key, and you can skip ahead to Using the Console (p. 55).
3. Configure your credentials (p. 54) (used to access DynamoDB programmatically).

Signing Up for AWS

To use the DynamoDB service, you must have an AWS account. If you don't already have an account, you are prompted to create one when you sign up. You're not charged for any AWS services that you sign up for unless you use them.

**To sign up for AWS**

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Getting an AWS Access Key

Before you can access DynamoDB programmatically or through the AWS Command Line Interface (AWS CLI), you must have an AWS access key. You don't need an access key if you plan to use the DynamoDB console only.

Access keys consist of an access key ID and secret access key, which are used to sign programmatic requests that you make to AWS. If you don't have access keys, you can create them from the AWS Management Console. As a best practice, do not use the AWS account root user access keys for any task where it's not required. Instead, create a new administrator IAM user with access keys for yourself.

The only time that you can view or download the secret access key is when you create the keys. You cannot recover them later. However, you can create new access keys at any time. You must also have permissions to perform the required IAM actions. For more information, see Permissions Required to Access IAM Resources in the IAM User Guide.

**To create access keys for an IAM user**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. In the navigation pane, choose Users.
3. Choose the name of the user whose access keys you want to create, and then choose the Security credentials tab.
4. In the Access keys section, choose Create access key.
5. To view the new access key pair, choose Show. You will not have access to the secret access key again after this dialog box closes. Your credentials will look something like this:
• Access key ID: AKIAIOSFODNN7EXAMPLE
• Secret access key: wJalrXUttnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY

6. To download the key pair, choose **Download .csv file**. Store the keys in a secure location. You will not have access to the secret access key again after this dialog box closes.

   Keep the keys confidential in order to protect your AWS account and never email them. Do not share them outside your organization, even if an inquiry appears to come from AWS or Amazon.com. No one who legitimately represents Amazon will ever ask you for your secret key.

7. After you download the .csv file, choose **Close**. When you create an access key, the key pair is active by default, and you can use the pair right away.

Configuring Your Credentials

Before you can access DynamoDB programmatically or through the AWS CLI, you must configure your credentials to enable authorization for your applications.

There are several ways to do this. For example, you can manually create the credentials file to store your access key ID and secret access key. You also can use the **aws configure** command of the AWS CLI to automatically create the file. Alternatively, you can use environment variables. For more information about configuring your credentials, see the programming-specific AWS SDK developer guide.

To install and configure the AWS CLI, see **Using the AWS CLI (p. 57)**.
Accessing DynamoDB

You can access Amazon DynamoDB using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API.

Topics
- Using the Console (p. 55)
- Using the AWS CLI (p. 57)
- Using the API (p. 59)
- Using the NoSQL Workbench for DynamoDB (p. 59)
- IP Address Ranges (p. 59)

Using the Console

You can access the AWS Management Console for Amazon DynamoDB at https://console.aws.amazon.com/dynamodb/home.

You can use the console to do the following in DynamoDB:
- Monitor recent alerts, total capacity, service health, and the latest DynamoDB news on the DynamoDB dashboard.
- Create, update, and delete tables. The capacity calculator provides estimates of how many capacity units to request based on the usage information you provide.
- Manage streams.
- View, add, update, and delete items that are stored in tables. Manage Time to Live (TTL) to define when items in a table expire so that they can be automatically deleted from the database.
- Query and scan a table.
- Set up and view alarms to monitor your table's capacity usage. View your table's top monitoring metrics on real-time graphs from CloudWatch.
- Modify a table's provisioned capacity.
- Create and delete global secondary indexes.
- Create triggers to connect DynamoDB streams to AWS Lambda functions.
- Apply tags to your resources to help organize and identify them.
- Purchase reserved capacity.

The console displays an introductory screen that prompts you to create your first table. To view your tables, in the navigation pane on the left side of the console, choose **Tables**.

Here's a high-level overview of the actions available per table within each navigation tab:
- **Overview** – View stream and table details, and manage streams and Time to Live (TTL).
- **Items** – Manage items and perform queries and scans.
- **Metrics** – Monitor Amazon CloudWatch metrics.
- **Alarms** – Manage CloudWatch alarms.
- **Capacity** – Modify a table's provisioned capacity.
- **Indexes** – Manage global secondary indexes.
- **Triggers** – Manage triggers to connect DynamoDB streams to Lambda functions.
Working with User Preferences

You can configure some of the default settings in the Amazon DynamoDB console. For example, you can change the default query type that is used when you access the **Items** tab. If you're signed in to the console as an IAM user, you can store information about how you prefer to use the console. This information, also known as your *user preferences*, is stored and applied every time you use the console. Any time you access the DynamoDB console, these preferences are applied to all tables in all AWS Regions for your IAM user. They are not table-specific or Region-specific. They don't affect your interactions with the AWS CLI, DynamoDB API, or other services that interact with DynamoDB.

You can still change individual settings on console pages without having saved any user preferences. Those choices persist until you close the console window. When you return to the console, any saved user preferences are applied.

**Note**
User preferences are available only for IAM users. You can't set preferences if you use federated access, temporary access, or an AWS account root user to access the console.

User preferences include the following:

- **Table detail view mode**: View all the table-specific information vertically, horizontally, or covering the full screen (if enabled, the navigation bar still appears).
- **Show navigation bar**: Enable this option to show the navigation bar on the left side (expanded). Disable it to automatically collapse the navigation bar (you can expand it using the right chevron).
- **Default entry page (Dashboard or Tables)**: Choose the page that loads when you access DynamoDB. This option automatically loads the Dashboard or the Tables page, respectively.
- **Items editor mode (Tree or Text)**: Choose the default editor mode to use when you create or edit an item.
- **Items default query type (Scan or Query)**: Choose the default query type to use when you access the **Items** tab. Choose **Scan** if you want to either enable or disable the automatic scan operation that occurs when accessing the **Items** tab.
- **Automatic scan operation when accessing the items tab**: If **Scan** is the default query type for items and you enable this setting, an automatic scan operation occurs when you access the **Items** tab. If you disable this setting, you can perform a scan by choosing **Start search** on the **Items** tab.

View and Save User Preferences

You can view and change your user preferences for the DynamoDB console. These settings apply only to your IAM user in the DynamoDB console. They don't affect other IAM users in your AWS account.

**To view and save preferences on the DynamoDB console for your IAM user**

2. Sign in as an IAM user. You can't configure user preferences for other user types.
3. In **Preferences**, choose **Preferences**.
4. In **Preferences**, configure your preferences.
5. Do one of the following:
   - To save and apply your changes, choose **Save**.
• To view the DynamoDB console default settings, choose **Restore**. These defaults are applied if you choose **Save**.

The default settings are as follows:

• **Table detail view mode**: Vertical
• **Show navigation bar**: Yes
• **Default entry page**: Dashboard
• **Items editor mode**: Tree
• **Items default query type**: Scan
• **Automatic scan operation when accessing the items tab**: Yes

• To return to the console page that you were on previously, choose **Back**. Or, choose **Dashboard** to go to the DynamoDB Dashboard page.

# Using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to control multiple AWS services from the command line and automate them through scripts. You can use the AWS CLI for ad hoc operations, such as creating a table. You can also use it to embed Amazon DynamoDB operations within utility scripts.

Before you can use the AWS CLI with DynamoDB, you must get an access key ID and secret access key. For more information, see **Getting an AWS Access Key (p. 53)**.

For a complete listing of all the commands available for DynamoDB in the AWS CLI, see the **AWS CLI Command Reference**.

## Topics

- Downloading and Configuring the AWS CLI (p. 57)
- Using the AWS CLI with DynamoDB (p. 57)
- Using the AWS CLI with Downloadable DynamoDB (p. 58)

## Downloading and Configuring the AWS CLI

The AWS CLI is available at [http://aws.amazon.com/cli](http://aws.amazon.com/cli). It runs on Windows, macOS, or Linux. After you download the AWS CLI, follow these steps to install and configure it:

2. Follow the instructions for Installing the AWS CLI and Configuring the AWS CLI.

## Using the AWS CLI with DynamoDB

The command line format consists of a DynamoDB operation name followed by the parameters for that operation. The AWS CLI supports a shorthand syntax for the parameter values, as well as JSON.

For example, the following command creates a table named **Music**. The partition key is **Artist**, and the sort key is **SongTitle**. (For easier readability, long commands in this section are broken into separate lines.)

```bash
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions
```
The following commands add new items to the table. These examples use a combination of shorthand syntax and JSON.

```bash
aws dynamodb put-item
--table-name Music
--item '{
  "Artist": {"S": "No One You Know"},
  "SongTitle": {"S": "Call Me Today"},
  "AlbumTitle": {"S": "Somewhat Famous"}
}'
--return-consumed-capacity TOTAL

aws dynamodb put-item
--table-name Music
--item '{
  "Artist": {"S": "Acme Band"},
  "SongTitle": {"S": "Happy Day"},
  "AlbumTitle": {"S": "Songs About Life"}
}'
--return-consumed-capacity TOTAL
```

On the command line, it can be difficult to compose valid JSON. However, the AWS CLI can read JSON files. For example, consider the following JSON code snippet, which is stored in a file named `key-conditions.json`.

```json
{
  "Artist": {
    "AttributeValueList": [
      {
        "S": "No One You Know"
      }
    ],
    "ComparisonOperator": "EQ"
  },
  "SongTitle": {
    "AttributeValueList": [
      {
        "S": "Call Me Today"
      }
    ],
    "ComparisonOperator": "EQ"
  }
}
```

You can now issue a `Query` request using the AWS CLI. In this example, the contents of the `key-conditions.json` file are used for the `--key-conditions` parameter.

```bash
aws dynamodb query --table-name Music --key-conditions file://key-conditions.json
```

## Using the AWS CLI with Downloadable DynamoDB

The AWS CLI can also interact with DynamoDB (Downloadable Version) that runs on your computer. To enable this, add the following parameter to each command:

```bash
--endpoint-url http://localhost:8000
```

The following example uses the AWS CLI to list the tables in a local database.
You can use the AWS Management Console and the AWS Command Line Interface to work interactively with Amazon DynamoDB. However, to get the most out of DynamoDB, you can write application code using the AWS SDKs.

The AWS SDKs provide broad support for DynamoDB in Java, JavaScript in the browser, .NET, Node.js, PHP, Python, Ruby, C++, Go, Android, and iOS. To get started quickly with these languages, see Getting Started with DynamoDB and AWS SDKs (p. 77).

Before you can use the AWS SDKs with DynamoDB, you must get an AWS access key ID and secret access key. For more information, see Setting Up DynamoDB (Web Service) (p. 53).

For a high-level overview of DynamoDB application programming with the AWS SDKs, see Programming with DynamoDB and the AWS SDKs (p. 211).

You can also access DynamoDB, by downloading and using the NoSQL Workbench for Amazon DynamoDB (p. 770).

Amazon Web Services (AWS) publishes its current IP address ranges in JSON format. To view the current ranges, download ip-ranges.json. For more information, see AWS IP Address Ranges in the AWS General Reference.

To find the IP address ranges that you can use to access DynamoDB tables and indexes, search the ip-ranges.json file for the following string: "service": "DYNAMODB".

The IP address ranges do not apply to DynamoDB Streams or DynamoDB Accelerator (DAX).
Getting Started with DynamoDB

Use the hands-on tutorials in this section to help you get started and learn more about Amazon DynamoDB.

Basic Concepts in DynamoDB

Before you begin, you should familiarize yourself with the basic concepts in Amazon DynamoDB. For more information, see DynamoDB Core Components.

Then continue on to Prerequisites to learn about setting up DynamoDB.

Prerequisites - Getting Started Tutorial

Before starting the Amazon DynamoDB tutorial, follow the steps in Setting Up DynamoDB. Then continue on to Step 1: Create a Table (p. 60).

**Note**

- If you plan to interact with DynamoDB only through the AWS Management Console, you don't need an AWS access key. Complete the steps in Signing Up for AWS, and then continue on to Step 1: Create a Table (p. 60).
- If you don't want to sign up for a free tier account, you can set up DynamoDB Local (Downloadable Version). Then continue on to Step 1: Create a Table (p. 60).

Step 1: Create a Table

In this step, you create a Music table in Amazon DynamoDB. The table has the following details:

- Partition key — Artist
- Sort key — SongTitle
For more information about table operations, see Working with Tables and Data in DynamoDB (p. 336).

**Note**
Before you begin, make sure that you followed the steps in Prerequisites - Getting Started Tutorial (p. 60).

AWS Management Console

To create a new Music table using the DynamoDB console:

2. In the navigation pane on the left side of the console, choose **Dashboard**.
3. On the right side of the console, choose **Create Table**.
4. Enter the table details as follows:
   a. For the table name, enter **Music**.
   b. For the partition key, enter **Artist**.
   c. Choose **Add sort key**.
   d. Enter **SongTitle** as the sort key.
5. Choose **Create** to create the table.
AWS CLI

The following AWS CLI example creates a new Music table using create-table.

```
aws dynamodb create-table --table-name Music --attribute-definitions AttributeName=Artist,AttributeType=S AttributeName=SongTitle,AttributeType=S --key-schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5
```

Using create-table returns the following sample result.

```
{
  "TableDescription": {
    "TableArn": "arn:aws:dynamodb:us-west-2:522194210714:table/Music",
    "AttributeDefinitions": [
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "WriteCapacityUnits": 5,
      "ReadCapacityUnits": 10
    },
    "TableSizeBytes": 0,
    "TableName": "Music",
    "TableStatus": "CREATING",
    "TableId": "d04c7240-0e46-435d-b231-d54091fe1017",
    "KeySchema": [
      {
        "KeyType": "HASH",
        "AttributeName": "Artist"
      },
      {
        "KeyType": "RANGE",
        "AttributeName": "SongTitle"
      }
    ],
    "ItemCount": 0,
    "CreationDateTime": 1558028402.69
  }
}
```

Note that the value of the TableStatus field is set to CREATING.

To verify that DynamoDB has finished creating the Music table, use the describe-table command.

```
aws dynamodb describe-table --table-name Music | grep TableStatus
```
This command returns the following result. When DynamoDB finishes creating the table, the value of the `TableStatus` field is set to `ACTIVE`.

```
"TableStatus": "ACTIVE",
```

After creating the new table, proceed to Step 2: Write Data to a Table Using the Console or AWS CLI (p. 63).

**Step 2: Write Data to a Table Using the Console or AWS CLI**

In this step, you insert two items into the `Music` table that you created in Step 1: Create a Table (p. 60).

For more information about write operations, see Writing an Item (p. 376).

**AWS Management Console**

Follow these steps to write data to the `Music` table using the DynamoDB console.

2. In the navigation pane on the left side of the console, choose `Tables`.
3. In the table list, choose the `Music` table.
5. On the `Items` tab, choose `Create item`.
6. Choose the plus sign (`+`) symbol next to `SongTitle`.
7. Choose `Append`, and then choose `Number`. Name the field `Awards`.
8. Repeat this process to create an **AlbumTitle** of type **String**.

9. Choose the following values for your item:
   
   a. For **Artist**, enter *No One You Know* as the value.
   
   b. For **SongTitle**, enter *Call Me Today*.
   
   c. For **AlbumTitle**, enter *Somewhat Famous*.
   
   d. For **Awards**, enter 1.

10. Choose **Save**.

11. Repeat this process and create another item with the following values:

   a. For **Artist**, enter *Acme Band*.
b. For **SongTitle** enter **Happy Day**.

c. For **AlbumTitle**, enter **Songs About Life**.

d. For **Awards**, enter **10**.

### AWS CLI

The following AWS CLI example creates two new items in the **Music** table using **put-item**.

```
aws dynamodb put-item \
--table-name Music \ 
--item \ 
'|{"Artist": {"S": "No One You Know"}, "SongTitle": {"S": "Call Me Today"},\ 
"AlbumTitle": {"S": "Somewhat Famous"}, "Awards": {"N": "1"}}' 

aws dynamodb put-item \
--table-name Music \
--item \
'|{"Artist": {"S": "Acme Band"}, "SongTitle": {"S": "Happy Day"}, "AlbumTitle": {"S":\ 
"Songs About Life"}, "Awards": {"N": "10"}}' 
```

For more information about supported data types in DynamoDB, see [Data Types](#).

For more information about how to represent DynamoDB data types in JSON, see [Attribute Values](#).

After writing data to your table, proceed to [Step 3: Read Data from a Table](#) (p. 65).

### Step 3: Read Data from a Table

In this step, you will read back an item that was created in [Step 2: Write Data to a Table Using the Console or AWS CLI](#) (p. 63). You can use the DynamoDB console or the AWS CLI to read an item from the **Music** table by specifying **Artist** and **SongTitle**.

For more information about read operations in DynamoDB, see [Reading an Item](#) (p. 376).

### AWS Management Console

Follow these steps to read data from the **Music** table using the DynamoDB console.

2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Choose the **Items** tab for the **Music** table.
5. On the **Items** tab, view the list of items stored in the table, sorted by **Artist** and **SongTitle**.

   The first item in the list is the one with the **Artist** **Acme Band** and the **SongTitle** **Happy Day**.
Step 4: Update Data

In this step, you update an item that you created in Step 2: Write Data to a Table Using the Console or AWS CLI (p. 63). You can use the DynamoDB console or the AWS CLI to update the AlbumTitle of an item in the Music table by specifying Artist, SongTitle, and the updated AlbumTitle.
AWS Management Console

You can use the DynamoDB console to update data in the Music table.

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the Music table from the table list.
5. Choose the item whose Artist value is Acme Band and SongTitle value is Happy Day.
6. Update the AlbumTitle value to Updated Album Title, and then choose Save.

The following image shows the updated item on the console.

AWS CLI

The following AWS CLI example updates an item in the Music table using update-item.

```
aws dynamodb update-item
    --table-name Music
    --key '{ "Artist": {"S": "Acme Band"}, "SongTitle": {"S": "Happy Day"}}' 
    --update-expression "SET AlbumTitle = :newval" 
    --expression-attribute-values '{":newval":{"S":"Updated Album Title"}}' 
    --return-values ALL_NEW
```

Using update-item returns the following sample result.

```json
{
}
```
To query the data in the Music table, proceed to Step 5: Query Data in a Table (p. 68).

Step 5: Query Data in a Table

In this step, you query the data that you wrote to the Music table in the section called “Step 2: Write Data” (p. 63) by specifying Artist.

For more information about query operations, see Working with Queries in DynamoDB (p. 459).

AWS Management Console

Follow these steps to use the DynamoDB console to query data in the Music table.

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the Music table from the table list.
5. In the drop-down list, choose Query.

6. For Partition key, enter Acme Band, and then choose Start search.
AWS CLI

The following AWS CLI example queries an item in the Music table using query.

```bash
aws dynamodb query \
  --table-name Music \
  --key-condition-expression "Artist = :name" \
  --expression-attribute-values '{"name":{"S":"Acme Band"}}'
```

Using query returns the following sample result.

```json
{
  "Count": 1,
  "Items": [
    {
      "AlbumTitle": {
        "S": "Updated Album Title"
      },
      "Awards": {
        "N": "10"
      },
      "SongTitle": {
        "S": "Happy Day"
      },
      "Artist": {
        "S": "Acme Band"
      }
    }
  ],
  "ScannedCount": 1,
  "ConsumedCapacity": null
}
```

To create a global secondary index for your table, proceed to Step 6: Create a Global Secondary Index (p. 70).
Step 6: Create a Global Secondary Index

In this step, you create a global secondary index for the Music table that you created in Step 1: Create a Table (p. 60).

For more information about global secondary indexes, see Using Global Secondary Indexes in DynamoDB (p. 500).

AWS Management Console

To use the Amazon DynamoDB console to create a global secondary index AlbumTitle-index for the Music table:

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the Music table from the table list.
5. Choose Create index.
6. For the Partition key, enter AlbumTitle, and then choose Create index.
AWS CLI

The following AWS CLI example creates a global secondary index AlbumTitle-index for the Music table using update-table.

```
aws dynamodb update-table \
  --table-name Music \
  --attribute-definitions AttributeName=AlbumTitle,AttributeType=S \
  --global-secondary-index-updates \
  "[{
    "Create": {
      "IndexName": "AlbumTitle-index",
      "KeySchema": [{"AttributeName": "AlbumTitle","KeyType": "HASH"}],
      "ProvisionedThroughput": {"ReadCapacityUnits": 10, "WriteCapacityUnits": 5 },
      "Projection": {"ProjectionType": "ALL"}}]"
```

Using update-table returns the following sample result.

```
{
  "TableDescription": {
    "TableArn": "arn:aws:dynamodb:us-west-2:522194210714:table/Music",
    "AttributeDefinitions": [
      {"AttributeName": "AlbumTitle",
       "AttributeType": "S"},
    ],
    "KeySchema": [{"AttributeName": "AlbumTitle","KeyType": "HASH"}],
    "ProvisionedThroughput": {"ReadCapacityUnits": 10, "WriteCapacityUnits": 5 },
    "GlobalSecondaryIndexes": [{"IndexName": "AlbumTitle-index",
      "KeySchema": [{"AttributeName": "AlbumTitle","KeyType": "HASH"}],
      "ProvisionedThroughput": {"ReadCapacityUnits": 10, "WriteCapacityUnits": 5 },
      "Projection": {"ProjectionType": "ALL"}]
  }
}
```
Step 6: Create a Global Secondary Index

```
{
    "AttributeName": "Artist",
    "AttributeType": "S"
},
{
    "AttributeName": "SongTitle",
    "AttributeType": "S"
}
],
"GlobalSecondaryIndexes": [
    {
        "IndexSizeBytes": 0,
        "IndexName": "AlbumTitle-index",
        "Projection": {
            "ProjectionType": "ALL"
        },
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "WriteCapacityUnits": 5,
            "ReadCapacityUnits": 10
        },
        "IndexStatus": "CREATING",
        "Backfilling": false,
        "KeySchema": [
            {
                "KeyType": "HASH",
                "AttributeName": "AlbumTitle"
            }
        ],
        "IndexArn": "arn:aws:dynamodb:us-west-2:522194210714:table/Music/index/AlbumTitle-index",
        "ItemCount": 0
    }
],
"ProvisionedThroughput": {
    "NumberOfDecreasesToday": 0,
    "WriteCapacityUnits": 5,
    "ReadCapacityUnits": 10
},
"TableSizeBytes": 0,
"TableName": "Music",
"TableStatus": "UPDATING",
"TableId": "d04c7240-0e46-435d-b231-d54091fe1017",
"KeySchema": [
    {
        "KeyType": "HASH",
        "AttributeName": "Artist"
    },
    {
        "KeyType": "RANGE",
        "AttributeName": "SongTitle"
    }
],
"ItemCount": 0,
"CreationDateTime": 1558028402.69
}
```

Note that the value of the `IndexStatus` field is set to CREATING.

To verify that DynamoDB has finished creating the `AlbumTitle-index` global secondary index, use the `describe-table` command.

```
aws dynamodb describe-table --table-name Music | grep IndexStatus
```
This command returns the following result. The index is ready for use when the value of the `IndexStatus` field returned is set to `ACTIVE`.

```
"IndexStatus": "ACTIVE",
```

Next, you can query the global secondary index. For details, see Step 7: Query the Global Secondary Index (p. 73).

**Step 7: Query the Global Secondary Index**

In this step, you query a global secondary index on the `Music` table using the Amazon DynamoDB console or the AWS CLI.

For more information about global secondary indexes, see Using Global Secondary Indexes in DynamoDB (p. 500).

**AWS Management Console**

Follow these steps to use the DynamoDB console to query data through the `AlbumTitle-index` global secondary index.

2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Choose the **Items** tab for the **Music** table.
5. In the drop-down list, choose **Query**.
6. In the drop-down list next to **Query**, choose **[Index] AlbumTitle-index: AlbumTitle**.

For **AlbumTitle**, enter **Somewhat Famous**, and then choose **Start search**.
AWS CLI

The following AWS CLI example queries a global secondary index AlbumTitle-index on the Music table.

```
aws dynamodb query \
  --table-name Music \
  --index-name AlbumTitle-index \
  --key-condition-expression "AlbumTitle = :name" \n  --expression-attribute-values '{":name":{"S":"Somewhat Famous"}}'
```

Using query returns the following sample result.

```json
{
  "Count": 1,
  "Items": [
    {
      "AlbumTitle": {
        "S": "Somewhat Famous"
      },
      "Awards": {
        "N": "1"
      },
      "SongTitle": {
        "S": "Call Me Today"
      },
      "Artist": {
        "S": "No One You Know"
      }
    }
  ],
  "ScannedCount": 1,
  "ConsumedCapacity": null
}
```
Step 8: (Optional) Clean Up Resources

If you no longer need the Amazon DynamoDB table that you created for the tutorial, you can delete it. This step helps ensure that you aren't charged for resources that you aren't using. You can use the DynamoDB console or the AWS CLI to delete the Music table that you created in Step 1: Create a Table (p. 60).

For more information about table operations in DynamoDB, see Working with Tables and Data in DynamoDB (p. 336).

AWS Management Console

To delete the Music table using the console:

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the Music table from the table list.
5. Choose Delete table.

AWS CLI

The following AWS CLI example deletes the Music table using delete-table.

```
aws dynamodb delete-table --table-name Music
```

Getting Started with DynamoDB and AWS SDKs

This section contains hands-on tutorials to help you learn about Amazon DynamoDB. We encourage you to work through one of the language-specific tutorials. The code examples in these tutorials can run against either the downloadable version of DynamoDB or the DynamoDB web service.

Note
AWS SDKs are available for a wide variety of languages. For a complete list, see Tools for Amazon Web Services.

Getting Started with Java and DynamoDB

In this tutorial, you use the AWS SDK for Java to write simple programs to perform the following Amazon DynamoDB operations:

• Create a table called Movies and load sample data in JSON format.
• Perform create, read, update, and delete operations on the table.
• Run simple queries.

The SDK for Java offers several programming models for different use cases. In this exercise, the Java code uses the document model that provides a level of abstraction that makes it easier for you to work with JSON documents.

As you work through this tutorial, you can refer to the AWS SDK for Java Documentation.

Tutorial Prerequisites

• Download and run DynamoDB on your computer. For more information, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).

DynamoDB (downloadable version) is also available as part of the AWS Toolkit for Eclipse. For more information, see AWS Toolkit For Eclipse.

Note
You use the downloadable version of DynamoDB in this tutorial. For information about how to run the same code against the DynamoDB web service, see the Summary (p. 96).

• Set up an AWS access key to use the AWS SDKs. For more information, see Setting Up DynamoDB (Web Service) (p. 53).
• Set up the AWS SDK for Java:
• Install a Java development environment. If you are using the Eclipse IDE, install the AWS Toolkit for Eclipse.
• Install the AWS SDK for Java.
• Set up your AWS security credentials for use with the SDK for Java.

For instructions, see Getting Started in the AWS SDK for Java Developer Guide.

Step 1: Create a Table using Java and DynamoDB

In this step, you create a table named Movies. The primary key for the table is composed of the following attributes:

• year – The partition key. The ScalarAttributeType is N for number.
• title – The sort key. The ScalarAttributeType is S for string.

1. Copy the following program and paste it into your Java development environment.

```java
package com.amazonaws.codesamples.gsg;

import java.util.Arrays;
import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.model.AttributeDefinition;
import com.amazonaws.services.dynamodbv2.model.KeySchemaElement;
import com.amazonaws.services.dynamodbv2.model.KeyType;
import com.amazonaws.services.dynamodbv2.model.ProvisionedThroughput;
import com.amazonaws.services.dynamodbv2.model.ScalarAttributeType;

public class MoviesCreateTable {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .withEndpointConfiguration(new
            .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        String tableName = "Movies";
```
```java
try {
    System.out.println("Attempting to create table; please wait...");
    Table table = dynamoDB.createTable(tableName,
        Arrays.asList(new KeySchemaElement("year", KeyType.HASH), // Partition key
        new KeySchemaElement("title", KeyType.RANGE)), // Sort key
            Arrays.asList(new AttributeDefinition("year", ScalarAttributeType.N),
        new AttributeDefinition("title", ScalarAttributeType.S)),
            new ProvisionedThroughput(10L, 10L));
    table.waitForActive();
    System.out.println("Success. Table status: " +
        table.getDescription().getTableStatus());
}
catch (Exception e) {
    System.err.println("Unable to create table: ");
    System.err.println(e.getMessage());
}
```
In the JSON data, note the following:

- You use the `year` and `title` as the primary key attribute values for the `Movies` table.
- You store the rest of the `info` values in a single attribute called `info`. This program illustrates how you can store JSON in an Amazon DynamoDB attribute.

The following is an example of movie data.

```json
{
    "year" : 2013,
    "title" : "Turn It Down, Or Else!",
    "info" : {
        "directors" : ["Alice Smith", "Bob Jones"],
        "release_date" : "2013-01-18T00:00:00Z",
        "rating" : 6.2,
        "genres" : ["Comedy", "Drama"],
        "image_url" : "http://ia.media-imdb.com/images/N/09ERWAVU7PS797A7J7LUBH8N09AMUP9068LLu65JF90ENKB7LJKQ78@_V1_SX400_.jpg",
        "plot" : "A rock band plays their music at high volumes, annoying the neighbors.",
        "rank" : 11,
        "running_time_secs" : 5215,
        "actors" : ["David Matthewman", "Ann Thomas", "Jonathan G. Neff"
    ]
}
```

### Step 2.1: Download the Sample Data File

1. Download the sample data archive: `moviedata.zip`
2. Extract the data file (`moviedata.json`) from the archive.
3. Copy and paste the `moviedata.json` file into your current directory.

### Step 2.2: Load the Sample Data into the Movies Table

After you download the sample data, you can run the following program to populate the `Movies` table.

1. Copy the following program and paste it into your Java development environment.

```java
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 */
```
```
package com.amazonaws.codesamples.gsg;

import java.io.File;
import java.util.Iterator;
import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.fasterxml.jackson.core.JsonFactory;
import com.fasterxml.jackson.core.JsonParser;
import com.fasterxml.jackson.databind.JsonNode;
import com.fasterxml.jackson.databind.ObjectMapper;
import com.fasterxml.jackson.databind.node.ObjectNode;

public class MoviesLoadData {

    public static void main(String[] args) throws Exception {

        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().
            .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");

        JsonParser parser = new JsonFactory().createParser(new File("moviedata.json"));
        JsonNode rootNode = new ObjectMapper().readTree(parser);

        Iterator<JsonNode> iter = rootNode.iterator();
        ObjectNode currentNode;

        while (iter.hasNext()) {
            currentNode = (ObjectNode) iter.next();

            int year = currentNode.path("year").asInt();
            String title = currentNode.path("title").asText();

            try {
                table.putItem(new Item().withPrimaryKey("year", year, "title", title).
                    withJSON("info", currentNode.path("info").toString()));

                System.out.println("PutItem succeeded: " + year + " " + title);
            }
            catch (Exception e) {
                System.err.println("Unable to add movie: " + year + " " + title);
                System.err.println(e.getMessage());
                break;
            }
        }
    }
}
```
This program uses the open source Jackson library to process JSON. Jackson is included in the AWS SDK for Java. You don't have to install it separately.

2. Compile and run the program.

**Step 3: Create, Read, Update, and Delete an Item**

In this step, you perform read and write operations on an item in the Movies table.

To learn more about reading and writing data, see Working with Items and Attributes (p. 375).

**Topics**
- Step 3.1: Create a New Item (p. 82)
- Step 3.2: Read an Item (p. 83)
- Step 3.3: Update an Item (p. 85)
- Step 3.4: Increment an Atomic Counter (p. 86)
- Step 3.5: Update an Item (Conditionally) (p. 88)
- Step 3.6: Delete an Item (p. 89)

**Step 3.1: Create a New Item**

In this step, you add a new item to the Movies table.

1. Copy the following program and paste it into your Java development environment.

```java
package com.amazonaws.codesamples.gsg;
import java.util.HashMap;
import java.util.Map;
import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.PutItemOutcome;
```

This program uses the open source Jackson library to process JSON. Jackson is included in the AWS SDK for Java. You don't have to install it separately.
import com.amazonaws.services.dynamodbv2.document.Table;

public class MoviesItemOps01 {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
                .withEndpointConfiguration(new
                .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");

        int year = 2015;
        String title = "The Big New Movie";

        final Map<String, Object> infoMap = new HashMap<String, Object>();
        infoMap.put("plot", "Nothing happens at all.");
        infoMap.put("rating", 0);

        try {
            System.out.println("Adding a new item...");
            PutItemOutcome outcome = table
                    .putItem(new Item().withPrimaryKey("year", year, "title",
                            title).withMap("info", infoMap));

            System.out.println("PutItem succeeded:
                    + outcome.getPutItemResult());
        }
        catch (Exception e) {
            System.err.println("Unable to add item: " + year + " " + title);
            System.err.println(e.getMessage());
        }
    }
}

Note
The primary key is required. This code adds an item that has primary key (year, title) and info attributes. The info attribute stores JSON example code that provides more information about the movie.

2. Compile and run the program.

**Step 3.2: Read an Item**

In the previous program, you added the following item to the table.

```json
{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Nothing happens at all.",
        rating: 0
    }
}
```

You can use the `getItem` method to read the item from the Movies table. You must specify the primary key values so that you can read any item from Movies if you know its year and title.
1. Copy the following program and paste it into your Java development environment.

```java

package com.amazonaws.codesamples.gsg;

import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.spec.GetItemSpec;

public class MoviesItemOps02 {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");
        int year = 2015;
        String title = "The Big New Movie";
        GetItemSpec spec = new GetItemSpec().withPrimaryKey("year", year, "title", title);

        try {
            System.out.println("Attempting to read the item...");
            Item outcome = table.getItem(spec);
            System.out.println("GetItem succeeded: "+ outcome);
        }
        catch (Exception e) {
            System.err.println("Unable to read item: "+ year + " "+ title);
            System.err.println(e.getMessage());
        }
    }
}
```

2. Compile and run the program.
Step 3.3: Update an Item

You can use the `updateItem` method to modify an existing item. You can update values of existing attributes, add new attributes, or remove attributes.

In this example, you perform the following updates:

- Change the value of the existing attributes (`rating`, `plot`).
- Add a new list attribute (`actors`) to the existing `info` map.

The item changes from the following:

```
{  
  year: 2015,  
  title: "The Big New Movie",  
  info: {  
    plot: "Nothing happens at all.",  
    rating: 0  
  }  
}
```

To this:

```
{  
  year: 2015,  
  title: "The Big New Movie",  
  info: {  
    plot: "Everything happens all at once.",  
    rating: 5.5,  
    actors: ["Larry", "Moe", "Curly"]  
  }  
}
```

1. Copy the following program and paste it into your Java development environment.

```java
/**

import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.UpdateItemOutcome;
```
public class MoviesItemOps03 {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .withEndpointConfiguration(new
            .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");

        int year = 2015;
        String title = "The Big New Movie";

        UpdateItemSpec updateItemSpec = new UpdateItemSpec()
            .withPrimaryKey("year", year, "title", title)
            .withUpdateExpression("set info.rating = :r, info.plot=:p, info.actors=:a")
            .withValueMap(new ValueMap()
                .withNumber(":r", 5.5)
                .withString(":p", "Everything happens all at once.")
                .withList(":a", Arrays.asList("Larry", "Moe", "Curly")))
            .withReturnValues(ReturnValue.UPDATED_NEW);

        try {
            System.out.println("Updating the item...");
            UpdateItemOutcome outcome = table.updateItem(updateItemSpec);
            System.out.println("UpdateItem succeeded:
" + outcome.getItem().toJSONPretty());
        }
        catch (Exception e) {
            System.err.println("Unable to update item: " + year + " " + title);
            System.err.println(e.getMessage());
        }
    }
}

Note
This program uses an UpdateExpression to describe all updates you want to perform on
the specified item.
The ReturnValues parameter instructs Amazon DynamoDB to return only the updated
attributes (UPDATED_NEW).

2. Compile and run the program.

Step 3.4: Increment an Atomic Counter

DynamoDB supports atomic counters. Use the updateItem method to increment or decrement the
value of an existing attribute without interfering with other write requests. (All write requests are
applied in the order in which they are received.)

The following program shows how to increment the rating for a movie. Each time you run it, the
program increments this attribute by one.

1. Copy the following program and paste it into your Java development environment.
public class MoviesItemOps04 {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .withEndpointConfiguration(new
            .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");

        int year = 2015;
        String title = "The Big New Movie";

        UpdateItemSpec updateItemSpec = new UpdateItemSpec().withPrimaryKey("year", year, "title", title)
            .withUpdateExpression("set info.rating = info.rating + :val")
            .withValueMap(new ValueMap().withNumber(":val", 1)).withReturnValues(ReturnValue.UPDATED_NEW);

        try {
            System.out.println("Incrementing an atomic counter...");
            UpdateItemOutcome outcome = table.updateItem(updateItemSpec);
            System.out.println("UpdateItem succeeded:
" + outcome.getItem().toJSONPretty());
        } catch (Exception e) {
            System.err.println("Unable to update item: " + year + " " + title);
            System.err.println(e.getMessage());
        }
    }
}

2. Compile and run the program.
Step 3.5: Update an Item (Conditionally)

The following program shows how to use `UpdateItem` with a condition. If the condition evaluates to true, the update succeeds; otherwise, the update is not performed.

In this case, the movie item is updated only if there are more than three actors.

1. Copy the following program and paste it into your Java development environment.

```java
package com.amazonaws.codesamples.gsg;

import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.PrimaryKey;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.UpdateItemOutcome;
import com.amazonaws.services.dynamodbv2.document.spec.UpdateItemSpec;
import com.amazonaws.services.dynamodbv2.document.utils.ValueMap;
import com.amazonaws.services.dynamodbv2.model.ReturnValue;

public class MoviesItemOps05 {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .withEndpointConfiguration(new
            .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");

        int year = 2015;
        String title = "The Big New Movie";

        UpdateItemSpec updateItemSpec = new UpdateItemSpec()
            .withPrimaryKey(new PrimaryKey("year", year, "title", title))
            .withUpdateExpression("remove info.actors[0]")
            .withConditionExpression("size(info.actors) > :num").withValueMap(new
                ValueMap().withNumber(":num", 3))
            .withReturnValues(ReturnValue.UPDATED_NEW);

        // Conditional update (we expect this to fail)
        try {
            System.out.println("Attempting a conditional update...");
```
UpdateItemOutcome outcome = table.updateItem(updateItemSpec);
System.out.println("UpdateItem succeeded:
" + outcome.getItem().toJSONPretty());
}

} catch (Exception e) {
    System.err.println("Unable to update item: " + year + " " + title);
    System.err.println(e.getMessage());
}

2. Compile and run the program.

   The program should fail with the following message:

   The conditional request failed

   This is because the movie has three actors in it, but the condition is checking for greater than three actors.

3. Modify the program so that the ConditionExpression looks like the following.

   .withConditionExpression("size(info.actors) >= :num")

   The condition is now greater than or equal to 3 instead of greater than 3.

4. Compile and run the program. The UpdateItem operation should now succeed.

Step 3.6: Delete an Item

You can use the deleteItem method to delete one item by specifying its primary key. You can optionally provide a ConditionExpression to prevent the item from being deleted if the condition is not met.

In the following example, you try to delete a specific movie item if its rating is 5 or less.

1. Copy the following program and paste it into your Java development environment.

   ```java
   package com.amazonaws.codesamples.gsg;

   import com.amazonaws.client.builder.AwsClientBuilder;
   import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
   import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
   import com.amazonaws.services.dynamodbv2.document.DynamoDB;
   import com.amazonaws.services.dynamodbv2.document.PrimaryKey;
   ```
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.spec.DeleteItemSpec;
import com.amazonaws.services.dynamodbv2.document.utils.ValueMap;

public class MoviesItemOps06 {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
                .build();

        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");

        int year = 2015;
        String title = "The Big New Movie";

        DeleteItemSpec deleteItemSpec = new DeleteItemSpec()
                .withPrimaryKey(new PrimaryKey("year", year, "title", title)).withConditionExpression("info.rating <= :val")
                .withValueMap(new ValueMap().withNumber(":val", 5.0));

        // Conditional delete (we expect this to fail)
        try {
            System.out.println("Attempting a conditional delete...");
            table.deleteItem(deleteItemSpec);
            System.out.println("DeleteItem succeeded");
        }
        catch (Exception e) {
            System.err.println("Unable to delete item: " + year + " " + title);
            System.err.println(e.getMessage());
        }
    }
}

2. Compile and run the program.

The program should fail with the following message:

The conditional request failed

This is because the rating for this particular move is greater than 5.

3. Modify the program to remove the condition in DeleteItemSpec.

DeleteItemSpec deleteItemSpec = new DeleteItemSpec()
        .withPrimaryKey(new PrimaryKey("year", 2015, "title", "The Big New Movie"));

4. Compile and run the program. Now, the delete succeeds because you removed the condition.

Step 4: Query and Scan the Data

You can use the query method to retrieve data from a table. You must specify a partition key value. The sort key is optional.

The primary key for the Movies table is composed of the following:

- year – The partition key. The attribute type is number.
Step 4: Query and Scan the Data

- title – The sort key. The attribute type is string.

To find all movies released during a year, you need to specify only the year. You can also provide the title to retrieve a subset of movies based on some condition (on the sort key). For example, you can find movies released in 2014 that have a title starting with the letter "A".

In addition to the query method, there is also a scan method that can retrieve all of the table data.

To learn more about querying and scanning data, see Working with Queries in DynamoDB (p. 459) and Working with Scans in DynamoDB (p. 476), respectively.

Topics
- Step 4.1: Query (p. 91)
- Step 4.2: Scan (p. 93)

Step 4.1: Query

The code included in this step performs the following queries:

- Retrieve all movies released in the year 1985.
- Retrieve all movies released in the year 1992, with a title beginning with the letter "A" through the letter "L".

import com.amazonaws.services.dynamodbv2.document.QueryOutcome;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.spec.QuerySpec;

public class MoviesQuery {
    public static void main(String[] args) throws Exception {
        // Code implementation
    }
}
```
Amazon DynamoDB client = AmazonDynamoDBClientBuilder.standard()
.withEndpointConfiguration(new
.build();

DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("Movies");

HashMap<String, String> nameMap = new HashMap<String, String>();
nameMap.put("#yr", "year");

HashMap<String, Object> valueMap = new HashMap<String, Object>();
valueMap.put(":yyyy", 1985);

QuerySpec querySpec = new QuerySpec().withKeyConditionExpression("#yr = :yyyy")
.withNameMap(nameMap)
.withValueMap(valueMap);

ItemCollection<QueryOutcome> items = null;
Iterator<Item> iterator = null;
Item item = null;

try {
    System.out.println("Movies from 1985");
    items = table.query(querySpec);
    iterator = items.iterator();
    while (iterator.hasNext()) {
        item = iterator.next();
        System.out.println(item.getNumber("year") + ": " + item.getString("title");
    }
}

catch (Exception e) {
    System.err.println("Unable to query movies from 1985");
    System.err.println(e.getMessage());
}

valueMap.put(":yyyy", 1992);
valueMap.put(":letter1", "A");
valueMap.put(":letter2", "L");

querySpec.withProjectionExpression("#yr, title, info.genres, info.actors[0]"
.withKeyConditionExpression("#yr = :yyyy and title between :letter1
and :letter2")
.withNameMap(nameMap)
.withValueMap(valueMap);

try {
    System.out.println("Movies from 1992 - titles A-L, with genres and lead
actor");
    items = table.query(querySpec);
    iterator = items.iterator();
    while (iterator.hasNext()) {
        item = iterator.next();
        System.out.println(item.getNumber("year") + ": " + item.getString("title") + " " + item.getMap("info");
    }
}

} catch (Exception e) {
    System.err.println("Unable to query movies from 1992:");
    System.err.println(e.getMessage());
Step 4: Query and Scan the Data

Note

- **nameMap** provides name substitution. This is used because `year` is a reserved word in Amazon DynamoDB. You can't use it directly in any expression, including `KeyConditionExpression`. You use the expression attribute name `#yr` to address this.
- **valueMap** provides value substitution. This is used because you can't use literals in any expression, including `KeyConditionExpression`. You use the expression attribute value `:yyyy` to address this.

First, you create the `querySpec` object, which describes the query parameters, and then you pass the object to the `query` method.

2. Compile and run the program.

Note

The preceding program shows how to query a table by its primary key attributes. In DynamoDB, you can optionally create one or more secondary indexes on a table, and query those indexes in the same way that you query a table. Secondary indexes give your applications additional flexibility by allowing queries on non-key attributes. For more information, see Improving Data Access with Secondary Indexes (p. 497).

Step 4.2: Scan

The `scan` method reads every item in the entire table and returns all the data in the table. You can provide an optional `filter_expression` so that only the items matching your criteria are returned. However, the filter is applied only after the entire table has been scanned.

The following program scans the entire `Movies` table, which contains approximately 5,000 items. The `scan` specifies the optional filter to retrieve only the movies from the 1950s (approximately 100 items) and discard all the others.

1. Copy the following program and paste it into your Java development environment.

```java
package com.amazonaws.codesamples.gsg;

import java.util.Iterator;
import com.amazonaws.client.builder.AwsClientBuilder;
```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.ItemCollection;
import com.amazonaws.services.dynamodbv2.document.ScanOutcome;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.spec.ScanSpec;
import com.amazonaws.services.dynamodbv2.document.utils.NameMap;
import com.amazonaws.services.dynamodbv2.document.utils.ValueMap;

public class MoviesScan {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .withEndpointConfiguration(new
            .build();
        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");
        ScanSpec scanSpec = new ScanSpec().withProjectionExpression("#yr, title,
            info.rating")
            .withFilterExpression("#yr between :start_yr and :end_yr").withNameMap(new
                NameMap().with("#yr", "year"))
            .withValueMap(new ValueMap().withNumber(":start_yr", 1950).withNumber(":end_yr", 1959));
        try {
            ItemCollection<ScanOutcome> items = table.scan(scanSpec);
            Iterator<Item> iter = items.iterator();
            while (iter.hasNext()) {
                Item item = iter.next();
                System.out.println(item.toString());
            }
        }
        catch (Exception e) {
            System.err.println("Unable to scan the table:");
            System.err.println(e.getMessage());
        }
    }
}

In the code, note the following:

• ProjectionExpression specifies the attributes you want in the scan result.
• FilterExpression specifies a condition that returns only items that satisfy the condition. All
other items are discarded.

2. Compile and run the program.

Note
You can also use the Scan operation with any secondary indexes that you created on the table.
For more information, see Improving Data Access with Secondary Indexes (p. 497).
Step 5: (Optional) Delete the Table

To delete the Movies table:

1. Copy the following program and paste it into your Java development environment.

```java
/**

package com.amazonaws.codesamples.gsg;

import com.amazonaws.client.builder.AwsClientBuilder;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Table;

public class MoviesDeleteTable {
    public static void main(String[] args) throws Exception {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
            .withEndpointConfiguration(new
            .build();
        DynamoDB dynamoDB = new DynamoDB(client);
        Table table = dynamoDB.getTable("Movies");
        try {
            System.out.println("Attempting to delete table; please wait...");
            table.delete();
            table.waitForDelete();
            System.out.println("Success.");
        } catch (Exception e) {
            System.err.println("Unable to delete table: ");
            System.err.println(e.getMessage());
        }
    }
}
```

2. Compile and run the program.
Summary

In this tutorial, you created the Movies table in Amazon DynamoDB on your computer and performed basic operations. The downloadable version of DynamoDB is useful during application development and testing. However, when you're ready to run your application in a production environment, you must modify your code so that it uses the DynamoDB web service.

Modifying the Code to Use the DynamoDB Service

To use the DynamoDB service, you must change the endpoint in your application.

1. Remove the following import.

   ```java
   import com.amazonaws.client.builder.AwsClientBuilder;
   ```

2. Next, go to AmazonDynamoDB in the code.

   ```java
   AmazonDynamoDB client =
   .build();
   ```

3. Now modify the client so that it accesses an AWS Region instead of a specific endpoint.

   ```java
   AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
   .withRegion(Regions.REGION)
   .build();
   ```

   For example, if you want to access the us-west-2 region, you would do the following.

   ```java
   AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
   .withRegion(Regions.US_WEST_2)
   .build();
   ```

Instead of using DynamoDB on your computer, the program now uses the DynamoDB web service endpoint in the US West (Oregon) Region.

DynamoDB is available in AWS Regions worldwide. For the complete list, see Regions and Endpoints in the AWS General Reference. For more information about setting Regions and endpoints in your code, see AWS Region Selection in the AWS SDK for Java Developer Guide.

Getting Started with JavaScript and DynamoDB

In this tutorial, you use JavaScript to write simple programs to perform the following Amazon DynamoDB operations:

- Create a table called Movies and load sample data in JSON format.
- Perform create, read, update, and delete operations on the table.
- Run simple queries.

As you work through this tutorial, you can refer to the AWS SDK for JavaScript API Reference.
Tutorial Prerequisites

- Download and run DynamoDB on your computer. For more information, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).
  
  **Note**
  You use the downloadable version of DynamoDB in this tutorial. For information about how to run the same code against the DynamoDB web service, see the Summary and Review of JavaScript and DynamoDB Tutorial (p. 118).

- Set up an AWS access key to use AWS SDKs. For more information, see Setting Up DynamoDB (Web Service) (p. 53).

- Set up the AWS SDK for JavaScript. To do this, add or modify the following script tag to your HTML pages:

  `<script src="https://sdk.amazonaws.com/js/aws-sdk-2.7.16.min.js"></script>`

  **Note**
  The version of AWS SDK for JavaScript might have been updated. For the latest version, see the AWS SDK for JavaScript API Reference.

- Enable cross-origin resource sharing (CORS) so that your computer's browser can communicate with the downloadable version of DynamoDB.

  **To enable CORS**

  1. Download the free ModHeader Chrome browser extension (or any other browser extension that allows you to modify HTTP response headers).
  2. Run the ModHeader Chrome browser extension, and add an HTTP response header with the name set to "Access-Control-Allow-Origin" and a value of "null" or ".*".
    
    **Important**
    This configuration is required only while running this tutorial program for JavaScript on your computer. After you finish the tutorial, you should disable or remove this configuration.
  3. You can now run the JavaScript tutorial program files.

If you prefer to run a complete version of the JavaScript tutorial program instead of performing step-by-step instructions, do the following:

1. Download the following file: MoviesJavaScript.zip.
2. Extract the file MoviesJavaScript.html from the archive.
3. Modify the MoviesJavaScript.html file to use your endpoint.

**Step 1: Create a DynamoDB Table with JavaScript**

In this step, you create a table named Movies. The primary key for the table is composed of the following attributes:

- **year** – The partition key. The AttributeType is N for number.
- **title** – The sort key. The AttributeType is S for string.

1. Copy the following program and paste it into a file named MoviesCreateTable.html.
Step 1: Create a Table

```html
<script src="https://sdk.amazonaws.com/js/aws-sdk-2.7.16.min.js"></script>

AWS.config.update({
  region: "us-west-2",
  endpoint: 'http://localhost:8000',
  // accessKeyId default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  accessKeyId: "fakeMyKeyId",
  // secretAccessKey default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  secretAccessKey: "fakeSecretAccessKey"
});

var dynamodb = new AWS.DynamoDB();

function createMovies() {
  var params = {
    TableName: "Movies",
    KeySchema: [
      { AttributeName: "year", KeyType: "HASH" },
      { AttributeName: "title", KeyType: "RANGE" }
    ],
    AttributeDefinitions: [
      { AttributeName: "year", AttributeType: "N" },
      { AttributeName: "title", AttributeType: "S" }
    ],
    ProvisionedThroughput: {
      ReadCapacityUnits: 5,
      WriteCapacityUnits: 5
    }
  };

  dynamodb.createTable(params, function(err, data) {
    if (err) {
      document.getElementById('textarea').innerHTML = "Unable to create table: " + "\n" + JSON.stringify(err, undefined, 2);
    } else {
      document.getElementById('textarea').innerHTML = "Created table: " + "\n" + JSON.stringify(data, undefined, 2);
    }
  });
}
</script>
</head>
```
Step 2: Load Sample Data with JavaScript into DynamoDB

In this step, you populate the Movies table with sample data.

Topics
- Step 2.1: Download the Sample Data File (p. 100)
- Step 2.2: Load the Sample Data into the Movies Table (p. 100)

This scenario uses a sample data file that contains information about a few thousand movies from the Internet Movie Database (IMDb). The movie data is in JSON format, as shown in the following example. For each movie, there is a year, a title, and a JSON map named info.

```json
[
  {
    "year" : ... ,
    "title" : ... ,
    "info" : { ... }
  },
  {
    "year" : ... ,
    "title" : ... ,
    "info" : { ... }
  },
  ...
]
```

In the JSON data, note the following:
- The year and title are used as the primary key attribute values for the Movies table.
• The rest of the info values are stored in a single attribute called info. This program illustrates how you can store JSON in an Amazon DynamoDB attribute.

The following is an example of movie data.

```json
{
  "year" : 2013,
  "title" : "Turn It Down, Or Else!",
  "info" : {
    "directors" : [
      "Alice Smith",
      "Bob Jones"
    ],
    "release_date" : "2013-01-18T00:00:00Z",
    "rating" : 6.2,
    "genres" : [
      "Comedy",
      "Drama"
    ],
    "image_url" : "http://ia.media-imdb.com/images/N/O9ERWAU7FS797AJ7LUBSHN09AMUF908RL05JF90EWR7LJKQ7@@._V1_SX400_.jpg",
    "plot" : "A rock band plays their music at high volumes, annoying the neighbors.",
    "rank" : 11,
    "running_time_secs" : 5215,
    "actors" : [
      "David Matthewman",
      "Ann Thomas",
      "Jonathan G. Neff"
    ]
  }
}
```

**Step 2.1: Download the Sample Data File**

1. Download the sample data archive: moviedata.zip
2. Extract the data file (moviedata.json) from the archive.
3. Copy and paste the moviedata.json file into your current directory.

**Step 2.2: Load the Sample Data into the Movies Table**

After you download the sample data, you can run the following program to populate the Movies table.

1. Copy the following program and paste it into a file named MoviesLoadData.html.
<head>
<script src="https://sdk.amazonaws.com/js/aws-sdk-2.7.16.min.js"></script>
</head>

〈script type="text/javascript"
AWS.config.update({
  region: "us-west-2",
  endpoint: 'http://localhost:8000',
  // accessKeyId default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  accessKeyId: "fakeMyKeyId",
  // secretAccessKey default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  secretAccessKey: "fakeSecretAccessKey"
});

var docClient = new AWS.DynamoDB.DocumentClient();

function processFile(evt) {
  document.getElementById('textarea').innerHTML = "Importing movies into DynamoDB. Please wait..." + "\n";
  var file = evt.target.files[0];
  if (file) {
    var r = new FileReader();
    r.onload = function(e) {
      var contents = e.target.result;
      var allMovies = JSON.parse(contents);
      allMovies.forEach(function (movie) {
        document.getElementById('textarea').innerHTML += "Processing: " + movie.title + "\n";
        var params = {
          TableName: "Movies",
          Item: {
            "year": movie.year,
            "title": movie.title,
            "info": movie.info
          }
        };
        docClient.put(params, function (err, data) {
          if (err) {
            document.getElementById('textarea').innerHTML += "Unable to add movie: " + count + movie.title + "\n";
            document.getElementById('textarea').innerHTML += "Error JSON: " + JSON.stringify(err) + "\n";
          } else {
            document.getElementById('textarea').innerHTML += "PutItem succeeded: " + movie.title + "\n";
            textarea.scrollTop = textarea.scrollHeight;
          }
        });
      });
    r.readAsText(file);
  }
else {
  alert("Could not read movie data file");
}
</script>
</body>
2. Open the MoviesLoadData.html file in your browser.
3. Choose Browse, and load the moviedata.json file.

Step 3: Create, Read, Update, and Delete an Item

In this step, you perform read and write operations on an item in the Movies table.

To learn more about reading and writing data, see Working with Items and Attributes (p. 375).

Topics

• Step 3.1: Create a New Item (p. 102)
• Step 3.2: Read an Item (p. 103)
• Step 3.3: Update an Item (p. 105)
• Step 3.4: Increment an Atomic Counter (p. 107)
• Step 3.5: Update an Item (Conditionally) (p. 108)
• Step 3.6: Delete an Item (p. 110)

Step 3.1: Create a New Item

In this step, you add a new item to the Movies table.

1. Copy the following program and paste it into a file named MoviesItemOps01.html.

```

    endpoint: 'http://localhost:8000',
    // accessKeyId default can be used while using the downloadable version of DynamoDB.
```

API Version 2012-08-10

// For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
accessKeyId: "fakeMyKeyId",
// secretAccessKey default can be used while using the downloadable version of DynamoDB.
// For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
secretAccessKey: "fakeSecretAccessKey"
});

var docClient = new AWS.DynamoDB.DocumentClient();

function createItem() {
  var params = {
    TableName: "Movies",
    Item: {
      "year": 2015,
      "title": "The Big New Movie",
      "info": {
        "plot": "Nothing happens at all.",
        "rating": 0
      }
    }
  }
  docClient.put(params, function(err, data) {
    if (err) {
      document.getElementById('textarea').innerHTML = "Unable to add item: " + "\n" + JSON.stringify(err, undefined, 2);
    } else {
      document.getElementById('textarea').innerHTML = "PutItem succeeded: " + "\n" + JSON.stringify(data, undefined, 2);
    }
  });
}

</script>
</head>

<body>
<input id="createItem" type="button" value="Create Item" onclick="createItem();" />
<br><br>
<textarea readonly id="textarea" style="width:400px; height:800px"></textarea>
</body>
</html>

**Note**
The primary key is required. This code adds an item that has a primary key (`year`, `title`) and `info` attributes. The `info` attribute stores sample JSON that provides more information about the movie.

2. Open the `MoviesItemOps01.html` file in your browser.

3. Choose **Create Item**.

### Step 3.2: Read an Item

In the previous program, you added the following item to the table.

```json
{
  year: 2015,
  title: "The Big New Movie",
  info: {
```
You can use the `get` method to read the item from the `Movies` table. You must specify the primary key values, so you can read any item from `Movies` if you know its `year` and `title`.

1. Copy the following program and paste it into a file named `MoviesItemOps02.html`.

```html

</head>
<script src="https://sdk.amazonaws.com/js/aws-sdk-2.7.16.min.js"></script>

AWS.config.update({
  region: "us-west-2",
  endpoint: 'http://localhost:8000',
  // accessKeyId default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon
  // Cognito instead.
  accessKeyId: "fakeMyKeyId",
  // secretAccessKey default can be used while using the downloadable version of
  // DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon
  // Cognito instead.
  secretAccessKey: "fakeSecretAccessKey"
});
var docClient = new AWS.DynamoDB.DocumentClient();

function readItem() {
  var table = "Movies";
  var year = 2015;
  var title = "The Big New Movie";

  var params = {
    TableName: table,
    Key: {
      "year": year,
      "title": title
    }
  };
  docClient.get(params, function(err, data) {
    if (err) {
      document.getElementById('textarea').innerHTML = "Unable to read item: " + "\n" + JSON.stringify(err, undefined, 2);
    } else {
      document.getElementById('textarea').innerHTML = "GetItem succeeded: " + "\n" + JSON.stringify(data, undefined, 2);
    }
  });
}
```
2. Open the MoviesItemOps02.html file in your browser.

3. Choose Read Item.

**Step 3.3: Update an Item**

You can use the update method to modify an item. You can update values of existing attributes, add new attributes, or remove attributes.

In this example, you perform the following updates:

- Change the value of the existing attributes (rating, plot).
- Add a new list attribute (actors) to the existing info map.

The item changes from the following:

```json
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Nothing happens at all.",
    rating: 0
  }
}
```

To this:

```json
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Everything happens all at once.",
    rating: 5.5,
    actors: ["Larry", "Moe", "Curly"]
  }
}
```

1. Copy the following program and paste it into a file named MoviesItemOps03.html.

  // accessKeyId default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  accessKeyId: "fakeMyKeyId",
  // secretAccessKey default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  secretAccessKey: "fakeSecretAccessKey"
});

var docClient = new AWS.DynamoDB.DocumentClient();

function updateItem() {

Note
This program uses UpdateExpression to describe all updates you want to perform on the
specified item.
The ReturnValue parameter instructs Amazon DynamoDB to return only the updated
attributes ("UPDATED_NEW").

2. Open the MoviesItemOps03.html file in your browser.
3. Choose Update Item.

Step 3.4: Increment an Atomic Counter

DynamoDB supports atomic counters, where you use the update method to increment or decrement the
value of an attribute without interfering with other write requests. (All write requests are applied in the
order in which they are received.)

The following program shows how to increment the rating for a movie. Each time you run it, the
program increments this attribute by one.

1. Copy the following program and paste it into a file named MoviesItemOps04.html.

```html

  var expressionAttributeNames = {
    '#year': year
  }
  var expressionAttributeValues = {
    ':year': 2015
  }
  var updateExpression = "ADD #year :year"
  docClient.updateTableItem({

  }, function(err, data) {
    if (err) { console.log(err); return; }
    console.log("Updated item.");
  });
}
```
Amazon DynamoDB Developer Guide
Step 3: Create, Read, Update, and Delete an Item

var params = {
TableName:table,
Key:{
"year": year,
"title": title
},
UpdateExpression: "set info.rating = info.rating + :val",
ExpressionAttributeValues:{
":val":1
},
ReturnValues:"UPDATED_NEW"
};
docClient.update(params, function(err, data) {
if (err) {
document.getElementById('textarea').innerHTML = "Unable to update rating: "
+ "\n" + JSON.stringify(err, undefined, 2);
} else {
document.getElementById('textarea').innerHTML = "Increase Rating succeeded:
" + "\n" + JSON.stringify(data, undefined, 2);
}
});

}

</script>
</head>
<body>
<input id="increaseRating" type="button" value="Increase Rating"
onclick="increaseRating();" />
<br><br>
<textarea readonly id= "textarea" style="width:400px; height:800px"></textarea>
</body>
</html>

2.

Open the MoviesItemOps04.html ﬁle in your browser.

3.

Choose Increase Rating.

Step 3.5: Update an Item (Conditionally)
The following program shows how to use UpdateItem with a condition. If the condition evaluates to
true, the update succeeds; otherwise, the update is not performed.
In this case, the item is updated only if there are more than three actors in the movie.
1.

Copy the following program and paste it into a ﬁle named MoviesItemOps05.html.
<!-Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

2. Open the MoviesItemOps05.html file in your browser.

3. Choose Conditional Update.
The program should fail with the following message:

The conditional update failed

This is because the movie has three actors in it, but the condition is checking for greater than three actors.

4. Modify the program so that the ConditionExpression looks like the following.

```
ConditionExpression: "size(info.actors) >= :num",
```

The condition is now greater than or equal to 3 instead of greater than 3.

5. Run the program again. The updateItem operation should now succeed.

**Step 3.6: Delete an Item**

You can use the delete method to delete one item by specifying its primary key. You can optionally provide a ConditionExpression to prevent the item from being deleted if the condition is not met.

In the following example, you try to delete a specific movie item if its rating is 5 or less.

1. Copy the following program and paste it into a file named MoviesItemOps06.html.

```html
<html>
<head>
<script src="https://sdk.amazonaws.com/js/aws-sdk-2.7.16.min.js"></script>
<script>
AWS.config.update({
  region: "us-west-2",
  endpoint: 'http://localhost:8000',
  // accessKeyId default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  accessKeyId: "fakeMyKeyId",
  // secretAccessKey default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  secretAccessKey: "fakeSecretAccessKey"
});

var docClient = new AWS.DynamoDB.DocumentClient();

function conditionalDelete() {
  var table = "Movies";
  var year = 2015;
```
2. Open the MoviesItemOps06.html file in your browser.

3. Choose Conditional Delete.

The program should fail with the following message:

The conditional delete failed

This is because the rating for this particular movie is greater than 5.

4. Modify the program to remove the condition from params.

```javascript
var title = "The Big New Movie";
var params = {
    TableName:table,
    Key:{
        "year":year,
        "title":title
    },
    ConditionExpression:"info.rating <= :val",
    ExpressionAttributeValues:
        { 
            ":val": 5.0
        }
};
docClient.delete(params, function(err, data) {
    if (err) {
        document.getElementById('textarea').innerHTML = "The conditional delete
failed: " + "\n" + JSON.stringify(err, undefined, 2);
    } else {
        document.getElementById('textarea').innerHTML = "The conditional delete
succeeded: " + "\n" + JSON.stringify(data, undefined, 2);
    }
});
</script>
</head>
<body>
<input id="conditionalDelete" type="button" value="Conditional Delete"
onclick="conditionalDelete();" />
<br><br>
<textarea readonly id="textarea" style="width:400px; height:800px"></textarea>
</body>
</html>
```

5. Run the program again. The delete succeeds because you removed the condition.
Step 4: Query and Scan the Data with JavaScript and DynamoDB

You can use the `query` method to retrieve data from a table. You must specify a partition key value; the sort key is optional.

The primary key for the `Movies` table is composed of the following:

- `year` – The partition key. The attribute type is number.
- `title` – The sort key. The attribute type is string.

To find all movies released during a year, you need to specify only the `year`. You can also provide the `title` to retrieve a subset of movies based on some condition (on the sort key); for example, to find movies released in 2014 that have a title starting with the letter "A".

In addition to the `query` method, you can use the `scan` method to retrieve all the table data.

To learn more about querying and scanning data, see Working with Queries in DynamoDB (p. 459) and Working with Scans in DynamoDB (p. 476), respectively.

Topics

- Step 4.1: Query - All Movies Released in a Year (p. 112)
- Step 4.2: Query - All Movies Released in a Year with Certain Titles (p. 114)
- Step 4.3: Scan (p. 115)

Step 4.1: Query - All Movies Released in a Year

The program included in this step retrieves all movies released in the year 1985.

1. Copy the following program and paste it into a file named `MoviesQuery01.html`.

```html

// secretAccessKey default can be used while using the downloadable version of DynamoDB.
// For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
secretAccessKey: "fakeSecretAccessKey"
});

var docClient = new AWS.DynamoDB.DocumentClient();

function queryData() {
  document.getElementById('textarea').innerHTML += "Querying for movies from 1985."

  var params = {
    TableName : "Movies",
    KeyConditionExpression: "#yr = :yyyy",
    ExpressionAttributeNames:{
      "#yr": "year"
    },
    ExpressionAttributeValues: {
      ":yyyy":1985
    }
  };

docClient.query(params, function(err, data) {
  if (err) {
    document.getElementById('textarea').innerHTML += "Unable to query. Error: " + "\n" + JSON.stringify(err, undefined, 2);
  } else {
    document.getElementById('textarea').innerHTML += "Querying for movies from 1985: " + "\n" + JSON.stringify(data, undefined, 2);
  }
});
</script>
</head>

<body>
<input id="queryData" type="button" value="Query" onclick="queryData();" />
<br>
<textarea readonly id= "textarea" style= "width:400px; height:800px"></textarea>
</body>
</html>

**Note**

ExpressionAttributeNames provides name substitution. This is used because year is a reserved word in Amazon DynamoDB. You can't use it directly in any expression, including KeyConditionExpression. For this reason, you use the expression attribute name #yr. ExpressionAttributeValues provides value substitution. This is used because you can't use literals in any expression, including KeyConditionExpression. For this reason, you use the expression attribute value :yyyy.

2. Open the MoviesQuery01.html file in your browser.
3. Choose Query.

**Note**

The preceding program shows how to query a table by its primary key attributes. In DynamoDB, you can optionally create one or more secondary indexes on a table, and query those indexes in the same way that you query a table. Secondary indexes give your applications additional flexibility by allowing queries on non-key attributes. For more information, see Improving Data Access with Secondary Indexes (p. 497).
Step 4.2: Query - All Movies Released in a Year with Certain Titles

The program included in this step retrieves all movies released in year 1992, with title beginning with the letter "A" through the letter "L".

1. Copy the following program and paste it into a file named MoviesQuery02.html.

```html

  // accessKeyId default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  accessKeyId: "fakeMyKeyId",
  // secretAccessKey default can be used while using the downloadable version of DynamoDB.
  // For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
  secretAccessKey: "fakeSecretAccessKey"
});
var docClient = new AWS.DynamoDB.DocumentClient();

function queryData() {
  document.getElementById('textarea').innerHTML += "Querying for movies from 1985."
;
  var params = {
    TableName : "Movies",
    ProjectionExpression: "#yr, title, info.genres, info.actors[0]",
    KeyConditionExpression: "#yr = :yyyy and title between :letter1 and :letter2",
    ExpressionAttributeNames: {
      "#yr": "year"
    },
    ExpressionAttributeValues: {
      ":yyyy": 1992,
      ":letter1": "A",
      ":letter2": "L"
    }
  }

  docClient.query(params, function(err, data) {
    if (err) {
      document.getElementById('textarea').innerHTML += "Unable to query. Error: " + "\n" + JSON.stringify(err, undefined, 2);
    } else {
      document.getElementById('textarea').innerHTML += "Query completed. Results: " + JSON.stringify(data, undefined, 2);
    }
  });
</script>
</head>
<body>
<textarea id="textarea"></textarea>
</body>
</html>
```
2. Open the MoviesQuery02.html file in your browser.
3. Choose Query.

Step 4.3: Scan

The scan method reads every item in the entire table, and returns all the data in the table. You can provide an optional filter expression, so that only the items matching your criteria are returned. However, the filter is applied only after the entire table has been scanned.

The following program scans the entire Movies table, which contains approximately 5,000 items. The scan specifies the optional filter to retrieve only the movies from the 1950s (approximately 100 items), and discard all the others.

1. Copy the following program and paste it into a file named MoviesScan.html.

```html

// For security reasons, do not store AWS Credentials in your files. Use Amazon Cognito instead.
secretAccessKey: "fakeSecretAccessKey"
});

var docClient = new AWS.DynamoDB.DocumentClient();

function scanData() {
  document.getElementById('textarea').innerHTML += "Scanning Movies table." + "\n";

  var params = {
    TableName: "Movies",
    ProjectionExpression: "#yr, title, info.rating",
    FilterExpression: "#yr between :start_yr and :end_yr",
    ExpressionAttributeNames: {
      "#yr": "year",
    },
    ExpressionAttributeValues: {
      ":start_yr": 1950,
      ":end_yr": 1959
    }
  };

  docClient.scan(params, onScan);

  function onScan(err, data) {
    if (err) {
      document.getElementById('textarea').innerHTML += "Unable to scan the table: " + "\n" + JSON.stringify(err, undefined, 2);
    } else {
      // Print all the movies
      data.Items.forEach(function(movie) {
        document.getElementById('textarea').innerHTML += movie.year + " - rating: " + movie.info.rating + "\n";
      });

      // Continue scanning if we have more movies (per scan 1MB limitation)
      params.ExclusiveStartKey = data.LastEvaluatedKey;
      docClient.scan(params, onScan);
    }
  }

  </script>
</head>

<body>
<input id="scanData" type="button" value="Scan" onclick="scanData();" />
<textarea readonly id= "textarea" style="width:400px; height:800px"></textarea></body>
</html>

In the code, note the following:

- **ProjectionExpression** specifies the attributes you want in the scan result.
- **FilterExpression** specifies a condition that returns only items that satisfy the condition. All other items are discarded.

2. Open the MoviesScan.html file in your browser.
3. Choose Scan.

**Note**
You also can use the Scan operation with any secondary indexes that you create on the table. For more information, see Improving Data Access with Secondary Indexes (p. 497).

**Step 5: Delete the Table with JavaScript**

To delete the Movies table:

1. Copy the following program and paste it into a file named MoviesDeleteTable.html.

```html

var dynamodb = new AWS.DynamoDB();

function deleteMovies() {
  var params = {

Summary and Review of JavaScript and DynamoDB Tutorial

In this tutorial, you created the Movies table in Amazon DynamoDB on your computer and performed basic operations. The downloadable version of DynamoDB is useful during application development and testing. However, when you're ready to run your application in a production environment, you must modify your code so that it uses the DynamoDB web service.

Updating the AWS Configuration Region to Use the DynamoDB Web Service

To use the DynamoDB web service, you must update the AWS Region in your application. You also have to make sure that Amazon Cognito is available in that same Region so that your browser scripts can authenticate successfully.

```javascript
AWS.config.update({region: "aws-region"});
```

For example, if you want to use the us-west-2 Region, set the following Region.

```javascript
AWS.config.update({region: "us-west-2"});
```

The program now uses the Amazon DynamoDB web service in the US West (Oregon) Region.

DynamoDB is available in AWS Regions worldwide. For the complete list, see Regions and Endpoints in the AWS General Reference. For more information about setting Regions and endpoints in your code, see Setting the Region in the AWS SDK for JavaScript Getting Started Guide.

Configuring AWS Credentials in Your Files Using Amazon Cognito

The recommended way to obtain AWS credentials for your web and mobile applications is to use Amazon Cognito. Amazon Cognito helps you avoid hardcoding your AWS credentials in your files. Amazon Cognito uses AWS Identity and Access Management (IAM) roles to generate temporary credentials for your application's authenticated and unauthenticated users.

For more information, see Configuring AWS Credentials in Your Files Using Amazon Cognito (p. 931).
Getting Started with Node.js and DynamoDB

In this tutorial, you use the AWS SDK for JavaScript to write simple applications to perform the following Amazon DynamoDB operations:

• Create a table named Movies and load sample data in JSON format.
• Perform create, read, update, and delete operations on the table.
• Run simple queries.

As you work through this tutorial, you can refer to the AWS SDK for JavaScript API Reference.

Tutorial Prerequisites

• Download and run DynamoDB on your computer. For more information, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).

  Note
  You use the downloadable version of DynamoDB in this tutorial. For information about how to run the same code against the DynamoDB web service, see the Summary (p. 136).

• Set up an AWS access key to use the AWS SDKs. For more information, see Setting Up DynamoDB (Web Service) (p. 53).

• Set up the AWS SDK for JavaScript:
  • Install Node.js.
  • Install the AWS SDK for JavaScript.

  For more information, see the AWS SDK for JavaScript Getting Started Guide.

Step 1: Create a Table with in DynamoDB with AWS SDK for JavaScript

In this step, you create a table named Movies. The primary key for the table is composed of the following attributes:

• year – The partition key. The AttributeType is N for number.
• title – The sort key. The AttributeType is S for string.

1. Copy the following program and paste it into a file named MoviesCreateTable.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 * http://aws.amazon.com/apache2.0/
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
```
Step 2: Load Sample Data in DynamoDB with AWS SDK for JavaScript

In this step, you populate the Movies table with sample data.

Topics
- Step 2.1: Download the Sample Data File (p. 121)
- Step 2.2: Load the Sample Data into the Movies Table (p. 122)
You use a sample data file that contains information about a few thousand movies from the Internet Movie Database (IMDb). The movie data is in JSON format, as shown in the following example. For each movie, there is a year, a title, and a JSON map named info.

```json
[
  {
    "year" : ... ,
    "title" : ... ,
    "info" : { ... }
  },
  {
    "year" : ...,
    "title" : ...,
    "info" : { ... }
  },
  ...
]
```

In the JSON data, note the following:

- The year and title are used as the primary key attribute values for the Movies table.
- The rest of the info values are stored in a single attribute called info. This program illustrates how you can store JSON in an Amazon DynamoDB attribute.

The following is an example of movie data.

```json
{
  "year" : 2013,
  "title" : "Turn It Down, Or Else!",
  "info" : {
    "directors" : [
      "Alice Smith",
      "Bob Jones"
    ],
    "release_date" : "2013-01-18T00:00:00Z",
    "rating" : 6.2,
    "genres" : [
      "Comedy",
      "Drama"
    ],
    "image_url" : "http://ia.media-imdb.com/images/N/09ERWAU7FS797A77L0US8H09AMUP908ELL05JF90EWR7LJKQ7@_V1_SX400_.jpg",
    "plot" : "A rock band plays their music at high volumes, annoying the neighbors.",

```

**Step 2.1: Download the Sample Data File**

1. Download the sample data archive: moviedata.zip
2. Extract the data file (moviedata.json) from the archive.
3. Copy and paste the `moviedata.json` file into your current directory.

**Step 2.2: Load the Sample Data into the Movies Table**

After you download the sample data, you can run the following program to populate the `Movies` table.

1. Copy the following program and paste it into a file named `MoviesLoadData.js`.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 *

 * specific language governing permissions and limitations under the License.
 */
var AWS = require("aws-sdk");
var fs = require('fs');

AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
});

var docClient = new AWS.DynamoDB.DocumentClient();

console.log("Importing movies into DynamoDB. Please wait.");

var allMovies = JSON.parse(fs.readFileSync('moviedata.json', 'utf8'));
allMovies.forEach(function(movie) {
  var params = {
    TableName: "Movies",
    Item: {
      "year": movie.year,
      "title": movie.title,
      "info": movie.info
    }
  };

  docClient.put(params, function(err, data) {
    if (err) {
      console.error("Unable to add movie", movie.title, ".
      Error JSON:",
      JSON.stringify(err, null, 2));
    } else {
      console.log("PutItem succeeded:", movie.title);
    }
  });
});
```

2. To run the program, enter the following command.

   `node MoviesLoadData.js`
Step 3: Create, Read, Update, and Delete an Item

In this step, you perform read and write operations on an item in the Movies table.

To learn more about reading and writing data, see Working with Items and Attributes (p. 375).

Topics
- Step 3.1: Create a New Item (p. 123)
- Step 3.2: Read an Item (p. 124)
- Step 3.3: Update an Item (p. 125)
- Step 3.4: Increment an Atomic Counter (p. 127)
- Step 3.5: Update an Item (Conditionally) (p. 128)
- Step 3.6: Delete an Item (p. 129)

Step 3.1: Create a New Item

In this step, you add a new item to the Movies table.

1. Copy the following program and paste it into a file named MoviesItemOps01.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 * http://aws.amazon.com/apache2.0/
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */

var AWS = require("aws-sdk");

AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
});

var docClient = new AWS.DynamoDB.DocumentClient();

var table = "movies";

var year = 2015;
var title = "The Big New Movie";

var params = {
  TableName: table,
  Item: {
    "year": year,
    "title": title,
    "info": {
      "plot": "Nothing happens at all.",
      "rating": 0
    }
  }
};
```
Step 3: Create, Read, Update, and Delete an Item

```javascript
console.log("Adding a new item...");
docClient.put(params, function(err, data) {
    if (err) {
        console.error("Unable to add item. Error JSON:", JSON.stringify(err, null, 2));
    } else {
        console.log("Added item:", JSON.stringify(data, null, 2));
    }
});
```

**Note**
The primary key is required. This code adds an item that has a primary key (year, title) and info attributes. The info attribute stores sample JSON that provides more information about the movie.

2. To run the program, enter the following command.

`node MoviesItemOps01.js`

**Step 3.2: Read an Item**

In the previous program, you added the following item to the table.

```json
{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Nothing happens at all.",
        rating: 0
    }
}
```

You can use the `get` method to read the item from the Movies table. You must specify the primary key values so that you can read any item from Movies if you know its year and title.

1. Copy the following program and paste it into a file named `MoviesItemOps02.js`.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of

 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
var AWS = require("aws-sdk");
AWS.config.update({
    region: "us-west-2",
    endpoint: "http://localhost:8000"
});
```
var docClient = new AWS.DynamoDB.DocumentClient();

var table = "Movies";

var year = 2015;
var title = "The Big New Movie";

var params = {
  TableName: table,
  Key: {
    "year": year,
    "title": title
  }
};

docClient.get(params, function(err, data) {
  if (err) {
    console.error("Unable to read item. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("GetItem succeeded:", JSON.stringify(data, null, 2));
  }
});

2. To run the program, enter the following command.

    node MoviesItemOps02.js

### Step 3.3: Update an Item

You can use the `update` method to modify an existing item. You can update values of existing attributes, add new attributes, or remove attributes.

In this example, you perform the following updates:

- Change the value of the existing attributes (`rating`, `plot`).
- Add a new list attribute (`actors`) to the existing `info` map.

Previously, you added the following item to the table.

```
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Nothing happens at all.",
    rating: 0
  }
}
```

The item is updated as follows.

```
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Everything happens all at once.",
    rating: 5.5,
    actors: ["Larry", "Moe", "Curly"]
  }
}
```
1. Copy the following program and paste it into a file named MoviesItemOps03.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 *
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at

 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
var AWS = require("aws-sdk");
AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
});

var docClient = new AWS.DynamoDB.DocumentClient();
var table = "Movies";
var year = 2015;
var title = "The Big New Movie";

// Update the item, unconditionally,
var params = {
  TableName: table,
  Key: {
    "year": year,
    "title": title
  },
  UpdateExpression: "set info.rating = :r, info.plot=:p, info.actors=:a",
  ExpressionAttributeValues: {
    ":r": 5.5,
    ":p": "Everything happens all at once.",
    ":a": ["Larry", "Moe", "Curly"]
  },
  ReturnValues: "UPDATED_NEW"
};

console.log("Updating the item...");
docClient.update(params, function(err, data) {
  if (err) {
    console.error("Unable to update item. Error JSON: ", JSON.stringify(err, null, 2));
  } else {
    console.log("UpdateItem succeeded: ", JSON.stringify(data, null, 2));
  }
});
```
Note
This program uses UpdateExpression to describe all updates you want to perform on the specified item.
The ReturnValue parameter instructs DynamoDB to return only the updated attributes ("UPDATED_NEW").

2. To run the program, enter the following command.

   node MoviesItemOps03.js

**Step 3.4: Increment an Atomic Counter**

DynamoDB supports atomic counters, where you use the update method to increment or decrement the value of an existing attribute without interfering with other write requests. (All write requests are applied in the order in which they are received.)

The following program shows how to increment the rating for a movie. Each time you run the program, it increments this attribute by one.

1. Copy the following program and paste it into a file named MoviesItemOps04.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 * http://aws.amazon.com/apache2.0/
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
var AWS = require("aws-sdk");
AWS.config.update({
    region: "us-west-2",
    endpoint: "http://localhost:8000"
});
var docClient = new AWS.DynamoDB.DocumentClient()
var table = "Movies";
var year = 2015;
var title = "The Big New Movie";
// Increment an atomic counter
var params = {
    TableName:table,
    Key:{
        "year": year,
        "title": title
    },
    UpdateExpression: "set info.rating = info.rating + :val",
    ExpressionAttributeValues:{
        ":val": 1
    },
...
Step 3: Create, Read, Update, and Delete an Item

Step 3.5: Update an Item (Conditionally)

The following program shows how to use UpdateItem with a condition. If the condition evaluates to true, the update succeeds; otherwise, the update is not performed.

In this case, the item is updated only if there are more than three actors in the movie.

1. Copy the following program and paste it into a file named MoviesItemOps05.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 * http://aws.amazon.com/apache2.0/
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
var AWS = require("aws-sdk");
AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
});
var docClient = new AWS.DynamoDB.DocumentClient()
var table = "Movies";
var year = 2015;
var title = "The Big New Movie"
// Conditional update (will fail)
var params = {
  TableName:table,
  Key:{
    "year": year,
    "title": title
  },
  ReturnConsumedCapacity: "NONE",
  ReturnValues:"UPDATED_NEW"
};
console.log("Updating the item...");
docClient.update(params, function(err, data) {
  if (err) {
    console.error("Unable to update item. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("UpdateItem succeeded:", JSON.stringify(data, null, 2));
  }
});

2. To run the program, enter the following command.

node MoviesItemOps04.js
Step 3: Create, Read, Update, and Delete an Item

```
"title": title
},
UpdateExpression: "remove info.actors[0]",
ConditionExpression: "size(info.actors) > :num",
ExpressionAttributeValues:{
  ":num": 3
},
ReturnValues: "UPDATED_NEW"
};

console.log("Attempting a conditional update...");
docClient.update(params, function(err, data) {
  if (err) {
    console.error("Unable to update item. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("UpdateItem succeeded:", JSON.stringify(data, null, 2));
  }
});
```

2. To run the program, enter the following command.

```
npm MoviesItemOps05.js
```

The program should fail with the following message.

The conditional request failed

This is because the movie has three actors in it, but the condition is checking for greater than three actors.

3. Modify the program so that the ConditionExpression looks like the following.

```
ConditionExpression: "size(info.actors) >= :num",
```

The condition is now greater than or equal to 3 instead of greater than 3.

4. Run the program again. The updateItem operation should now succeed.

Step 3.6: Delete an Item

You can use the delete method to delete one item by specifying its primary key. You can optionally provide a ConditionExpression to prevent the item from being deleted if the condition is not met.

In the following example, you try to delete a specific movie item if its rating is 5 or less.

1. Copy the following program and paste it into a file named MoviesItemOps06.js.

```
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 *
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 *
 * http://aws.amazon.com/apache2.0/
 *
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
```
Step 3: Create, Read, Update, and Delete an Item

```
/* CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */

var AWS = require("aws-sdk");

AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
});

var docClient = new AWS.DynamoDB.DocumentClient();
var table = "Movies";
var year = 2015;
var title = "The Big New Movie";

var params = {
  TableName:table,
  Key:{
    "year": year,
    "title": title
  },
  ConditionExpression:"info.rating <= :val",
  ExpressionAttributeValues: {
    ":val": 5.0
  }
};

console.log("Attempting a conditional delete...");
docClient.delete(params, function(err, data) {
  if (err) {
    console.error("Unable to delete item. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("DeleteItem succeeded:", JSON.stringify(data, null, 2));
  }
});
```

2. To run the program, enter the following command.

```
node MoviesItemOps06.js
```

The program should fail with the following message.

The conditional request failed

This is because the rating for this particular movie is greater than 5.

3. Modify the program to remove the condition from `params`.

```
var params = {
  TableName:table,
  Key:{
    "title":title,
    "year":year
  }
};
```

4. Run the program again. Now, the delete succeeds because you removed the condition.
Step 4: Query and Scan Data with AWS SDK for
JavaScript in DynamoDB

You can use the `query` method to retrieve data from a table. You must specify a partition key value; the sort key is optional.

The primary key for the `Movies` table is composed of the following:

- `year` – The partition key. The attribute type is number.
- `title` – The sort key. The attribute type is string.

To find all movies released during a year, you need to specify only the `year`. You can also provide the `title` to retrieve a subset of movies based on some condition (on the sort key). For example, you can find movies released in 2014 that have a title starting with the letter "A".

In addition to the `query` method, you also can use the `scan` method, which can retrieve all the table data.

To learn more about querying and scanning data, see Working with Queries in DynamoDB (p. 459) and Working with Scans in DynamoDB (p. 476), respectively.

Topics
- Step 4.1: Query - All Movies Released in a Year (p. 131)
- Step 4.2: Query - All Movies Released in a Year with Certain Titles (p. 132)
- Step 4.3: Scan (p. 133)

Step 4.1: Query - All Movies Released in a Year

The program included in this step retrieves all movies released in the year 1985.

1. Copy the following program and paste it into a file named `MoviesQuery01.js`.

```javascript
/*
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 * http://aws.amazon.com/apache2.0/
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
*/
var AWS = require("aws-sdk");
AWS.config.update({
    region: "us-west-2",
    endpoint: "http://localhost:8000"
});
var docClient = new AWS.DynamoDB.DocumentClient();
```
console.log("Querying for movies from 1985.");

var params = {
    TableName : "Movies",
    KeyConditionExpression: "#yr = :yyyy",
    ExpressionAttributeNames:{
        "#yr": "year"
    },
    ExpressionAttributeValues: {
        ":yyyy": 1985
    }
};

docClient.query(params, function(err, data) {
    if (err) {
        console.error("Unable to query. Error: ", JSON.stringify(err, null, 2));
    } else {
        console.log("Query succeeded.");
        data.Items.forEach(function(item) {
            console.log(" -", item.year +": " + item.title);
        });
    }
});

**Note**

ExpressionAttributeNames provides name substitution. You use this because year is a reserved word in Amazon DynamoDB. You can't use it directly in any expression, including KeyConditionExpression. You use the expression attribute name #yr to address this. ExpressionAttributeValues provides value substitution. You use this because you cannot use literals in any expression, including KeyConditionExpression. You use the expression attribute value :yyyy to address this.

2. To run the program, enter the following command.

   node MoviesQuery01.js

**Note**

The preceding program shows how to query a table by its primary key attributes. In DynamoDB, you can optionally create one or more secondary indexes on a table, and query those indexes in the same way that you query a table. Secondary indexes give your applications additional flexibility by allowing queries on non-key attributes. For more information, see Improving Data Access with Secondary Indexes (p. 497).

**Step 4.2: Query - All Movies Released in a Year with Certain Titles**

The program included in this step retrieves all movies released in year 1992, with title beginning with the letter "A" through the letter "L".

1. Copy the following program and paste it into a file named MoviesQuery02.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 *
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 */
```
Step 4: Query and Scan Data

2. To run the program, enter the following command.

    node MoviesQuery02.js

**Step 4.3: Scan**

The scan method reads every item in the table and returns all the data in the table. You can provide an optional filter_expression, so that only the items matching your criteria are returned. However, the filter is applied only after the entire table has been scanned.

The following program scans the entire Movies table, which contains approximately 5,000 items. The scan specifies the optional filter to retrieve only the movies from the 1950s (approximately 100 items), and discard all of the others.
Step 4: Query and Scan Data

1. Copy the following program and paste it into a file named MoviesScan.js.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 *
 * This file is licensed under the Apache License, Version 2.0 (the "License").

 * specific language governing permissions and limitations under the License.
 */

var AWS = require("aws-sdk");

AWS.config.update(
    {
        region: "us-west-2",
        endpoint: "http://localhost:8000"
    });

var docClient = new AWS.DynamoDB.DocumentClient();

var params = {
    TableName: "Movies",
    ProjectionExpression: "#yr, title, info.rating",
    FilterExpression: "#yr between :start_yr and :end_yr",
    ExpressionAttributeNames: {
        "#yr": "year",
    },
    ExpressionAttributeValues: {
        ":start_yr": 1950,
        ":end_yr": 1959
    }
};

console.log("Scanning Movies table.");

docClient.scan(params, onScan);

function onScan(err, data) {
    if (err) {
        console.error("Unable to scan the table. Error JSON:", JSON.stringify(err, null, 2));
    } else {
        // print all the movies
        console.log("Scan succeeded.");
        data.Items.forEach(function(movie) {
            console.log(
                movie.year + ": ",
                movie.title, "- rating:", movie.info.rating);
        });

        // continue scanning if we have more movies, because
        // scan can retrieve a maximum of 1MB of data
        if (typeof data.LastEvaluatedKey != "undefined") {
            console.log("Scanning for more...");
            params.ExclusiveStartKey = data.LastEvaluatedKey;
            docClient.scan(params, onScan);
        }
    }
}
```

API Version 2012-08-10

134
In the code, note the following:

- **ProjectionExpression** specifies the attributes you want in the scan result.
- **FilterExpression** specifies a condition that returns only items that satisfy the condition. All other items are discarded.

2. To run the program, enter the following command.

   node MoviesScan.js

**Note**
You can also use the **Scan** operation with any secondary indexes that you have created on the table. For more information, see **Improving Data Access with Secondary Indexes** (p. 497).

**Step 5: (Optional): Delete the Table using AWS SDK for JavaScript**

To delete the **Movies** table:

1. Copy the following program and paste it into a file named **MoviesDeleteTable.js**.

```javascript
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * 
 * This file is licensed under the Apache License, Version 2.0 (the "License").

 * specific language governing permissions and limitations under the License.
 */
var AWS = require("aws-sdk");

AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
});

var dynamodb = new AWS.DynamoDB();

var params = {
  TableName : "Movies"
};

dynamodb.deleteTable(params, function(err, data) {
  if (err) {
    console.error("Unable to delete table. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("Deleted table. Table description JSON:", JSON.stringify(data, null, 2));
  }
});
```
2. To run the program, enter the following command.

   \texttt{node MoviesDeleteTable.js}

**Summary**

In this tutorial, you created the \texttt{Movies} table in Amazon DynamoDB on your computer and performed basic operations. The downloadable version of DynamoDB is useful during application development and testing. However, when you're ready to run your application in a production environment, you must modify your code so that it uses the DynamoDB web service.

**Modifying the Code to Use the DynamoDB Service**

To use the DynamoDB service, you must change the endpoint in your application. To do this, modify the following code.

\begin{verbatim}
AWS.config.update({endpoint: "https://dynamodb.aws-region.amazonaws.com");
\end{verbatim}

For example, if you want to use the us-west-2 Region, set the following endpoint.

\begin{verbatim}
AWS.config.update({endpoint: "https://dynamodb.us-west-2.amazonaws.com");
\end{verbatim}

Instead of using DynamoDB on your computer, the program now uses the DynamoDB web service endpoint in the US West (Oregon) Region.

DynamoDB is available in AWS Regions worldwide. For the complete list, see Regions and Endpoints in the \textit{AWS General Reference}. For more information about setting Regions and endpoints in your code, see Setting the Region in the \textit{AWS SDK for JavaScript Developer Guide}.

**Getting Started with .NET and DynamoDB**

In this tutorial, you use the AWS SDK for .NET to write simple programs to perform the following Amazon DynamoDB operations:

- Create a table named \texttt{Movies} using a utility program written in C#, and load sample data in JSON format.
- Perform create, read, update, and delete operations on the table.
- Run simple queries.

The DynamoDB module of the AWS SDK for .NET offers several programming models for different use cases. In this exercise, the C# code uses the document model, which provides a level of abstraction that is often convenient. It also uses the low-level API, which handles nested attributes more effectively.

For information about the document model API, see \texttt{.NET: Document Model (p. 274)}. For information about the low-level API, see Working with DynamoDB Tables in .NET (p. 368).

.NET and DynamoDB Tutorial Prerequisites

The Microsoft .NET and DynamoDB Tutorial (p. 136) describes how to use the AWS SDK for .NET to create simple programs for performing Amazon DynamoDB operations.

Before you begin, follow these steps to ensure that you have all the prerequisites needed to complete the tutorial:

• Use a computer that is running a recent version of Windows and a current version of Microsoft Visual Studio. If you don't have Visual Studio installed, you can download a free copy of the Community edition from the Microsoft Visual Studio website.
• Download and run DynamoDB (downloadable version). For more information, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).
  
  Note
  You use the downloadable version of DynamoDB in this tutorial. For more information about how to run the same code against the DynamoDB web service, see Step 1: Create a DynamoDB Client (p. 138).
• Set up an AWS access key to use the AWS SDKs. For more information, see Setting Up DynamoDB (Web Service) (p. 53).
• Set up a security profile for DynamoDB in Visual Studio. For step-by-step instructions, see .NET Code Examples (p. 333).
• Open the getting started demo solution that is used in this tutorial in Visual Studio:
  1. Download a .zip archive containing the solution from DynamoDB_intro.zip.
  2. Save the archive to a convenient place on your computer, and extract (unzip) the files in it.
  4. Navigate to DynamoDB_intro.sln in the DynamoDB_intro directory that you unzipped, and choose Open.
• Build the DynamoDB_intro solution, and then open the 00_Main.cs file in Visual Studio.
  1. On the Build menu, choose Build Solution (or press Ctrl+Shift+B). The solution should build successfully.
  2. Make sure that the Solution Explorer pane is being displayed and pinned in Visual Studio. If it isn't, you can find it in the View menu, or by pressing Ctrl+Alt+L.
  3. In Solution Explorer, open the 00_Main.cs file. This is the file that controls the execution of the demo program that is used in this tutorial.

  Note
  This tutorial shows how to use asynchronous methods rather than synchronous methods. This is because .NET core supports only asynchronous methods, and also because the asynchronous model is generally preferable when performance is crucial. For more information, see AWS Asynchronous APIs for .NET.
Installing the External Dependencies of the DynamoDB_intro Solution

The DynamoDB_intro solution already has the Amazon DynamoDB SDK installed in it. It also has the open-source Newtonsoft Json.NET library for deserializing JSON data, licensed under the MIT License (MIT) (see https://github.com/JamesNK/Newtonsoft.Json/blob/master/LICENSE.md).

To install the NuGet package for the DynamoDB module of the AWS SDK for .NET version 3 in your own programs, open the NuGet Package Manager Console on the Tools menu in Visual Studio. Then enter the following command at the PM> prompt.

```
PM> Install-Package AWSSDK.DynamoDBv2
```

In a similar way, you can use the NuGet Package Manager Console to load the Json.NET library into your own projects in Visual Studio. At the PM> prompt, enter the following command.

```
PM> Install-Package Newtonsoft.Json
```

Next Step

Step 1: Create a DynamoDB Client (p. 138)

Step 1: Create a DynamoDB Client

The first step in the Microsoft .NET and DynamoDB Tutorial (p. 136) is to create a client that gives you access to the Amazon DynamoDB API. The Main function in DynamoDB_intro does this by calling a createClient function implemented in the 01_CreateClient.cs file.

```csharp
using System;
using System.Net.Sockets;
using Amazon.DynamoDBv2;

namespace DynamoDB_intro
{
    public static partial class Ddb_Intro
    {
        /*-----------------------------------------------------------------------------------
        * If you are creating a client for the DynamoDB service, make sure your credentials
        * are set up first, as explained in:
        *-----------------------------------------------------------------------------------
        * If you are creating a client for DynamoDBLocal (for testing purposes),
        * DynamoDB-Local should be started first. For most simple testing, you can keep
        */
    }
}```
**Step 1: Create a Client**

* data in memory only, without writing anything to disk. To do this, use the
* following command line:
*    java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar -inMemory
* For information about DynamoDBLocal, see:

```csharp
/*
 *--------------------------------------------------------------------------
 *          createClient
 *--------------------------------------------------------------------------*/
public static bool createClient( bool useDynamoDBLocal )
{
    if( useDynamoDBLocal )
    {
        operationSucceeded = false;
        operationFailed = false;
        // First, check to see whether anyone is listening on the DynamoDB local port
        // (by default, this is port 8000, so if you are using a different port, modify
        this accordingly)
        bool localFound = false;
        try
        {
            using (var tcp_client = new TcpClient())
            {
                var result = tcp_client.BeginConnect("localhost", 8000, null, null);
                localFound = result.AsyncWaitHandle.WaitOne(3000); // Wait 3 seconds
                tcp_client.EndConnect(result);
            }
        } catch
        {
            localFound = false;
        }
        if( !localFound )
        {
            Console.WriteLine( "\n      ERROR: DynamoDB Local does not appear to have been started..."
"\n        (checked port 8000)"");
            operationFailed = true;
            return (false);
        }
        // If DynamoDB-Local does seem to be running, so create a client
        Console.WriteLine( "-- Setting up a DynamoDB-Local client (DynamoDB Local seems
        to be running)"");
        AmazonDynamoDBConfig ddbConfig = new AmazonDynamoDBConfig();
        ddbConfig.ServiceURL = "http://localhost:8000";
        try { client = new AmazonDynamoDBClient( ddbConfig ); } catch( Exception ex )
        {
            Console.WriteLine( "    FAILED to create a DynamoDBLocal client; " +
            ex.Message );
            operationFailed = true;
            return false;
        }
    } else
    {
        try { client = new AmazonDynamoDBClient( ); } catch( Exception ex )
        {
```

API Version 2012-08-10

139
Main calls this function with the `useDynamoDBLocal` parameter set to `true`. Therefore the local test version of DynamoDB must already be running on your computer using the default port (8000), or the call fails. If you do not have it installed yet, see Running DynamoDB on Your Computer (p. 46).

Setting the `useDynamoDBLocal` parameter to `false` creates a client for the DynamoDB service itself rather than the local test program.

**Next Step**

**Step 2: Create a DynamoDB Table Using the Low-Level API (p. 140)**

**Step 2: Create a DynamoDB Table Using the Low-Level API**

The document model in the AWS SDK for .NET doesn't provide for creating tables, so you have to use the low-level APIs. For more information, see Working with DynamoDB Tables in .NET (p. 368).

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you create a table named Movies in Amazon DynamoDB. The primary key for the table is composed of the following attributes:

- **year** – The partition key. The `AttributeType` is `N` for number.

  **Note**

  Because "year" is a reserved word in DynamoDB, you need to create an alias for it (such as `#yr`) using an `ExpressionAttributeNames` object when referring to it in a low-level expression.

- **title** – The sort key. The `AttributeType` is `S` for string.

The `Main` function in `DynamoDB_intro` does this by waiting on an asynchronous `CreatingTable_async` function implemented in the `02_CreatingTable.cs` file.
using System.Threading.Tasks;
using Amazon.DynamoDBv2.Model;

namespace DynamoDB_intro
{
    public static partial class Ddb_Intro
    {
        /*--------------------------------------------------------------------------
         *                       CreatingTable_async
         *--------------------------------------------------------------------------*/
        public static async Task CreatingTable_async( string new_table_name,
                                                       List<AttributeDefinition> table_attributes,
                                                       List<KeySchemaElement> table_key_schema,
                                                       ProvisionedThroughput provisionedThroughput )
        {
            Console.WriteLine( "  -- Creating a new table named {0}...", new_table_name );
            if( await checkingTableExistence_async( new_table_name ) )
            {
                Console.WriteLine( "     -- No need to create a new table..." );
                return;
            }
            if( operationFailed )
                return;
            operationSucceeded = false;
            Task<bool> newTbl = CreateNewTable_async( new_table_name,
                                                       table_attributes,
                                                       table_key_schema,
                                                       provisionedThroughput );
            await newTbl;
        }

        /*--------------------------------------------------------------------------
         *                      checkingTableExistence_async
         *--------------------------------------------------------------------------*/
        static async Task<bool> checkingTableExistence_async( string tblNm )
        {
            DescribeTableResponse descResponse;
            operationSucceeded = false;
            operationFailed = false;
            ListTablesResponse tblResponse = await Ddb_Intro.client.ListTablesAsync();
            if (tblResponse.TableNames.Contains(tblNm))
            {
                Console.WriteLine("     A table named {0} already exists in DynamoDB!", tblNm);
                // If the table exists, get its description
                try
                {
                    descResponse = await Ddb_Intro.client.DescribeTableAsync(Ddb_Intro.movies_table_name);
                    operationSucceeded = true;
                }
                catch (Exception ex)
                {
                    Console.WriteLine("     However, its description is not available ({0})", ex.Message);
                    Ddb_Intro.moviesTableDescription = null;
                    operationFailed = true;
                    return ( true );
                }
                Ddb_Intro.moviesTableDescription = descResponse.Table;
                return ( true );
            }
            return ( false );
        }
    }
}
```csharp
/* *--------------------------------------------------------------------------
 *                CreateNewTable_async
 *--------------------------------------------------------------------------*/
public static async Task<bool> CreateNewTable_async( string table_name,
List<AttributeDefinition> table_attributes,
List<KeySchemaElement> table_key_schema,
ProvisionedThroughput provisioned_throughput )
{
    CreateTableRequest request;
    CreateTableResponse response;

    // Build the 'CreateTableRequest' structure for the new table
    request = new CreateTableRequest
    {
        TableName = table_name,
        AttributeDefinitions = table_attributes,
        KeySchema = table_key_schema,
        // Provisioned-throughput settings are always required,
        // although the local test version of DynamoDB ignores them.
        ProvisionedThroughput = provisioned_throughput
    };

    operationSucceeded = false;
    operationFailed = false;
    try
    {
        Task<CreateTableResponse> makeTbl = Ddb_Intro.client.CreateTableAsync( request );
        response = await makeTbl;
        Console.WriteLine( "     -- Created the "{0}" table successfully!", table_name );
        operationSucceeded = true;
    }
    catch( Exception ex )
    {
        Console.WriteLine( "     FAILED to create the new table, because: {0}.", ex.Message );
        operationFailed = true;
        return( false );
    }

    // Report the status of the new table...
    Console.WriteLine( "     Status of the new table: '{0}'.", response.TableDescription.TableStatus );
    Ddb_Intro.moviesTableDescription = response.TableDescription;
    return ( true );
}
```

The `CreatingTable_async` function starts by waiting on an asynchronous `checkingTableExistence_async` function to determine whether a table named "Movies" already exists. If the table exists, `checkingTableExistence_async` retrieves the `TableDescription` for the existing Table.

If the table doesn’t already exist, `CreatingTable_async` waits on `CreateNewTable_async` to create the Movies table using the DynamoDB client API `CreateTableAsync`.

The `DynamoDB_intro` sample uses asynchronous methods rather than synchronous methods wherever possible. This is because .NET core supports only asynchronous methods, and the asynchronous model...
is generally preferable when performance is crucial. For more information, see AWS Asynchronous APIs for .NET.

To learn more about managing tables, see Working with Tables and Data in DynamoDB (p. 336).

**Next Step**

**Step 3: Load Sample Data into the DynamoDB Table (p. 143)**

**Step 3: Load Sample Data into the DynamoDB Table**

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you populate the new movies table in Amazon DynamoDB with sample data from the Internet Movie Database (IMDb). This data is stored in JSON format in a local text file named moviedata.json.

For each movie, moviedata.json defines a year name-value pair, a title name-value pair, and a complex info object, as illustrated by the following example.

```json
{
    "year": 2013,
    "title": "Turn It Down, Or Else!",
    "info": {
        "directors": [
            "Alice Smith",
            "Bob Jones"
        ],
        "release_date": "2013-01-18T00:00:00Z",
        "rating": 6.2,
        "genres": [
            "Comedy",
            "Drama"
        ],
        "image_url": "http://ia.media-imdb.com/images/N/O9ERWAU7FS797AJ7LU8HN09AMUP908RLlo5JF909W87LJKQ7@@._V1_SX400_.jpg",
        "plot": "A rock band plays their music at high volumes, annoying the neighbors."
    }
}
```

Before loading the moviedata.json file, the Main function in DynamoDB_intro checks to determine whether the movies table exists and is still empty. If so, it waits on an asynchronous LoadingData_async function that is implemented in the 03_LoadingData.cs file.

            operationFailed = false;
            try
            {
                sr = new StreamReader( JsonMovieFilePath );
                jtr = new JsonTextReader( sr );
                movieArray = (JArray) await JToken.ReadFromAsync( jtr );
                operationSucceeded = true;
            }
            catch( Exception ex )
            {
                Console.WriteLine( "     ERROR: could not read the file!
                      Reason: {0}.",
                      ex.Message );
                operationFailed = true;
            }
            finally
            {
                if( jtr != null )
                    jtr.Close();
                if( sr != null )
                    sr.Close();
            }
            if( operationSucceeded )
            {
                Console.WriteLine( "     -- Succeeded in reading the JSON file!" );
                return ( movieArray );
            }
        }
    }
}
LoadingData_async begins by waiting on ReadJsonMovieFile_async. This function reads the moviedata.json file using the open-source Newtonsoft Json.NET library, which is licensed under the MIT License.

When the data has been read successfully, LoadingData_async waits on LoadJsonMovieData_async to load the movie records into the Movies table using the DynamoDB document-model Table.PutItemAsync API. For information about the document model API, see .NET: Document Model (p. 274).

**Next Step**

Step 4: Add a Movie to the DynamoDB Table (p. 146)
Step 4: Add a Movie to the DynamoDB Table

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you add a new movie record to the Movies table in Amazon DynamoDB. The Main function in DynamoDB_intro starts by creating a DynamoDB document model Document and then waits on WritingNewMovie_async, which is implemented in the 04_WritingNewItem.cs file.

```csharp
using System;
using System.Threading.Tasks;
using Amazon.DynamoDBv2.DocumentModel;
namespace DynamoDB_intro
{
    public static partial class Ddb_Intro
    {
        //********************************************************************************
        /* WritingNewMovie
        *********************************************************************************/
        public static async Task WritingNewMovie_async( Document newItem )
        {
            operationSucceeded = false;
            operationFailed = false;

            int year = (int) newItem["year"];
            string name = newItem["title"];

            if( await ReadingMovie_async( year, name, false ) )
                Console.WriteLine( "  The {0} movie "{1}" is already in the Movies table...
            " + "  -- No need to add it again... its info is as follows:
            " + "      name, movie_record.ToJsonPretty( ) );
            else
                try
                {
                    Task<Document> writeNew = moviesTable.PutItemAsync(newItem, token);
                    Console.WriteLine( "      -- Writing a new movie to the Movies table..."
                        + "      -- Wrote the item successfully!");
                    operationSucceeded = true;
                }
                catch (Exception ex)
                {
                    Console.WriteLine( "      FAILED to write the new movie, because:
                        " + "      {0}.", ex.Message);
                    operationFailed = true;
                }
        }
    }
}
```
WritingNewMovie_async begins by checking to determine whether the new movie has already been added to the Movies table. If it has not, it waits for the DynamoDB Table.PutItemAsync method to add the new movie record.

Next Step

Step 5: Read and Display a Record from the DynamoDB Table (p. 147)

Step 5: Read and Display a Record from the DynamoDB Table

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you retrieve and display the new movie record that you added in Step 4 (p. 146). The Main function in DynamoDB_intro does this by waiting on ReadingMovie_async, which is implemented in the 05_ReadingItem.cs file.

```csharp
using System;
using Amazon.DynamoDBv2.DocumentModel;
namespace DynamoDB_intro

public static partial class Ddb_Intro
{
    /*-------------------------------
     * ReadingMovie_async
     *-------------------------------*/
    public static async Task<bool> ReadingMovie_async( int year, string title, bool report )
    {
        // Create Primitives for the HASH and RANGE portions of the primary key
        Primitive hash = new Primitive(year.ToString(), true);
        Primitive range = new Primitive(title, false);
        operationSucceeded = false;
        operationFailed = false;
        try
```
Step 6: Update the Movie

```csharp
Task<Document> readMovie = moviesTable.GetItemAsync(hash, range, token);
if( report )
    Console.WriteLine( " -- Reading the {0} movie "{1}" from the Movies table...", year, title );
movie_record = await readMovie;
if( movie_record == null )
{
    if( report )
        Console.WriteLine( " -- Sorry, that movie isn't in the Movies table." );
} else {
    if( report )
        Console.WriteLine( " -- Found it! The movie record looks like this:
            movie_record.ToJsonPretty( )
        operationSucceeded = true;
    return ( true );
} }
catch( Exception ex )
{
    Console.WriteLine( " FAILED to get the movie, because: {0}.", ex.Message );
    operationFailed = true;
} return ( false );
```

ReadingMovie_async in turn waits on the DynamoDB Table.GetItemAsync method to retrieve the new movie record as a Document. ReadingMovie_async then displays the movie as JSON text using the Document.ToJsonPretty method.

Next Step

Step 6: Update the New Movie Record in the DynamoDB Table (p. 148)

Step 6: Update the New Movie Record in the DynamoDB Table

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you update the new movie record in several different ways.

Topics

- Change Plot and Rating, and Add Actors (p. 149)
- Increment the Movie Rating Atomically (p. 150)
- Try to Update Using a Condition That Fails (p. 151)
- For More Information (p. 151)
Step 6: Update the Movie

Next Step (p. 151)

Change Plot and Rating, and Add Actors

The `Main` function in `DynamoDB_intro` changes the plot and rating of the movie record that you added in Step 4 (p. 146), and it also adds a list of actors to it. The document model in the AWS SDK for .NET doesn’t support updating nested attributes such as the items under the `info` attribute. Because of this, `Main` uses the low-level client API rather than a document-model `Table` method.

It starts by creating a low-level `UpdateItemRequest` to make this change.

```csharp
UpdateItemRequest updateRequest = new UpdateItemRequest()
{
    TableName = movies_table_name,
    Key = new Dictionary<string, AttributeValue>
    {
        { partition_key_name, new AttributeValue { N = "2018" } },
        { sort_key_name, new AttributeValue { S = "The Big New Movie" } }
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>
    {
        { ":r", new AttributeValue { N = "5.5" } },
        { ":p", new AttributeValue { S = "Everything happens all at once!" } },
        { ":a", new AttributeValue { L = new List<AttributeValue>
            { new AttributeValue { S = "Larry" },
            new AttributeValue { S = "Moe" },
            new AttributeValue { S = "Curly" } }
        }
    },
    UpdateExpression = "SET info.rating = :r, info.plot = :p, info.actors = :a",
    ReturnValues = "NONE"
};
```

Setting `ReturnValues` to `NONE` specifies that no update information should be returned. However, when `Main` then waits on `UpdatingMovie_async`, it sets the `report` parameter to true. This causes `UpdatingMovie_async` to change `ReturnValues` to `ALL_NEW`, meaning that the updated item should be returned in its entirety.

The `UpdatingMovie_async` is implemented in the `06_UpdateItem.cs` file.

```csharp

 */
using System;
using System.Threading.Tasks;
using System.Collections.Generic;
using System.Text;
using Amazon.DynamoDBv2.Model;
```
namespace DynamoDB_intro
{
    public static partial class Ddb_Intro
    {
    /*--------------------------------------------------------------------------
     *                             UpdatingMovie_async
     *--------------------------------------------------------------------------*/
    public static async Task<bool> UpdatingMovie_async( UpdateItemRequest updateRequest,
      bool report )
    {
        UpdateItemResponse updateResponse = null;
        operationSucceeded = false;
        operationFailed = false;
        if( report )
        {
            Console.WriteLine( " -- Trying to update a movie item..." );
            updateRequest.ReturnValues = "ALL_NEW";
        }
        try
        {
            updateResponse = await client.UpdateItemAsync( updateRequest );
            Console.WriteLine( " -- SUCCEEDED in updating the movie item!" );
        }
        catch( Exception ex )
        {
            Console.WriteLine( " -- FAILED to update the movie item, because:
      {0}.", ex.Message );
            if( updateResponse != null )
                Console.WriteLine( " -- The status code was " +
            updateResponse.HttpStatusCode.ToString( ) );
            operationFailed = true;return ( false );
        }
        if( report )
        {
            Console.WriteLine( " -- Here is the updated movie information:" );
            Console.WriteLine( movieAttributesToJson( updateResponse.Attributes ) );
        }
        operationSucceeded = true;
        return ( true );
    }
}

UpdatingMovie_async waits on the low-level DynamoDB Client.UpdateItemAsync method to update the movie record. If the update is successful, and if the report parameter is true, UpdatingMovie_async displays the updated movie record.

Where the document model has a handy Document.ToJsonPretty( ) method for displaying document content, working with low-level attribute values is a little more complicated. The 00b_DDB_Attributes.cs file can provide some examples of how to access and work with AttributeValue objects.

Increment the Movie Rating Atomically

DynamoDB supports the atomic update of counters, where you use a low-level update method to increment or decrement the value of an existing attribute without interference from other write requests. (All write requests in DynamoDB are applied in the order in which they are received.)

To increment the rating value in the movie that you just created, the Main function makes the following changes in the UpdateItemRequest that it used in the previous update.
Try to Update Using a Condition That Fails

You can also add a condition to an update request, so that if the condition is not met, the update does not occur.

To demonstrate this, the Main function makes the following changes to the UpdateItemRequest that it just used to increment the movie rating.

```csharp
updateRequest.ExpressionAttributeValues.Add( ":n", new AttributeValue { N = "3" } );
updateRequest.ConditionExpression = "size(info.actors) > :n";
```

The update can now occur only if there are more than three actors in the movie record being updated. Because there are only three actors listed, the condition fails when Main waits on UpdatingMovie_async, and the update does not occur.

For More Information

- To learn more about reading and writing data in DynamoDB tables, see Working with Items and Attributes (p. 375).
- For more information about the DynamoDB document model API, see .NET: Document Model (p. 274).

Next Step

Step 7: Conditionally Delete (p. 151)

Step 7: Conditionally Delete

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you try to delete a movie record with a condition that is not met, and the deletion fails. Then, when the condition is changed so that it is met, the deletion succeeds.

The Main function in DynamoDB_intro starts by creating a condition as follows.

```csharp
Expression condition = new Expression();
condition.ExpressionAttributeValues[":val"] = 5.0;
condition.ExpressionStatement = "info.rating <= :val";
```

The Main function then passes the Expression as one of the parameters of DeletingItem_async and waits on it. DeletingItem_async is implemented in the 07_DeletingItem.cs file.
DeletingItem_async in turn includes the condition Expression in a DeleteItemOperationConfig object that it passes to the DynamoDB Table.DeleteItemAsync method when it waits on it.

Because the movie's rating is 6.5, which is higher than 5.0, the condition is not met, and the deletion fails.
Then, when the `Main` function changes the rating threshold in the condition to 7.0 instead of 5.0, the deletion succeeds.

**Next Step**

**Step 8: Query a DynamoDB Table with .NET (p. 153)**

**Step 8: Query a DynamoDB Table with .NET**

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you query the `Movies` table in three different ways.

**Topics**
- Use a Simple Document Model Search to Query for 1985 Movies (p. 153)
- Use a QueryOperationConfig to Create a More Complex Query Search (p. 155)
- Use a Low-Level Query to Find 1992 Movies with Titles Between 'M...' and 'Tzz..' (p. 155)
- Next Step (p. 156)

**Use a Simple Document Model Search to Query for 1985 Movies**

To set up a simple document-model query, the `Main` function in `DynamoDB_intro` creates a `Search` object by calling the `Table.Query` API with 1985 as the `partition key` (also known as the `hash key`), and an empty filter `Expression`.

```
try { search = moviesTable.Query(1985, new Expression()); }
```

It then waits on `SearchListing_async`, which is implemented in `08_Querying.cs` to retrieve and display the query results.
public static async Task<bool> SearchListing_async( Search search )
{
    int i = 0;
    List<Document> docList = new List<Document>();

    Console.WriteLine( "Here are the movies retrieved:
                    
                    
                    " );

    Task<List<Document>> getNextBatch;
    operationSucceeded = false;
    operationFailed = false;

    do
    {
        try
        {
            getNextBatch = search.GetNextSetAsync();
            docList = await getNextBatch;
        }
        catch( Exception ex )
        {
            Console.WriteLine( "FAILED to get the next batch of movies from Search!

Reason:
" + ex.Message );
            operationFailed = true;
            return ( false );
        }

        foreach( Document doc in docList )
        {
            i++;
            showMovieDocShort( doc );
        }
    } while( !search.IsDone );

    Console.WriteLine( "-- Retrieved {0} movies.", i );
    operationSucceeded = true;
    return ( true );
}

/*------------------------------*/
public static async Task<bool> ClientQuerying_async( QueryRequest qRequest )
{
    operationSucceeded = false;
    operationFailed = false;

    QueryResponse qResponse;
    try
    {
        Task<QueryResponse> clientQueryTask = client.QueryAsync( qRequest );
        qResponse = await clientQueryTask;
    }
    catch( Exception ex )
    {
        Console.WriteLine( "The low-level query FAILED, because:

{0}.", ex.Message );
        operationFailed = true;
        return ( false );
    }

    Console.WriteLine( "-- The low-level query succeeded, and returned {0} movies!",
qResponse.Items.Count );
    if( !pause( ) )
    {
        
    }
operationFailed = true;
return (false);
}
Console.WriteLine("Here are the movies retrieved: "+
"--------------------------------------------------------------------------");
foreach(Dictionary<string, AttributeValue> item in qResponse.Items)
showMovieAttrsShort(item);
Console.WriteLine("-- Retrieved {0} movies.", qResponse.Items.Count);
operationSucceeded = true;
return (true);
}

Use a QueryOperationConfig to Create a More Complex Query Search

To query for 1992 movies with titles from "B..." to "Hzz...", the Main function creates a QueryOperationConfig object with a QueryFilter and various other fields.

```
QueryOperationConfig config = new QueryOperationConfig();
config.Filter = new QueryFilter();
config.AttributesToGet = new List<string> {"year", "title", "info"};
config.Select = SelectValues.SpecificAttributes;
```

Once again, it then creates a Search object by calling the Table.Query API, this time with the QueryOperationConfig object as the only parameter.

And again, it waits on SearchListing_async to retrieve and display the query results.

Use a Low-Level Query to Find 1992 Movies with Titles Between 'M...' and 'Tzz...'

To use a low-level query to retrieve 1992 movies with titles from "M..." to "Tzz...", the Main function creates a QueryRequest object.

```
QueryRequest qRequest = new QueryRequest{
    TableName = "Movies",
    ExpressionAttributeNames = new Dictionary<string, string>
        {
            {"#yr", "year"}
        },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>
        {
            {":qYr", new AttributeValue {N = "1992"}},
            {":tSt", new AttributeValue {S = "M"}},
            {":tEn", new AttributeValue {S = "Tzz"}}
        },
    KeyConditionExpression = "#yr = :qYr and title between :tSt and :tEn",
    ProjectionExpression = "#yr, title, info.actors[0], info.genres, info.running_time_secs"
};
```
It then waits on the `ClientQuerying_async` function implemented in the `08_Querying.cs` file. `ClientQuerying_async` waits in turn on the low-level DynamoDB method `AmazonDynamoDBClient.QueryAsync` to retrieve the query results.

**Note**
Because "year" is a reserved word in DynamoDB, you need to create an alias for it (here `#yr`) using `ExpressionAttributeNames` in order to use it in a low-level expression.

### Next Step

**Step 9: Scan the Movies Table with .NET (p. 156)**

**Step 9: Scan the Movies Table with .NET**

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you scan the `Movies` table in two different ways: by using a document model scan and a low-level scan.

**Topics**
- Use a Document Model Search to Scan for 1950s Movies (p. 156)
- Use a Low-Level Scan to Retrieve 1960s Movies (p. 156)
- Next Step (p. 157)

**Use a Document Model Search to Scan for 1950s Movies**

To set up a document model scan for 1950s movies, the `Main` function in `DynamoDB_intro` creates a `ScanOperationConfig` object with a `ScanFilter`:

```csharp
ScanFilter filter = new ScanFilter();
filter.AddCondition( "year", ScanOperator.Between, new DynamoDBEntry[ ] { 1950, 1959 } );
ScanOperationConfig scanConfig = new ScanOperationConfig
{ AttributesToGet = new List<string> { "year, title, info" },
  Filter = filter
};
```

To obtain a `Search` object for the scan, it passes the `ScanOperationConfig` object to `Table.Scan`. Using the `Search` object, it then waits on `SearchListing_async` (implemented in `08_Querying.cs`) to retrieve and display the scan results.

**Use a Low-Level Scan to Retrieve 1960s Movies**

To set up a low-level scan for 1960s movies, the `Main` function in `DynamoDB_intro` creates a `ScanRequest` object with various fields.

```csharp
ScanRequest sRequest = new ScanRequest
{ TableName = "Movies",
  ExpressionAttributeNames = new Dictionary<string, string>
  { "#yr", "year" } ,
  ExpressionAttributeValues = new Dictionary<string, AttributeValue>
  { ":y_a", new AttributeValue { N = "1960" } },
  ":y_z", new AttributeValue { N = "1969" } },
```
FilterExpression = "#yr between :y_a and :y_z",
ProjectionExpression = "#yr, title, info.actors[0], info.directors, info.running_time_secs"
);}

It then waits on the ClientScanning_async function implemented in the 09_Scanninging.cs file. ClientScanning_async waits in turn on the low-level DynamoDB method AmazonDynamoDBClient.ScanAsync to retrieve the query results.

**Note**

Because "year" is a reserved word in DynamoDB, you must create an alias for it (here #yr) using ExpressionAttributeNames in order to use it in a low-level expression.

**Next Step**

**Step 10: Delete the Movies Table with .NET**

In this step of the Microsoft .NET and DynamoDB Tutorial (p. 136), you delete the Movies table in Amazon DynamoDB.

The Main function in DynamoDB_intro waits on DeletingTable_async, which is implemented in the 10_DeletingTable.cs file.

```csharp
namespace DynamoDB_intro
{
    public static partial class Ddb_Intro
    {
        /***********************************************************************
         * DeletingTable_async
         ***********************************************************************/
        public static async Task<bool> DeletingTable_async( string tableName )
        {
            operationSucceeded = false;
            operationFailed = false;
            Console.WriteLine( "  -- Trying to delete the table named "{0}"...", tableName );
            pause( );
            Task tblDelete = client.DeleteTableAsync( tableName );
            try
            {
                await tblDelete;
            }
```
catch( Exception ex )
{
    Console.WriteLine( "     ERROR: Failed to delete the table, because:
            
" + ex.Message );
    operationFailed = true;
    return ( false );
}

DeletingTable_async waits on the low-level DynamoDB method
AmazonDynamoDBClient.DeleteTableAsync to delete the table.

For More Information

• To learn more about reading and writing data in DynamoDB tables, see Working with Items and
  Attributes (p. 375).

PHP and DynamoDB

In this tutorial, you use the AWS SDK for PHP to write simple programs to perform the following Amazon
DynamoDB operations:

• Create a table called Movies and load sample data in JSON format.
• Perform create, read, update, and delete operations on the table.
• Run simple queries.

As you work through this tutorial, you can refer to the AWS SDK for PHP Developer Guide. The Amazon
DynamoDB section in the AWS SDK for PHP API Reference describes the parameters and results for
DynamoDB operations.

Tutorial Prerequisites

• Download and run DynamoDB on your computer. For more information, see Setting Up DynamoDB
  Local (Downloadable Version) (p. 46).

  Note
  You use the downloadable version of DynamoDB in this tutorial. For information about how to
  run the same code against the DynamoDB service, see the Summary (p. 178).

• Set up an AWS access key to use the AWS SDKs. For more information, see Setting Up DynamoDB (Web
  Service) (p. 53).
• Set up the AWS SDK for PHP:
  • Install PHP.
  • Install the SDK for PHP.

For more information, see Getting Started in the AWS SDK for PHP Getting Started Guide.
Step 1: Create a Table

In this step, you create a table named Movies. The primary key for the table is composed of the following two attributes:

- **year** – The partition key. The **AttributeType** is **N** for number.
- **title** – The sort key. The **AttributeType** is **S** for string.

1. Copy the following program and paste it into a file named MoviesCreateTable.php.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 *
 * This file is licensed under the Apache License, Version 2.0 (the "License").

 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */

require 'vendor/autoload.php';

date_default_timezone_set('UTC');

use Aws\DynamoDb\Exception\DynamoDbException;

$url = new Aws\Sdk([  // Partition key
    'endpoint' => 'http://localhost:8000',
    'region'   => 'us-west-2',
    'version'  => 'latest'
]);

$dynamodb = $url->createDynamoDb();

$params = [
    'TableName' => 'Movies',
    'KeySchema' => [
        [
            'AttributeName' => 'year',
            'KeyType' => 'HASH' // Partition key
        ],
        [
            'AttributeName' => 'title',
            'KeyType' => 'RANGE' // Sort key
        ]
    ],
    'AttributeDefinitions' => [
        [
            'AttributeName' => 'year',
            'AttributeType' => 'N'
        ],
        [
            'AttributeName' => 'title',
            'AttributeType' => 'S'
        ]
    ]
];
```

159
Step 2: Load Sample Data

In this step, you populate the Movies table with sample data.

Topics
- Step 2.1: Download the Sample Data File (p. 161)
- Step 2.2: Load the Sample Data into the Movies Table (p. 161)

This scenario uses a sample data file that contains information about a few thousand movies from the Internet Movie Database (IMDb). The movie data is in JSON format, as shown in the following example. For each movie, there is a year, a title, and a JSON map named info.

```json
[
  {
    "year" : ... ,
    "title" : ... ,
    "info" : { ... }
  },
  {
    "year" : ...,
    "title" : ...,
    "info" : { ... }
  },
  ...  
]  
```

API Version 2012-08-10

160
In the JSON data, note the following:

- The **year** and **title** are used as the primary key attribute values for the **Movies** table.
- The rest of the **info** values are stored in a single attribute called **info**. This program illustrates how you can store JSON in an Amazon DynamoDB attribute.

The following is an example of movie data.

```json
{
    "year" : 2013,
    "title" : "Turn It Down, Or Else!",
    "info" : {
        "directors" : [
            "Alice Smith",
            "Bob Jones"
        ],
        "release_date" : "2013-01-18T00:00:00Z",
        "rating" : 6.2,
        "genres" : [
            "Comedy",
            "Drama"
        ],
        "image_url" : "http://ia.media-imdb.com/images/N/O9ERWA7F5979J7L6HN09AMU9F90ERL05J5F900W7LJKE7@_V1_SX400_.jpg",
        "plot" : "A rock band plays their music at high volumes, annoying the neighbors.",
        "rank" : 11,
        "running_time_secs" : 5215,
        "actors" : [
            "David Matthewman",
            "Ann Thomas",
            "Jonathan G. Neff"
        ]
    }
}
```

### Step 2.1: Download the Sample Data File

1. Download the sample data archive: `moviedata.zip`
2. Extract the data file (`moviedata.json`) from the archive.
3. Copy and paste the `moviedata.json` file into your current directory.

### Step 2.2: Load the Sample Data into the Movies Table

After you download the sample data, you can run the following program to populate the **Movies** table.

1. Copy the following program and paste it into a file named `MoviesLoadData.php`.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * 
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
*/
```
Note

The DynamoDB Marshaler class has methods for converting JSON documents and PHP arrays to the DynamoDB format. In this program, $marshaler->marshalJson($json) takes a JSON document and converts it into a DynamoDB item.

2. To run the program, enter the following command.

```php
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;

$sdk = new Aws\Sdk([    'endpoint' => 'http://localhost:8000',    'region' => 'us-west-2',    'version' => 'latest' ]);

$dynamodb = $sdk->createDynamoDb();
$marshaler = new Marshaler();
$tableName = 'Movies';

$movies = json_decode(file_get_contents('moviedata.json'), true);

foreach ($movies as $movie) {
    
    $year = $movie['year'];
    $title = $movie['title'];
    $info = $movie['info'];

    $json = json_encode([        'year' => $year,        'title' => $title,        'info' => $info    ]);

    $params = [
        'TableName' => $tableName,
        'Item' => $marshaler->marshalJson($json)    ];

    try {
        $result = $dynamodb->putItem($params);
        echo "Added movie: " . $movie['year'] . " " . $movie['title'] . "\n";
    } catch (DynamoDbException $e) {
        echo "Unable to add movie:\n";
        echo $e->getMessage() . "\n";
        break;
    }
}
```
php MoviesLoadData.php

Step 3: Create, Read, Update, and Delete an Item

In this step, you perform read and write operations on an item in the Movies table.

To learn more about reading and writing data, see Working with Items and Attributes (p. 375).

Topics
• Step 3.1: Create a New Item (p. 163)
• Step 3.2: Read an Item (p. 164)
• Step 3.3: Update an Item (p. 166)
• Step 3.4: Increment an Atomic Counter (p. 168)
• Step 3.5: Update an Item (Conditionally) (p. 169)
• Step 3.6: Delete an Item (p. 170)

Step 3.1: Create a New Item

In this step, you add a new item to the Movies table.

1. Copy the following program and paste it into a file named MoviesItemOps01.php.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * *
 * This file is licensed under the Apache License, Version 2.0 (the "License").

 * *
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;
/sdk = new Aws\Sdk([
   'endpoint' => 'http://localhost:8000',
   'region' => 'us-west-2',
   'version' => 'latest'
]);
$ddb = $sdk->createDynamoDb();
$marshaler = new Marshaler();
$tableName = 'Movies';
$year = 2015;
$title = 'The Big New Movie';
```
$item = $marshaler->marshalJson(''
    "year": ' . $year . ',
    "title": "' . $title . '",
    "info": {
        "plot": "Nothing happens at all.",
        "rating": 0
    }
);''

$params = [
    'TableName' => 'Movies',
    'Item' => $item
];

try {
    $result = $dynamodb->putItem($params);
    echo "Added item: $year - $title\n";
} catch (DynamoDbException $e) {
    echo "Unable to add item:\n";
    echo $e->getMessage() . "\n";
}

Note
The primary key is required. This code adds an item that has primary key (year, title) and
info attributes. The info attribute stores a map that provides more information about the
movie.

2. To run the program, enter the following command.

   php MoviesItemOps01.php

Step 3.2: Read an Item

In the previous program, you added the following item to the table.

{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Nothing happens at all.",
        rating: 0
    }
}

You can use the getItem method to read the item from the Movies table. You must specify the primary
key values so that you can read any item from Movies if you know its year and title.

1. Copy the following program and paste it into a file named MoviesItemOps02.php.

   /**
   * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
   *

```php
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;

/sdk = new Aws\Sdk([  
    'endpoint' => 'http://localhost:8000',  
    'region' => 'us-west-2',  
    'version' => 'latest'
]);
$dynamodb = $sdk->createDynamoDb();
$marshaler = new Marshaler();
$tableName = 'Movies';
$year = 2015;
$title = 'The Big New Movie';

$key = $marshaler->marshalJson('  
    {  
        "year": ' . $year . ',  
        "title": "' . $title . '"  
    }  
');

$params = [
    'TableName' => $tableName,
    'Key' => $key
];

try {
    $result = $dynamodb->getItem($params);
    print_r($result["Item"]);
} catch (DynamoDbException $e) {
    echo "Unable to get item:\n";
    echo $e->getMessage() . "\n";
}
```

2. To run the program, enter the following command.

    php MoviesItemOps02.php
Step 3: Create, Read, Update, and Delete an Item

Step 3.3: Update an Item

You can use the `updateItem` method to modify an existing item. You can update values of existing attributes, add new attributes, or remove attributes.

In this example, you perform the following updates:

- Change the value of the existing attributes (`rating`, `plot`).
- Add a new list attribute (`actors`) to the existing `info` map.

The following shows the existing item.

```json
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Nothing happens at all.”,
    rating: 0
  }
}
```

The item is updated as follows.

```json
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Everything happens all at once.",
    rating: 5.5,
    actors: ["Larry", "Moe", "Curly"]
  }
}
```

1. Copy the following program and paste it into a file named `MoviesItemOps03.php`.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;

/sdk = new Aws\Sdk([
    'endpoint' => 'http://localhost:8000',
    'region' => 'us-west-2',
```

API Version 2012-08-10

Note

This program uses UpdateExpression to describe all updates you want to perform on the specified item.

The ReturnValues parameter instructs Amazon DynamoDB to return only the updated attributes (UPDATED_NEW).

2. To run the program, enter the following command.

    php MoviesItemOps03.php
Step 3.4: Increment an Atomic Counter

DynamoDB supports atomic counters, which use the `updateItem` method to increment or decrement the value of an existing attribute without interfering with other write requests. (All write requests are applied in the order in which they are received.)

The following program shows how to increment the `rating` for a movie. Each time you run the program, it increments this attribute by one.

1. Copy the following program and paste it into a file named `MoviesItemOps04.php`.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

 */
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;
/sdk = new Aws\Sdk([  'endpoint' => 'http://localhost:8000',  'region' => 'us-west-2',  'version' => 'latest'
]);
$dynamodb = $sdk->createDynamoDb();
$marshaler = new Marshaler();
$tableName = 'Movies';
$year = 2015;
$title = 'The Big New Movie';
$key = $marshaler->marshalJson('  
    "year": ' . $year . ',
    "title": "' . $title . ""
  ');,
$eav = $marshaler->marshalJson('  
    "val": 1
  ');,
$params = [
    'TableName' => $tableName,
    'Key' => $key,
    'UpdateExpression' => 'set info.rating = info.rating + :val',
];
```
Step 3: Create, Read, Update, and Delete an Item

```
<ExpressionAttributeValues' => $eav,
'ReturnValues' => 'UPDATED_NEW'
];

try {
    $result = $dynamodb->updateItem($params);
    echo "Updated item. ReturnValues are:\n";
    print_r($result['Attributes']);
} catch (DynamoDbException $e) {
    echo "Unable to update item:\n";
    echo $e->getMessage() . '\n';
}
```

2. To run the program, enter the following command.

   php MoviesItemOps04.php

Step 3.5: Update an Item (Conditionally)

The following program shows how to use UpdateItem with a condition. If the condition evaluates to true, the update succeeds; otherwise, the update is not performed.

In this case, the item is updated only if there are more than three actors in the movie.

1. Copy the following program and paste it into a file named MoviesItemOps05.php.

   ```
   /*
   * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

   * CONDITIONS OF ANY KIND, either express or implied. See the License for the
   * specific language governing permissions and limitations under the License.
   */
   require 'vendor/autoload.php';
   date_default_timezone_set('UTC');
   use Aws\DynamoDb\Exception\DynamoDbException;
   use Aws\DynamoDb\Marshaler;
   $sdk = new Aws\Sdk([ 'endpoint' => 'http://localhost:8000', 'region' => 'us-west-2', 'version' => 'latest' ]);,
   $dynamodb = $sdk->createDynamoDb();
   $marshaler = new Marshaler();
   $tableName = 'Movies';
```
$year = 2015;
$title = 'The Big New Movie';

$key = $marshaler->marshalJson(' {
    "year": ' . $year . ',
    "title": "' . $title . '"
}');

$eav = $marshaler->marshalJson(' {
    ":num": 3
}');

$params = [
    'TableName' => $tableName,
    'Key' => $key,
    'UpdateExpression' => 'remove info.actors[0]',
    'ConditionExpression' => 'size(info.actors) > :num',
    'ExpressionAttributeValues'=> $eav,
    'ReturnValues' => 'UPDATED_NEW'
];

try {
    $result = $dynamodb->updateItem($params);
    echo "Updated item. ReturnValues are:\n";
    print_r($result['Attributes']);
} catch (DynamoDbException $e) {
    echo "Unable to update item:\n";
    echo $e->getMessage() . "\n";
}

2. To run the program, enter the following command.

    php MoviesItemOps05.php

    The program should fail with the following message.

    The conditional request failed

    The program fails because the movie has three actors in it, but the condition is checking for greater than three actors.

3. Modify the program so that the ConditionExpression looks like the following.

    ConditionExpression="size(info.actors) >= :num",

    The condition is now greater than or equal to 3 instead of greater than 3.

4. Run the program again. The UpdateItem operation should now succeed.

Step 3.6: Delete an Item

You can use the deleteItem method to delete one item by specifying its primary key. You can optionally provide a ConditionExpression to prevent the item from being deleted if the condition is not met.
In the following example, you try to delete a specific movie item if its rating is 5 or less.

1. Copy the following program and paste it into a file named `MoviesItemOps06.php`.

```php
/*
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of

 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;
/sdk = new Aws\Sdk([  'endpoint' => 'http://localhost:8000',  'region' => 'us-west-2',  'version' => 'latest']);
$dynamodb = $sdk->createDynamoDb();
$marshaler = new Marshaler();
$tableName = 'Movies';
$year = 2015;
$title = 'The Big New Movie';
$key = $marshaler->marshalJson('  {    "year": ' . $year . ',    "title": "' . $title . '"  }');
$eav = $marshaler->marshalJson('  {    ":val": 5  }');
$params = [
    'TableName' => $tableName,
    'Key' => $key,
    'ConditionExpression' => 'info.rating <= :val',
    'ExpressionAttributeValues'=> $eav
];
try {
    $result = $dynamodb->deleteItem($params);
    echo "Deleted item.\n";
} catch (DynamoDbException $e) {
```
Step 4: Query and Scan the Data

You can use the query method to retrieve data from a table. You must specify a partition key value. The sort key is optional.

The primary key for the Movies table is composed of the following:

- `year` – The partition key. The attribute type is number.
- `title` – The sort key. The attribute type is string.

To find all movies released during a year, you need to specify only the `year`. You can also provide the `title` to retrieve a subset of movies based on some condition (on the sort key). For example, to find movies released in 2014 that have a title starting with the letter "A".

In addition to the query method, you can use the scan method to retrieve all of the table data.

To learn more about querying and scanning data, see Working with Queries in DynamoDB (p. 459) and Working with Scans in DynamoDB (p. 476), respectively.

Topics
- Step 4.1: Query - All Movies Released in a Year (p. 172)
- Step 4.2: Query - All Movies Released in a Year with Certain Titles (p. 174)
- Step 4.3: Scan (p. 175)

Step 4.1: Query - All Movies Released in a Year

The program included in this step retrieves all movies released in the `year` 1985.

1. Copy the following program and paste it into a file named `MoviesQuery01.php`.

```php
    echo "Unable to delete item:\n";
    echo $e->getMessage() . "\n";
}
```

2. To run the program, enter the following command.

```
    php MoviesItemOps06.php
```

   The program should fail with the following message.

   The conditional request failed

   The program fails because the rating for this particular move is greater than 5.

3. Modify the program to remove the condition.

```
   $params = [
     'TableName' => $tableName,
     'Key' => $key
   ];
```

4. Run the program. Now, the delete succeeds because you removed the condition.

   'ExpressionAttributeNames'=> [ '#yr' => 'year' ],
   'ExpressionAttributeValues'=> $eav
 ];

try {
   $result = $dynamodb->query($params);
   echo "Query succeeded.\n";
   foreach ($result['Items'] as $movie) {
      echo $marshaler->unmarshalValue($movie['year']) . ': ' .
      $marshaler->unmarshalValue($movie['title']) . "\n";
   }
} catch (DynamoDbException $e) {
   echo "Unable to query:\n";
   echo $e->getMessage() . "\n";
}
```

### Step 4: Query and Scan the Data

#### Note

- `ExpressionAttributeNames` provides name substitution. We use this because `year` is a reserved word in DynamoDB—you can't use it directly in any expression, including `KeyConditionExpression`. You can use the expression attribute name `#yr` to address this.

- `ExpressionAttributeValues` provides value substitution. You use this because you can't use literals in any expression, including `KeyConditionExpression`. You can use the expression attribute value `:yyy` to address this.

2. To run the program, enter the following command:

   ```bash
   php MoviesItemQuery01.php
   ```

#### Note

The preceding program shows how to query a table by its primary key attributes. In Amazon DynamoDB, you can optionally create one or more secondary indexes on a table, and query those indexes in the same way that you query a table. Secondary indexes give your applications additional flexibility by allowing queries on non-key attributes. For more information, see Improving Data Access with Secondary Indexes (p. 497).

## Step 4.2: Query - All Movies Released in a Year with Certain Titles

The program included in this step retrieves all movies released in year 1992 with `title` beginning with the letter "A" through the letter "L".

1. Copy the following program and paste it into a file named `MoviesQuery02.php`.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
 * This file is licensed under the Apache License, Version 2.0 (the "License").
 * You may not use this file except in compliance with the License. A copy of
 * the License is located at
 * http://aws.amazon.com/apache2.0/
 * This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
 * CONDITIONS OF ANY KIND, either express or implied. See the License for the
 * specific language governing permissions and limitations under the License.
 */
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;

/sdk = new Aws\Sdk([  'endpoint' => 'http://localhost:8000',  'region' => 'us-west-2',  'version' => 'latest' ]);  
dynamodb = $sdk->createDynamoDb();
$marshaler = new Marshaler();
```
$tableName = 'Movies';

$eav = $marshaler->marshalJson('{
   ":yyyy":1992,
   ":letter1": "A",
   ":letter2": "L"
}
);

$params = [
   'TableName' => $tableName,
   'ProjectionExpression' => '#yr, title, info.genres, info.actors[0]',
   'KeyConditionExpression' => #yr = :yyyy and title between :letter1 and :letter2',
   'ExpressionAttributeNames'=> [ #yr => 'year' ],
   'ExpressionAttributeValues'=> $eav
]
;

echo "Querying for movies from 1992 - titles A-L, with genres and lead actor\n";

try {
   $result = $dynamodb->query($params);
   echo "Query succeeded.\n";
   foreach ($result['Items'] as $i) {
      $movie = $marshaler->unmarshalItem($i);
      print $movie['year'] . ': ' . $movie['title'] . ' ... ';
      foreach ($movie['info']['genres'] as $gen) {
         print $gen . ' ';
      }
      echo ' ... ' . $movie['info']['actors'][0] . "\n";
   }
} catch (DynamoDbException $e) {
   echo "Unable to query:\n";
   echo $e->getMessage() . "\n";
}

2. To run the program, enter the following command.

   php MoviesQuery02.php

**Step 4.3: Scan**

The scan method reads every item in the entire table, and returns all of the data in the table. You can provide an optional filter_expression so that only the items matching your criteria are returned. However, the filter is applied only after the entire table has been scanned.

The following program scans the entire Movies table, which contains approximately 5,000 items. The scan specifies the optional filter to retrieve only the movies from the 1950s (approximately 100 items), and discard all of the others.

1. Copy the following program and paste it into a file named MoviesScan.php.
require 'vendor/autoload.php';
date_default_timezone_set('UTC');
use Aws\DynamoDb\Exception\DynamoDbException;
use Aws\DynamoDb\Marshaler;

$sdk = new Aws\Sdk([  'endpoint' => 'http://localhost:8000',  'region' => 'us-west-2',  'version' => 'latest']);
$dynamodb = $sdk->createDynamoDb();

$marshaler = new Marshaler();

// Expression attribute values
$eav = $marshaler->marshalJson('  
  {  
    "start_yr": 1950,  
    "end_yr": 1959  
  }  
  ',);

$params = [  'TableName' => 'Movies',  'ProjectionExpression' => '#yr, title, info.rating',  'FilterExpression' => '#yr between :start_yr and :end_yr',  'ExpressionAttributeNames' => [ '#yr' => 'year' ],  'ExpressionAttributeValues' => $eav ];

echo "Scanning Movies table.\n";
try {
  while (true) {
    $result = $dynamodb->scan($params);
    foreach ($result['Items'] as $i) {
      $movie = $marshaler->unmarshalItem($i);
      echo $movie['year'] . ': ' . $movie['title'];
      echo ' ... ' . $movie['info']['rating'] . "\n";
    }
    if (isset($result['LastEvaluatedKey'])) {
      $params['ExclusiveStartKey'] = $result['LastEvaluatedKey'];
    } else {
      break;
    }
  }
} catch (DynamoDbException $e) {  
  echo 'Error: ' . $e->getMessage();
}  

API Version 2012-08-10
In the code, note the following:

- **ProjectionExpression** specifies the attributes you want in the scan result.
- **FilterExpression** specifies a condition that returns only items that satisfy the condition. All other items are discarded.

2. To run the program, enter the following command.

```bash
php MoviesScan.php
```

**Note**

You can also use the **Scan** operation with any secondary indexes that you have created on the table. For more information, see **Improving Data Access with Secondary Indexes** (p. 497).

## Step 5: (Optional) Delete the Table

To delete the **Movies** table:

1. Copy the following program and paste it into a file named **MoviesDeleteTable.php**.

```php
/**
 * Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

 */

require 'vendor/autoload.php';

date_default_timezone_set('UTC');

use Aws\DynamoDb\Exception\DynamoDbException;

$sdk = new Aws\Sdk([    'endpoint' => 'http://localhost:8000',
    'region' => 'us-west-2',
    'version' => 'latest'
]);

$dynamodb = $sdk->createDynamoDb();
$params = [
    'TableName' => 'Movies'
];

try {
    $result = $dynamodb->deleteTable($params);
    echo "Deleted table.\n";
} catch (DynamoDbException $e) {
    echo "Unable to delete table:\n";
    echo $e->getMessage() . "\n";
}

2. To run the program, enter the following command.

   php MoviesDeleteTable.php

Summary

In this tutorial, you created the Movies table in Amazon DynamoDB on your computer and performed basic operations. The downloadable version of DynamoDB is useful during application development and testing. However, when you're ready to run your application in a production environment, you need to modify your code so that it uses the DynamoDB web service.

Modifying the Code to Use the DynamoDB Service

To use the DynamoDB web service, you must change the endpoint in your application. To do this, find the following lines in the code.

```php
$sdk = new Aws\Sdk([  
    'endpoint' => 'http://localhost:8000',  
    'region' => 'us-west-2',  
    'version' => 'latest'  
]);
```

Remove the endpoint parameter so that the code looks like the following.

```php
$sdk = new Aws\Sdk([  
    'region' => 'us-west-2',  
    'version' => 'latest'  
]);
```

After you remove this line, the code can access the DynamoDB web service in the AWS Region specified by the region config value. For example, the following line specifies that you want to use the US West (Oregon) Region.

```php
'region' => 'us-west-2',
```

Instead of using the downloadable version of DynamoDB on your computer, the program now uses the DynamoDB service endpoint in the US West (Oregon) Region.

DynamoDB is available in AWS Regions worldwide. For the complete list, see Regions and Endpoints in the AWS General Reference. For more information about setting Regions and endpoints in your code, see the boto: A Python interface to Amazon Web Services.
Getting Started Developing with Python and DynamoDB

In this tutorial, you use the AWS SDK for Python (Boto 3) to write simple programs to perform the following Amazon DynamoDB operations:

- Create a table called *Movies* and load sample data in JSON format.
- Perform create, read, update, and delete operations on the table.
- Run simple queries.

As you work through this tutorial, you can refer to the AWS SDK for Python (Boto) documentation. The following sections are specific to DynamoDB:

- DynamoDB tutorial
- DynamoDB low-level client

Tutorial Prerequisites

- Download and run DynamoDB on your computer. For more information, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).

  **Note**
  You use the downloadable version of DynamoDB in this tutorial. In the Summary (p. 192), we explain how to run the same code against the DynamoDB web service.

- Set up an AWS access key to use the AWS SDKs. For more information, see Setting Up DynamoDB (Web Service) (p. 53).

- Install Python 2.6 or later. For more information, see https://www.python.org/downloads. For instructions, see Quickstart in the Boto 3 documentation.

Step 1: Create a Table with Python

In this step, you create a table named *Movies*. The primary key for the table is composed of the following attributes:

- **year** – The partition key. The `AttributeType` is `N` for number.
- **title** – The sort key. The `AttributeType` is `S` for string.

1. Copy the following program and paste it into a file named `MoviesCreateTable.py`.

```python
import boto3

def create_movie_table(dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")
    table = dynamodb.create_table(
        TableName='Movies',
        KeySchema=[
            {'AttributeName': 'year',
             'AttributeType': 'N'}
        ]
    )
```

API Version 2012-08-10

Step 2: Load Sample Data

In this step, you populate the Movies table with sample data.

Topics
- Step 2.1: Download the Sample Data File (p. 181)
- Step 2.2: Load the Sample Data into the Movies Table (p. 182)

This scenario uses a sample data file that contains information about a few thousand movies from the Internet Movie Database (IMDb). The movie data is in JSON format, as shown in the following example. For each movie, there is a year, a title, and a JSON map named info.

```
{
'KeyType': 'HASH'  # Partition key
},
{
  'AttributeName': 'title',
  'KeyType': 'RANGE'  # Sort key
}
],
AttributeDefinitions=[
  {
    'AttributeName': 'year',
    'AttributeType': 'N'
  },
  {
    'AttributeName': 'title',
    'AttributeType': 'S'
  },
],
ProvisionedThroughput={
  'ReadCapacityUnits': 10,
  'WriteCapacityUnits': 10
}
)
return table

if __name__ == '__main__':
movie_table = create_movie_table()
print("Table status:", movie_table.table_status)
```

Note
- You set the endpoint to indicate that you are creating the table in the downloadable version of DynamoDB on your computer.
- In the create_table call, you specify the table name, primary key attributes, and its data types.
- The ProvisionedThroughput parameter is required. However, the downloadable version of DynamoDB ignores it. (Provisioned throughput is beyond the scope of this exercise.)
- These examples use the Python 3 style print function. The line from __future__ import print_function enables Python 3 printing in Python 2.6 and later.

2. To run the program, enter the following command.

```
python MoviesCreateTable.py
```

To learn more about managing tables, see Working with Tables and Data in DynamoDB (p. 336).
In the JSON data, note the following:

- The `year` and `title` are used as the primary key attribute values for the `Movies` table.
- The rest of the `info` values are stored in a single attribute called `info`. This program illustrates how you can store JSON in an Amazon DynamoDB attribute.

The following is an example of movie data.

```json
{
    "year" : 2013,
    "title" : "Turn It Down, Or Else!",
    "info" : {
        "directors" : ["Alice Smith", "Bob Jones"],
        "release_date" : "2013-01-18T00:00:00Z",
        "rating" : 6.2,
        "genres" : ["Comedy", "Drama"],
        "image_url" : "http://ia.media-imdb.com/images/N/O9ERWAU7FS797A7JLUI8H09AMUP908RL105JF90EWR7LJQ7@@._V1_SX400_.jpg",
        "plot" : "A rock band plays their music at high volumes, annoying the neighbors.",
        "rank" : 11,
        "running_time_secs" : 5215,
        "actors" : ["David Matthewman", "Ann Thomas", "Jonathan G. Neff"
    ]
}
```

**Step 2.1: Download the Sample Data File**

1. Download the sample data archive: `moviedata.zip`
2. Extract the data file (`moviedata.json`) from the archive.
3. Copy the `moviedata.json` file into your current directory.
Step 2.2: Load the Sample Data into the Movies Table

After you download the sample data, you can run the following program to populate the Movies table.

1. Copy the following program and paste it into a file named MoviesLoadData.py.

```python
from decimal import Decimal
import json
import boto3

def load_movies(movies, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")

    table = dynamodb.Table('Movies')
    for movie in movies:
        year = int(movie['year'])
        title = movie['title']
        print("Adding movie:", year, title)
        table.put_item(Item=movie)

if __name__ == '__main__':
    with open("moviedata.json") as json_file:
        movie_list = json.load(json_file, parse_float=Decimal)
    load_movies(movie_list)
```

2. To run the program, enter the following command.

   python MoviesLoadData.py

Step 3: Create, Read, Update, and Delete an Item with Python

In this step, you perform read and write operations on an item in the Movies table.

To learn more about reading and writing data, see Working with Items and Attributes (p. 375).

Topics
- Step 3.1: Create a New Item (p. 182)
- Step 3.2: Read an Item (p. 183)
- Step 3.3: Update an Item (p. 184)
- Step 3.4: Increment an Atomic Counter (p. 185)
- Step 3.5: Update an Item (Conditionally) (p. 186)
- Step 3.6: Delete an Item (p. 187)

Step 3.1: Create a New Item

In this step, you add a new item to the Movies table.

1. Copy the following program and paste it into a file named MoviesItemOps01.py.

```python
from pprint import pprint
import boto3
```
def put_movie(title, year, plot, rating, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")
    table = dynamodb.Table('Movies')
    response = table.put_item(
        Item={
            'year': year,
            'title': title,
            'info': {
                'plot': plot,
                'rating': rating
            }
        }
    )
    return response

if __name__ == '__main__':
    movie_resp = put_movie("The Big New Movie", 2015,
                           "Nothing happens at all.", 0)
    print("Put movie succeeded:")
    pprint(movie_resp, sort_dicts=False)

Note

- The primary key is required. This code adds an item that has primary key (year, title) and info attributes. The info attribute stores sample JSON that provides more information about the movie.
- The DecimalEncoder class is used to print out numbers stored using the Decimal class. The Boto SDK uses the Decimal class to hold Amazon DynamoDB number values.

2. To run the program, enter the following command.
   
   python MoviesItemOps01.py

Step 3.2: Read an Item

In the previous program, you added the following item to the table.

{  
    year: 2015,  
    title: "The Big New Movie",  
    info: {  
        plot: "Nothing happens at all.",  
        rating: 0  
    }  
}

You can use the get_item method to read the item from the Movies table. You must specify the primary key values so that you can read any item from Movies if you know its year and title.

1. Copy the following program and paste it into a file named MoviesItemOps02.py.

   from pprint import pprint
   import boto3
   from botocore.exceptions import ClientError

   def get_movie(title, year, dynamodb=None):

   if __name__ == '__main__':
       movie_resp = get_movie("The Big New Movie", 2015,
                              "Nothing happens at all.", 0)
       print("Get movie succeeded:")
       pprint(movie_resp, sort_dicts=False)
if not dynamodb:
    dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")

table = dynamodb.Table('Movies')

try:
    response = table.get_item(Key={'year': year, 'title': title})
except ClientError as e:
    print(e.response['Error']['Message'])
else:
    return response['Item']

if __name__ == '__main__':
    movie = get_movie("The Big New Movie", 2015)
    if movie:
        print("Get movie succeeded:")
        pprint(movie, sort_dicts=False)

2. To run the program, enter the following command.

   python MoviesItemOps02.py

Step 3.3: Update an Item

You can use the update_item method to modify an existing item. You can update values of existing attributes, add new attributes, or remove attributes.

In this example, you perform the following updates:

- Change the value of the existing attributes (rating, plot).
- Add a new list attribute (actors) to the existing info map.

The following shows the existing item.

```json
{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Nothing happens at all.",
        rating: 0
    }
}
```

The item is updated as follows.

```json
{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Everything happens all at once.",
        rating: 5.5,
        actors: ["Larry", "Moe", "Curly"]
    }
}
```

1. Copy the following program and paste it into a file named MoviesItemOps03.py.

```python
from decimal import Decimal
```
from pprint import pprint
import boto3

def update_movie(title, year, rating, plot, actors, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")
    table = dynamodb.Table('Movies')
    response = table.update_item(
        Key={
            'year': year,
            'title': title
        },
        UpdateExpression="set info.rating=:r, info.plot=:p, info.actors=:a",
        ExpressionAttributeValues={
            ':r': Decimal(rating),
            ':p': plot,
            ':a': actors
        },
        ReturnValues="UPDATED_NEW"
    )
    return response

if __name__ == '__main__':
    update_response = update_movie("The Big New Movie", 2015, 5.5, "Everything happens all at once.", ['Larry', 'Moe', 'Curly'])
    print("Update movie succeeded:")
    pprint(update_response, sort_dicts=False)

Note
This program uses UpdateExpression to describe all updates you want to perform on the specified item.
The ReturnValues parameter instructs DynamoDB to return only the updated attributes (UPDATED_NEW).

Step 3.4: Increment an Atomic Counter

DynamoDB supports atomic counters, which use the update_item method to increment or decrement the value of an existing attribute without interfering with other write requests. (All write requests are applied in the order in which they are received.)

The following program shows how to increment the rating for a movie. Each time you run the program, it increments this attribute by one.

1. Copy the following program and paste it into a file named MoviesItemOps04.py.

```python
from decimal import Decimal
from pprint import pprint
import boto3

def increase_rating(title, year, rating_increase, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")
```
```
table = dynamodb.Table('Movies')

response = table.update_item(
    Key={'
        'year': year,
        'title': title
    },
    UpdateExpression="set info.rating = info.rating + :val",
    ExpressionAttributeValues={
        ':val': Decimal(rating_increase)
    },
    ReturnValues="UPDATED_NEW"
)
return response
```

if __name__ == '__main__':
    update_response = increase_rating("The Big New Movie", 2015, 1)
    print("Update movie succeeded:")
    pprint(update_response, sort_dicts=False)

2. To run the program, enter the following command.
   ```bash
   python MoviesItemOps04.py
   ```

**Step 3.5: Update an Item (Conditionally)**

The following program shows how to use `update_item` with a condition. If the condition evaluates to true, the update succeeds; otherwise, the update is not performed.

In this case, the item is updated only if there are more than three actors.

1. Copy the following program and paste it into a file named `MoviesItemOps05.py`.

   ```python
   from pprint import pprint
   import boto3
   from botocore.exceptions import ClientError

   def remove_actors(title, year, actor_count, dynamodb=None):
       if not dynamodb:
           dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")

       table = dynamodb.Table('Movies')

       try:
           response = table.update_item(
               Key={'
                   'year': year,
                   'title': title
               },
               UpdateExpression="remove info.actors[0]",
               ConditionExpression="size(info.actors) > :num",
               ExpressionAttributeValues={':num': actor_count},
               ReturnValues="UPDATED_NEW"
           )
       except ClientError as e:
           if e.response['Error']['Code'] == "ConditionalCheckFailedException":
               print(e.response['Error']['Message'])
           else:
               raise
       else:
```

API Version 2012-08-10
186
Step 3: Crud Operations

return response

if __name__ == '__main__':
    print("Attempting conditional update (expecting failure)...")
    update_response = remove_actors("The Big New Movie", 2015, 3)
    if update_response:
        print("Update movie succeeded:")
        pprint(update_response, sort_dicts=False)

2. To run the program, enter the following command.

```bash
python MoviesItemOps05.py
```

The program should fail with the following message.

The conditional request failed

The program fails because the movie has three actors in it, but the condition is checking for greater than three actors.

3. Modify the program so that the ConditionExpression looks like the following.

```python
ConditionExpression="size(info.actors) >= :num",
```

The condition is now greater than or equal to 3 instead of greater than 3.

4. Run the program again. The UpdateItem operation should now succeed.

Step 3.6: Delete an Item

You can use the delete_item method to delete one item by specifying its primary key. Optionally, you can provide a ConditionExpression to prevent the item from being deleted if the condition is not met.

In the following example, you try to delete a specific movie item if its rating is 5 or less.

1. Copy the following program and paste it into a file named MoviesItemOps06.py.

```python
from decimal import Decimal
from pprint import pprint
import boto3
from botocore.exceptions import ClientError

def delete_underrated_movie(title, year, rating, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")
    table = dynamodb.Table('Movies')

    try:
        response = table.delete_item(
            Key={
                'year': year,
                'title': title
            },
            ConditionExpression="info.rating <= :val",
            ExpressionAttributeValues={
                ":val": Decimal(rating)
            }
        )
    return response
```

In the following example, you try to delete a specific movie item if its rating is 5 or less.
except ClientError as e:
    if e.response['Error']['Code'] == "ConditionalCheckFailedException":
        print(e.response['Error']['Message'])
    else:
        raise
else:
    return response

if __name__ == '__main__':
    print("Attempting a conditional delete...")
    delete_response = delete_underrated_movie("The Big New Movie", 2015, 5)
    if delete_response:
        print("Delete movie succeeded:")
        pprint(delete_response, sort_dicts=False)

2. To run the program, enter the following command.

    python MoviesItemOps06.py

    The program should fail with the following message.

    The conditional request failed

    The program fails because the rating for this particular move is greater than 5.

3. Modify the program to remove the condition in table.delete_item.

    response = table.delete_item(
       Key={
           'year': year,
           'title': title
       }
    )

4. Run the program. Now, the delete succeeds because you removed the condition.

### Step 4: Query and Scan the Data

You can use the `query` method to retrieve data from a table. You must specify a partition key value. The sort key is optional.

The primary key for the `Movies` table is composed of the following:

- **year** – The partition key. The attribute type is `number`.
- **title** – The sort key. The attribute type is `string`.

To find all movies released during a year, you need to specify only the `year`. You can also provide the `title` to retrieve a subset of movies based on some condition (on the sort key). For example, you can find movies released in 2014 that have a title starting with the letter "A".

In addition to the `query` method, you can use the `scan` method to retrieve all the table data.

To learn more about querying and scanning data, see Working with Queries in DynamoDB (p. 459) and Working with Scans in DynamoDB (p. 476), respectively.

**Topics**

- **Step 4.1: Query - All Movies Released in a Year (p. 189)**
- **Step 4.2: Query - All Movies Released in a Year with Certain Titles (p. 189)**
Step 4.1: Query - All Movies Released in a Year

The program included in this step retrieves all movies released in the year 1985.

1. Copy the following program and paste it into a file named MoviesQuery01.py.

```python
import boto3
from boto3.dynamodb.conditions import Key

def query_movies(year, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")

    table = dynamodb.Table('Movies')
    response = table.query(
        KeyConditionExpression=Key('year').eq(year)
    )
    return response['Items']

if __name__ == '__main__':
    query_year = 1985
    print(f"Movies from {query_year}"
    movies = query_movies(query_year)
    for movie in movies:
        print(movie['year'], ":", movie['title'])
```

**Note**
The Boto 3 SDK constructs a ConditionExpression for you when you use the Key and Attr functions imported from boto3.dynamodb.conditions. You can also specify a ConditionExpression as a string.

For a list of available conditions for Amazon DynamoDB, see DynamoDB Conditions in AWS SDK for Python (Boto 3) Getting Started.
For more information, see Condition Expressions (p. 393).

2. To run the program, enter the following command.

```
python MoviesQuery01.py
```

**Note**
The preceding program shows how to query a table by its primary key attributes. In DynamoDB, you can optionally create one or more secondary indexes on a table and query those indexes in the same way that you query a table. Secondary indexes give your applications additional flexibility by allowing queries on non-key attributes. For more information, see Improving Data Access with Secondary Indexes (p. 497).

Step 4.2: Query - All Movies Released in a Year with Certain Titles

The program included in this step retrieves all movies released in year 1992 with title beginning with the letter "A" through the letter "L".

1. Copy the following program and paste it into a file named MoviesQuery02.py.

```python
from pprint import pprint
```

API Version 2012-08-10
189
import boto3
from boto3.dynamodb.conditions import Key

def query_and_project_movies(year, title_range, dynamodb=None):
    if not dynamodb:
        dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")

table = dynamodb.Table('Movies')
print("Get year, title, genres, and lead actor")

# Expression attribute names can only reference items in the projection expression.
response = table.query(
    ProjectionExpression="#yr, title, info.genres, info.actors[0]",
    ExpressionAttributeNames={"#yr": "year"},
    KeyConditionExpression=Key('year').eq(year) & Key('title').between(title_range[0], title_range[1])
)
return response['Items']

if __name__ == '__main__':
    query_year = 1992
    query_range = ('A', 'L')
    print("Get movies from {} with titles from "
f"{} to {}")
    movies = query_and_project_movies(query_year, query_range)
    for movie in movies:
        print("\n{} : {}")
        pprint(movie['info'])

2. To run the program, enter the following command.

    python MoviesQuery02.py

**Step 4.3: Scan**

The *scan* method reads every item in the entire table and returns all the data in the table. You can provide an optional *filter_expression* so that only the items matching your criteria are returned. However, the filter is applied only after the entire table has been scanned.

The following program scans the entire *Movies* table, which contains approximately 5,000 items. The scan specifies the optional filter to retrieve only the movies from the 1950s (approximately 100 items) and discard all the others.

1. Copy the following program and paste it into a file named *MoviesScan.py*.

    from pprint import pprint
    import boto3
    from boto3.dynamodb.conditions import Key

    def scan_movies(year_range, display_movies, dynamodb=None):
        if not dynamodb:
            dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")

table = dynamodb.Table('Movies')
scan_kwargs = {
    'FilterExpression': Key('year').between(*year_range),
    'ProjectionExpression': "#yr, title, info.rating",
    'ExpressionAttributeNames': {"#yr": "year"}
}
Step 5: (Optional) Delete the Table

To delete the Movies table:

1. Copy the following program and paste it into a file named MoviesDeleteTable.py.

```python
import boto3

def delete_movie_table(dynamodb=None):
    API Version 2012-08-10
```

In the code, note the following:

- **ProjectionExpression** specifies the attributes you want in the scan result.
- **FilterExpression** specifies a condition that returns only items that satisfy the condition. All other items are discarded.
- The **scan** method returns a subset of the items each time, called a **page**. The **LastEvaluatedKey** value in the response is then passed to the **scan** method via the **ExclusiveStartKey** parameter. When the last page is returned, **LastEvaluatedKey** is not part of the response.

**Note**

- **ExpressionAttributeNames** provides name substitution. We use this because **year** is a reserved word in DynamoDB—you can't use it directly in any expression, including **KeyConditionExpression**. You can use the expression attribute name #yr to address this.
- **ExpressionAttributeValues** provides value substitution. You use this because you can't use literals in any expression, including **KeyConditionExpression**. You can use the expression attribute value :yyyy to address this.

2. To run the program, enter the following command.

   ```bash
tpthon MoviesScan.py
```

**Note**

You can also use the **Scan** operation with any secondary indexes that you create on the table. For more information, see Improving Data Access with Secondary Indexes (p. 497).

Step 5: (Optional) Delete the Table

To delete the Movies table:

1. Copy the following program and paste it into a file named MoviesDeleteTable.py.
Summary

In this tutorial, you created the Movies table in the downloadable version of Amazon DynamoDB on your computer and performed basic operations. The downloadable version of DynamoDB is useful during application development and testing. However, when you're ready to run your application in a production environment, you must modify your code so that it uses the DynamoDB web service.

Modifying the Code to Use the DynamoDB Service

To use the DynamoDB web service, you must change the endpoint in your application. To do this, modify the following line.

```python
dynamodb = boto3.resource('dynamodb', endpoint_url="http://localhost:8000")
```

For example, if you want to use the us-west-2 Region, change the code to the following.

```python
dynamodb = boto3.resource('dynamodb', region_name='us-west-2')
```

Instead of using the downloadable version of DynamoDB on your computer, the program now uses the DynamoDB web service in the US West (Oregon) Region.

DynamoDB is available in AWS Regions worldwide. For the complete list, see Regions and Endpoints in the AWS General Reference. For more information about setting Regions and endpoints in your code, see AWS Region Selection in the AWS SDK for Java Developer Guide.

Ruby and DynamoDB

In this tutorial, you use the AWS SDK for Ruby to write simple programs to perform the following Amazon DynamoDB operations:

- Create a table called Movies and load sample data in JSON format.
- Perform create, read, update, and delete operations on the table.
- Run simple queries.

As you work through this tutorial, you can refer to the AWS SDK for Ruby API Reference. The DynamoDB section describes the parameters and results for DynamoDB operations.
Tutorial Prerequisites

- Download and run DynamoDB on your computer. For more information, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).
  
  **Note**  
  You use the downloadable version of DynamoDB in this tutorial. For information about how to run the same code against the DynamoDB web service, see the Summary (p. 209).

- Set up an AWS access key to use the AWS SDKs. For more information, see Setting Up DynamoDB (Web Service) (p. 53).

- Set up the AWS SDK for Ruby:
  - Install Ruby.
  - Install the AWS SDK for Ruby.

  For more information, see Installation in the AWS SDK for Ruby API Reference.

Step 1: Create a Table

In this step, you create a table named *Movies* in Amazon DynamoDB. The primary key for the table is composed of the following two attributes:

- **year** – The partition key. The `attribute_type` is `N` for number.
- **title** – The sort key. The `attribute_type` is `S` for string.

1. Copy the following program and paste it into a file named `MoviesCreateTable.rb`.

```ruby
#  Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#  This file is licensed under the Apache License, Version 2.0 (the "License").
#  You may not use this file except in compliance with the License. A copy of
#  the License is located at

#  This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
#  CONDITIONS OF ANY KIND, either express or implied. See the License for the
#  specific language governing permissions and limitations under the License.

require "aws-sdk"
Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})
dynamodb = Aws::DynamoDB::Client.new
params = {
  table_name: "Movies",
  key_schema: [
    {attribute_name: "year",
     key_type: "HASH" #Partition key
    },
    {attribute_name: "title",
     key_type: "RANGE" #Sort key
    }
  ]
}
```

API Version 2012-08-10

193
Step 2: Load Sample Data

In this step, you populate the Movies table in Amazon DynamoDB with sample data.

Topics
- Step 2.1: Download the Sample Data File (p. 195)
- Step 2.2: Load the Sample Data into the Movies Table (p. 196)

You use a sample data file that contains information about a few thousand movies from the Internet Movie Database (IMDb). The movie data is in JSON format, as shown in the following example. For each movie, there is a year, a title, and a JSON map named info.

```json
[
]
```
In the JSON data, note the following:

- The `year` and `title` are used as the primary key attribute values for the `Movies` table.
- You store the rest of the `info` values in a single attribute called `info`. This program illustrates how you can store JSON in a DynamoDB attribute.

The following is an example of movie data.

```json
{
    "year" : 2013,
    "title" : "Turn It Down, Or Else!",
    "info" : {
        "directors" : [
            "Alice Smith",
            "Bob Jones"
        ],
        "release_date" : "2013-01-18T00:00:00Z",
        "rating" : 6.2,
        "genres" : [
            "Comedy",
            "Drama"
        ],
        "image_url" : "http://ia.media-imdb.com/images/N/09EWAU7FSJ7A7L8SHN09AMUF908RL103JF908WR7LJF97Z@@.V1.SX400_.jpg",
        "plot" : "A rock band plays their music at high volumes, annoying the neighbors.",
        "rank" : 11,
        "running_time_secs" : 5215,
        "actors" : [
            "David Matthewman",
            "Ann Thomas",
            "Jonathan G. Neff"
        ]
    }
}
```

### Step 2.1: Download the Sample Data File

1. Download the sample data archive: `moviedata.zip`
2. Extract the data file (`moviedata.json`) from the archive.
3. Copy the `moviedata.json` file and paste it into your current directory.
Step 2.2: Load the Sample Data into the Movies Table

After you download the sample data, run the following program to populate the Movies table.

1. Copy the following program and paste it into a file named MoviesLoadData.rb.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#
# This file is licensed under the Apache License, Version 2.0 (the "License").

# CONDITIONS OF ANY KIND, either express or implied. See the License for the
# specific language governing permissions and limitations under the License.
#
require "aws-sdk"
require "json"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = 'Movies'

file = File.read('moviedata.json')
movies = JSON.parse(file)
movies.each{|movie|
  params = {
    table_name: table_name,
    item: movie
  }

  begin
    dynamodb.put_item(params)
    puts "Added movie: #{movie['year']} #{movie['title']}"
  rescue Aws::DynamoDB::Errors::ServiceError => error
    puts "Unable to add movie:"
    puts "#{error.message}"
  end
}
```

2. To run the program, enter the following command.

   ruby MoviesLoadData.rb

Step 3: Create, Read, Update, and Delete an Item

In this step, you perform read and write operations on an item in the Movies table in Amazon DynamoDB.

To learn more about reading and writing data, see Working with Items and Attributes (p. 375).
Step 3: Create, Read, Update, and Delete an Item

Topics

- Step 3.1: Create a New Item (p. 197)
- Step 3.2: Read an Item (p. 198)
- Step 3.3: Update an Item (p. 199)
- Step 3.4: Increment an Atomic Counter (p. 201)
- Step 3.5: Update an Item (Conditionally) (p. 202)
- Step 3.6: Delete an Item (p. 203)

Step 3.1: Create a New Item

In this step, you add a new item to the table.

1. Copy the following program and paste it into a file named MoviesItemOps01.rb.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#
# This file is licensed under the Apache License, Version 2.0 (the "License").
# You may not use this file except in compliance with the License. A copy of

#
require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = 'Movies'

year = 2015
title = "The Big New Movie"

item = {
  year: year,
  title: title,
  info: {
    plot: "Nothing happens at all.",
    rating: 0
  }
}

params = {
  table_name: table_name,
  item: item
}

begin
  dynamodb.put_item(params)
  puts "Added item: #{year} - #{title}"
end
```

API Version 2012-08-10

197
rescue Aws::DynamoDB::Errors::ServiceError => error
  puts "Unable to add item:"
  puts "#{error.message}"
end

Note
The primary key is required. This code adds an item that has primary key (year, title) and info attributes. The info attribute stores a map that provides more information about the movie.

2. To run the program, enter the following command.

   ruby MoviesItemOps01.rb

Step 3.2: Read an Item

In the previous program, you added the following item to the table.

```
{
  year: 2015,
  title: "The Big New Movie",
  info: {
    plot: "Nothing happens at all.",
    rating: 0
  }
}
```

You can use the get_item method to read the item from the Movies table. You must specify the primary key values so that you can read any item from Movies if you know its year and title.

1. Copy the following program and paste it into a file named MoviesItemOps02.rb.

```
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

#
require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = 'Movies'

year = 2015
title = "The Big New Movie"

params = {
```
table_name: table_name,
key: {
    year: year,
    title: title
}
}

begin
    result = dynamodb.get_item(params)
    printf "%i - %s\n%",
    result.item["year"],
    result.item["title"],
    result.item["info"]["plot"],
    result.item["info"]["rating"]
rescue Aws::DynamoDB::Errors::ServiceError => error
    puts "Unable to read item:"
    puts "#{error.message}"
end

2. To run the program, enter the following command.

   ruby MoviesItemOps02.rb

**Step 3.3: Update an Item**

You can use the `update_item` method to modify an existing item. You can update values of existing attributes, add new attributes, or remove attributes.

In this example, you perform the following updates:

- Change the value of the existing attributes (`rating`, `plot`).
- Add a new list attribute (`actors`) to the existing `info` map.

The following shows the existing item.

```
{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Nothing happens at all.",
        rating: 0
    }
}
```

The item is updated as follows.

```
{
    year: 2015,
    title: "The Big New Movie",
    info: {
        plot: "Everything happens all at once.",
        rating: 5.5,
        actors: ["Larry", "Moe", "Curly"]
    }
}
```

1. Copy the following program and paste it into a file named `MoviesItemOps03.rb`.  

---
require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = 'Movies'

year = 2015

title = "The Big New Movie"

params = {
  table_name: table_name,
  key: {
    year: year,
    title: title
  },
  update_expression: "set info.rating = :r, info.plot=:p, info.actors=:a",
  expression_attribute_values: {
    ":r" => 5.5,
    ":p" => "Everything happens all at once.", # value
    ":a" => ["Larry", "Moe", "Curly"]
  },
  return_values: "UPDATED_NEW"
}

begin
  dynamodb.update_item(params)
  puts "Added item: #{year}  - #{title}"
rescue Aws::DynamoDB::Errors::ServiceError => error
  puts "Unable to add item:"
  puts "#{error.message}"
end

Note
This program uses update_expression to describe all updates you want to perform on the specified item.
The return_values parameter instructs Amazon DynamoDB to return only the updated attributes (UPDATED_NEW).

2. To run the program, enter the following command.

  ruby MoviesItemOps03.rb
Step 3.4: Increment an Atomic Counter

DynamoDB supports atomic counters, which use the `update_item` method to increment or decrement the value of an existing attribute without interfering with other write requests. (All write requests are applied in the order in which they are received.)

The following program shows how to increment the `rating` for a movie. Each time you run the program, it increments this attribute by one.

1. Copy the following program and paste it into a file named `MoviesItemOps04.rb`.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#

#
require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = 'Movies'

year = 2015

title = "The Big New Movie"

params = {
  table_name: table_name,
  key: {
    year: year,
    title: title
  },
  update_expression: "set info.rating = info.rating + :val",
  expression_attribute_values: {
    ":val" => 1
  },
  return_values: "UPDATED_NEW"
}

begin
  result = dynamodb.update_item(params)
  puts "Updated item. ReturnValues are:"
  result.attributes["info"].each do |key, value|
    if key == "rating"
      puts "#{key}: #{value.to_f}"    
    else
      puts "#{key}: #{value}"    
    end
  end
rescue Aws::DynamoDB::Errors::ServiceError => error
  puts "Unable to update item:
```
2. To run the program, enter the following command.

    ruby MoviesItemOps04.rb

**Step 3.5: Update an Item (Conditionally)**

The following program shows how to use `update_item` with a condition. If the condition evaluates to true, the update succeeds; otherwise, the update is not performed.

In this case, the item is updated only if the number of actors is greater than three.

1. Copy the following program and paste it into a file named `MoviesItemOps05.rb`.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#
# This file is licensed under the Apache License, Version 2.0 (the "License").
# You may not use this file except in compliance with the License. A copy of
# the License is located at

#
# This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
# CONDITIONS OF ANY KIND, either express or implied. See the License for the
# specific language governing permissions and limitations under the License.
#
require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = 'Movies'

year = 2015
title = "The Big New Movie"

params = {
  table_name: table_name,
  key: {
    year: year,
    title: title
  },
  update_expression: "remove info.actors[0]",
  condition_expression: "size(info.actors) > :num",
  expression_attribute_values: {
    ":num" => 3
  },
  return_values: "UPDATED_NEW"
}

begin
  result = dynamodb.update_item(params)
  puts "Updated item. ReturnValues are:"
  result.attributes["info"].each do |key, value|
    if key == "rating"
      puts "#{value}
    end
  end

  if result.success
    puts "Update succeeded.""}
To run the program, enter the following command.

```ruby
ruby MoviesItemOps05.rb
```

The program should fail with the following message.

The conditional request failed

The program fails because the movie has three actors in it, but the condition is checking for greater than three actors.

3. Modify the program so that the `ConditionExpression` looks like the following.

```ruby
condition_expression: "size(info.actors) >= :num",
```

The condition is now greater than or equal to 3 instead of greater than 3.

4. Run the program again. The `update_item` method should now succeed.

### Step 3.6: Delete an Item

You can use the `delete_item` method to delete one item by specifying its primary key. You can optionally provide a `condition_expression` to prevent the item from being deleted if the condition is not met.

In the following example, you try to delete a specific movie item if its rating is 5 or less.

1. Copy the following program and paste it into a file named `MoviesItemOps06.rb`.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
# This file is licensed under the Apache License, Version 2.0 (the "License").
# You may not use this file except in compliance with the License. A copy of
# the License is located at
# http://aws.amazon.com/apache2.0/
# This file is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
# CONDITIONS OF ANY KIND, either express or implied. See the License for the
# specific language governing permissions and limitations under the License.
# require "aws-sdk"

AWS.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new
```
table_name = 'Movies'
year = 2015
title = "The Big New Movie"

params = {
    table_name: table_name,
    key: {
        year: year,
        title: title
    },
    condition_expression: "info.rating <= :val",
    expression_attribute_values: {
        ':val' => 5
    }
}

begin
    dynamodb.delete_item(params)
    puts "Deleted item."
rescue Aws::DynamoDB::Errors::ServiceError => error
    puts "Unable to update item:"
    puts "#{error.message}"
end

2. To run the program, enter the following command.

    ruby MoviesItemOps06.rb

The program should fail with the following message.

    The conditional request failed

3. Modify the program to remove the condition.

    params = {
        table_name: "Movies",
        key: {
            year: year,
            title: title
        }
    }

4. Run the program. Now, the delete succeeds because you removed the condition.

Step 4: Query and Scan the Data

You can use the query method to retrieve data from a table. You must specify a partition key value. The sort key is optional.

The primary key for the Movies table is composed of the following:

- **year** – The partition key. The attribute type is number.
- **title** – The sort key. The attribute type is string.
To find all movies released during a year, you need to specify only the year. You can also provide the title to retrieve a subset of movies based on some condition (on the sort key). For example, you can find movies released in 2014 that have a title starting with the letter "A".

In addition to the query method, you can use the scan method to retrieve all of the table data.

To learn more about querying and scanning data, see Working with Queries in DynamoDB (p. 459) and Working with Scans in DynamoDB (p. 476), respectively.

Topics
• Step 4.1: Query - All Movies Released in a Year (p. 205)
• Step 4.2: Query - All Movies Released in a Year with Certain Titles (p. 206)
• Step 4.3: Scan (p. 207)

Step 4.1: Query - All Movies Released in a Year

The following program retrieves all movies released in the year 1985.

1. Copy the following program and paste it into a file named MoviesQuery01.rb.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#

#
require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

table_name = "Movies"

params = {
  table_name: table_name,
  key_condition_expression: "#yr = :yyy",
  expression_attribute_names: {
    "#yr" => "year"
  },
  expression_attribute_values: {
    ":yyy" => 1985
  }
}

puts "Querying for movies from 1985.;"

begin
  result = dynamodb.query(params)
  puts "Query succeeded."
end
```

Amazon DynamoDB Developer Guide
Step 4: Query and Scan the Data

result.items.each{|movie|
puts "#{movie["year"].to_i} #{movie["title"]}"
}
rescue Aws::DynamoDB::Errors::ServiceError => error
puts "Unable to query table:"
puts "#{error.message}"
end

Note
• expression_attribute_names provides name substitution. We use this because year
is a reserved word in Amazon DynamoDB. You can't use it directly in any expression,
including KeyConditionExpression. You can use the expression attribute name #yr to
address this.
• expression_attribute_values provides value substitution. You use this because you
can't use literals in any expression, including key_condition_expression. You can use
the expression attribute value :yyyy to address this.
2.

To run the program, enter the following command.
ruby MoviesItemQuery01.rb

Note

The preceding program shows how to query a table by its primary key attributes. In DynamoDB,
you can optionally create one or more secondary indexes on a table and query those indexes
in the same way that you query a table. Secondary indexes give your applications additional
ﬂexibility by allowing queries on non-key attributes. For more information, see Improving Data
Access with Secondary Indexes (p. 497).

Step 4.2: Query - All Movies Released in a Year with Certain
Titles
The following program retrieves all movies released in year 1992 with a title beginning with the
letter "A" through the letter "L".
1.

Copy the following program and paste it into a ﬁle named MoviesQuery02.rb.

  }
}

puts "Querying for movies from 1992 - titles A-L, with genres and lead actor";

begin
  result = dynamodb.query(params)
  puts "Query succeeded."

  result.items.each{|movie|
    print "#{movie["year"].to_i}: #{movie["title"]} ... "
    movie["info"]['genres'].each{|gen|
      print gen + " 
    }
    print " ... #{movie["info"]['actors'][0]}\n"
  }
rescueAws::DynamoDB::Errors::ServiceError => error
  puts "Unable to query table:"
  puts "#{error.message}"
end

2. To run the program, enter the following command.

    ruby MoviesQuery02.rb

**Step 4.3: Scan**

The **scan** method reads every item in the entire table and returns all the data in the table. You can provide an optional **filter_expression** so that only the items matching your criteria are returned. However, note that the filter is only applied after the entire table has been scanned.

The following program scans the **Movies** table, which contains approximately 5,000 items. The scan specifies the optional filter to retrieve only the movies from the 1950s (approximately 100 items) and discard all the others.

1. Copy the following program and paste it into a file named **MoviesScan.rb**.

```ruby
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
# This file is licensed under the Apache License, Version 2.0 (the "License").
# You may not use this file except in compliance with the License. A copy of
```
In the code, note the following:

- **projection_expression** specifies the attributes you want in the scan result.
- **filter_expression** specifies a condition that returns only items that satisfy the condition. All other items are discarded.

2. To run the program, enter the following command.

    ruby MoviesScan.rb
Note

You can also use the scan method with any secondary indexes that you create on the table. For more information, see Improving Data Access with Secondary Indexes (p. 497).

Step 5: (Optional) Delete the Table

Follow these steps to delete the Movies table.

1. Copy the following program and paste it into a file named MoviesDeleteTable.rb.

```ruby
#
# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.
#
# This file is licensed under the Apache License, Version 2.0 (the "License").

require "aws-sdk"

Aws.config.update({
  region: "us-west-2",
  endpoint: "http://localhost:8000"
})

dynamodb = Aws::DynamoDB::Client.new

params = {
  table_name: "Movies"
}

begin
  dynamodb.delete_table(params)
  puts "Deleted table."
rescue Aws::DynamoDB::Errors::ServiceError => error
  puts "Unable to delete table:"
  puts "#{error.message}"
end
```

2. To run the program, enter the following command.

```
ruby MoviesDeleteTable.rb
```

Summary

In this tutorial, you created the Movies table in the downloadable version of Amazon DynamoDB on your computer and performed basic operations. The downloadable version of DynamoDB is useful during application development and testing. However, when you're ready to run your application in a production environment, you must modify your code so that it uses the DynamoDB web service.
Modifying the Code to Use the DynamoDB Service

To use the DynamoDB service, you must change the endpoint in your application. To do this, find the following lines in the code.

```javascript
Aws.config.update({
    region: "us-west-2",
    endpoint: "http://localhost:8000"
});
```

Remove the `endpoint` parameter so that the code looks like the following.

```javascript
Aws.config.update({
    region: "us-west-2"
});
```

After you remove this line, the code can access the DynamoDB service in the AWS Region specified by the `region` config value.

Instead of using the version of DynamoDB on your computer, the program uses the DynamoDB web service endpoint in the US West (Oregon) Region.

DynamoDB is available in AWS Regions worldwide. For the complete list, see Regions and Endpoints in the AWS General Reference. For more information, see the AWS SDK for Ruby Getting Started Guide.
Programming with DynamoDB and the AWS SDKs

This section covers developer-related topics. If you want to run code examples instead, see Running the Code Examples in This Developer Guide (p. 325).

Note
In December 2017, AWS began the process of migrating all Amazon DynamoDB endpoints to use secure certificates issued by Amazon Trust Services (ATS). For more information, see Troubleshooting SSL/TLS connection establishment issues (p. 972).

Overview of AWS SDK Support for DynamoDB

The following diagram provides a high-level overview of Amazon DynamoDB application programming using the AWS SDKs.
1. You write an application using an AWS SDK for your programming language.

2. Each AWS SDK provides one or more programmatic interfaces for working with DynamoDB. The specific interfaces available depend on which programming language and AWS SDK you use.

3. The AWS SDK constructs HTTP(S) requests for use with the low-level DynamoDB API.

4. The AWS SDK sends the request to the DynamoDB endpoint.

5. DynamoDB executes the request. If the request is successful, DynamoDB returns an HTTP 200 response code (OK). If the request is unsuccessful, DynamoDB returns an HTTP error code and an error message.

6. The AWS SDK processes the response and propagates it back to your application.

Each of the AWS SDKs provides important services to your application, including the following:

- Formatting HTTP(S) requests and serializing request parameters.
- Generating a cryptographic signature for each request.
- Forwarding requests to a DynamoDB endpoint and receiving responses from DynamoDB.
• Extracting the results from those responses.
• Implementing basic retry logic in case of errors.

You do not need to write code for any of these tasks.

**Note**
For more information about AWS SDKs, including installation instructions and documentation, see [Tools for Amazon Web Services](#).

**Programmatic Interfaces**

![Diagram of programmatic interfaces](image)

Every AWS SDK provides one or more programmatic interfaces for working with Amazon DynamoDB. These interfaces range from simple low-level DynamoDB wrappers to object-oriented persistence layers. The available interfaces vary depending on the AWS SDK and programming language that you use.

The following section highlights some of the interfaces available, using the AWS SDK for Java as an example. (Not all interfaces are available in all AWS SDKs.)

**Topics**
Low-Level Interfaces

Every language-specific AWS SDK provides a low-level interface for Amazon DynamoDB, with methods that closely resemble low-level DynamoDB API requests.

In some cases, you will need to identify the data types of the attributes using Data Type Descriptors (p. 219), such as S for string or N for number.

Note
A low-level interface is available in every language-specific AWS SDK.

The following Java program uses the low-level interface of the AWS SDK for Java. The program issues a GetItem request for a song in the Music table and prints the year that the song was released.

The com.amazonaws.services.dynamodbv2.AmazonDynamoDB class implements the DynamoDB low-level interface.

```java
package com.amazonaws.codesamples;
import java.util.HashMap;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;
public class MusicLowLevelDemo {
    public static void main(String[] args) {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Call Me Today"));
        GetItemRequest request = new GetItemRequest()
            .withTableName("Music")
            .withKey(key);
        try {
            GetItemResult result = client.getItem(request);
            if (result && result.getItem() != null) {
                AttributeValue year = result.getItem().get("Year");
                System.out.println("The song was released in " + year.getN());
            } else {
                System.out.println("No matching song was found");
            }
        } catch (Exception e) {
            System.err.println("Unable to retrieve data: ");
            System.err.println(e.getMessage());
        }
    }
}
```
Document Interfaces

Many AWS SDKs provide a document interface, allowing you to perform data plane operations (create, read, update, delete) on tables and indexes. With a document interface, you do not need to specify Data Type Descriptors (p. 219). The data types are implied by the semantics of the data itself. These AWS SDKs also provide methods to easily convert JSON documents to and from native Amazon DynamoDB data types.

**Note** Document interfaces are available in the AWS SDKs for Java, .NET, Node.js, and JavaScript in the browser.

The following Java program uses the document interface of the AWS SDK for Java. The program creates a Table object that represents the Music table, and then asks that object to use GetItem to retrieve a song. The program then prints the year that the song was released.

The com.amazonaws.services.dynamodbv2.document.DynamoDB class implements the DynamoDB document interface. Note how DynamoDB acts as a wrapper around the low-level client (AmazonDynamoDB).

```java
package com.amazonaws.codesamples.gsg;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.GetItemOutcome;
import com.amazonaws.services.dynamodbv2.document.Table;

public class MusicDocumentDemo {
    public static void main(String[] args) {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
        DynamoDB docClient = new DynamoDB(client);
        Table table = docClient.getTable("Music");
        GetItemOutcome outcome = table.getItemOutcome("Artist", "No One You Know",
                                                        "SongTitle", "Call Me Today");
        int year = outcome.getItem().getInt("Year");
        System.out.println("The song was released in "+ year);
    }
}
```

Object Persistence Interface

Some AWS SDKs provide an object persistence interface where you do not directly perform data plane operations. Instead, you create objects that represent items in Amazon DynamoDB tables and indexes, and interact only with those objects. This allows you to write object-centric code, rather than database-centric code.

**Note** Object persistence interfaces are available in the AWS SDKs for Java and .NET. For more information, see Higher-Level Programming Interfaces for DynamoDB (p. 226).

The following Java program uses DynamoDBMapper, the object persistence interface of the AWS SDK for Java. The MusicItem class represents an item in the Music table.

```java
package com.amazonaws.codesamples;
```
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBAttribute;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBRangeKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;

@DynamoDBTable(tableName="Music")
public class MusicItem {
    private String artist;
    private String songTitle;
    private String albumTitle;
    private int year;

    @DynamoDBHashKey(attributeName="Artist")
    public String getArtist() { return artist;}
    public void setArtist(String artist) {this.artist = artist;}

    @DynamoDBRangeKey(attributeName="SongTitle")
    public String getSongTitle() { return songTitle;}
    public void setSongTitle(String songTitle) {this.songTitle = songTitle;}

    @DynamoDBAttribute(attributeName = "AlbumTitle")
    public String getAlbumTitle() { return albumTitle;}
    public void setAlbumTitle(String albumTitle) {this.albumTitle = albumTitle;}

    @DynamoDBAttribute(attributeName = "Year")
    public int getYear() { return year; }
    public void setYear(int year) { this.year = year; }
}

You can then instantiate a MusicItem object, and retrieve a song using the load() method of DynamoDBMapper. The program then prints the year that the song was released.

The com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper class implements the DynamoDB object persistence interface. Note how DynamoDBMapper acts as a wrapper around the low-level client (AmazonDynamoDB).

package com.amazonaws.codesamples;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;

public class MusicMapperDemo {
    public static void main(String[] args) {
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
        DynamoDBMapper mapper = new DynamoDBMapper(client);
        MusicItem keySchema = new MusicItem();
        keySchema.setArtist("No One You Know");
        keySchema.setSongTitle("Call Me Today");
        try {
            MusicItem result = mapper.load(keySchema);
            if (result != null) {
                System.out.println("The song was released in "+ result.getYear());
            } else {
                System.out.println("No matching song was found");
            }
        }
DynamoDB Low-Level API

Topics
- Request Format (p. 218)
- Response Format (p. 219)
- Data Type Descriptors (p. 219)
- Numeric Data (p. 220)
- Binary Data (p. 220)
The Amazon DynamoDB low-level API is the protocol-level interface for DynamoDB. At this level, every HTTP(S) request must be correctly formatted and carry a valid digital signature.

The AWS SDKs construct low-level DynamoDB API requests on your behalf and process the responses from DynamoDB. This lets you focus on your application logic, instead of low-level details. However, you can still benefit from a basic knowledge of how the low-level DynamoDB API works.

For more information about the low-level DynamoDB API, see Amazon DynamoDB API Reference.

**Note**
DynamoDB Streams has its own low-level API, which is separate from that of DynamoDB and is fully supported by the AWS SDKs. For more information, see Capturing Table Activity with DynamoDB Streams (p. 574). For the low-level DynamoDB Streams API, see the Amazon DynamoDB Streams API Reference.

The low-level DynamoDB API uses JavaScript Object Notation (JSON) as a wire protocol format. JSON presents data in a hierarchy so that both data values and data structure are conveyed simultaneously. Name-value pairs are defined in the format `name:value`. The data hierarchy is defined by nested brackets of name-value pairs.

DynamoDB uses JSON only as a transport protocol, not as a storage format. The AWS SDKs use JSON to send data to DynamoDB, and DynamoDB responds with JSON. DynamoDB does not store data persistently in JSON format.

**Note**
For more information about JSON, see Introducing JSON on the JSON.org website.

## Request Format

The DynamoDB low-level API accepts HTTP(S) POST requests as input. The AWS SDKs construct these requests for you.

Suppose that you have a table named `Pets`, with a key schema consisting of `AnimalType` (partition key) and `Name` (sort key). Both of these attributes are of type `string`. To retrieve an item from `Pets`, the AWS SDK constructs the following request.

```plaintext
POST / HTTP/1.1
Host: dynamodb.<region>.<domain>
Accept-Encoding: identity
Content-Length: <PayloadSizeBytes>
User-Agent: <UserAgentString>
Content-Type: application/x-amz-json-1.0
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>, Signature=<Signature>
X-Amz-Date: <Date>
X-Amz-Target: DynamoDB_20120810.GetItem

{
    "TableName": "Pets",
    "Key": {
        "AnimalType": {"S": "Dog"},
        "Name": {"S": "Fido"}
    }
}
```

Note the following about this request:

- The `Authorization` header contains information required for DynamoDB to authenticate the request. For more information, see Signing AWS API Requests and Signature Version 4 Signing Process in the Amazon Web Services General Reference.
• The X-Amz-Target header contains the name of a DynamoDB operation: GetItem. (This is also accompanied by the low-level API version, in this case 20120810.)

• The payload (body) of the request contains the parameters for the operation, in JSON format. For the GetItem operation, the parameters are TableName and Key.

Response Format

Upon receipt of the request, DynamoDB processes it and returns a response. For the request shown previously, the HTTP(S) response payload contains the results from the operation, as shown in the following example.

```
HTTP/1.1 200 OK
x-amzn-RequestId: <RequestId>
x-amz-crc32: <Checksum>
Content-Type: application/x-amz-json-1.0
Content-Length: <PayloadSizeBytes>
Date: <Date>
{
  "Item": {
    "Age": {"N": "8"},
    "Colors": {
      "L": [
        {"S": "White"},
        {"S": "Brown"},
        {"S": "Black"}
      ]
    },
    "Name": {"S": "Fido"},
    "Vaccinations": {
      "M": {
        "Rabies": {"L": [
          {"S": "2009-03-17"},
          {"S": "2011-09-21"},
          {"S": "2014-07-08"}
        ]
      },
      "Distemper": {"S": "2015-10-13"}
    },
    "Breed": {"S": "Beagle"},
    "AnimalType": {"S": "Dog"}
  }
}
```

At this point, the AWS SDK returns the response data to your application for further processing.

**Note**

If DynamoDB can’t process a request, it returns an HTTP error code and message. The AWS SDK propagates these to your application in the form of exceptions. For more information, see Error Handling with DynamoDB (p. 220).

Data Type Descriptors

The low-level DynamoDB API protocol requires each attribute to be accompanied by a data type descriptor. *Data type descriptors* are tokens that tell DynamoDB how to interpret each attribute.

The examples in Request Format (p. 218) and Response Format (p. 219) show examples of how data type descriptors are used. The GetItem request specifies S for the Pets key schema attributes.
(AnimalType and Name), which are of type string. The GetItem response contains a Pets item with attributes of type string (S), number (N), map (M), and list (L).

The following is a complete list of DynamoDB data type descriptors:

- **S** – String
- **N** – Number
- **B** – Binary
- **BOOL** – Boolean
- **NULL** – Null
- **M** – Map
- **L** – List
- **SS** – String Set
- **NS** – Number Set
- **BS** – Binary Set

**Note**
For detailed descriptions of DynamoDB data types, see Data Types (p. 13).

## Numeric Data

Different programming languages offer different levels of support for JSON. In some cases, you might decide to use a third-party library for validating and parsing JSON documents.

Some third-party libraries build upon the JSON number type, providing their own types such as int, long, or double. However, the native number data type in DynamoDB does not map exactly to these other data types, so these type distinctions can cause conflicts. In addition, many JSON libraries do not handle fixed-precision numeric values, and they automatically infer a double data type for digit sequences that contain a decimal point.

To solve these problems, DynamoDB provides a single numeric type with no data loss. To avoid unwanted implicit conversions to a double value, DynamoDB uses strings for the data transfer of numeric values. This approach provides flexibility for updating attribute values while maintaining proper sorting semantics, such as putting the values "01", "2", and "03" in the proper sequence.

If number precision is important to your application, you should convert numeric values to strings before you pass them to DynamoDB.

## Binary Data

DynamoDB supports binary attributes. However, JSON does not natively support encoding binary data. To send binary data in a request, you will need to encode it in base64 format. Upon receiving the request, DynamoDB decodes the base64 data back to binary.

The base64 encoding scheme used by DynamoDB is described at RFC 4648 on the Internet Engineering Task Force (IETF) website.

## Error Handling with DynamoDB

This section describes runtime errors and how to handle them. It also describes error messages and codes that are specific to Amazon DynamoDB.
Topics

- Error Components (p. 221)
- Error Messages and Codes (p. 221)
- Error Handling in Your Application (p. 224)
- Error Retries and Exponential Backoff (p. 225)
- Batch Operations and Error Handling (p. 225)

Error Components

When your program sends a request, DynamoDB attempts to process it. If the request is successful, DynamoDB returns an HTTP success status code (200 OK), along with the results from the requested operation.

If the request is unsuccessful, DynamoDB returns an error. Each error has three components:

- An HTTP status code (such as 400).
- An exception name (such as ResourceNotFoundException).
- An error message (such as Requested resource not found: Table: tablename not found).

The AWS SDKs take care of propagating errors to your application so that you can take appropriate action. For example, in a Java program, you can write try-catch logic to handle a ResourceNotFoundException.

If you are not using an AWS SDK, you need to parse the content of the low-level response from DynamoDB. The following is an example of such a response.

HTTP/1.1 400 Bad Request
x-amzn-RequestId: LDM6CJP8RMQ1FHKSC1RBVJFPNVV49QNR05AEMF66Q9ASUAAJG
Content-Type: application/x-amz-json-1.0
Content-Length: 240
Date: Thu, 15 Mar 2012 23:56:23 GMT

{"__type":"com.amazonaws.dynamodb.v20120810#ResourceNotFoundException",
"message":"Requested resource not found: Table: tablename not found"}

Error Messages and Codes

The following is a list of exceptions returned by DynamoDB, grouped by HTTP status code. If OK to retry? is Yes, you can submit the same request again. If OK to retry? is No, you need to fix the problem on the client side before you submit a new request.

HTTP Status Code 400

An HTTP 400 status code indicates a problem with your request, such as authentication failure, missing required parameters, or exceeding a table's provisioned throughput. You have to fix the issue in your application before submitting the request again.

AccessDeniedException

Message: Access denied.

The client did not correctly sign the request. If you are using an AWS SDK, requests are signed for you automatically; otherwise, go to the Signature Version 4 Signing Process in the AWS General Reference.
OK to retry? No

**ConditionalCheckFailedException**

Message: *The conditional request failed.*

You specified a condition that evaluated to false. For example, you might have tried to perform a conditional update on an item, but the actual value of the attribute did not match the expected value in the condition.

OK to retry? No

**IncompleteSignatureException**

Message: *The request signature does not conform to AWS standards.*

The request signature did not include all of the required components. If you are using an AWS SDK, requests are signed for you automatically; otherwise, go to the Signature Version 4 Signing Process in the AWS General Reference.

OK to retry? No

**ItemCollectionSizeLimitExceedededException**

Message: *Collection size exceeded.*

For a table with a local secondary index, a group of items with the same partition key value has exceeded the maximum size limit of 10 GB. For more information on item collections, see Item Collections (p. 545).

OK to retry? Yes

**LimitExceededException**

Message: *Too many operations for a given subscriber.*

There are too many concurrent control plane operations. The cumulative number of tables and indexes in the CREATING, DELETING, or UPDATING state cannot exceed 50.

OK to retry? Yes

**MissingAuthenticationTokenException**

Message: *Request must contain a valid (registered) AWS Access Key ID.*

The request did not include the required authorization header, or it was malformed. See DynamoDB Low-Level API (p. 217).

OK to retry? No

**ProvisionedThroughputExceededException**

Message: *You exceeded your maximum allowed provisioned throughput for a table or for one or more global secondary indexes. To view performance metrics for provisioned throughput vs. consumed throughput, open the Amazon CloudWatch console.*
Example: Your request rate is too high. The AWS SDKs for DynamoDB automatically retry requests that receive this exception. Your request is eventually successful, unless your retry queue is too large to finish. Reduce the frequency of requests using Error Retries and Exponential Backoff (p. 225).

OK to retry? Yes

RequestLimitExceeded

Message: Throughput exceeds the current throughput limit for your account. To request a limit increase, contact AWS Support at https://aws.amazon.com/support.

Example: Rate of on-demand requests exceeds the allowed account throughput.

OK to retry? Yes

ResourceInUseException

Message: The resource which you are attempting to change is in use.

Example: You tried to re-create an existing table, or delete a table currently in the CREATING state.

OK to retry? No

ResourceNotFoundException

Message: Requested resource not found.

Example: The table that is being requested does not exist, or is too early in the CREATING state.

OK to retry? No

ThrottlingException

Message: Rate of requests exceeds the allowed throughput.

This exception is returned as an AmazonServiceException response with a THROTTLING_EXCEPTION status code. This exception might be returned if you perform control plane API operations too rapidly.

For tables using on-demand mode, this exception might be returned for any data plane API operation if your request rate is too high. To learn more about on-demand scaling, see Peak Traffic and Scaling Properties

OK to retry? Yes

UnrecognizedClientException

Message: The Access Key ID or security token is invalid.

The request signature is incorrect. The most likely cause is an invalid AWS access key ID or secret key.

OK to retry? Yes

ValidationException

Message: Varies, depending upon the specific error(s) encountered
This error can occur for several reasons, such as a required parameter that is missing, a value that is out of range, or mismatched data types. The error message contains details about the specific part of the request that caused the error.

OK to retry? No

**HTTP Status Code 5xx**

An HTTP 5xx status code indicates a problem that must be resolved by AWS. This might be a transient error, in which case you can retry your request until it succeeds. Otherwise, go to the AWS Service Health Dashboard to see if there are any operational issues with the service.

**Internal Server Error (HTTP 500)**

DynamoDB could not process your request.

OK to retry? Yes

*Note*

You might encounter internal server errors while working with items. These are expected during the lifetime of a table. Any failed requests can be retried immediately.

**Service Unavailable (HTTP 503)**

DynamoDB is currently unavailable. (This should be a temporary state.)

OK to retry? Yes

**Error Handling in Your Application**

For your application to run smoothly, you need to add logic to catch and respond to errors. Typical approaches include using `try-catch` blocks or `if-then` statements.

The AWS SDKs perform their own retries and error checking. If you encounter an error while using one of the AWS SDKs, the error code and description can help you troubleshoot it.

You should also see a Request ID in the response. The Request ID can be helpful if you need to work with AWS Support to diagnose an issue.

The following Java code example tries to get an item from a DynamoDB table and performs rudimentary error handling. (In this case, it simply informs the user that the request failed.)

```java
Table table = dynamoDB.getTable("Movies");

try {
    Item item = table.getItem("year", 1978, "title", "Superman");
    if (item != null) {
        System.out.println("Result: " + item);
    } else {
        // No such item exists in the table
        System.out.println("Item not found");
    }
} catch (AmazonServiceException ase) {
    System.err.println("Could not complete operation");
    System.err.println("Error Message: " + ase.getMessage());
    System.err.println("HTTP Status: " + ase.getStatusCode());
}
In this code example, the try–catch construct handles two different kinds of exceptions:

- `AmazonServiceException`—Thrown if the client request was correctly transmitted to DynamoDB, but DynamoDB could not process the request and returned an error response instead.
- `AmazonClientException`—Thrown if the client could not get a response from a service, or if the client could not parse the response from a service.

### Error Retries and Exponential Backoff

Numerous components on a network, such as DNS servers, switches, load balancers, and others, can generate errors anywhere in the life of a given request. The usual technique for dealing with these error responses in a networked environment is to implement retries in the client application. This technique increases the reliability of the application.

Each AWS SDK implements retry logic automatically. You can modify the retry parameters to your needs. For example, consider a Java application that requires a fail-fast strategy, with no retries allowed in case of an error. With the AWS SDK for Java, you could use the `ClientConfiguration` class and provide a `maxErrorRetry` value of 0 to turn off the retries. For more information, see the AWS SDK documentation for your programming language.

If you're not using an AWS SDK, you should retry original requests that receive server errors (5xx). However, client errors (4xx, other than a `ThrottlingException` or a `ProvisionedThroughputExceededException`) indicate that you need to revise the request itself to correct the problem before trying again.

In addition to simple retries, each AWS SDK implements an exponential backoff algorithm for better flow control. The concept behind exponential backoff is to use progressively longer waits between retries for consecutive error responses. For example, up to 50 milliseconds before the first retry, up to 100 milliseconds before the second, up to 200 milliseconds before third, and so on. However, after a minute, if the request has not succeeded, the problem might be the request size exceeding your provisioned throughput, and not the request rate. Set the maximum number of retries to stop around one minute. If the request is not successful, investigate your provisioned throughput options.

**Note**
The AWS SDKs implement automatic retry logic and exponential backoff.

Most exponential backoff algorithms use jitter (randomized delay) to prevent successive collisions. Because you aren't trying to avoid such collisions in these cases, you do not need to use this random number. However, if you use concurrent clients, jitter can help your requests succeed faster. For more information, see the blog post about Exponential Backoff and Jitter.

### Batch Operations and Error Handling

The DynamoDB low-level API supports batch operations for reads and writes. `BatchGetItem` reads items from one or more tables, and `BatchWriteItem` puts or deletes items in one or more tables. These batch operations are implemented as wrappers around other non-batch DynamoDB operations. In other words, `BatchGetItem` invokes `GetItem` once for each item in the batch. Similarly, `BatchWriteItem` invokes `DeleteItem` or `PutItem`, as appropriate, for each item in the batch.
A batch operation can tolerate the failure of individual requests in the batch. For example, consider a BatchGetItem request to read five items. Even if some of the underlying GetItem requests fail, this does not cause the entire BatchGetItem operation to fail. However, if all five read operations fail, then the entire BatchGetItem fails.

The batch operations return information about individual requests that fail so that you can diagnose the problem and retry the operation. For BatchGetItem, the tables and primary keys in question are returned in the UnprocessedKeys value of the response. For BatchWriteItem, similar information is returned in UnprocessedItems.

The most likely cause of a failed read or a failed write is throttling. For BatchGetItem, one or more of the tables in the batch request does not have enough provisioned read capacity to support the operation. For BatchWriteItem, one or more of the tables does not have enough provisioned write capacity.

If DynamoDB returns any unprocessed items, you should retry the batch operation on those items. However, we strongly recommend that you use an exponential backoff algorithm. If you retry the batch operation immediately, the underlying read or write requests can still fail due to throttling on the individual tables. If you delay the batch operation using exponential backoff, the individual requests in the batch are much more likely to succeed.

Higher-Level Programming Interfaces for DynamoDB

The AWS SDKs provide applications with low-level interfaces for working with Amazon DynamoDB. These client-side classes and methods correspond directly to the low-level DynamoDB API. However, many developers experience a sense of disconnect, or impedance mismatch, when they need to map complex data types to items in a database table. With a low-level database interface, developers must write methods for reading or writing object data to database tables, and vice versa. The amount of extra code required for each combination of object type and database table can seem overwhelming.

To simplify development, the AWS SDKs for Java and .NET provide additional interfaces with higher levels of abstraction. The higher-level interfaces for DynamoDB let you define the relationships between objects in your program and the database tables that store those objects' data. After you define this mapping, you can call simple object methods such as save, load, or delete, and the underlying low-level DynamoDB operations are automatically invoked on your behalf. This allows you to write object-centric code, rather than database-centric code.

The higher-level programming interfaces for DynamoDB are available in the AWS SDKs for Java and .NET.

Java: DynamoDBMapper

Topics
The AWS SDK for Java provides a `DynamoDBMapper` class, allowing you to map your client-side classes to Amazon DynamoDB tables. To use `DynamoDBMapper`, you define the relationship between items in a DynamoDB table and their corresponding object instances in your code. The `DynamoDBMapper` class enables you to access your tables; perform various create, read, update, and delete (CRUD) operations; and execute queries.

**Note**

The `DynamoDBMapper` class does not allow you to create, update, or delete tables. To perform those tasks, use the low-level SDK for Java interface instead. For more information, see Working with DynamoDB Tables in Java (p. 363).

The SDK for Java provides a set of annotation types so that you can map your classes to tables. For example, consider a `ProductCatalog` table that has `Id` as the partition key.

```java
ProductCatalog(Id, ...)
```

You can map a class in your client application to the `ProductCatalog` table as shown in the following Java code. This code defines a plain old Java object (POJO) named `CatalogItem`, which uses annotations to map object fields to DynamoDB attribute names.

**Example**

```java
package com.amazonaws.codesamples;
import java.util.Set;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBAttribute;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIgnore;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;

@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {
    private Integer id;
    private String title;
    private String ISBN;
    private Set<String> bookAuthors;
    private String someProp;

    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() { return id; }
    public void setId(Integer id) {this.id = id; }

    @DynamoDBAttribute(attributeName="Title")
    @DynamoDBIgnore
    public String getTitle() { return title; }
    public void setTitle(String title) {this.title = title; }

    // Other getters and setters...
}
```
public String getTitle() {return title; }
public void setTitle(String title) { this.title = title; }

@DynamoDBAttribute(attributeName="ISBN")
public String getISBN() { return ISBN; }

@DynamoDBAttribute(attributeName="Authors")
public Set<String> getBookAuthors() { return bookAuthors; }
public void setBookAuthors(Set<String> bookAuthors) { this.bookAuthors = bookAuthors; }

@DynamoDBIgnore
public String getSomeProp() { return someProp; }
public void setSomeProp(String someProp) { this.someProp = someProp; }
}

In the preceding code, the @DynamoDBTable annotation maps the CatalogItem class to the ProductCatalog table. You can store individual class instances as items in the table. In the class definition, the @DynamoDBHashKey annotation maps the Id property to the primary key.

By default, the class properties map to the same name attributes in the table. The properties Title and ISBN map to the same name attributes in the table.

The @DynamoDBAttribute annotation is optional when the name of the DynamoDB attribute matches the name of the property declared in the class. When they differ, use this annotation with the attributeName() parameter to specify which DynamoDB attribute this property corresponds to.

In the preceding example, the @DynamoDBAttribute annotation is added to each property to ensure that the property names match exactly with the tables created in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), and to be consistent with the attribute names used in other code examples in this guide.

Your class definition can have properties that don't map to any attributes in the table. You identify these properties by adding the @DynamoDBIgnore annotation. In the preceding example, the SomeProp property is marked with the @DynamoDBIgnore annotation. When you upload a CatalogItem instance to the table, your DynamoDBMapper instance does not include the SomeProp property. In addition, the mapper does not return this attribute when you retrieve an item from the table.

After you define your mapping class, you can use DynamoDBMapper methods to write an instance of that class to a corresponding item in the Catalog table. The following code example demonstrates this technique.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDBMapper mapper = new DynamoDBMapper(client);

CatalogItem item = new CatalogItem();
item.setId(102);
item.setTitle("Book 102 Title");
item.setISBN("222-2222222222");
item.setBookAuthors(new HashSet<String>(Arrays.asList("Author 1", "Author 2")));
item.setSomeProp("Test");
mapper.save(item);
```

The following code example shows how to retrieve the item and access some of its attributes.

```java
CatalogItem partitionKey = new CatalogItem();
partitionKey.setId(102);
```
DynamoDBMapper offers an intuitive, natural way of working with DynamoDB data within Java. It also provides several built-in features, such as optimistic locking, ACID transactions, autogenerated partition key and sort key values, and object versioning.

**Supported Data Types**

This section describes the supported primitive Java data types, collections, and arbitrary data types in Amazon DynamoDB.

Amazon DynamoDB supports the following primitive Java data types and primitive wrapper classes.

- String
- Boolean, boolean
- Byte, byte
- Date (as ISO_8601 millisecond-precision string, shifted to UTC)
- Calendar (as ISO_8601 millisecond-precision string, shifted to UTC)
- Long, long
- Integer, int
- Double, double
- Float, float
- BigDecimal
- BigInteger

**Note**

- For more information about DynamoDB naming rules and the various supported data types, see Naming Rules and Data Types (p. 12).
- Empty Binary values are supported by the DynamoDBMapper.
- Empty String values are supported by AWS SDK for Java 2.0.

In AWS SDK for Java 1.0, DynamoDBMapper supports reading of empty String attribute values, however, it will not write empty String attribute values because these attributes are dropped from the request.

DynamoDB supports the Java `Set`, `List`, and `Map` collection types. The following table summarizes how these Java types map to the DynamoDB types.

<table>
<thead>
<tr>
<th>Java type</th>
<th>DynamoDB type</th>
</tr>
</thead>
<tbody>
<tr>
<td>All number types</td>
<td>N (number type)</td>
</tr>
<tr>
<td>Strings</td>
<td>S (string type)</td>
</tr>
<tr>
<td>Java type</td>
<td>DynamoDB type</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>Boolean</td>
<td>BOOL (Boolean type), 0 or 1.</td>
</tr>
<tr>
<td>ByteBuffer</td>
<td>B (binary type)</td>
</tr>
<tr>
<td>Date</td>
<td>S (string type). The Date values are stored as ISO-8601 formatted strings.</td>
</tr>
<tr>
<td>Set collection types</td>
<td>SS (string set type), NS (number set type), or BS (binary set type).</td>
</tr>
</tbody>
</table>

The `DynamoDBTypeConverter` interface lets you map your own arbitrary data types to a data type that is natively supported by DynamoDB. For more information, see Mapping Arbitrary Data (p. 270).

**Java Annotations for DynamoDB**

This section describes the annotations that are available for mapping your classes and properties to tables and attributes in Amazon DynamoDB.

For the corresponding Javadoc documentation, see Annotation Types Summary in the AWS SDK for Java API Reference.

**Note**

In the following annotations, only `DynamoDBTable` and the `DynamoDBHashKey` are required.

**Topics**

- `DynamoDBAttribute` (p. 230)
- `DynamoDBAutoGeneratedKey` (p. 231)
- `DynamoDBDocument` (p. 231)
- `DynamoDBHashKey` (p. 232)
- `DynamoDBIgnore` (p. 233)
- `DynamoDBIndexHashKey` (p. 233)
- `DynamoDBIndexRangeKey` (p. 233)
- `DynamoDBRangeKey` (p. 233)
- `DynamoDBTable` (p. 234)
- `DynamoDBTypeConverted` (p. 234)
- `DynamoDBTyped` (p. 234)
- `DynamoDBVersionAttribute` (p. 234)

**DynamoDBAttribute**

Maps a property to a table attribute. By default, each class property maps to an item attribute with the same name. However, if the names are not the same, you can use this annotation to map a property to the attribute. In the following Java snippet, the `DynamoDBAttribute` maps the `BookAuthors` property to the `Authors` attribute name in the table.

```java
@DynamoDBAttribute(attributeName = "Authors")
public List<String> getBookAuthors() { return BookAuthors; }
public void setBookAuthors(List<String> BookAuthors) { this.BookAuthors = BookAuthors; }
```

The `DynamoDBMapper` uses `Authors` as the attribute name when saving the object to the table.
DynamoDBAutoGeneratedKey

Marks a partition key or sort key property as being autogenerated. DynamoDBMapper generates a random UUID when saving these attributes. Only String properties can be marked as autogenerated keys.

The following example demonstrates using autogenerated keys.

```java
@DynamoDBTable(tableName="AutoGeneratedKeysExample")
public class AutoGeneratedKeys {
    private String id;
    private String payload;

    @DynamoDBHashKey(attributeName = "Id")
    @DynamoDBAutoGeneratedKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    @DynamoDBAttribute(attributeName="payload")
    public String getPayload() { return this.payload; }
    public void setPayload(String payload) { this.payload = payload; }

    public static void saveItem() {
        AutoGeneratedKeys obj = new AutoGeneratedKeys();
        obj.setPayload("abc123");
        // id field is null at this point
        DynamoDBMapper mapper = new DynamoDBMapper(dynamoDBClient);
        mapper.save(obj);
        System.out.println("Object was saved with id " + obj.getId());
    }
}
```

DynamoDBDocument

Indicates that a class can be serialized as an Amazon DynamoDB document.

For example, suppose that you wanted to map a JSON document to a DynamoDB attribute of type Map (M). The following code example defines an item containing a nested attribute (Pictures) of type Map.

```java
public class ProductCatalogItem {
    private Integer id;  //partition key
    private Pictures pictures;  
    /* ...other attributes omitted... */

    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() { return id; }
    public void setId(Integer id) {this.id = id;}

    @DynamoDBAttribute(attributeName="Pictures")
    public Pictures getPictures() { return pictures; }
    public void setPictures(Pictures pictures) {this.pictures = pictures; }

    // Additional properties go here.

    @DynamoDBDocument
    public static class Pictures {
        private String frontView;
        private String rearView;
        private String sideView;
    }
}
```
You could then save a new ProductCatalog item, with Pictures, as shown in the following example.

```java
ProductCatalogItem item = new ProductCatalogItem();
Pictures pix = new Pictures();
pix.setFrontView("http://example.com/products/123_front.jpg");
pix.setRearView("http://example.com/products/123_rear.jpg");
pix.setSideView("http://example.com/products/123_left_side.jpg");
item.setPictures(pix);
item.setId(123);
mapper.save(item);
```

The resulting ProductCatalog item would look like the following (in JSON format).

```
{
  "Id" : 123
  "Pictures" : {
    "RearView" : "http://example.com/products/123_rear.jpg",
    "FrontView" : "http://example.com/products/123_front.jpg"
  }
}
```

**DynamoDBHashKey**

Maps a class property to the partition key of the table. The property must be one of the scalar string, number, or binary types. The property can't be a collection type.

Assume that you have a table, ProductCatalog, that has Id as the primary key. The following Java code defines a CatalogItem class and maps its Id property to the primary key of the ProductCatalog table using the @DynamoDBHashKey tag.

```java
@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {
  private Integer Id;
  @DynamoDBHashKey(attributeName="Id")
  public Integer getId() {
    return Id;
  }
  public void setId(Integer Id) {
    this.Id = Id;
  }
  // Additional properties go here.
}
```
DynamoDBIgnore

Indicates to the DynamoDBMapper instance that the associated property should be ignored. When saving data to the table, the DynamoDBMapper does not save this property to the table.

Applied to the getter method or the class field for a non-modeled property. If the annotation is applied directly to the class field, the corresponding getter and setter must be declared in the same class.

DynamoDBIndexHashKey

Maps a class property to the partition key of a global secondary index. The property must be one of the scalar string, number, or binary types. The property can't be a collection type.

Use this annotation if you need to Query a global secondary index. You must specify the index name (globalSecondaryIndexName). If the name of the class property is different from the index partition key, you also must specify the name of that index attribute (attributeName).

DynamoDBIndexRangeKey

Maps a class property to the sort key of a global secondary index or a local secondary index. The property must be one of the scalar string, number, or binary types. The property can't be a collection type.

Use this annotation if you need to Query a local secondary index or a global secondary index and want to refine your results using the index sort key. You must specify the index name (either globalSecondaryIndexName or localSecondaryIndexName). If the name of the class property is different from the index sort key, you must also specify the name of that index attribute (attributeName).

DynamoDBRangeKey

Maps a class property to the sort key of the table. The property must be one of the scalar string, number, or binary types. It cannot be a collection type.

If the primary key is composite (partition key and sort key), you can use this tag to map your class field to the sort key. For example, assume that you have a Reply table that stores replies for forum threads. Each thread can have many replies. So the primary key of this table is both the ThreadId and ReplyDateTime. The ThreadId is the partition key, and ReplyDateTime is the sort key.

The following Java code defines a Reply class and maps it to the Reply table. It uses both the @DynamoDBHashKey and @DynamoDBRangeKey tags to identify class properties that map to the primary key.

```java
@DynamoDBTable(tableName="Reply")
public class Reply {
    private Integer id;
    private String replyDateTime;

    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() { return id; }
    public void setId(Integer id) { this.id = id; }

    @DynamoDBRangeKey(attributeName="ReplyDateTime")
    public String getReplyDateTime() { return replyDateTime; }
    public void setReplyDateTime(String replyDateTime) { this.replyDateTime = replyDateTime; }
}
```
// Additional properties go here.
}

DynamoDBTable

Identifies the target table in DynamoDB. For example, the following Java code defines a class Developer and maps it to the People table in DynamoDB.

```java
@DynamoDBTable(tableName="People")
public class Developer { ...}
```

The @DynamoDBTable annotation can be inherited. Any new class that inherits from the Developer class also maps to the People table. For example, assume that you create a Lead class that inherits from the Developer class. Because you mapped the Developer class to the People table, the Lead class objects are also stored in the same table.

The @DynamoDBTable can also be overridden. Any new class that inherits from the Developer class by default maps to the same People table. However, you can override this default mapping. For example, if you create a class that inherits from the Developer class, you can explicitly map it to another table by adding the @DynamoDBTable annotation as shown in the following Java code example.

```java
@DynamoDBTable(tableName="Managers")
public class Manager extends Developer { ...}
```

DynamoDBTypeConverted

An annotation to mark a property as using a custom type converter. Can be annotated on a user-defined annotation to pass additional properties to the DynamoDBTypeConverter.

The DynamoDBTypeConverter interface lets you map your own arbitrary data types to a data type that is natively supported by DynamoDB. For more information, see Mapping Arbitrary Data (p. 270).

DynamoDBTyped

An annotation to override the standard attribute type binding. Standard types do not require the annotation if applying the default attribute binding for that type.

DynamoDBVersionAttribute

Identifies a class property for storing an optimistic locking version number. DynamoDBMapper assigns a version number to this property when it saves a new item, and increments it each time you update the item. Only number scalar types are supported. For more information about data types, see Data Types (p. 13). For more information about versioning, see Optimistic Locking with Version Number (p. 268).

DynamoDBMapper Class

The DynamoDBMapper class is the entry point to Amazon DynamoDB. It provides access to a DynamoDB endpoint and enables you to access your data in various tables. It also enables you to perform various create, read, update, and delete (CRUD) operations on items, and execute queries and scans against tables. This class provides the following methods for working with DynamoDB.

For the corresponding Javadoc documentation, see DynamoDBMapper in the AWS SDK for Java API Reference.
Topics

- save (p. 235)
- load (p. 235)
- delete (p. 236)
- query (p. 236)
- queryPage (p. 237)
- scan (p. 237)
- scanPage (p. 238)
- parallelScan (p. 238)
- batchSave (p. 239)
- batchLoad (p. 239)
- batchDelete (p. 239)
- batchWrite (p. 240)
- transactionWrite (p. 240)
- transactionLoad (p. 241)
- count (p. 241)
- generateCreateTableRequest (p. 241)
- createS3Link (p. 241)
- getS3ClientCache (p. 242)

**save**

Saves the specified object to the table. The object that you want to save is the only required parameter for this method. You can provide optional configuration parameters using the `DynamoDBMapperConfig` object.

If an item that has the same primary key does not exist, this method creates a new item in the table. If an item that has the same primary key exists, it updates the existing item. If the partition key and sort key are of type String and are annotated with `@DynamoDBAutoGeneratedKey`, they are given a random universally unique identifier (UUID) if left uninitialized. Version fields that are annotated with `@DynamoDBVersionAttribute` are incremented by one. Additionally, if a version field is updated or a key generated, the object passed in is updated as a result of the operation.

By default, only attributes corresponding to mapped class properties are updated. Any additional existing attributes on an item are unaffected. However, if you specify `SaveBehavior.CLOBBER`, you can force the item to be completely overwritten.

```java
mapper.save(obj, new DynamoDBMapperConfig(DynamoDBMapperConfig.SaveBehavior.CLOBBER));
```

If you have versioning enabled, the client-side and server-side item versions must match. However, the version does not need to match if the `SaveBehavior.CLOBBER` option is used. For more information about versioning, see Optimistic Locking with Version Number (p. 268).

**load**

Retrieves an item from a table. You must provide the primary key of the item that you want to retrieve. You can provide optional configuration parameters using the `DynamoDBMapperConfig` object. For example, you can optionally request strongly consistent reads to ensure that this method retrieves only the latest item values as shown in the following Java statement.
CatalogItem item = mapper.load(CatalogItem.class, item.getId(),
    new DynamoDBMapperConfig(DynamoDBMapperConfig.ConsistentReads.CONSISTENT));

By default, DynamoDB returns the item that has values that are eventually consistent. For information about the eventual consistency model of DynamoDB, see Read Consistency (p. 16).

delete

Deletes an item from the table. You must pass in an object instance of the mapped class.

If you have versioning enabled, the client-side and server-side item versions must match. However, the version does not need to match if the SaveBehavior.CLOBBER option is used. For more information about versioning, see Optimistic Locking with Version Number (p. 268).

query

Queries a table or a secondary index. You can query a table or an index only if it has a composite primary key (partition key and sort key). This method requires you to provide a partition key value and a query filter that is applied on the sort key. A filter expression includes a condition and a value.

Assume that you have a table, Reply, that stores forum thread replies. Each thread subject can have zero or more replies. The primary key of the Reply table consists of the Id and ReplyDateTime fields, where Id is the partition key and ReplyDateTime is the sort key of the primary key.

Assume that you created a mapping between a Reply class and the corresponding Reply table in DynamoDB. The following Java code uses DynamoDBMapper to find all replies in the past two weeks for a specific thread subject.

Example

String forumName = "&DDB;";
String forumSubject = "&DDB; Thread 1";
String partitionKey = forumName + "#" + forumSubject;
long twoWeeksAgoMilli = (new Date()).getTime() - (14L*24L*60L*60L*1000L);
Date twoWeeksAgo = new Date();
twoWeeksAgo.setT ime(twoWeeksAgoMilli);
SimpleDateFormat df = new SimpleDateFormat("yyyy-MM-dd'T'HH:mm:ss.SSS'Z'");
String twoWeeksAgoStr = df.format(twoWeeksAgo);
Map<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
eav.put(":v1", new AttributeValue().withS(partitionKey));
eav.put(":v2", new AttributeValue().withS(twoWeeksAgoStr.toString()));
DynamoDBQueryExpression<Reply> queryExpression = new DynamoDBQueryExpression<Reply>()
    .withKeyConditionExpression("Id = :v1 and ReplyDateTime > :v2")
    .withExpressionAttributeValues(eav);
List<Reply> latestReplies = mapper.query(Reply.class, queryExpression);

The query returns a collection of Reply objects.

By default, the query method returns a "lazy-loaded" collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, iterate over the latestReplies collection.
To query an index, you must first model the index as a mapper class. Suppose that the Reply table has a global secondary index named PostedBy-Message-Index. The partition key for this index is PostedBy, and the sort key is Message. The class definition for an item in the index would look like the following.

```java
@DynamoDBTable(tableName="Reply")
public class PostedByMessage {
    private String postedBy;
    private String message;

    @DynamoDBIndexHashKey(globalSecondaryIndexName = "PostedBy-Message-Index",
                          attributeName = "PostedBy")
    public String getPostedBy() { return postedBy; }
    public void setPostedBy(String postedBy) { this.postedBy = postedBy; }

    @DynamoDBIndexRangeKey(globalSecondaryIndexName = "PostedBy-Message-Index",
                          attributeName = "Message")
    public String getMessage() { return message; }
    public void setMessage(String message) { this.message = message; }

    // Additional properties go here.
}
```

The `@DynamoDBTable` annotation indicates that this index is associated with the Reply table. The `@DynamoDBIndexHashKey` annotation denotes the partition key (PostedBy) of the index, and the `@DynamoDBIndexRangeKey` denotes the sort key (Message) of the index.

Now you can use DynamoDBMapper to query the index, retrieving a subset of messages that were posted by a particular user. You must specify `withIndexName` so that DynamoDB knows which index to query. The following code queries a global secondary index. Because global secondary indexes support eventually consistent reads but not strongly consistent reads, you must specify `withConsistentRead(false)`.

```java
HashMap<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
eav.put(":v1", new AttributeValue().withS("User A"));
eav.put(":v2", new AttributeValue().withS("DynamoDB"));

DynamoDBQueryExpression<PostedByMessage> queryExpression = new DynamoDBQueryExpression<PostedByMessage>()
    .withIndexName("PostedBy-Message-Index")
    .withConsistentRead(false)
    .withKeyConditionExpression("PostedBy = :v1 and begins_with(Message, :v2)"
    .withExpressionAttributeValues(eav);
List<PostedByMessage> iList = mapper.query(PostedByMessage.class, queryExpression);
```

The query returns a collection of PostedByMessage objects.

**queryPage**

Queries a table or secondary index and returns a single page of matching results. As with the `query` method, you must specify a partition key value and a query filter that is applied on the sort key attribute. However, `queryPage` returns only the first "page" of data, that is, the amount of data that fits in 1 MB.

**scan**

Scans an entire table or a secondary index. You can optionally specify a `FilterExpression` to filter the result set.

Assume that you have a table, Reply, that stores forum thread replies. Each thread subject can have zero or more replies. The primary key of the Reply table consists of the Id and ReplyDateTime fields, where Id is the partition key and ReplyDateTime is the sort key of the primary key.
Reply (Id, ReplyDateTime, ...)

If you mapped a Java class to the Reply table, you can use the DynamoDBMapper to scan the table. For example, the following Java code scans the entire Reply table, returning only the replies for a particular year.

**Example**

```java
HashMap<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
eav.put(':v1', new AttributeValue().withS("2015"));

DynamoDBScanExpression scanExpression = new DynamoDBScanExpression()
    .withFilterExpression("begins_with(ReplyDateTime,:v1)"
    .withExpressionAttributeValues(eav);
List<Reply> replies = mapper.scan(Reply.class, scanExpression);
```

By default, the `scan` method returns a "lazy-loaded" collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, iterate over the replies collection.

To scan an index, you must first model the index as a mapper class. Suppose that the Reply table has a global secondary index named PostedBy-Message-Index. The partition key for this index is PostedBy, and the sort key is Message. A mapper class for this index is shown in the query (p. 236) section. It uses the `@DynamoDBIndexHashKey` and `@DynamoDBIndexRangeKey` annotations to specify the index partition key and sort key.

The following code example scans PostedBy-Message-Index. It does not use a scan filter, so all of the items in the index are returned to you.

```java
DynamoDBScanExpression scanExpression = new DynamoDBScanExpression()
    .withIndexName("PostedBy-Message-Index")
    .withConsistentRead(false);
List<PostedByMessage> iList = mapper.scan(PostedByMessage.class, scanExpression);
```

**scanPage**

Scans a table or secondary index and returns a single page of matching results. As with the `scan` method, you can optionally specify a `FilterExpression` to filter the result set. However, `scanPage` only returns the first "page" of data, that is, the amount of data that fits within 1 MB.

**parallelScan**

Performs a parallel scan of an entire table or secondary index. You specify a number of logical segments for the table, along with a scan expression to filter the results. The `parallelScan` divides the scan task among multiple workers, one for each logical segment; the workers process the data in parallel and return the results.

The following Java code example performs a parallel scan on the Product table.
DynamoDBScanExpression scanExpression = new DynamoDBScanExpression()
    .withFilterExpression("Price <= :n")
    .withExpressionAttributeValues(eav);
List<Product> scanResult = mapper.parallelScan(Product.class, scanExpression, numberOfThreads);

For a Java code example illustrating the usage of parallelScan, see Example: Query and Scan (p. 252).

batchSave

Saves objects to one or more tables using one or more calls to the AmazonDynamoDB.batchWriteItem method. This method does not provide transaction guarantees.

The following Java code saves two items (books) to the ProductCatalog table.

Book book1 = new Book();
book1.id = 901;
book1.productCategory = "Book";
book1.title = "Book 901 Title";

Book book2 = new Book();
book2.id = 902;
book2.productCategory = "Book";
book2.title = "Book 902 Title";
mapper.batchSave(Arrays.asList(book1, book2));

batchLoad

Retrieves multiple items from one or more tables using their primary keys.

The following Java code retrieves two items from two different tables.

ArrayList<Object> itemsToGet = new ArrayList<Object>();
ForumItem forumItem = new ForumItem();
forumItem.setForumName("Amazon DynamoDB");
itemsToGet.add(forumItem);

ThreadItem threadItem = new ThreadItem();
threadItem.setForumName("Amazon DynamoDB");
threadItem.setSubject("Amazon DynamoDB thread 1 message text");
itemsToGet.add(threadItem);
Map<String, List<Object>> items = mapper.batchLoad(itemsToGet);

batchDelete

Deletes objects from one or more tables using one or more calls to the AmazonDynamoDB.batchWriteItem method. This method does not provide transaction guarantees.

The following Java code deletes two items (books) from the ProductCatalog table.

Book book1 = mapper.load(Book.class, 901);
Book book2 = mapper.load(Book.class, 902);
mapper.batchDelete(Arrays.asList(book1, book2));

**batchWrite**

Saves objects to and deletes objects from one or more tables using one or more calls to the AmazonDynamoDB.batchWriteItem method. This method does not provide transaction guarantees or support versioning (conditional puts or deletes).

The following Java code writes a new item to the Forum table, writes a new item to the Thread table, and deletes an item from the ProductCatalog table.

```java
// Create a Forum item to save
Forum forumItem = new Forum();
forumItem.name = "Test BatchWrite Forum";

// Create a Thread item to save
Thread threadItem = new Thread();
threadItem.forumName = "AmazonDynamoDB";
threadItem.subject = "My sample question";

// Load a ProductCatalog item to delete
Book book3 = mapper.load(Book.class, 903);
List<Object> objectsToWrite = Arrays.asList(forumItem, threadItem);
List<Book> objectsToDelete = Arrays.asList(book3);
mapper.batchWrite(objectsToWrite, objectsToDelete);
```

**transactionWrite**

Saves objects to and deletes objects from one or more tables using one call to the AmazonDynamoDB.transactWriteItems method.

For a list of transaction-specific exceptions, see TransactWriteItems errors.

For more information about DynamoDB transactions and the provided atomicity, consistency, isolation, and durability (ACID) guarantees see Amazon DynamoDB Transactions.

**Note**

This method does not support the following:

- DynamoDBMapperConfig.SaveBehavior.

The following Java code writes a new item to each of the Forum and Thread tables, transactionally.

```java
Thread s3ForumThread = new Thread();
s3ForumThread.forumName = "S3 Forum";
s3ForumThread.subject = "Sample Subject 1";
s3ForumThread.message = "Sample Question 1";

Forum s3Forum = new Forum();
s3Forum.name = "S3 Forum";
s3Forum.category = "Amazon Web Services";
s3Forum.threads = 1;

TransactionWriteRequest transactionWriteRequest = new TransactionWriteRequest();
transactionWriteRequest.addPut(s3Forum);
transactionWriteRequest.addPut(s3ForumThread);
mapper.transactionWrite(transactionWriteRequest);
```
transactionLoad

Loads objects from one or more tables using one call to the AmazonDynamoDB.transactGetItems method.

For a list of transaction-specific exceptions, see TransactGetItems errors.

For more information about DynamoDB transactions and the provided atomicity, consistency, isolation, and durability (ACID) guarantees see Amazon DynamoDB Transactions.

The following Java code loads one item from each of the Forum and Thread tables, transactionally.

```java
Forum dynamodbForum = new Forum();
dynamodbForum.name = "DynamoDB Forum";
Thread dynamodbForumThread = new Thread();
dynamodbForumThread.forumName = "DynamoDB Forum";

TransactionLoadRequest transactionLoadRequest = new TransactionLoadRequest();
transactionLoadRequest.addLoad(dynamodbForum);
transactionLoadRequest.addLoad(dynamodbForumThread);
mapper.transactionLoad(transactionLoadRequest);
```

count

Evaluates the specified scan expression and returns the count of matching items. No item data is returned.

generateCreateTableRequest

Parses a POJO class that represents a DynamoDB table, and returns a CreateTableRequest for that table.

createS3Link

Creates a link to an object in Amazon S3. You must specify a bucket name and a key name, which uniquely identifies the object in the bucket.

To use createS3Link, your mapper class must define getter and setter methods. The following code example illustrates this by adding a new attribute and getter/setter methods to the CatalogItem class.

```java
@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {
    ...

    public S3Link productImage;
    ....

    @DynamoDBAttribute(attributeName = "ProductImage")
    public S3Link getProductImage() {
        return productImage;
    }

    public void setProductImage(S3Link productImage) {
        this.productImage = productImage;
    }

    ...
```
The following Java code defines a new item to be written to the Product table. The item includes a link to a product image; the image data is uploaded to Amazon S3.

```java
CatalogItem item = new CatalogItem();
item.id = 150;
item.title = "Book 150 Title";
String myS3Bucket = "myS3bucket";
String myS3Key = "productImages/book_150_cover.jpg";
item.setProductImage(mapper.createS3Link(myS3Bucket, myS3Key));
item.getProductImage().uploadFrom(new File("/file/path/book_150_cover.jpg"));
mapper.save(item);
```

The S3Link class provides many other methods for manipulating objects in Amazon S3. For more information, see the Javadocs for S3Link.

**getS3ClientCache**

Returns the underlying S3ClientCache for accessing Amazon S3. An S3ClientCache is a smart Map for AmazonS3Client objects. If you have multiple clients, an S3ClientCache can help you keep the clients organized by AWS Region, and can create new Amazon S3 clients on demand.

### Optional Configuration Settings for DynamoDBMapper

When you create an instance of DynamoDBMapper, it has certain default behaviors; you can override these defaults by using the DynamoDBMapperConfig class.

The following code snippet creates a DynamoDBMapper with custom settings:

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDBMapperConfig mapperConfig = DynamoDBMapperConfig.builder()
    .withSaveBehavior(DynamoDBMapperConfig.SaveBehavior.CLOBBER)
    .withConsistentReads(DynamoDBMapperConfig.ConsistentReads.CONSISTENT)
    .withTableNameOverride(null)
    .withPaginationLoadingStrategy(DynamoDBMapperConfig.PaginationLoadingStrategy.EAGER_LOADING)
    .build();
DynamoDBMapper mapper = new DynamoDBMapper(client, mapperConfig);
```

For more information, see DynamoDBMapperConfig in the AWS SDK for Java API Reference.

You can use the following arguments for an instance of DynamoDBMapperConfig:

- A DynamoDBMapperConfig.ConsistentReads enumeration value:
  - EVENTUAL—the mapper instance uses an eventually consistent read request.
  - CONSISTENT—the mapper instance uses a strongly consistent read request. You can use this optional setting with load, query, or scan operations. Strongly consistent reads have implications for performance and billing; see the DynamoDB product detail page for more information.

  If you do not specify a read consistency setting for your mapper instance, the default is EVENTUAL.

- A DynamoDBMapperConfig.PaginationLoadingStrategy enumeration value—Controls how the mapper instance processes a paginated list of data, such as the results from a query or scan:
• **LAZY_LOADING**—the mapper instance loads data when possible, and keeps all loaded results in memory.

• **EAGER_LOADING**—the mapper instance loads the data as soon as the list is initialized.

• **ITERATION_ONLY**—you can only use an Iterator to read from the list. During the iteration, the list will clear all the previous results before loading the next page, so that the list will keep at most one page of the loaded results in memory. This also means the list can only be iterated once. This strategy is recommended when handling large items, in order to reduce memory overhead.

If you do not specify a pagination loading strategy for your mapper instance, the default is **LAZY_LOADING**.

• A **DynamoDBMapperConfig.SaveBehavior** enumeration value - Specifies how the mapper instance should deal with attributes during save operations:
  
  • **UPDATE**—during a save operation, all modeled attributes are updated, and unmodeled attributes are unaffected. Primitive number types (byte, int, long) are set to 0. Object types are set to null.
  
  • **CLOBBER**—clears and replaces all attributes, included unmodeled ones, during a save operation. This is done by deleting the item and re-creating it. Versioned field constraints are also disregarded.

If you do not specify the save behavior for your mapper instance, the default is **UPDATE**.

**Note**

DynamoDBMapper transactional operations do not support
DynamoDBMapperConfig.SaveBehavior enumeration.

• A **DynamoDBMapperConfig.TableNameOverride** object—Instructs the mapper instance to ignore the table name specified by a class's **DynamoDBTable** annotation, and instead use a different table name that you supply. This is useful when partitioning your data into multiple tables at runtime.

You can override the default configuration object for DynamoDBMapper per operation, as needed.

**Example: CRUD Operations**

The following Java code example declares a **CatalogItem** class that has **Id**, **Title**, **ISBN**, and **Authors** properties. It uses the annotations to map these properties to the **ProductCatalog** table in DynamoDB. The example then uses the **DynamoDBMapper** to save a book object, retrieve it, update it, and then delete the book item.

**Note**

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section.

For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

Example: Batch Write Operations

The following Java code example declares Book, Forum, Thread, and Reply classes and maps them to the Amazon DynamoDB tables using the DynamoDBMapper class.

The code illustrates the following batch write operations:

- batchSave to put book items in the ProductCatalog table.
- batchDelete to delete items from the ProductCatalog table.
- batchWrite to put and delete items from the Forum and the Thread tables.

For more information about the tables used in this example, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326). For step-by-step instructions for testing the following example, see Java Code Examples (p. 331).

## Example: Query and Scan

The Java example in this section defines the following classes and maps them to the tables in Amazon DynamoDB. For more information about creating sample tables, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

- The `Book` class maps to `ProductCatalog` table
- The `Forum`, `Thread`, and `Reply` classes map to tables of the same name.

The example then executes the follow query and scan operations using a `DynamoDBMapper` instance.

- Get a book by `Id`.
  - The `ProductCatalog` table has `Id` as its primary key. It does not have a sort key as part of its primary key. Therefore, you cannot query the table. You can get an item using its `Id` value.
- Execute the following queries against the `Reply` table.
  - The `Reply` table's primary key is composed of `Id` and `ReplyDateTime` attributes. `ReplyDateTime` is a sort key. Therefore, you can query this table.
  - Find replies to a forum thread posted in the last 15 days.
  - Find replies to a forum thread posted in a specific date range.
  - Scan the `ProductCatalog` table to find books whose price is less than a specified value.

For performance reasons, you should use the query operation instead of the scan operation. However, there are times you might need to scan a table. Suppose that there was a data entry error and one of the book prices was set to less than 0. This example scans the `ProductCategory` table to find book items (`ProductCategory` is book) whose price is less than 0.

- Perform a parallel scan of the `ProductCatalog` table to find bicycles of a specific type.

### Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section.

For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

Example: Transaction Operations

The following Java code example declares a Forum and a Thread class and maps them to the DynamoDB tables using the DynamoDBMapper class.

The code illustrates the following transactional operations:

- `transactionWrite` to add, update, and delete multiple items from one or more tables in one transaction.
- `transactionLoad` to retrieve multiple items from one or more tables in one transaction.

Example

```java
public void setCategory(String category) {
    this.category = category;
}

@DynamoDBAttribute(attributeName = "Threads")
public int getThreads() {
    return threads;
}

public void setThreads(int threads) {
    this.threads = threads;
}
}

**Optimistic Locking with Version Number**

*Optimistic locking* is a strategy to ensure that the client-side item that you are updating (or deleting) is the same as the item in Amazon DynamoDB. If you use this strategy, your database writes are protected from being overwritten by the writes of others, and vice versa.

With optimistic locking, each item has an attribute that acts as a version number. If you retrieve an item from a table, the application records the version number of that item. You can update the item, but only if the version number on the server side has not changed. If there is a version mismatch, it means that someone else has modified the item before you did. The update attempt fails, because you have a stale version of the item. If this happens, you simply try again by retrieving the item and then trying to update it. Optimistic locking prevents you from accidentally overwriting changes that were made by others. It also prevents others from accidentally overwriting your changes.

To support optimistic locking, the AWS SDK for Java provides the `@DynamoDBVersionAttribute` annotation. In the mapping class for your table, you designate one property to store the version number, and mark it using this annotation. When you save an object, the corresponding item in the DynamoDB table will have an attribute that stores the version number. The `DynamoDBMapper` assigns a version number when you first save the object, and it automatically increments the version number each time you update the item. Your update or delete requests succeed only if the client-side object version matches the corresponding version number of the item in the DynamoDB table.

`ConditionalCheckFailedException` is thrown if:

- You use optimistic locking with `@DynamoDBVersionAttribute` and the version value on the server is different from the value on the client side.
- You specify your own conditional constraints while saving data by using `DynamoDBMapper` with `DynamoDBSaveExpression` and these constraints failed.

**Note**

- DynamoDB global tables use a “last writer wins” reconciliation between concurrent updates. If you use global tables, last writer policy wins. So in this case, the locking strategy does not work as expected.
- `DynamoDBMapper` transactional write operations do not support `@DynamoDBVersionAttribute` annotation and condition expressions within
the same API call. If an object within a transactional write is annotated with
@DynamoDBVersionAttribute and also has a condition expression, then an
SdkClientException will be thrown.

For example, the following Java code defines a CatalogItem class that has several properties. The
Version property is tagged with the @DynamoDBVersionAttribute annotation.

Example

```java
@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {

    private Integer id;
    private String title;
    private String ISBN;
    private Set<String> bookAuthors;
    private String someProp;
    private Long version;

    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() { return id; }
    public void setId(Integer Id) { this.id = Id; }

    @DynamoDBAttribute(attributeName="Title")
    public String getTitle() { return title; }
    public void setTitle(String title) { this.title = title; }

    @DynamoDBAttribute(attributeName="ISBN")
    public String getISBN() { return ISBN; }

    @DynamoDBAttribute(attributeName = "Authors")
    public Set<String> getBookAuthors() { return bookAuthors; }
    public void setBookAuthors(Set<String> bookAuthors) { this.bookAuthors = bookAuthors; }

    @DynamoDBIgnore
    public String getSomeProp() { return someProp; }
    public void setSomeProp(String someProp) { this.someProp = someProp; }

    @DynamoDBVersionAttribute
    public Long getVersion() { return version; }
    public void setVersion(Long version) { this.version = version; }
}
```

You can apply the @DynamoDBVersionAttribute annotation to nullable types provided by the
primitive wrappers classes that provide a nullable type, such as Long and Integer.

Optimistic locking has the following impact on these DynamoDBMapper methods:

- **save** — For a new item, the DynamoDBMapper assigns an initial version number of 1. If you
  retrieve an item, update one or more of its properties, and attempt to save the changes, the save
  operation succeeds only if the version number on the client side and the server side match. The
  DynamoDBMapper increments the version number automatically.

- **delete** — The delete method takes an object as a parameter, and the DynamoDBMapper
  performs a version check before deleting the item. The version check can be disabled if
  DynamoDBMapperConfig.SaveBehavior.CLOBBER is specified in the request.

  The internal implementation of optimistic locking within DynamoDBMapper uses conditional update
  and conditional delete support provided by DynamoDB.

- **transactionWrite** —
- **Put** — For a new item, the DynamoDBMapper assigns an initial version number of 1. If you retrieve an item, update one or more of its properties, and attempt to save the changes, the put operation succeeds only if the version number on the client side and the server side match. The DynamoDBMapper increments the version number automatically.

- **Update** — For a new item, the DynamoDBMapper assigns an initial version number of 1. If you retrieve an item, update one or more of its properties, and attempt to save the changes, the update operation succeeds only if the version number on the client side and the server side match. The DynamoDBMapper increments the version number automatically.

- **Delete** — The DynamoDBMapper performs a version check before deleting the item. The delete operation succeeds only if the version number on the client side and the server side match.

- **ConditionCheck** — The @DynamoDBVersionAttribute annotation is not supported for ConditionCheck operations. An SdkClientException will be thrown when a ConditionCheck item is annotated with @DynamoDBVersionAttribute.

### Disabling Optimistic Locking

To disable optimistic locking, you can change the DynamoDBMapperConfig.SaveBehavior enumeration value from `UPDATE` to `CLOBBER`. You can do this by creating a DynamoDBMapperConfig instance that skips version checking and use this instance for all your requests. For information about DynamoDBMapperConfig.SaveBehavior and other optional DynamoDBMapper parameters, see Optional Configuration Settings for DynamoDBMapper (p. 242).

You can also set locking behavior for a specific operation only. For example, the following Java snippet uses the DynamoDBMapper to save a catalog item. It specifies DynamoDBMapperConfig.SaveBehavior by adding the optional DynamoDBMapperConfig parameter to the save method.

**Note**
The transactionWrite method does not support DynamoDBMapperConfig.SaveBehavior configuration. Disabling optimistic locking for transactionWrite is not supported.

#### Example

```java
DynamoDBMapper mapper = new DynamoDBMapper(client);

// Load a catalog item.
CatalogItem item = mapper.load(CatalogItem.class, 101);
item.setTitle("This is a new title for the item");
...

// Save the item.
mapper.save(item,
   new DynamoDBMapperConfig(
      DynamoDBMapperConfig.SaveBehavior.CLOBBER));
```

### Mapping Arbitrary Data

In addition to the supported Java types (see Supported Data Types (p. 229)), you can use types in your application for which there is no direct mapping to the Amazon DynamoDB types. To map these types, you must provide an implementation that converts your complex type to a DynamoDB supported type and vice versa, and annotate the complex type accessor method using the @DynamoDBTypeConverted annotation. The converter code transforms data when objects are saved or loaded. It is also used for all operations that consume complex types. Note that when comparing data during query and scan operations, the comparisons are made against the data stored in DynamoDB.

For example, consider the following CatalogItem class that defines a property, Dimension, that is of DimensionType. This property stores the item dimensions as height, width, and thickness. Assume that you decide to store these item dimensions as a string (such as 8.5x11x.05) in DynamoDB. The following
example provides converter code that converts the DimensionType object to a string and a string to the DimensionType.

Note
This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section.
For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

- Example: Batch Operations Using the AWS SDK for .NET Document Model API (p. 287)
- Querying Tables in DynamoDB Using the AWS SDK for .NET Document Model (p. 289)

The AWS SDK for .NET provides document model classes that wrap some of the low-level Amazon DynamoDB operations, further simplifying your coding. In the document model, the primary classes are Table and Document. The Table class provides data operation methods such as PutItem, GetItem, and DeleteItem. It also provides the Query and the Scan methods. The Document class represents a single item in a table.

The preceding document model classes are available in the Amazon.DynamoDBv2.DocumentModel namespace.

Operations Not Supported by the Document Model

You can't use the document model classes to create, update, and delete tables. However, the document model does support most common data operations.

Supported Data Types

The document model supports a set of primitive .NET data types and collections data types. The model supports the following primitive data types.

- bool
- byte
• char
• DateTime
• decimal
• double
• float
• Guid
• Int16
• Int32
• Int64
• SByte
• string
• UInt16
• UInt32
• UInt64

The following table summarizes the mapping of the preceding .NET types to the DynamoDB types.

AWS .NET SDK defines types for mapping DynamoDB’s Boolean, null, list and map types to .NET document model API:

• Use DynamoDBBool for Boolean type.
• Use DynamoDBNull for null type.
• Use DynamoDBList for list type.
• Use Document for map type.

**Note**

• Empty binary values are supported.
• Reading of empty string values is supported. Empty string attribute values are supported within attribute values of string Set type while writing to DynamoDB. Empty string attribute values of string type and empty string values contained within List or Map type are dropped from write requests.

Working with Items in DynamoDB Using the AWS SDK for .NET Document Model

Topics
- Putting an Item - Table.PutItem Method (p. 277)
- Specifying Optional Parameters (p. 278)

To perform data operations using the document model, you must first call the Table.LoadTable method, which creates an instance of the Table class that represents a specific table. The following C# example creates a Table object that represents the ProductCatalog table in Amazon DynamoDB.

Example

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");
```

Note
In general, you use the LoadTable method once at the beginning of your application because it makes a DescribeTable call that adds to the round trip to DynamoDB.

You can then use the Table object to perform various data operations. Each data operation has two types of overloads: One takes the minimum required parameters and the other takes optional, operation-specific configuration information. For example, to retrieve an item, you must provide the table's primary key value, in which case you can use the following GetItem overload.

Example

```csharp
// Get the item from a table that has a primary key that is composed of only a partition key.
Table.GetItem(Primitive partitionKey);
// Get the item from a table whose primary key is composed of both a partition key and sort key.
Table.GetItem(Primitive partitionKey, Primitive sortKey);
```

You also can pass optional parameters to these methods. For example, the preceding GetItem returns the entire item including all its attributes. You can optionally specify a list of attributes to retrieve. In this case, you use the following GetItem overload that takes in the operation-specific configuration object parameter.

Example

```csharp
// Configuration object that specifies optional parameters.
.GetItemOperationConfig config = new GetItemOperationConfig()

    // Attributes to get.
    AttributesToGet = new List<string>() { "Id", "Title" },

    // Pass in the configuration to the GetItem method.
    Table.GetItem(Primitive partitionKey, GetItemOperationConfig config);
    Table.GetItem(Primitive partitionKey, Primitive sortKey, GetItemOperationConfig config);
```

You can use the configuration object to specify several optional parameters such as request a specific list of attributes or specify the page size (number of items per page). Each data operation method has its own configuration class. For example, you can use the GetItemOperationConfig class to provide options for the GetItem operation. You can use the PutItemOperationConfig class to provide optional parameters for the PutItem operation.
The following sections discuss each of the data operations that are supported by the Table class.

**Putting an Item - Table.PutItem Method**

The PutItem method uploads the input Document instance to the table. If an item that has a primary key that is specified in the input Document exists in the table, the PutItem operation replaces the entire existing item. The new item is identical to the Document object that you provided to the PutItem method. If your original item had any extra attributes, they are no longer present in the new item.

The following are the steps to put a new item into a table using the AWS SDK for .NET document model.

1. Execute the Table.LoadTable method that provides the table name in which you want to put an item.
2. Create a Document object that has a list of attribute names and their values.
3. Execute Table.PutItem by providing the Document instance as a parameter.

The following C# code example demonstrates the preceding tasks. The example uploads an item to the ProductCatalog table.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 101;
book["Title"] = "Book 101 Title";
book["Authors"] = new List<string> { "Author 1", "Author 2" }; // Note: Use the Document constructor for Lists.
book["InStock"] = new DynamoDBBool(true);
book["QuantityOnHand"] = new DynamoDBNull();

table.PutItem(book);
```

In the preceding example, the Document instance creates an item that has Number, String, String Set, Boolean, and Null attributes. (Null is used to indicate that the QuantityOnHand for this product is unknown.) For Boolean and Null, use the constructor methods DynamoDBBool and DynamoDBNull.

In DynamoDB, the List and Map data types can contain elements composed of other data types. Here is how to map these data types to the document model API:

- **List** — use the DynamoDBList constructor.
- **Map** — use the Document constructor.

You can modify the preceding example to add a List attribute to the item. To do this, use a DynamoDBList constructor, as shown in the following code example.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 101;
/*other attributes omitted for brevity...*/

var relatedItems = new DynamoDBList();
relatedItems.Add(341);
relatedItems.Add(472);
relatedItems.Add(649);

// Note: Use the DynamoDBList constructor for Lists.
```
item.Add("RelatedItems", relatedItems);

table.PutItem(book);

To add a Map attribute to the book, you define another Document. The following code example illustrates how to do this.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 101;

/*other attributes omitted for brevity...*/

var pictures = new Document();
pictures.Add("FrontView", "http://example.com/products/101_front.jpg");

book.Add("Pictures", pictures);

table.PutItem(book);
```

These examples are based on the item shown in [Specifying Item Attributes When Using Expressions](p. 386). The document model lets you create complex nested attributes, such as the `ProductReviews` attribute shown in the case study.

**Specifying Optional Parameters**

You can configure optional parameters for the `PutItem` operation by adding the `PutItemOperationConfig` parameter. For a complete list of optional parameters, see `PutItem`. The following C# code example puts an item in the `ProductCatalog` table. It specifies the following optional parameter:

- The `ConditionalExpression` parameter to make this a conditional put request. The example creates an expression that specifies the `ISBN` attribute must have a specific value that has to be present in the item that you are replacing.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 555;
book["Title"] = "Book 555 Title";
book["Price"] = "25.00";
book["Name"] = "Item 1 updated";
book["Authors"] = new List<string> { "Author x", "Author y" };
book["InStock"] = new DynamoDBBool(true);
book["QuantityOnHand"] = new DynamoDBNull();

// Create a condition expression for the optional conditional put operation.
Expression expr = new Expression();
expr.ExpressionStatement = "ISBN = :val";
expr.ExpressionAttributeValues[":val"] = "55-55-55-55";

PutItemOperationConfig config = new PutItemOperationConfig()
{
    // Optional parameter.
```
Getting an Item - Table.GetItem

The GetItem operation retrieves an item as a Document instance. You must provide the primary key of the item that you want to retrieve as shown in the following C# code example.

Example

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");
Document document = table.GetItem(101); // Primary key 101.
```

The GetItem operation returns all the attributes of the item and performs an eventually consistent read (see Read Consistency (p. 16)) by default.

Specifying Optional Parameters

You can configure additional options for the GetItem operation by adding the GetItemOperationConfig parameter. For a complete list of optional parameters, see GetItem. The following C# code example retrieves an item from the ProductCatalog table. It specifies the GetItemOperationConfig to provide the following optional parameters:

- The AttributesToGet parameter to retrieve only the specified attributes.
- The ConsistentRead parameter to request the latest values for all the specified attributes. To learn more about data consistency, see Read Consistency (p. 16).

Example

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");
GetItemOperationConfig config = new GetItemOperationConfig()
{
  AttributesToGet = new List<string>() { "Id", "Title", "Authors", "InStock", "QuantityOnHand" },
  ConsistentRead = true
};
Document doc = table.GetItem(101, config);
```

When you retrieve an item using the document model API, you can access individual elements within the Document object is returned, as shown in the following example.

Example

```csharp
int id = doc["Id"].AsInt();
string title = doc["Title"].AsString();
List<string> authors = doc["Authors"].AsListOfString();
bool inStock = doc["InStock"].AsBoolean();
DynamoDBNull quantityOnHand = doc["QuantityOnHand"].AsDynamoDBNull();
```

For attributes that are of type List or Map, here is how to map these attributes to the document model API:

- List — Use the AsDynamoDBList method.
- Map — Use the AsDocument method.
The following code example shows how to retrieve a List (RelatedItems) and a Map (Pictures) from the Document object:

**Example**

```csharp
DynamoDBList relatedItems = doc["RelatedItems"].AsDynamoDBList();
Document pictures = doc["Pictures"].AsDocument();
```

### Deleting an Item - Table.DeleteItem

The DeleteItem operation deletes an item from a table. You can pass the item's primary key as a parameter. Or, if you've already read an item and have the corresponding Document object, you can pass it as a parameter to the DeleteItem method, as shown in the following C# code example.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");

// Retrieve a book (a Document instance)
Document document = table.GetItem(111);

// 1) Delete using the Document instance.
table.DeleteItem(document);

// 2) Delete using the primary key.
int partitionKey = 222;
table.DeleteItem(partitionKey)
```

### Specifying Optional Parameters

You can configure additional options for the Delete operation by adding the DeleteItemOperationConfig parameter. For a complete list of optional parameters, see [DeleteTable](#). The following C# code example specifies the two following optional parameters:

- The ConditionalExpression parameter to ensure that the book item being deleted has a specific value for the ISBN attribute.
- The ReturnValues parameter to request that the Delete method return the item that it deleted.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");
int partitionKey = 111;

Expression expr = new Expression();
expr.ExpressionStatement = "ISBN = :val";
expr.ExpressionAttributeValues[":val"] = "11-11-11-11";

// Specify optional parameters for Delete operation.
DeleteItemOperationConfig config = new DeleteItemOperationConfig {
    ConditionalExpression = expr,
    ReturnValues = ReturnValues.AllOldAttributes // This is the only supported value when using the document model.
};

// Delete the book.
Document d = table.DeleteItem(partitionKey, config);
```
Updating an Item - Table.UpdateItem

The UpdateItem operation updates an existing item if it is present. If the item that has the specified primary key is not found, the UpdateItem operation adds a new item.

You can use the UpdateItem operation to update existing attribute values, add new attributes to the existing collection, or delete attributes from the existing collection. You provide these updates by creating a Document instance that describes the updates that you want to perform.

The UpdateItem action uses the following guidelines:

- If the item does not exist, UpdateItem adds a new item using the primary key that is specified in the input.
- If the item exists, UpdateItem applies the updates as follows:
  - Replaces the existing attribute values with the values in the update.
  - If an attribute that you provide in the input does not exist, it adds a new attribute to the item.
  - If the input attribute value is null, it deletes the attributes, if it is present.

**Note**
This midlevel UpdateItem operation does not support the Add action (see UpdateItem) that is supported by the underlying DynamoDB operation.

**Note**
The PutItem operation (Putting an Item - Table.PutItem Method (p. 277)) can also perform an update. If you call PutItem to upload an item and the primary key exists, the PutItem operation replaces the entire item. If there are attributes in the existing item and those attributes are not specified on the Document that is being put, the PutItem operation deletes those attributes. However, UpdateItem only updates the specified input attributes. Any other existing attributes of that item remain unchanged.

The following are the steps to update an item using the AWS SDK for .NET document model:

1. Execute the Table.LoadTable method by providing the name of the table in which you want to perform the update operation.
2. Create a Document instance by providing all the updates that you want to perform.
   - To delete an existing attribute, specify the attribute value as null.
3. Call the Table.UpdateItem method and provide the Document instance as an input parameter.
   - You must provide the primary key either in the Document instance or explicitly as a parameter.

The following C# code example demonstrates the preceding tasks. The code example updates an item in the Book table. The UpdateItem operation updates the existing Authors attribute, deletes the PageCount attribute, and adds a new XYZ attribute. The Document instance includes the primary key of the book to update.

**Example**

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();

// Set the attributes that you wish to update.
book["Id"] = 111; // Primary key.
// Replace the authors attribute.
book["Authors"] = new List<string> { "Author x", "Author y" };
// Add a new attribute.
```

Specifying Optional Parameters

You can configure additional options for the UpdateItem operation by adding the UpdateItemOperationConfig parameter. For a complete list of optional parameters, see UpdateItem.

The following C# code example updates a book item price to 25. It specifies the two following optional parameters:

- The ConditionalExpression parameter that identifies the Price attribute with value 20 that you expect to be present.
- The ReturnValues parameter to request the UpdateItem operation to return the item that is updated.

Example

```csharp
Table table = Table.LoadTable(client, "ProductCatalog");
string partitionKey = "111";
var book = new Document();
book["Id"] = partitionKey;
book["Price"] = 25;
Expression expr = new Expression();
expr.ExpressionStatement = "Price = :val";
expr.ExpressionAttributeValues[":val"] = "20";
UpdateOperationConfig config = new UpdateOperationConfig()
{
    ConditionalExpression = expr,
    ReturnValues = ReturnValues.AllOldAttributes
};
Document d1 = table.Update(book, config);
```

Batch Write - Putting and Deleting Multiple Items

Batch write refers to putting and deleting multiple items in a batch. The operation enables you to put and delete multiple items from one or more tables in a single call. The following are the steps to put or delete multiple items from a table using the AWS SDK for .NET document model API.

1. Create a Table object by executing the Table.LoadTable method by providing the name of the table in which you want to perform the batch operation.
2. Execute the CreateBatchWrite method on the table instance you created in the preceding step and create a DocumentBatchWrite object.
3. Use the DocumentBatchWrite object methods to specify the documents that you want to upload or delete.
4. Call the DocumentBatchWrite.Execute method to execute the batch operation.

When using the document model API, you can specify any number of operations in a batch. However, DynamoDB limits the number of operations in a batch and the total size of the batch in a batch operation. For more information about the specific limits, see BatchWriteItem. If the document model API detects that your batch write request exceeded the number of allowed write requests, or the HTTP
payload size of a batch exceeded the limit allowed by BatchWriteItem, it breaks the batch into several smaller batches. Additionally, if a response to a batch write returns unprocessed items, the document model API automatically sends another batch request with those unprocessed items.

The following C# code example demonstrates the preceding steps. The example uses batch write operation to perform two writes; upload a book item and delete another book item.

```csharp
table productCatalog = Table.LoadTable(client, "ProductCatalog");
var batchWrite = productCatalog.CreateBatchWrite();

var book1 = new Document();
book1["Id"] = 902;
book1["Title"] = "My book1 in batch write using .NET document model";
book1["Price"] = 10;
book1["Authors"] = new List<string> { "Author 1", "Author 2", "Author 3" };  
book1["InStock"] = new DynamoDBBool(true);
book1["QuantityOnHand"] = 5;
batchWrite.AddDocumentToPut(book1);
// specify delete item using overload that takes PK.
batchWrite.AddKeyToDelete(12345);
batchWrite.Execute();
```

For a working example, see Example: Batch Operations Using the AWS SDK for .NET Document Model API (p. 287).

You can use the batchWrite operation to perform put and delete operations on multiple tables. The following are the steps to put or delete multiple items from multiple tables using the AWS SDK for .NET document model.

1. You create a DocumentBatchWrite instance for each table in which you want to put or delete multiple items, as described in the preceding procedure.
2. Create an instance of the MultiTableDocumentBatchWrite and add the individual DocumentBatchWrite objects to it.
3. Execute the MultiTableDocumentBatchWrite.Execute method.

The following C# code example demonstrates the preceding steps. The example uses the batch write operation to perform the following write operations:

- Put a new item in the Forum table item.
- Put an item in the Thread table and delete an item from the same table.

```csharp
// 1. Specify item to add in the Forum table.
table forum = Table.LoadTable(client, "Forum");
var forumBatchWrite = forum.CreateBatchWrite();

var forum1 = new Document();
forum1["Name"] = "Test BatchWrite Forum";
forum1["Threads"] = 0;
forumBatchWrite.AddDocumentToPut(forum1);

// 2a. Specify item to add in the Thread table.
table thread = Table.LoadTable(client, "Thread");
var threadBatchWrite = thread.CreateBatchWrite();
```
```csharp
var thread1 = new Document();
thread1["ForumName"] = "Amazon S3 forum";
thread1["Subject"] = "My sample question";
thread1["Message"] = "Message text";
thread1["KeywordTags"] = new List<string> { "Amazon S3", "Bucket" };
threadBatchWrite.AddDocumentToPut(thread1);

// 2b. Specify item to delete from the Thread table.
threadBatchWrite.AddKeyToDelete("someForumName", "someSubject");

var superBatch = new MultiTableDocumentBatchWrite();
superBatch.AddBatch(forumBatchWrite);
superBatch.AddBatch(threadBatchWrite);
superBatch.Execute();
```

Example: CRUD Operations Using the AWS SDK for .NET Document Model

The following C# code example performs the following actions:

- Creates a book item in the ProductCatalog table.
- Retrieves the book item.
- Updates the book item. The code example shows a normal update that adds new attributes and updates existing attributes. It also shows a conditional update that updates the book price only if the existing price value is as specified in the code.
- Deletes the book item.

For step-by-step instructions to test the following example, see .NET Code Examples (p. 333).

Example: Batch Write Using the AWS SDK for .NET Document Model

The following C# code example illustrates single table and multi-table batch write operations. The example performs the following tasks:

- Illustrates a single table batch write. It adds two items to the ProductCatalog table.
- Illustrates a multi-table batch write. It adds an item to both the Forum and Thread tables and deletes an item from the Thread table.

If you followed the steps in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), you already have the ProductCatalog, Forum, and Thread tables created. You can also create these sample tables programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for .NET (p. 990). Querying Tables in DynamoDB Using the AWS SDK for .NET Document Model

Table.Query Method in the AWS SDK for .NET

The `Query` method enables you to query your tables. You can only query the tables that have a composite primary key (partition key and sort key). If your table's primary key is made of only a partition key, then the `Query` operation is not supported. By default, `Query` internally performs queries that are eventually consistent. To learn about the consistency model, see Read Consistency (p. 16).

The `Query` method provides two overloads. The minimum required parameters to the `Query` method are a partition key value and a sort key filter. You can use the following overload to provide these minimum required parameters.

**Example**

```csharp
Query(Primitive partitionKey, RangeFilter Filter);
```

For example, the following C# code queries for all forum replies that were posted in the last 15 days.

**Example**

```csharp
string tableName = "Reply";
Table table = Table.LoadTable(client, tableName);
DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);
RangeFilter filter = new RangeFilter(QueryOperator.GreaterThan, twoWeeksAgoDate);
Search search = table.Query("DynamoDB Thread 2", filter);
```

This creates a `Search` object. You can now call the `Search.GetNextSet` method iteratively to retrieve one page of results at a time, as shown in the following C# code example. The code prints the attribute values for each item that the query returns.

**Example**

```csharp
List<Document> documentSet = new List<Document>();
do
{
    documentSet = search.GetNextSet();
    foreach (var document in documentSet)
    {
        PrintDocument(document);
```
Specifying Optional Parameters

You can also specify optional parameters for Query, such as specifying a list of attributes to retrieve, strongly consistent reads, page size, and the number of items returned per page. For a complete list of parameters, see Query. To specify optional parameters, you must use the following overload in which you provide the QueryOperationConfig object.

Example

```csharp
Query(QueryOperationConfig config);
```

Assume that you want to execute the query in the preceding example (retrieve forum replies posted in the last 15 days). However, assume that you want to provide optional query parameters to retrieve only specific attributes and also request a strongly consistent read. The following C# code example constructs the request using the QueryOperationConfig object.

Example

```csharp
Table table = Table.LoadTable(client, "Reply");
DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);
QueryOperationConfig config = new QueryOperationConfig()
{
    HashKey = "DynamoDB Thread 2", //Partition key
    AttributesToGet = new List<string>
    { "Subject", "ReplyDateTime", "PostedBy" },
    ConsistentRead = true,
    Filter = new RangeFilter(QueryOperator.GreaterThan, twoWeeksAgoDate)
};
Search search = table.Query(config);
```

Example: Query Using the Table.Query Method

The following C# code example uses the Table.Query method to execute the following sample queries.

- The following queries are executed against the Reply table.
- Find forum thread replies that were posted in the last 15 days.

This query is executed twice. In the first Table.Query call, the example provides only the required query parameters. In the second Table.Query call, you provide optional query parameters to request a strongly consistent read and a list of attributes to retrieve.
- Find forum thread replies posted during a period of time.

This query uses the `Between` query operator to find replies posted in between two dates.

- Get a product from the `ProductCatalog` table.

Because the `ProductCatalog` table has a primary key that is only a partition key, you can only get items; you cannot query the table. The example retrieves a specific product item using the `itemId`.

**Table.Scan Method in the AWS SDK for .NET**

The `Scan` method performs a full table scan. It provides two overloads. The only parameter required by the `Scan` method is the scan filter, which you can provide using the following overload.
Example

```csharp
Scan(ScanFilter filter);
```

For example, assume that you maintain a table of forum threads tracking information such as thread subject (primary), the related message, forum Id to which the thread belongs, Tags, and other information. Assume that the subject is the primary key.

Example

```csharp
Thread(Subject, Message, ForumId, Tags, LastPostedDateTime, .... )
```

This is a simplified version of forums and threads that you see on AWS forums (see Discussion Forums). The following C# code example queries all threads in a specific forum (ForumId = 101) that are tagged "sortkey". Because the ForumId is not a primary key, the example scans the table. The ScanFilter includes two conditions. The query returns all the threads that satisfy both of the conditions.

Example

```csharp
string tableName = "Thread";
Table ThreadTable = Table.LoadTable(client, tableName);

ScanFilter scanFilter = new ScanFilter();
scanFilter.AddCondition("ForumId", ScanOperator.Equal, 101);
scanFilter.AddCondition("Tags", ScanOperator.Contains, "sortkey");

Search search = ThreadTable.Scan(scanFilter);
```

Specifying Optional Parameters

You also can specify optional parameters to Scan, such as a specific list of attributes to retrieve or whether to perform a strongly consistent read. To specify optional parameters, you must create a ScanOperationConfig object that includes both the required and optional parameters and use the following overload.

Example

```csharp
Scan(ScanOperationConfig config);
```

The following C# code example executes the same preceding query (find forum threads in which the ForumId is 101 and the Tag attribute contains the "sortkey" keyword). Assume that you want to add an optional parameter to retrieve only a specific attribute list. In this case, you must create a ScanOperationConfig object by providing all the parameters, required and optional parameters, as shown in the following code example.

Example

```csharp
string tableName = "Thread";
Table ThreadTable = Table.LoadTable(client, tableName);

ScanFilter scanFilter = new ScanFilter();
scanFilter.AddCondition("ForumId", ScanOperator.Equal, forumId);
scanFilter.AddCondition("Tags", ScanOperator.Contains, "sortkey");

ScanOperationConfig config = new ScanOperationConfig()
{
    AttributesToGet = new List<string> { "Subject", "Message" },
    Filter = scanFilter
};
Example: Scan Using the Table.Scan Method

The `Scan` operation performs a full table scan making it a potentially expensive operation. You should use queries instead. However, there are times when you might need to execute a scan against a table. For example, you might have a data entry error in the product pricing, and you must scan the table as shown in the following C# code example. The example scans the `ProductCatalog` table to find products for which the price value is less than 0. The example illustrates the use of the two `Table.Scan` overloads.

- `Table.Scan` that takes the `ScanFilter` object as a parameter.
  
  You can pass the `ScanFilter` parameter when passing in only the required parameters.
- `Table.Scan` that takes the `ScanOperationConfig` object as a parameter.
  
  You must use the `ScanOperationConfig` parameter if you want to pass any optional parameters to the `Scan` method.

Example

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;

namespace com.amazonaws.codesamples
{
    class MidLevelScanOnly
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            Table productCatalogTable = Table.LoadTable(client, "ProductCatalog");
            // Scan example.
            FindProductsWithNegativePrice(productCatalogTable);
            FindProductsWithNegativePriceWithConfig(productCatalogTable);

            Console.WriteLine("To continue, press Enter");
            Console.ReadLine();
        }

        private static void FindProductsWithNegativePrice(Table productCatalogTable)
        {
            // Assume there is a price error. So we scan to find items priced < 0.
            ScanFilter scanFilter = new ScanFilter();
```
scanFilter.AddCondition("Price", ScanOperator.LessThan, 0);

Search search = productCatalogTable.Scan(scanFilter);

List<Document> documentList = new List<Document>();
do {
    documentList = search.GetNextSet();
    Console.WriteLine("\nFindProductsWithNegativePrice: printing ............\n");
    foreach (var document in documentList)
        PrintDocument(document);
} while (!search.IsDone);

private static void FindProductsWithNegativePriceWithConfig(Table productCatalogTable)
{
    // Assume there is a price error. So we scan to find items priced < 0.
    ScanFilter scanFilter = new ScanFilter();
    scanFilter.AddCondition("Price", ScanOperator.LessThan, 0);
    ScanOperationConfig config = new ScanOperationConfig()
        {
            Filter = scanFilter,
            Select = SelectValues.SpecificAttributes,
            AttributesToGet = new List<string> { "Title", "Id" }
        };
    Search search = productCatalogTable.Scan(config);
    List<Document> documentList = new List<Document>();
do {

            var value = document[attribute];
            if (value is Primitive)
                stringValue = value.AsPrimitive().Value.ToString();
            else if (value is PrimitiveList)
                stringValue = string.Join(",", (from primitive
                    in value.AsPrimitiveList().Entries
                    select primitive.Value).ToArray());
            Console.WriteLine("\n{0} - {1}\n", attribute, stringValue);

.NET: Object Persistence Model

Topics
The AWS SDK for .NET provides an object persistence model that enables you to map your client-side classes to Amazon DynamoDB tables. Each object instance then maps to an item in the corresponding tables. To save your client-side objects to the tables, the object persistence model provides the `DynamoDBContext` class, an entry point to DynamoDB. This class provides you a connection to DynamoDB and enables you to access tables, perform various CRUD operations, and execute queries.

The object persistence model provides a set of attributes to map client-side classes to tables, and properties/fields to table attributes.

**Note**
The object persistence model does not provide an API to create, update, or delete tables. It provides only data operations. You can use only the AWS SDK for .NET low-level API to create, update, and delete tables. For more information, see Working with DynamoDB Tables in .NET (p. 368).

The following example shows how the object persistence model works. It starts with the `ProductCatalog` table. It has `Id` as the primary key.

```csharp
ProductCatalog(Id, ...)
```

Suppose that you have a `Book` class with `Title`, `ISBN`, and `Authors` properties. You can map the `Book` class to the `ProductCatalog` table by adding the attributes defined by the object persistence model, as shown in the following C# code example.

**Example**

```csharp
[DynamoDBTable("ProductCatalog")] public class Book
{
    [DynamoDBHashKey]
    public int Id { get; set; }

    public string Title { get; set; }
    public int ISBN { get; set; }

    [DynamoDBProperty("Authors")]
    public List<string> BookAuthors { get; set; }

    [DynamoDBIgnore]
    public string CoverPage { get; set; }
}
```
In the preceding example, the `DynamoDBTable` attribute maps the `Book` class to the `ProductCatalog` table.

The object persistence model supports both the explicit and default mapping between class properties and table attributes.

- **Explicit mapping**—To map a property to a primary key, you must use the `DynamoDBHashKey` and `DynamoDBRangeKey` object persistence model attributes. Additionally, for the nonprimary key attributes, if a property name in your class and the corresponding table attribute to which you want to map it are not the same, you must define the mapping by explicitly adding the `DynamoDBProperty` attribute.

  In the preceding example, the `Id` property maps to the primary key with the same name, and the `BookAuthors` property maps to the `Authors` attribute in the `ProductCatalog` table.

- **Default mapping**—By default, the object persistence model maps the class properties to the attributes with the same name in the table.

  In the preceding example, the properties `Title` and `ISBN` map to the attributes with the same name in the `ProductCatalog` table.

You don't have to map every single class property. You identify these properties by adding the `DynamoDBIgnore` attribute. When you save a `Book` instance to the table, the `DynamoDBContext` does not include the `CoverPage` property. It also does not return this property when you retrieve the book instance.

You can map properties of .NET primitive types such as int and string. You also can map any arbitrary data types as long as you provide an appropriate converter to map the arbitrary data to one of the DynamoDB types. To learn about mapping arbitrary types, see [Mapping Arbitrary Data with DynamoDB Using the AWS SDK for .NET Object Persistence Model](p. 308).

The object persistence model supports optimistic locking. During an update operation, this ensures that you have the latest copy of the item you are about to update. For more information, see [Optimistic Locking Using a Version Number with DynamoDB Using the AWS SDK for .NET Object Persistence Model](p. 306).

### DynamoDB Attributes

This section describes the attributes that the object persistence model offers so that you can map your classes and properties to DynamoDB tables and attributes.

**Note**

In the following attributes, only `DynamoDBTable` and `DynamoDBHashKey` are required.

#### `DynamoDBGlobalSecondaryIndexHashKey`
Maps a class property to the partition key of a global secondary index. Use this attribute if you need to query a global secondary index.

#### `DynamoDBGlobalSecondaryIndexRangeKey`
Maps a class property to the sort key of a global secondary index. Use this attribute if you need to query a global secondary index and want to refine your results using the index sort key.

#### `DynamoDBHashKey`
Maps a class property to the partition key of the table's primary key. The primary key attributes cannot be a collection type.
The following C# code example maps the Book class to the ProductCatalog table, and the Id property to the table's primary key partition key.

```
[DynamoDBTable("ProductCatalog")]
public class Book {
    [DynamoDBHashKey]
    public int Id { get; set; }

    // Additional properties go here.
}
```

**DynamoDBIgnore**

Indicates that the associated property should be ignored. If you don't want to save any of your class properties, you can add this attribute to instruct DynamoDBContext not to include this property when saving objects to the table.

**DynamoDBLocalSecondaryIndexRangeKey**

Maps a class property to the sort key of a local secondary index. Use this attribute if you need to query a local secondary index and want to refine your results using the index sort key.

**DynamoDBProperty**

Maps a class property to a table attribute. If the class property maps to a table attribute of the same name, you don't need to specify this attribute. However, if the names are not the same, you can use this tag to provide the mapping. In the following C# statement, the DynamoDBProperty maps the BookAuthors property to the Authors attribute in the table.

```
[DynamoDBProperty("Authors")]
public List<string> BookAuthors { get; set; }
```

DynamoDBContext uses this mapping information to create the Authors attribute when saving object data to the corresponding table.

**DynamoDBRenamable**

Specifies an alternative name for a class property. This is useful if you are writing a custom converter for mapping arbitrary data to a DynamoDB table where the name of a class property is different from a table attribute.

**DynamoDBRangeKey**

Maps a class property to the sort key of the table's primary key. If the table has a composite primary key (partition key and sort key), you must specify both the DynamoDBHashKey and DynamoDBRangeKey attributes in your class mapping.

For example, the sample table Reply has a primary key made of the Id partition key and Replenishment sort key. The following C# code example maps the Reply class to the Reply table. The class definition also indicates that two of its properties map to the primary key.

For more information about sample tables, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

```
[DynamoDBTable("Reply")]
public class Reply {
```
public int ThreadId { get; set; } 
public string Replenishment { get; set; } 
// Additional properties go here.
}

[DynamoDBTable]
public class Developer { ...}

DynamoDBTable
Identifies the target table in DynamoDB to which the class maps. For example, the following C# code example maps the Developer class to the People table in DynamoDB.

[DynamoDBTable("People")]
public class Developer { ...}

This attribute can be inherited or overridden.

- The DynamoDBTable attribute can be inherited. In the preceding example, if you add a new class, Lead, that inherits from the Developer class, it also maps to the People table. Both the Developer and Lead objects are stored in the People table.
- The DynamoDBTable attribute can also be overridden. In the following C# code example, the Manager class inherits from the Developer class. However, the explicit addition of the DynamoDBTable attribute maps the class to another table (Managers).

[DynamoDBTable("Managers")]
public class Manager : Developer { ...}

You can add the optional parameter, LowerCamelCaseProperties, to request DynamoDB to make the first letter of the property name lowercase when storing the objects to a table, as shown in the following C# example.

[DynamoDBTable("People", LowerCamelCaseProperties=true)]
public class Developer {
    string DeveloperName;
    ...
}

When saving instances of the Developer class, DynamoDBContext saves the DeveloperName property as the developerName.

DynamoDBVersion
Identifies a class property for storing the item version number. For more information about versioning, see Optimistic Locking Using a Version Number with DynamoDB Using the AWS SDK for .NET Object Persistence Model (p. 306).

DynamoDBContext Class
The DynamoDBContext class is the entry point to the Amazon DynamoDB database. It provides a connection to DynamoDB and enables you to access your data in various tables, perform various CRUD operations, and execute queries. The DynamoDBContext class provides the following methods.

CreateMultiTableBatchGet
Creates a MultiTableBatchGet object, composed of multiple individual BatchGet objects. Each of these BatchGet objects can be used for retrieving items from a single DynamoDB table.
To retrieve the items from tables, use the `ExecuteBatchGet` method, passing the `MultiTableBatchGet` object as a parameter.

**CreateMultiTableBatchWrite**

Creates a `MultiTableBatchWrite` object, composed of multiple individual `BatchWrite` objects. Each of these `BatchWrite` objects can be used for writing or deleting items in a single DynamoDB table.

To write to tables, use the `ExecuteBatchWrite` method, passing the `MultiTableBatchWrite` object as a parameter.

**CreateBatchGet**

Creates a `BatchGet` object that you can use to retrieve multiple items from a table. For more information, see Batch Get: Getting Multiple Items (p. 313).

**CreateBatchWrite**

Creates a `BatchWrite` object that you can use to put multiple items into a table, or to delete multiple items from a table. For more information, see Batch Write: Putting and Deleting Multiple Items (p. 311).

**Delete**

Deletes an item from the table. The method requires the primary key of the item you want to delete. You can provide either the primary key value or a client-side object containing a primary key value as a parameter to this method.

- If you specify a client-side object as a parameter and you have enabled optimistic locking, the delete succeeds only if the client-side and the server-side versions of the object match.
- If you specify only the primary key value as a parameter, the delete succeeds regardless of whether you have enabled optimistic locking or not.

**Note**

To perform this operation in the background, use the `DeleteAsync` method instead.

**Dispose**

Disposes of all managed and unmanaged resources.

**ExecuteBatchGet**

Reads data from one or more tables, processing all of the `BatchGet` objects in a `MultiTableBatchGet`.

**Note**

To perform this operation in the background, use the `ExecuteBatchGetAsync` method instead.

**ExecuteBatchWrite**

Writes or deletes data in one or more tables, processing all of the `BatchWrite` objects in a `MultiTableBatchWrite`.

**Note**

To perform this operation in the background, use the `ExecuteBatchWriteAsync` method instead.
FromDocument

Given an instance of a Document, the FromDocument method returns an instance of a client-side class.

This is helpful if you want to use the document model classes along with the object persistence model to perform any data operations. For more information about the document model classes provided by the AWS SDK for .NET, see .NET: Document Model (p. 274).

Suppose that you have a Document object named doc, that contains a representation of a Forum item. (To see how to construct this object, see the description for the ToDocument method later in this topic.) You can use FromDocument to retrieve the Forum item from the Document, as shown in the following C# code example.

**Example**

```csharp
forum101 = context.FromDocument<Forum>(101);
```

**Note**

If your Document object implements the IEnumerable interface, you can use the FromDocuments method instead. This allows you to iterate over all of the class instances in the Document.

FromQuery

Executes a Query operation, with the query parameters defined in a QueryOperationConfig object.

**Note**

To perform this operation in the background, use the FromQueryAsync method instead.

FromScan

Executes a Scan operation, with the scan parameters defined in a ScanOperationConfig object.

**Note**

To perform this operation in the background, use the FromScanAsync method instead.

GetTargetTable

Retrieves the target table for the specified type. This is useful if you are writing a custom converter for mapping arbitrary data to a DynamoDB table, and you need to determine which table is associated with a custom data type.

Load

Retrieves an item from a table. The method requires only the primary key of the item you want to retrieve.

By default, DynamoDB returns the item with values that are eventually consistent. For information about the eventual consistency model, see Read Consistency (p. 16).

**Note**

To perform this operation in the background, use the LoadAsync method instead.

Query

Queries a table based on query parameters you provide.
You can query a table only if it has a composite primary key (partition key and sort key). When querying, you must specify a partition key and a condition that applies to the sort key.

Suppose that you have a client-side Reply class mapped to the Reply table in DynamoDB. The following C# code example queries the Reply table to find forum thread replies posted in the past 15 days. The Reply table has a primary key that has the Id partition key and the ReplyDateTime sort key. For more information about the Reply table, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

Example

```csharp
DynamoDBContext context = new DynamoDBContext(client);

string replyId = "DynamoDB#DynamoDB Thread 1"; //Partition key
DateTime twoWeeksAgoDate = DateTime.UtcNow.Subtract(new TimeSpan(14, 0, 0, 0)); // Date to compare.
IEnumerable<Reply> latestReplies = context.Query<Reply>(replyId, QueryOperator.GreaterThan, twoWeeksAgoDate);
```

This returns a collection of Reply objects.

The Query method returns a "lazy-loaded" IEnumerable collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, you need to iterate only over the IEnumerable.

If your table has a simple primary key (partition key), you can't use the Query method. Instead, you can use the Load method and provide the partition key to retrieve the item.

Note
To perform this operation in the background, use the QueryAsync method instead.

Save

Saves the specified object to the table. If the primary key specified in the input object doesn't exist in the table, the method adds a new item to the table. If the primary key exists, the method updates the existing item.

If you have optimistic locking configured, the update succeeds only if the client and the server-side versions of the item match. For more information, see Optimistic Locking Using a Version Number with DynamoDB Using the AWS SDK for .NET Object Persistence Model (p. 306).

Note
To perform this operation in the background, use the SaveAsync method instead.

Scan

Performs an entire table scan.

You can filter scan results by specifying a scan condition. The condition can be evaluated on any attributes in the table. Suppose that you have a client-side class Book mapped to the ProductCatalog table in DynamoDB. The following C# example scans the table and returns only the book items priced less than 0.

Example

```csharp
IEnumerable<Book> itemsWithWrongPrice = context.Scan<Book>(
    new ScanCondition("Price", ScanOperator.LessThan, price),
);```
new ScanCondition("ProductCategory", ScanOperator.Equal, "Book")
);

The Scan method returns a "lazy-loaded" IEnumerable collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, you only need to iterate over the IEnumerable.

For performance reasons, you should query your tables and avoid a table scan.

Note
To perform this operation in the background, use the ScanAsync method instead.

**ToDocument**

Returns an instance of the Document document model class from your class instance.

This is helpful if you want to use the document model classes along with the object persistence model to perform any data operations. For more information about the document model classes provided by the AWS SDK for .NET, see .NET: Document Model (p. 274).

Suppose that you have a client-side class mapped to the sample Forum table. You can then use a DynamoDBContext to get an item as a Document object from the Forum table, as shown in the following C# code example.

**Example**

```csharp
DynamoDBContext context = new DynamoDBContext(client);
Forum forum101 = context.Load<Forum>(101); // Retrieve a forum by primary key.
Document doc = context.ToDocument<Forum>(forum101);
```

**Specifying Optional Parameters for DynamoDBContext**

When using the object persistence model, you can specify the following optional parameters for the DynamoDBContext.

- **ConsistentRead**—When retrieving data using the Load, Query, or Scan operations, you can add this optional parameter to request the latest values for the data.
- **IgnoreNullValues**—This parameter informs DynamoDBContext to ignore null values on attributes during a Save operation. If this parameter is false (or if it is not set), then a null value is interpreted as a directive to delete the specific attribute.
- **SkipVersionCheck**—This parameter informs DynamoDBContext not to compare versions when saving or deleting an item. For more information about versioning, see Optimistic Locking Using a Version Number with DynamoDB Using the AWS SDK for .NET Object Persistence Model (p. 306).
- **TableNamePrefix**—Prefixes all table names with a specific string. If this parameter is null (or if it is not set), then no prefix is used.

The following C# example creates a new DynamoDBContext by specifying two of the preceding optional parameters.

**Example**

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
...
DynamoDBContext context =
```
new DynamoDBContext(client, new DynamoDBContextConfig { ConsistentRead = true, SkipVersionCheck = true });

DynamoDBContext includes these optional parameters with each request that you send using this context.

Instead of setting these parameters at the DynamoDBContext level, you can specify them for individual operations you execute using DynamoDBContext, as shown in the following C# code example. The example loads a specific book item. The Load method of DynamoDBContext specifies the preceding optional parameters.

**Example**

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
...
DynamoDBContext context = new DynamoDBContext(client);
Book bookItem = context.Load<Book>(productId, new DynamoDBContextConfig{ ConsistentRead = true, SkipVersionCheck = true });
```

In this case, DynamoDBContext includes these parameters only when sending the Get request.

**Supported Data Types**

The object persistence model supports a set of primitive .NET data types, collections, and arbitrary data types. The model supports the following primitive data types.

- bool
- byte
- char
- DateTime
- decimal
- double
- float
- Int16
- Int32
- Int64
- SByte
- string
- UInt16
- UInt32
- UInt64

The object persistence model also supports the .NET collection types. DynamoDBContext is able to convert concrete collection types and simple Plain Old CLR Objects (POCOs).

The following table summarizes the mapping of the preceding .NET types to the DynamoDB types.

<table>
<thead>
<tr>
<th>.NET primitive type</th>
<th>DynamoDB type</th>
</tr>
</thead>
<tbody>
<tr>
<td>All number types</td>
<td>N (number type)</td>
</tr>
<tr>
<td>All string types</td>
<td>S (string type)</td>
</tr>
<tr>
<td>.NET primitive type</td>
<td>DynamoDB type</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>MemoryStream, byte[]</td>
<td><code>B</code> (binary type)</td>
</tr>
<tr>
<td>bool</td>
<td><code>N</code> (number type). 0 represents false and 1 represents true.</td>
</tr>
<tr>
<td>Collection types</td>
<td><code>BS</code> (binary set) type, <code>SS</code> (string set) type, and <code>NS</code> (number set) type</td>
</tr>
<tr>
<td>DateTime</td>
<td><code>S</code> (string type). The <code>DateTime</code> values are stored as ISO-8601 formatted strings.</td>
</tr>
</tbody>
</table>

The object persistence model also supports arbitrary data types. However, you must provide converter
code to map the complex types to the DynamoDB types.

**Note**

- Empty binary values are supported.
- Reading of empty string values is supported. Empty string attribute values are supported within attribute values of string Set type while writing to DynamoDB. Empty string attribute values of string type and empty string values contained within List or Map type are dropped from write requests.

### Optimistic Locking Using a Version Number with DynamoDB

#### Using the AWS SDK for .NET Object Persistence Model

Optimistic locking support in the object persistence model ensures that the item version for your
application is the same as the item version on the server side before updating or deleting the item.
Suppose that you retrieve an item for update. However, before you send your updates back, some other
application updates the same item. Now your application has a stale copy of the item. Without optimistic
locking, any update you perform will overwrite the update made by the other application.

The optimistic locking feature of the object persistence model provides the `DynamoDBVersion` tag
that you can use to enable optimistic locking. To use this feature, you add a property to your class for
storing the version number. You add the `DynamoDBVersion` attribute to the property. When you first
save the object, the `DynamoDBContext` assigns a version number and increments this value each time
you update the item.

Your update or delete request succeeds only if the client-side object version matches the corresponding
version number of the item on the server side. If your application has a stale copy, it must get the latest
version from the server before it can update or delete that item.

The following C# code example defines a `Book` class with object persistence attributes mapping
it to the `ProductCatalog` table. The `VersionNumber` property in the class decorated with the
`DynamoDBVersion` attribute stores the version number value.

**Example**

```csharp
[DynamoDBTable("ProductCatalog")]
public class Book
{
    [DynamoDBHashKey] //Partition key
    public int Id { get; set; }
    [DynamoDBProperty]
    public string Title { get; set; }
```
Note
You can apply the DynamoDBVersion attribute only to a nullable numeric primitive type (such as int?).

Optimistic locking has the following impact on DynamoDBContext operations:

- For a new item, DynamoDBContext assigns initial version number 0. If you retrieve an existing item, update one or more of its properties, and try to save the changes, the save operation succeeds only if the version number on the client side and the server side match. DynamoDBContext increments the version number. You don’t need to set the version number.
- The Delete method provides overloads that can take either a primary key value or an object as parameter, as shown in the following C# code example.

Example

```csharp
DynamoDBContext context = new DynamoDBContext(client);
...
// Load a book.
Book book = context.Load<ProductCatalog>(111);
// Do other operations.
// Delete 1 - Pass in the book object.
context.Delete<ProductCatalog>(book);
// Delete 2 - Pass in the Id (primary key)
context.Delete<ProductCatalog>(222);
```

If you provide an object as the parameter, the delete succeeds only if the object version matches the corresponding server-side item version. However, if you provide a primary key value as the parameter, DynamoDBContext is unaware of any version numbers, and it deletes the item without making the version check.

Note that the internal implementation of optimistic locking in the object persistence model code uses the conditional update and the conditional delete API actions in DynamoDB.

Disabling Optimistic Locking

To disable optimistic locking, you use the SkipVersionCheck configuration property. You can set this property when creating DynamoDBContext. In this case, optimistic locking is disabled for any requests that you make using the context. For more information, see Specifying Optional Parameters for DynamoDBContext (p. 304).

Instead of setting the property at the context level, you can disable optimistic locking for a specific operation, as shown in the following C# code example. The example uses the context to delete a book item. The Delete method sets the optional SkipVersionCheck property to true, disabling version checking.

Example

```csharp
DynamoDBContext context = new DynamoDBContext(client);
```
Mapping Arbitrary Data with DynamoDB Using the AWS SDK for .NET Object Persistence Model

In addition to the supported .NET types (see Supported Data Types (p. 305)), you can use types in your application for which there is no direct mapping to the Amazon DynamoDB types. The object persistence model supports storing data of arbitrary types as long as you provide the converter to convert data from the arbitrary type to the DynamoDB type and vice versa. The converter code transforms data during both the saving and loading of the objects.

You can create any types on the client-side. However the data stored in the tables is one of the DynamoDB types, and during query and scan, any data comparisons made are against the data stored in DynamoDB.

The following C# code example defines a Book class with Id, Title, ISBN, and Dimension properties. The Dimension property is of the DimensionType that describes Height, Width, and Thickness properties. The example code provides the converter methods ToEntry and FromEntry to convert data between the DimensionType and the DynamoDB string types. For example, when saving a Book instance, the converter creates a book Dimension string such as "8.5x11x.05". When you retrieve a book, it converts the string to a DimensionType instance.

The example maps the Book type to the ProductCatalog table. It saves a sample Book instance, retrieves it, updates its dimensions, and saves the updated Book again.

For step-by-step instructions for testing the following example, see .NET Code Examples (p. 333).

Example

```csharp
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
using Amazon.Runtime;
using Amazon.SecurityToken;
namespace com.amazonaws.codesamples
{
    class HighLevelMappingArbitraryData
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();
        
```
static void Main(string[] args)
{
    try
    {
        DynamoDBContext context = new DynamoDBContext(client);

        DimensionType myBookDimensions = new DimensionType()
        {
            Length = 8M,
            Height = 11M,
            Thickness = 0.5M
        };

        Book myBook = new Book
        {
            Id = 501,
            Title = "AWS SDK for .NET Object Persistence Model Handling Arbitrary Data",
            ISBN = "999-9999999999",
            BookAuthors = new List<string> { "Author 1", "Author 2" },
            Dimensions = myBookDimensions
        };
        context.Save(myBook);

        // 2. Retrieve the book.
        Book bookRetrieved = context.Load<Book>(501);

        bookRetrieved.Dimensions.Height += 1;
        bookRetrieved.Dimensions.Length += 1;
        bookRetrieved.Dimensions.Thickness += 0.2M;
        // Update the book.
        context.Save(bookRetrieved);

Batch Operations Using the AWS SDK for .NET Object Persistence Model

Batch Write: Putting and Deleting Multiple Items

To put or delete multiple objects from a table in a single request, do the following:

- Execute the `CreateBatchWrite` method of the `DynamoDBContext`, and create an instance of the `BatchWrite` class.
- Specify the items that you want to put or delete.
  - To put one or more items, use either the `AddPutItem` or the `AddPutItems` method.
  - To delete one or more items, you can specify either the primary key of the item or a client-side object that maps to the item that you want to delete. Use the `AddDeleteItem`, `AddDeleteItems`, and `AddDeleteKey` methods to specify the list of items to delete.
- Call the `BatchWrite.Execute` method to put and delete all the specified items from the table.

**Note**

When using the object persistence model, you can specify any number of operations in a batch. However, note that Amazon DynamoDB limits the number of operations in a batch and the total size of the batch in a batch operation. For more information about the specific limits, see `BatchWriteItem`. If the API detects that your batch write request exceeded the allowed number of write requests or exceeded the maximum allowed HTTP payload size, it breaks the batch into several smaller batches. Additionally, if a response to a batch write returns unprocessed items, the API automatically sends another batch request with those unprocessed items.

Suppose that you defined a C# class `Book` class that maps to the `ProductCatalog` table in DynamoDB. The following C# code example uses the `BatchWrite` object to upload two items and delete one item from the `ProductCatalog` table.

**Example**

```csharp
dynamodbcontext context = new dynamodbcontext(client);
var bookBatch = context.createBatchWrite<Book>();

// 1. Specify two books to add.
book book1 = new book
{
  id = 902,
  isbn = "902-11-11-1111",
  productcategory = "Book",
  title = "My book3 in batch write"
};
{
  id = 903,
  isbn = "903-11-11-1111",
  productcategory = "Book",
  title = "My book4 in batch write"
};

// 2. Specify one book to delete.
bookBatch.AddDeleteKey(111);
```

API Version 2012-08-10

311
To put or delete objects from multiple tables, do the following:

- Create one instance of the BatchWrite class for each type and specify the items you want to put or delete as described in the preceding section.
- Create an instance of MultiTableBatchWrite using one of the following methods:
  - Execute the Combine method on one of the BatchWrite objects that you created in the preceding step.
  - Create an instance of the MultiTableBatchWrite type by providing a list of BatchWrite objects.
  - Execute the CreateMultiTableBatchWrite method of DynamoDBContext and pass in your list of BatchWrite objects.
- Call the Execute method of MultiTableBatchWrite, which performs the specified put and delete operations on various tables.

Suppose that you defined Forum and Thread C# classes that map to the Forum and Thread tables in DynamoDB. Also, suppose that the Thread class has versioning enabled. Because versioning is not supported when using batch operations, you must explicitly disable versioning as shown in the following C# code example. The example uses the MultiTableBatchWrite object to perform a multi-table update.

**Example**

```csharp
DynamoDBContext context = new DynamoDBContext(client);
// Create BatchWrite objects for each of the Forum and Thread classes.
var forumBatch = context.CreateBatchWrite<Forum>();
DynamoDBOperationConfig config = new DynamoDBOperationConfig();
config.SkipVersionCheck = true;
var threadBatch = context.CreateBatchWrite<Thread>(config);

// 1. New Forum item.
Forum newForum = new Forum
{ 
    Name = "Test BatchWrite Forum",
    Threads = 0
};
forumBatch.AddItem(newForum);

// 2. Specify a forum to delete by specifying its primary key.
forumBatch.AddDeleteKey("Some forum");

Thread newThread = new Thread
{ 
    ForumName = "Amazon S3 forum",
    Subject = "My sample question",
    KeywordTags = new List<string> { "Amazon S3", "Bucket" },
    Message = "Message text"
};
threadBatch.AddItem(newThread);

// Now execute multi-table batch write.
var superBatch = new MultiTableBatchWrite(forumBatch, threadBatch);
superBatch.Execute();
```

For a working example, see Example: Batch Write Operation Using the AWS SDK for .NET Object Persistence Model (p. 316).
Note
The DynamoDB batch API limits the number of writes in a batch and also limits the size of the batch. For more information, see BatchWriteItem. When using the .NET object persistence model API, you can specify any number of operations. However, if either the number of operations in a batch or the size exceeds the limit, the .NET API breaks the batch write request into smaller batches and sends multiple batch write requests to DynamoDB.

Batch Get: Getting Multiple Items

To retrieve multiple items from a table in a single request, do the following:

- Create an instance of the CreateBatchGet class.
- Specify a list of primary keys to retrieve.
- Call the Execute method. The response returns the items in the Results property.

The following C# code example retrieves three items from the ProductCatalog table. The items in the result are not necessarily in the same order in which you specified the primary keys.

Example

```csharp
DynamoDBContext context = new DynamoDBContext(client);
var bookBatch = context.CreateBatchGet<ProductCatalog>();
bookBatch.AddKey(101);
bookBatch.AddKey(102);
bookBatch.AddKey(103);
bookBatch.Execute();
// Process result.
Console.WriteLine(bookBatch.Results.Count);
Book book1 = bookBatch.Results[0];
Book book2 = bookBatch.Results[1];
Book book3 = bookBatch.Results[2];
```

To retrieve objects from multiple tables, do the following:

- For each type, create an instance of the CreateBatchGet type and provide the primary key values you want to retrieve from each table.
- Create an instance of the MultiTableBatchGet class using one of the following methods:
  - Execute the Combine method on one of the BatchGet objects you created in the preceding step.
  - Create an instance of the MultiBatchGet type by providing a list of BatchGet objects.
  - Call the Execute method of MultiTableBatchGet, which returns the typed results in the individual BatchGet objects.

The following C# code example retrieves multiple items from the Order and OrderDetail tables using the CreateBatchGet method.

Example

```csharp
var orderBatch = context.CreateBatchGet<Order>();
orderBatch.AddKey(101);
orderBatch.AddKey(102);

var orderDetailBatch = context.CreateBatchGet<OrderDetail>();
orderDetailBatch.AddKey(101, "P1");
```
Example: CRUD Operations Using the AWS SDK for .NET Object Persistence Model

The following C# code example declares a `Book` class with `Id`, `Title`, `ISBN`, and `Authors` properties. The example uses object persistence attributes to map these properties to the `ProductCatalog` table in Amazon DynamoDB. The example then uses the `DynamoDBContext` to illustrate typical create, read, update, and delete (CRUD) operations. The example creates a sample `Book` instance and saves it to the `ProductCatalog` table. It then retrieves the book item and updates its `ISBN` and `Authors` properties. Note that the update replaces the existing authors list. Finally, the example deletes the book item.

For more information about the `ProductCatalog` table used in this example, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326). For step-by-step instructions to test the following example, see .NET Code Examples (p. 333).

**Note**
The following example doesn’t work with .NET core because it doesn’t support synchronous methods. For more information, see AWS Asynchronous APIs for .NET.

Example: Batch Write Operation Using the AWS SDK for .NET Object Persistence Model

The following C# code example declares `Book`, `Forum`, `Thread`, and `Reply` classes and maps them to Amazon DynamoDB tables using the object persistence model attributes.

The example then uses the `DynamoDBContext` to illustrate the following batch write operations:

- BatchWrite object to put and delete book items from the `ProductCatalog` table.
- MultiTableBatchWrite object to put and delete items from the `Forum` and the `Thread` tables.

For more information about the tables used in this example, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326). For step-by-step instructions to test the following example, see .NET Code Examples (p. 333).

**Note**
The following example doesn't work with .NET core because it doesn't support synchronous methods. For more information, see AWS Asynchronous APIs for .NET.

Example: Query and Scan in DynamoDB Using the AWS SDK for .NET Object Persistence Model

The C# example in this section defines the following classes and maps them to the tables in DynamoDB. For more information about creating the tables used in this example, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

- The `Book` class maps to the `ProductCatalog` table.
- The `Forum`, `Thread`, and `Reply` classes map to tables of the same name.

The example then executes the following query and scan operations using `DynamoDBContext`.

- Get a book by Id.

  The `ProductCatalog` table has `Id` as its primary key. It does not have a sort key as part of its primary key. Therefore, you cannot query the table. You can get an item using its `Id` value.

- Execute the following queries against the `Reply` table. (The `Reply` table's primary key is composed of `Id` and `ReplyDateTime` attributes. The `ReplyDateTime` is a sort key. Therefore, you can query this table.)

  - Find replies to a forum thread posted in the last 15 days.
• Find replies to a forum thread posted in a specific date range.

• Scan the ProductCatalog table to find books whose price is less than zero.

For performance reasons, you should use a query operation instead of a scan operation. However, there are times you might need to scan a table. Suppose that there was a data entry error and one of the book prices is set to less than 0. This example scans the ProductCategory table to find book items (the ProductCategory is book) at price of less than 0.

For instructions about creating a working sample, see .NET Code Examples (p. 333).

The following example does not work with .NET core because it does not support synchronous methods. For more information, see AWS Asynchronous APIs for .NET.

Running the Code Examples in This Developer Guide

The AWS SDKs provide broad support for Amazon DynamoDB in the following languages:

- Java
- JavaScript in the browser
- .NET
- Node.js
- PHP
- Python
- Ruby
- C++
- Go
- Android
- iOS

To get started quickly with these languages, see Getting Started with DynamoDB and AWS SDKs (p. 77).

The code examples in this developer guide provide more in-depth coverage of DynamoDB operations, using the following programming languages:

- Java Code Examples (p. 331)
- .NET Code Examples (p. 333)

Before you can begin with this exercise, you need to create an AWS account, get your access key and secret key, and set up the AWS Command Line Interface (AWS CLI) on your computer. For more information, see Setting Up DynamoDB (Web Service) (p. 53).

**Note**

If you are using the downloadable version of DynamoDB, you need to use the AWS CLI to create the tables and sample data. You also need to specify the --endpoint-url parameter with each AWS CLI command. For more information, see Setting the Local Endpoint (p. 51).
Creating Tables and Loading Data for Code Examples in DynamoDB

In this tutorial, you use the AWS Management Console to create tables in Amazon DynamoDB. You then load data into these tables using the AWS Command Line Interface (AWS CLI).

These tables and their data are used as examples throughout this developer guide.

**Note**

If you are an application developer, we recommend that you also read Getting Started with DynamoDB and AWS SDKs (p. 77), which uses the downloadable version of DynamoDB. This lets you learn about the DynamoDB low-level API without having to pay any fees for throughput, storage, or data transfer.

**Topics**

- Step 1: Create Example Tables (p. 326)
- Step 2: Load Data into Tables (p. 328)
- Step 3: Query the Data (p. 329)
- Step 4: (Optional) Clean Up (p. 330)
- Summary (p. 331)

**Step 1: Create Example Tables**

In this section, you use the AWS Management Console to create tables in Amazon DynamoDB for two simple use cases.

**Use Case 1: Product Catalog**

Suppose that you want to store product information in DynamoDB. Each product has its own distinct attributes, so you need to store different information about each of these products.

You can create a `ProductCatalog` table, where each item is uniquely identified by a single, numeric attribute: `Id`.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Primary Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProductCatalog</td>
<td>Partition key: Id (Number)</td>
</tr>
</tbody>
</table>

**Use Case 2: Forum Application**

Suppose that you want to build an application for message boards or discussion forums. AWS Discussion Forums represent one example of such an application. Customers can engage with the developer community, ask questions, or reply to other customers' posts. Each AWS service has a dedicated forum. Anyone can start a new discussion thread by posting a message in a forum. Each thread might receive any number of replies.

You can model this application by creating three tables: `Forum`, `Thread`, and `Reply`.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Primary Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Forum</td>
<td>Partition key: Name (String)</td>
</tr>
</tbody>
</table>
The Reply table has a global secondary index named PostedBy-Message-Index. This index facilitates queries on two non-key attributes of the Reply table.

<table>
<thead>
<tr>
<th>Index Name</th>
<th>Primary Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostedBy-Message-Index</td>
<td>Partition key: PostedBy (String)</td>
</tr>
<tr>
<td></td>
<td>Sort key: Message (String)</td>
</tr>
</tbody>
</table>

Create the ProductCatalog Table

2. Choose Create Table.
3. In the Create DynamoDB table screen, do the following:
   a. On the Table name box, enter ProductCatalog.
   b. For the Primary key, in the Partition key box, enter Id. Set the data type to Number.
4. When the settings are as you want them, choose Create.

Create the Forum Table

2. Choose Create Table.
3. In the Create DynamoDB table screen, do the following:
   a. In the Table name box, enter Forum.
   b. For the Primary key, in the Partition key box, enter Name. Set the data type to String.
4. When the settings are as you want them, choose Create.

Create the Thread Table

2. Choose Create Table.
3. In the Create DynamoDB table screen, do the following:
   a. In the Table name box, enter Thread.
   b. For the Primary key, do the following:
      • In the Partition key box, enter ForumName. Set the data type to String.
      • Choose Add sort key.
      • In the Sort key box, enter Subject. Set the data type to String.
4. When the settings are as you want them, choose **Create**.

**Create the Reply Table**

2. Choose **Create Table**.
3. In the **Create DynamoDB table** screen, do the following:
   a. In the **Table name** box, enter **Reply**.
   b. For the **Primary key**, do the following:
      - In the **Partition key** box, enter **Id**. Set the data type to **String**.
      - Choose **Add sort key**.
      - In the **Sort key** box, enter **ReplyDateTime**. Set the data type to **String**.
   c. In the **Table settings** section, clear **Use default settings**.
   d. In the **Secondary indexes** section, choose **Add index**.
   e. In the **Add index** window, do the following:
      - For the **Primary key**, do the following:
         - In the **Partition key** box, enter **PostedBy**. Set the data type to **String**.
         - Choose **Add sort key**.
         - In the **Sort key** box, enter **Message**. Set the data type to **String**.
      - In the **Index name** box, enter **PostedBy-Message-Index**.
      - Set the **Projected attributes** to **All**.
      - Choose **Add index**.
4. When the settings are as you want them, choose **Create**.

**Step 2: Load Data into Tables**

In this step, you load sample data into the tables that you created. You could enter the data manually into the Amazon DynamoDB console. However, to save time, you use the AWS Command Line Interface (AWS CLI) instead.

**Note**

If you have not yet set up the AWS CLI, see Using the AWS CLI (p. 57) for instructions.

You will download a .zip archive that contains JSON files with sample data for each table. For each file, you use the AWS CLI to load the data into DynamoDB. Each successful data load produces the following output.

```json
{
    "UnprocessedItems": {}
}
```

**Download the Sample Data File Archive**

1. Download the sample data archive (**sampledata.zip**) using this link:
   - **sampledata.zip**
2. Extract the .json data files from the archive.
3. Copy the .json data files to your current directory.
Load the Sample Data into DynamoDB Tables

1. To load the ProductCatalog table with data, enter the following command.
   
   `aws dynamodb batch-write-item --request-items file://ProductCatalog.json`

2. To load the Forum table with data, enter the following command.
   
   `aws dynamodb batch-write-item --request-items file://Forum.json`

3. To load the Thread table with data, enter the following command.
   
   `aws dynamodb batch-write-item --request-items file://Thread.json`

4. To load the Reply table with data, enter the following command.
   
   `aws dynamodb batch-write-item --request-items file://Reply.json`

Verify Data Load

You can use the AWS Management Console to verify the data that you loaded into the tables.

**To verify the data using the AWS Management Console**

2. In the navigation pane, choose **Tables**.
3. In the list of tables, choose **ProductCatalog**.
4. Choose the **Items** tab to view the data that you loaded into the table.
5. To view an item in the table, choose its **Id**. (If you want, you can also edit the item.)
6. To return to the list of tables, choose **Cancel**.

Repeat this procedure for each of the other tables you created:

- Forum
- Thread
- Reply

Step 3: Query the Data

In this step, you try some simple queries against the tables that you created, using the Amazon DynamoDB console.

2. In the navigation pane, choose **Tables**.
3. In the list of tables, choose **Reply**.
4. Choose the **Items** tab to view the data that you loaded into the table.
5. Choose the data filtering link, located just below the **Create item** button.
6. In the data filtering pane, do the following:
   a. Change the operation from **Scan** to **Query**.
   b. For the **Partition key**, enter the value **Amazon DynamoDB#DynamoDB Thread 1**.
   c. Choose **Start**. Only the items that match your query criteria are returned from the **Reply** table.

7. The **Reply** table has a global secondary index on the **PostedBy** and **Message** attributes. You can use the data filtering pane to query the index. Do the following:
   a. Change the query source from the following:
      
      `[Table] Reply: Id, ReplyDateTime`
      
      To the following:
      
      `[Index] PostedBy-Message-Index: PostedBy, Message`
   b. For the **Partition key**, enter the value **User A**.
   c. Choose **Start**. Only the items that match your query criteria are returned from **PostedBy-Message-Index**.

Take some time to explore your other tables using the DynamoDB console:

- ProductCatalog
- Forum
- Thread

**Step 4: (Optional) Clean Up**

These sample tables are used throughout the *Amazon DynamoDB Developer Guide* to help illustrate table and item operations using the low-level API and various AWS SDKs. If you plan to read the rest of this guide, you might find the tables useful as a reference. However, if you don’t want to keep these tables, you should delete them to avoid being charged for resources that you don’t need.
To delete the sample tables

2. In the navigation pane, choose Tables.
3. In the list of tables, choose ProductCatalog.
4. Choose Delete Table. You are asked to confirm your selection.

Repeat this procedure for each of the other tables you created:

- Forum
- Thread
- Reply

Summary

In this exercise, you used the DynamoDB console to create several tables in DynamoDB. You then used the AWS CLI to load data into the tables, and performed some basic operations on the data using the console.

The console and the AWS CLI are helpful for getting started quickly. However, you probably want to learn more about how DynamoDB works, and how to write application programs with DynamoDB. The rest of this developer guide addresses those topics.

- Java: Setting the AWS Region and Endpoint (p. 332)

This Developer Guide contains Java code snippets and ready-to-run programs. You can find these code examples in the following sections:

- Working with Items and Attributes (p. 375)
- Working with Tables and Data in DynamoDB (p. 336)
- Working with Queries in DynamoDB (p. 459)
- Working with Scans in DynamoDB (p. 476)
- Improving Data Access with Secondary Indexes (p. 497)
- Java: DynamoDBMapper (p. 226)
- Capturing Table Activity with DynamoDB Streams (p. 574)

You can get started quickly by using Eclipse with the AWS Toolkit for Eclipse. In addition to a full-featured IDE, you also get the AWS SDK for Java with automatic updates, and preconfigured templates for building AWS applications.

To run the Java code examples (using Eclipse)

1. Download and install the Eclipse IDE.
2. Download and install the AWS Toolkit for Eclipse.
3. Start Eclipse, and on the Eclipse menu, choose File, New, and then Other.
4. In **Select a wizard**, choose **AWS**, choose **AWS Java Project**, and then choose **Next**.

5. In **Create an AWS Java**, do the following:
   a. In **Project name**, enter a name for your project.
   b. In **Select Account**, choose your credentials profile from the list.

   If this is your first time using the **AWS Toolkit for Eclipse**, choose **Configure AWS Accounts** to set up your AWS credentials.

6. Choose **Finish** to create the project.

7. From the **Eclipse** menu, choose **File**, **New**, and then **Class**.

8. In **Java Class**, enter a name for your class in **Name** (use the same name as the code example that you want to run), and then choose **Finish** to create the class.

9. Copy the code example from the documentation page into the Eclipse editor.

10. To run the code, choose **Run** on the Eclipse menu.

The SDK for Java provides thread-safe clients for working with DynamoDB. As a best practice, your applications should create one client and reuse the client between threads.

For more information, see the **AWS SDK for Java**.

**Note**

The code examples in this guide are intended for use with the latest version of the AWS SDK for Java.

If you are using the AWS Toolkit for Eclipse, you can configure automatic updates for the SDK for Java. To do this in Eclipse, go to **Preferences** and choose **AWS Toolkit, AWS SDK for Java, Download new SDKs automatically**.

### Java: Setting Your AWS Credentials

The SDK for Java requires that you provide AWS credentials to your application at runtime. The code examples in this guide assume that you are using an AWS credentials file, as described in **Set Up Your AWS Credentials** in the **AWS SDK for Java Developer Guide**.

The following is an example of an AWS credentials file named `~/.aws/credentials`, where the tilde character (`~`) represents your home directory.

```
[default]
aws_access_key_id = AWS access key ID goes here
aws_secret_access_key = Secret key goes here
```

### Java: Setting the AWS Region and Endpoint

By default, the code examples access DynamoDB in the US West (Oregon) Region. You can change the Region by modifying the `AmazonDynamoDB` properties.

The following code example instantiates a new `AmazonDynamoDB`.

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.regions.Regions;
...
// This client will default to US West (Oregon)
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
 .withRegion(Regions.US_WEST_2)
 .build();
```
You can use the `withRegion` method to run your code against DynamoDB in any Region where it is available. For a complete list, see AWS Regions and Endpoints in the Amazon Web Services General Reference.

If you want to run the code examples using DynamoDB locally on your computer, set the endpoint as follows.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().withEndpointConfiguration(
    .build();
```

### .NET Code Examples

#### Topics

- .NET: Setting Your AWS Credentials (p. 334)
- .NET: Setting the AWS Region and Endpoint (p. 334)

This guide contains .NET code snippets and ready-to-run programs. You can find these code examples in the following sections:

- Working with Items and Attributes (p. 375)
- Working with Tables and Data in DynamoDB (p. 336)
- Working with Queries in DynamoDB (p. 459)
- Working with Scans in DynamoDB (p. 476)

- .NET: Document Model (p. 274)
- .NET: Object Persistence Model (p. 296)
- Capturing Table Activity with DynamoDB Streams (p. 574)

You can get started quickly by using the AWS SDK for .NET with the Toolkit for Visual Studio.

### To run the .NET code examples (using Visual Studio)

1. Download and install Microsoft Visual Studio.
2. Download and install the Toolkit for Visual Studio.
4. In **New Project**, choose **AWS Empty Project**, and then choose **OK**.
5. In **AWS Access Credentials**, choose **Use existing profile**, choose your credentials profile from the list, and then choose **OK**.

   If this is your first time using Toolkit for Visual Studio, choose **Use a new profile** to set up your AWS credentials.

6. In your Visual Studio project, choose the tab for your program’s source code (**Program.cs**). Copy the code example from the documentation page into the Visual Studio editor, replacing any other code that you see in the editor.

7. If you see error messages of the form The type or namespace name...could not be found, you need to install the AWS SDK assembly for DynamoDB as follows:

   a. In Solution Explorer, open the context (right-click) menu for your project, and then choose **Manage NuGet Packages**.

   b. In NuGet Package Manager, choose **Browse**.
c. In the search box, enter `AWSSDK.DynamoDBv2`, and wait for the search to complete.

d. Choose `AWSSDK.DynamoDBv2`, and then choose **Install**.

e. When the installation is complete, choose the **Program.cs** tab to return to your program.

8. To run the code, choose **Start** in the Visual Studio toolbar.

The AWS SDK for .NET provides thread-safe clients for working with DynamoDB. As a best practice, your applications should create one client and reuse the client between threads.

For more information, see **AWS SDK for .NET**.

**Note**
The code examples in this guide are intended for use with the latest version of the AWS SDK for .NET.

**.NET: Setting Your AWS Credentials**

The AWS SDK for .NET requires that you provide AWS credentials to your application at runtime. The code examples in this guide assume that you are using the SDK Store to manage your AWS credentials file, as described in **Using the SDK Store** in the **AWS SDK for .NET Developer Guide**.

The Toolkit for Visual Studio supports multiple sets of credentials from any number of accounts. Each set is referred to as a **profile**. Visual Studio adds entries to the project's **App.config** file so that your application can find the AWS credentials at runtime.

The following example shows the default **App.config** file that is generated when you create a new project using Toolkit for Visual Studio.

```xml
<configuration>
  <appSettings>
    <add key="AWSProfileName" value="default"/>
    <add key="AWSRegion" value="us-west-2"/>
  </appSettings>
</configuration>
```

At runtime, the program uses the **default** set of AWS credentials, as specified by the **AWSProfileName** entry. The AWS credentials themselves are kept in the SDK Store in encrypted form. The Toolkit for Visual Studio provides a graphical user interface for managing your credentials, all from within Visual Studio. For more information, see **Specifying Credentials** in the **AWS Toolkit for Visual Studio User Guide**.

**Note**

By default, the code examples access DynamoDB in the US West (Oregon) Region. You can change the Region by modifying the **AWSRegion** entry in the **App.config** file. You can set **AWSRegion** to any Region where DynamoDB is available. For a complete list, see **AWS Regions and Endpoints** in the **Amazon Web Services General Reference**.

**.NET: Setting the AWS Region and Endpoint**

By default, the code examples access DynamoDB in the US West (Oregon) Region. You can change the Region by modifying the **AWSRegion** entry in the **App.config** file. Or, you can change the Region by modifying the **AmazonDynamoDBClient** properties.

The following code example instantiates a new **AmazonDynamoDBClient**. The client is modified so that the code runs against DynamoDB in a different Region.

```csharp
AmazonDynamoDBConfig clientConfig = new AmazonDynamoDBConfig();
// This client will access the US East 1 region.
```
clientConfig.RegionEndpoint = RegionEndpoint.USEast1;
AmazonDynamoDBClient client = new AmazonDynamoDBClient(clientConfig);

For a complete list of Regions, see AWS Regions and Endpoints in the Amazon Web Services General Reference.

If you want to run the code examples using DynamoDB locally on your computer, set the endpoint as follows.

AmazonDynamoDBConfig clientConfig = new AmazonDynamoDBConfig();
// Set the endpoint URL
clientConfig.ServiceURL = "http://localhost:8000"
AmazonDynamoDBClient client = new AmazonDynamoDBClient(clientConfig);

Working with Tables and Data in DynamoDB

This section describes how to use the AWS Command Line Interface (AWS CLI) and the AWS SDKs to create, update, and delete tables in Amazon DynamoDB.

Note
You can also perform these same tasks using the AWS Management Console. For more information, see Using the Console (p. 55).

This section also provides more information about throughput capacity using DynamoDB auto scaling or manually setting provisioned throughput.

Basic Operations on DynamoDB Tables

Similar to other database systems, Amazon DynamoDB stores data in tables. You can manage your tables using a few basic operations.

Topics
- Creating a Table (p. 337)
- Describing a Table (p. 339)
- Updating a Table (p. 339)
- Deleting a Table (p. 340)
- Listing Table Names (p. 340)
Basic Operations on Tables

Creating a Table

Use the `CreateTable` operation to create a table in Amazon DynamoDB. To create the table, you must provide the following information:

- **Table name.** The name must conform to the DynamoDB naming rules, and must be unique for the current AWS account and Region. For example, you could create a `People` table in US East (N. Virginia) and another `People` table in Europe (Ireland). However, these two tables would be entirely different from each other. For more information, see Naming Rules and Data Types (p. 12).

- **Primary key.** The primary key can consist of one attribute (partition key) or two attributes (partition key and sort key). You need to provide the attribute names, data types, and the role of each attribute: `HASH` (for a partition key) and `RANGE` (for a sort key). For more information, see Primary Key (p. 6).

- **Throughput settings (for provisioned tables).** If using provisioned mode, you must specify the initial read and write throughput settings for the table. You can modify these settings later, or enable DynamoDB auto scaling to manage the settings for you. For more information, see Managing Settings on DynamoDB Provisioned Capacity Tables (p. 342) and Managing Throughput Capacity Automatically with DynamoDB Auto Scaling (p. 346).

**Example 1: Create a Provisioned Table**

The following AWS CLI example shows how to create a table (`Music`). The primary key consists of `Artist` (partition key) and `SongTitle` (sort key), each of which has a data type of `String`. The maximum throughput for this table is 10 read capacity units and 5 write capacity units.

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
   AttributeName=Artist,AttributeType=S \
   AttributeName=SongTitle,AttributeType=S \
  --key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
    ReadCapacityUnits=10,WriteCapacityUnits=5
```

The `CreateTable` operation returns metadata for the table, as shown following.

```
{
  "TableDescription": {
    "TableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music",
    "AttributeDefinitions": [
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "WriteCapacityUnits": 5,
      "ReadCapacityUnits": 10
    }
  }
}
```
The `TableStatus` element indicates the current state of the table (CREATING). It might take a while to create the table, depending on the values you specify for `ReadCapacityUnits` and `WriteCapacityUnits`. Larger values for these require DynamoDB to allocate more resources for the table.

**Example 2: Create an On-Demand Table**

To create the same table `Music` using on-demand mode.

```bash
aws dynamodb create-table
  --table-name Music
  --attribute-definitions
    AttributeName=Artist,AttributeType=S
    AttributeName=SongTitle,AttributeType=S
  --key-schema
    AttributeName=Artist,KeyType=HASH
    AttributeName=SongTitle,KeyType=RANGE
  --billing-mode=PAY_PER_REQUEST
```

The `CreateTable` operation returns metadata for the table, as shown following.

```json
{
  "TableDescription": {
    "TableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music",
    "AttributeDefinitions": [
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "WriteCapacityUnits": 0,
      "ReadCapacityUnits": 0
    },
    "TableSizeBytes": 0,
    "TableName": "Music",
    "BillingModeSummary": {
      "BillingMode": "PAY_PER_REQUEST"
    }
  }
}
```
Basic Operations on Tables

```
{
"TableStatus": "CREATING",
"TableId": "12345678-0123-4567-a123-abcdefghijkl",
"KeySchema": [
{
"KeyType": "HASH",
"AttributeName": "Artist"
},
{
"KeyType": "RANGE",
"AttributeName": "SongTitle"
}
],
"ItemCount": 0,
"CreationDateTime": 1542397468.348
}
```

**Important**
When calling DescribeTable on an on-demand table, read capacity units and write capacity units are set to 0.

**Describing a Table**

To view details about a table, use the DescribeTable operation. You must provide the table name. The output from DescribeTable is in the same format as that from CreateTable. It includes the timestamp when the table was created, its key schema, its provisioned throughput settings, its estimated size, and any secondary indexes that are present.

**Important**
When calling DescribeTable on an on-demand table, read capacity units and write capacity units are set to 0.

**Example**

```
aws dynamodb describe-table --table-name Music
```

The table is ready for use when the TableStatus has changed from CREATING to ACTIVE.

**Note**
If you issue a DescribeTable request immediately after a CreateTable request, DynamoDB might return an error (ResourceNotFoundException). This is because DescribeTable uses an eventually consistent query, and the metadata for your table might not be available at that moment. Wait for a few seconds, and then try the DescribeTable request again.

For billing purposes, your DynamoDB storage costs include a per-item overhead of 100 bytes. (For more information, go to DynamoDB Pricing.) This extra 100 bytes per item is not used in capacity unit calculations or by the DescribeTable operation.

**Updating a Table**

The UpdateTable operation allows you to do one of the following:

- Modify a table's provisioned throughput settings (for provisioned mode tables).
- Change the table's read/write capacity mode.
- Manipulate global secondary indexes on the table (see Using Global Secondary Indexes in DynamoDB (p. 500)).
- Enable or disable DynamoDB Streams on the table (see Capturing Table Activity with DynamoDB Streams (p. 574)).
Example

The following AWS CLI example shows how to modify a table's provisioned throughput settings.

```
aws dynamodb update-table --table-name Music \
--provisioned-throughput ReadCapacityUnits=20,WriteCapacityUnits=10
```

Note

When you issue an UpdateTable request, the status of the table changes from AVAILABLE to UPDATING. The table remains fully available for use while it is UPDATING. When this process is completed, the table status changes from UPDATING to AVAILABLE.

Example

The following AWS CLI example shows how to modify a table's read/write capacity mode to on-demand mode.

```
aws dynamodb update-table --table-name Music \
--billing-mode PAY_PER_REQUEST
```

Deleting a Table

You can remove an unused table with the DeleteTable operation. Deleting a table is an unrecoverable operation.

Example

The following AWS CLI example shows how to delete a table.

```
aws dynamodb delete-table --table-name Music
```

When you issue a DeleteTable request, the table's status changes from ACTIVE to DELETING. It might take a while to delete the table, depending on the resources it uses (such as the data stored in the table, and any streams or indexes on the table).

When the DeleteTable operation concludes, the table no longer exists in DynamoDB.

Listing Table Names

The ListTables operation returns the names of the DynamoDB tables for the current AWS account and Region.

Example

The following AWS CLI example shows how to list the DynamoDB table names.

```
aws dynamodb list-tables
```

Describing Provisioned Throughput Limits

The DescribeLimits operation returns the current read and write capacity limits for the current AWS account and Region.
Example

The following AWS CLI example shows how to describe the current provisioned throughput limits.

```
aws dynamodb describe-limits
```

The output shows the upper limits of read and write capacity units for the current AWS account and Region.

For more information about these limits, and how to request limit increases, see Throughput Default Limits (p. 962).

Considerations When Changing Read/Write Capacity Mode

You can switch between read/write capacity modes once every 24 hours. Consider the following when updating your read/write capacity mode in Amazon DynamoDB.

Managing Capacity

When you update a table from provisioned to on-demand mode, you don't need to specify how much read and write throughput you expect your application to perform.

Consider the following when you update a table from on-demand to provisioned mode:

- If you’re using the AWS Management Console, the console estimates initial provisioned capacity values based on the consumed read and write capacity of your table and global secondary indexes over the past 30 minutes. To override these recommended values, choose Override recommended values.

- If you’re using the AWS CLI or AWS SDK, choose the right provisioned capacity settings of your table and global secondary indexes by using Amazon CloudWatch to look at your historical consumption (ConsumedWriteCapacityUnits and ConsumedReadCapacityUnits metrics) to determine the new throughput settings.

  **Note**

  If you’re switching a global table to provisioned mode, look at the maximum consumption across all your regional replicas for base tables and global secondary indexes when determining the new throughput settings.

Managing Auto Scaling

When you update a table from provisioned to on-demand mode:

- If you’re using the console, all of your auto scaling settings (if any) will be deleted.
- If you’re using the AWS CLI or AWS SDK, all of your auto scaling settings will be preserved. These settings can be applied when you update your table to provisioned billing mode again.

When you update a table from on-demand to provisioned mode:

- If you’re using the console, DynamoDB recommends enabling auto scaling with the following defaults:
  - Target utilization: 70%
  - Minimum provisioned capacity: 5 units
  - Maximum provisioned capacity: The Region maximum
- If you’re using the AWS CLI or SDK, your previous auto scaling settings (if any) are preserved.
Managing Settings on DynamoDB Provisioned Capacity Tables

When you create a new provisioned table in Amazon DynamoDB, you must specify its provisioned throughput capacity. This is the amount of read and write activity that the table can support. DynamoDB uses this information to reserve sufficient system resources to meet your throughput requirements.

**Note**
You can create an on-demand mode table instead so that you don't have to manage any capacity settings for servers, storage, or throughput. DynamoDB instantly accommodates your workloads as they ramp up or down to any previously reached traffic level. If a workload's traffic level hits a new peak, DynamoDB adapts rapidly to accommodate the workload. For more information, see On-Demand Mode (p. 17).

You can optionally allow DynamoDB auto scaling to manage your table's throughput capacity. However, you still must provide initial settings for read and write capacity when you create the table. DynamoDB auto scaling uses these initial settings as a starting point, and then adjusts them dynamically in response to your application's requirements. For more information, see Managing Throughput Capacity Automatically with DynamoDB Auto Scaling (p. 346).

As your application data and access requirements change, you might need to adjust your table's throughput settings. If you're using DynamoDB auto scaling, the throughput settings are automatically adjusted in response to actual workloads. You can also use the `UpdateTable` operation to manually adjust your table's throughput capacity. You might decide to do this if you need to bulk-load data from an existing data store into your new DynamoDB table. You could create the table with a large write throughput setting and then reduce this setting after the bulk data load is complete.

You specify throughput requirements in terms of capacity units—the amount of data your application needs to read or write per second. You can modify these settings later, if needed, or enable DynamoDB auto scaling to modify them automatically.

**Read Capacity Units**

A read capacity unit represents one strongly consistent read per second, or two eventually consistent reads per second, for an item up to 4 KB in size.

**Note**
To learn more about DynamoDB read consistency models, see Read Consistency (p. 16).

For example, suppose that you create a table with 10 provisioned read capacity units. This allows you to perform 10 strongly consistent reads per second, or 20 eventually consistent reads per second, for items up to 4 KB.

Reading an item larger than 4 KB consumes more read capacity units. For example, a strongly consistent read of an item that is 8 KB (4 KB × 2) consumes 2 read capacity units. An eventually consistent read on that same item consumes only 1 read capacity unit.
Item sizes for reads are rounded up to the next 4 KB multiple. For example, reading a 3,500-byte item consumes the same throughput as reading a 4 KB item.

**Capacity Unit Consumption for Reads**

The following describes how DynamoDB read operations consume read capacity units:

- **GetItem**—Reads a single item from a table. To determine the number of capacity units that GetItem will consume, take the item size and round it up to the next 4 KB boundary. If you specified a strongly consistent read, this is the number of capacity units required. For an eventually consistent read (the default), divide this number by two.

  For example, if you read an item that is 3.5 KB, DynamoDB rounds the item size to 4 KB. If you read an item of 10 KB, DynamoDB rounds the item size to 12 KB.

- **BatchGetItem**—Reads up to 100 items, from one or more tables. DynamoDB processes each item in the batch as an individual GetItem request, so DynamoDB first rounds up the size of each item to the next 4 KB boundary, and then calculates the total size. The result is not necessarily the same as the total size of all the items. For example, if BatchGetItem reads a 1.5 KB item and a 6.5 KB item, DynamoDB calculates the size as 12 KB (4 KB + 8 KB), not 8 KB (1.5 KB + 6.5 KB).

- **Query**—Reads multiple items that have the same partition key value. All items returned are treated as a single read operation, where DynamoDB computes the total size of all items and then rounds up to the next 4 KB boundary. For example, suppose your query returns 10 items whose combined size is 40.8 KB. DynamoDB rounds the item size for the operation to 44 KB. If a query returns 1500 items of 64 bytes each, the cumulative size is 96 KB.

- **Scan**—Reads all items in a table. DynamoDB considers the size of the items that are evaluated, not the size of the items returned by the scan.

If you perform a read operation on an item that does not exist, DynamoDB still consumes provisioned read throughput: A strongly consistent read request consumes one read capacity unit, while an eventually consistent read request consumes 0.5 of a read capacity unit.

For any operation that returns items, you can request a subset of attributes to retrieve. However, doing so has no impact on the item size calculations. In addition, Query and Scan can return item counts instead of attribute values. Getting the count of items uses the same quantity of read capacity units and is subject to the same item size calculations. This is because DynamoDB has to read each item in order to increment the count.

**Read Operations and Read Consistency**

The preceding calculations assume strongly consistent read requests. For an eventually consistent read request, the operation consumes only half the capacity units. For an eventually consistent read, if the total item size is 80 KB, the operation consumes only 10 capacity units.

**Write Capacity Units**

A write capacity unit represents one write per second, for an item up to 1 KB in size.

For example, suppose that you create a table with 10 write capacity units. This allows you to perform 10 writes per second, for items up to 1 KB in size per second.

Item sizes for writes are rounded up to the next 1 KB multiple. For example, writing a 500-byte item consumes the same throughput as writing a 1 KB item.

**Capacity Unit Consumption for Writes**

The following describes how DynamoDB write operations consume write capacity units:
• **PutItem**—Writes a single item to a table. If an item with the same primary key exists in the table, the operation replaces the item. For calculating provisioned throughput consumption, the item size that matters is the larger of the two.

• **UpdateItem**—Modifies a single item in the table. DynamoDB considers the size of the item as it appears before and after the update. The provisioned throughput consumed reflects the larger of these item sizes. Even if you update just a subset of the item's attributes, **UpdateItem** will still consume the full amount of provisioned throughput (the larger of the "before" and "after" item sizes).

• **DeleteItem**—Removes a single item from a table. The provisioned throughput consumption is based on the size of the deleted item.

• **BatchWriteItem**—Writes up to 25 items to one or more tables. DynamoDB processes each item in the batch as an individual **PutItem** or **DeleteItem** request (updates are not supported). So DynamoDB first rounds up the size of each item to the next 1 KB boundary, and then calculates the total size. The result is not necessarily the same as the total size of all the items. For example, if **BatchWriteItem** writes a 500-byte item and a 3.5 KB item, DynamoDB calculates the size as 5 KB (1 KB + 4 KB), not 4 KB (500 bytes + 3.5 KB).

For **PutItem**, **UpdateItem**, and **DeleteItem** operations, DynamoDB rounds the item size up to the next 1 KB. For example, if you put or delete an item of 1.6 KB, DynamoDB rounds the item size up to 2 KB.

**PutItem**, **UpdateItem**, and **DeleteItem** allow **conditional writes**, where you specify an expression that must evaluate to true in order for the operation to succeed. If the expression evaluates to false, DynamoDB still consumes write capacity units from the table:

• For an existing item, the number of write capacity units consumed depends on the size of the new item. (For example, a failed conditional write of a 1 KB item would consume one write capacity unit. If the new item were twice that size, the failed conditional write would consume two write capacity units.)

• For a new item, DynamoDB consumes one write capacity unit.

### Request Throttling and Burst Capacity

If your application performs reads or writes at a higher rate than your table can support, DynamoDB begins to **throttle** those requests. When DynamoDB throttles a read or write, it returns a **ProvisionedThroughputExceededException** to the caller. The application can then take appropriate action, such as waiting for a short interval before retrying the request.

**Note**

We recommend that you use the AWS SDKs for software development. The AWS SDKs provide built-in support for retrying throttled requests; you do not need to write this logic yourself. For more information, see Error Retries and Exponential Backoff (p. 225).

The DynamoDB console displays Amazon CloudWatch metrics for your tables, so you can monitor throttled read requests and write requests. If you encounter excessive throttling, you should consider increasing your table's provisioned throughput settings.

In some cases, DynamoDB uses **burst capacity** to accommodate reads or writes in excess of your table's throughput settings. With burst capacity, unexpected read or write requests can succeed where they otherwise would be throttled. For more information, see Using Burst Capacity Effectively (p. 901).

### Request Throttling and Adaptive Capacity

DynamoDB automatically distributes your data across partitions, which are stored on multiple servers in the AWS Cloud (For more information, see Partitions and Data Distribution (p. 21)). It's not always possible to distribute read and write activity evenly all the time. When data access is imbalanced, a
"hot" partition can receive such a higher volume of read and write traffic compared to other partitions. Adaptive capacity works by automatically increasing throughput capacity for partitions that receive more traffic. For more information, see Understanding DynamoDB Adaptive Capacity (p. 901).

Choosing Initial Throughput Settings

Every application has different requirements for reading and writing from a database. When you are determining the initial throughput settings for a DynamoDB table, take the following inputs into consideration:

- Item sizes. Some items are small enough that they can be read or written using a single capacity unit. Larger items require multiple capacity units. By estimating the sizes of the items that will be in your table, you can specify accurate settings for your table's provisioned throughput.

- Expected read and write request rates. In addition to item size, you should estimate the number of reads and writes you need to perform per second.

- Read consistency requirements. Read capacity units are based on strongly consistent read operations, which consume twice as many database resources as eventually consistent reads. You should determine whether your application requires strongly consistent reads, or whether it can relax this requirement and perform eventually consistent reads instead. (Read operations in DynamoDB are eventually consistent, by default. You can request strongly consistent reads for these operations if necessary.)

For example, suppose that you want to read 80 items per second from a table. The items are 3 KB in size, and you want strongly consistent reads. For this scenario, each read requires one provisioned read capacity unit. To determine this number, you divide the item size of the operation by 4 KB, and then round up to the nearest whole number, as in this example:

- \( \frac{3 \text{ KB}}{4 \text{ KB}} = 0.75 \), or \( 1 \) read capacity unit

For this scenario, you have to set the table's provisioned read throughput to 80 read capacity units:

- \( 1 \) read capacity unit per item \( \times \) 80 reads per second = 80 read capacity units

Now suppose that you want to write 100 items per second to your table, and that the items are 512 bytes in size. For this scenario, each write requires one provisioned write capacity unit. To determine this number, you divide the item size of the operation by 1 KB, and then round up to the nearest whole number:

- \( \frac{512 \text{ bytes}}{1 \text{ KB}} = 0.5 \), or \( 1 \)

For this scenario, you would want to set the table's provisioned write throughput to 100 write capacity units:

- \( 1 \) write capacity unit per item \( \times \) 100 writes per second = 100 write capacity units

Note
For recommendations on provisioned throughput and related topics, see Best Practices for Designing and Using Partition Keys Effectively (p. 901).

Modifying Throughput Settings

If you have enabled DynamoDB auto scaling for a table, then its throughput capacity is dynamically adjusted in response to actual usage. No manual intervention is required.
You can modify your table’s provisioned throughput settings using the AWS Management Console or the UpdateTable operation. For more information about throughput increases and decreases per day, see Service, Account, and Table Limits in Amazon DynamoDB (p. 961).

DynamoDB Item Sizes and Formats

DynamoDB tables are schemaless, except for the primary key, so the items in a table can all have different attributes, sizes, and data types.

The total size of an item is the sum of the lengths of its attribute names and values. You can use the following guidelines to estimate attribute sizes:

- **Strings** are Unicode with UTF-8 binary encoding. The size of a string is \((\text{length of attribute name}) + (\text{number of UTF-8-encoded bytes})\).
- **Numbers** are variable length, with up to 38 significant digits. Leading and trailing zeroes are trimmed. The size of a number is approximately \((\text{length of attribute name}) + (1 \text{ byte per two significant digits}) + (1 \text{ byte})\).
- A binary value must be encoded in base64 format before it can be sent to DynamoDB, but the value's raw byte length is used for calculating size. The size of a binary attribute is \((\text{length of attribute name}) + (\text{number of raw bytes})\).
- The size of a null attribute or a Boolean attribute is \((\text{length of attribute name}) + (1 \text{ byte})\).
- An attribute of type List or Map requires 3 bytes of overhead, regardless of its contents. The size of a List or Map is \((\text{length of attribute name}) + \text{sum (size of nested elements)} + (3 \text{ bytes})\). The size of an empty List or Map is \((\text{length of attribute name}) + (3 \text{ bytes})\).

**Note**
We recommend that you choose shorter attribute names rather than long ones. This helps you reduce the amount of storage required, but also can lower the amount of RCU/WCUs you use.

Managing Throughput Capacity Automatically with DynamoDB Auto Scaling

Many database workloads are cyclical in nature or are difficult to predict in advance. For example, consider a social networking app where most of the users are active during daytime hours. The database must be able to handle the daytime activity, but there's no need for the same levels of throughput at night. Another example might be a new mobile gaming app that is experiencing rapid adoption. If the game becomes too popular, it could exceed the available database resources, resulting in slow performance and unhappy customers. These kinds of workloads often require manual intervention to scale database resources up or down in response to varying usage levels.

Amazon DynamoDB auto scaling uses the AWS Application Auto Scaling service to dynamically adjust provisioned throughput capacity on your behalf, in response to actual traffic patterns. This enables a table or a global secondary index to increase its provisioned read and write capacity to handle sudden increases in traffic, without throttling. When the workload decreases, Application Auto Scaling decreases the throughput so that you don't pay for unused provisioned capacity.

**Note**
If you use the AWS Management Console to create a table or a global secondary index, DynamoDB auto scaling is enabled by default. You can modify your auto scaling settings at any time. For more information, see Using the AWS Management Console with DynamoDB Auto Scaling (p. 349).

With Application Auto Scaling, you create a *scaling policy* for a table or a global secondary index. The scaling policy specifies whether you want to scale read capacity or write capacity (or both), and the minimum and maximum provisioned capacity unit settings for the table or index.
The scaling policy also contains a *target utilization*—the percentage of consumed provisioned throughput at a point in time. Application Auto Scaling uses a *target tracking* algorithm to adjust the provisioned throughput of the table (or index) upward or downward in response to actual workloads, so that the actual capacity utilization remains at or near your target utilization.

You can set the auto scaling target utilization values between 20 and 90 percent for your read and write capacity.

**Note**
In addition to tables, DynamoDB auto scaling also supports global secondary indexes. Every global secondary index has its own provisioned throughput capacity, separate from that of its base table. When you create a scaling policy for a global secondary index, Application Auto Scaling adjusts the provisioned throughput settings for the index to ensure that its actual utilization stays at or near your desired utilization ratio.

### How DynamoDB Auto Scaling Works

**Note**
To get started quickly with DynamoDB auto scaling, see [Using the AWS Management Console with DynamoDB Auto Scaling](p. 349).

The following diagram provides a high-level overview of how DynamoDB auto scaling manages throughput capacity for a table.

The following steps summarize the auto scaling process as shown in the previous diagram:

1. You create an Application Auto Scaling policy for your DynamoDB table.
2. DynamoDB publishes consumed capacity metrics to Amazon CloudWatch.
3. If the table’s consumed capacity exceeds your target utilization (or falls below the target) for a specific length of time, Amazon CloudWatch triggers an alarm. You can view the alarm on the console and receive notifications using Amazon Simple Notification Service (Amazon SNS).
4. The CloudWatch alarm invokes Application Auto Scaling to evaluate your scaling policy.
5. Application Auto Scaling issues an `UpdateTable` request to adjust your table's provisioned throughput.
6. DynamoDB processes the `UpdateTable` request, dynamically increasing (or decreasing) the table's provisioned throughput capacity so that it approaches your target utilization.

To understand how DynamoDB auto scaling works, suppose that you have a table named `ProductCatalog`. The table is bulk-loaded with data infrequently, so it doesn't incur very much write activity. However, it does experience a high degree of read activity, which varies over time. By monitoring the Amazon CloudWatch metrics for `ProductCatalog`, you determine that the table requires 1,200 read capacity units (to avoid DynamoDB throttling read requests when activity is at its peak). You also determine that `ProductCatalog` requires 150 read capacity units at a minimum, when read traffic is at its lowest point.

Within the range of 150 to 1,200 read capacity units, you decide that a target utilization of 70 percent would be appropriate for the `ProductCatalog` table. Target utilization is the ratio of consumed capacity units to provisioned capacity units, expressed as a percentage. Application Auto Scaling uses its target tracking algorithm to ensure that the provisioned read capacity of `ProductCatalog` is adjusted as required so that utilization remains at or near 70 percent.

**Note**

DynamoDB auto scaling modifies provisioned throughput settings only when the actual workload stays elevated (or depressed) for a sustained period of several minutes. The Application Auto Scaling target tracking algorithm seeks to keep the target utilization at or near your chosen value over the long term. Sudden, short-duration spikes of activity are accommodated by the table's built-in burst capacity. For more information, see Using Burst Capacity Effectively (p. 901).

To enable DynamoDB auto scaling for the `ProductCatalog` table, you create a scaling policy. This policy specifies the following:

- The table or global secondary index that you want to manage
- Which capacity type to manage (read capacity or write capacity)
- The upper and lower boundaries for the provisioned throughput settings
- Your target utilization

When you create a scaling policy, Application Auto Scaling creates a pair of Amazon CloudWatch alarms on your behalf. Each pair represents your upper and lower boundaries for provisioned throughput settings. These CloudWatch alarms are triggered when the table's actual utilization deviates from your target utilization for a sustained period of time.

When one of the CloudWatch alarms is triggered, Amazon SNS sends you a notification (if you have enabled it). The CloudWatch alarm then invokes Application Auto Scaling, which in turn notifies DynamoDB to adjust the `ProductCatalog` table's provisioned capacity upward or downward as appropriate.

**Usage Notes**

Before you begin using DynamoDB auto scaling, you should be aware of the following:

- DynamoDB auto scaling can increase read capacity or write capacity as often as necessary, in accordance with your auto scaling policy. All DynamoDB limits remain in effect, as described in Limits in DynamoDB.
- DynamoDB auto scaling doesn't prevent you from manually modifying provisioned throughput settings. These manual adjustments don't affect any existing CloudWatch alarms that are related to DynamoDB auto scaling.
• If you enable DynamoDB auto scaling for a table that has one or more global secondary indexes, we highly recommend that you also apply auto scaling uniformly to those indexes. You can do this by choosing **Apply same settings to global secondary indexes** in the AWS Management Console. For more information, see [Enabling DynamoDB Auto Scaling on Existing Tables](p. 350).

**Using the AWS Management Console with DynamoDB Auto Scaling**

When you use the AWS Management Console to create a new table, Amazon DynamoDB auto scaling is enabled for that table by default. You can also use the console to enable auto scaling for existing tables, modify auto scaling settings, or disable auto scaling.

**Note**

For more advanced features like setting scale-in and scale-out cooldown times, use the AWS Command Line Interface (AWS CLI) to manage DynamoDB auto scaling. For more information, see [Using the AWS CLI to Manage DynamoDB Auto Scaling](p. 351).

**Topics**

- Before You Begin: Granting User Permissions for DynamoDB Auto Scaling (p. 349)
- Creating a New Table with Auto Scaling Enabled (p. 349)
- Enabling DynamoDB Auto Scaling on Existing Tables (p. 350)
- Viewing Auto Scaling Activities on the Console (p. 351)
- Modifying or Disabling DynamoDB Auto Scaling Settings (p. 351)

**Before You Begin: Granting User Permissions for DynamoDB Auto Scaling**

In AWS Identity and Access Management (IAM), the AWS managed policy `DynamoDBFullAccess` provides the required permissions for using the DynamoDB console. However, for DynamoDB auto scaling, IAM users require additional privileges.

**Important**

`application-autoscaling:*` permissions are required to delete an auto scaling-enabled table. The AWS managed policy `DynamoDBFullAccess` includes such permissions.

To set up an IAM user for DynamoDB console access and DynamoDB auto scaling, add the following policy.

**To attach the AmazonDynamoDBFullAccess policy**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. On the IAM console dashboard, choose **Users**, and then choose your IAM user from the list.
3. On the **Summary** page, choose **Add permissions**.
4. Choose **Attach existing policies directly**.
5. From the list of policies, choose `AmazonDynamoDBFullAccess`, and then choose **Next: Review**.
6. Choose **Add permissions**.

**Creating a New Table with Auto Scaling Enabled**

**Note**

DynamoDB auto scaling requires the presence of a service linked role (AWS_service_role_for_application_autoscaling_DynamoDBTable) that performs auto scaling actions on your behalf. This role is created automatically for you. For more information, see [Service-Linked Roles for Application Auto Scaling](Application Auto Scaling User Guide) in the Application Auto Scaling User Guide.
To create a new table with auto scaling enabled

2. Choose **Create Table**.
3. On the **Create DynamoDB table** page, enter a **Table name** and **Primary key** details.
4. Ensure that **Use default settings** is selected. (Your AWS account already has `AWSServiceRoleForApplicationAutoScaling_DynamoDBTable`.)

   Otherwise, for custom settings:
   1. Clear **Use default settings**.
   2. In the **Auto scaling** section, set the parameter settings and ensure that `AWSServiceRoleForApplicationAutoScaling_DynamoDBTable` is selected.

5. When the settings are as you want them, choose **Create**. Your table is created with the auto scaling parameters.

### Enabling DynamoDB Auto Scaling on Existing Tables

**Note**
DynamoDB auto scaling requires the presence of a service linked role (`AWSServiceRoleForApplicationAutoScaling_DynamoDBTable`) that performs auto scaling actions on your behalf. This role is created automatically for you. For more information, see [Service-Linked Roles for Application Auto Scaling](https://docs.aws.amazon.com/autoscaling/application/latest/userguide/awssrvcrl.html).

If you have never used DynamoDB auto scaling before, see [Creating a New Table with Auto Scaling Enabled](p. 349).

To enable DynamoDB auto scaling for an existing table

2. Choose the table that you want to work with, and then choose **Capacity**.
3. In the **Auto Scaling** section, do the following:
   - Select **Read capacity**, **Write capacity**, or both. (For write capacity, you can choose **Same settings as read**.) For each of these, do the following:
     - **Target utilization**—Enter your target utilization percentage for the table.
     - **Minimum provisioned capacity**—Enter your lower boundary for the auto scaling range.
     - **Maximum provisioned capacity**—Enter your upper boundary for the auto scaling range.
     - **Apply same settings to global secondary indexes**—Keep this option at its default setting (enabled).

   **Note**
   For best performance, we recommend that you enable **Apply same settings to global secondary indexes**. This option allows DynamoDB auto scaling to uniformly scale all the global secondary indexes on the base table. This includes existing global secondary indexes, and any others that you create for this table in the future. With this option enabled, you can't set a scaling policy on an individual global secondary index.

   (For **Write capacity**, you can choose **Same settings as read**.)

   In the **IAM Role** section, ensure that `AWSServiceRoleForApplicationAutoScaling_DynamoDBTable` is selected.

4. When the settings are as you want them, choose **Save**.
Viewing Auto Scaling Activities on the Console

As your application drives read and write traffic to your table, DynamoDB auto scaling dynamically modifies the table's throughput settings.

To view these auto scaling activities on the DynamoDB console, choose the table that you want to work with. Choose Capacity, and then expand the Scaling activities section. When your table's throughput settings are modified, you see informational messages here.

Modifying or Disabling DynamoDB Auto Scaling Settings

You can use the AWS Management Console to modify your DynamoDB auto scaling settings. To do this, go to the Capacity tab for your table, and modify the settings in the Auto Scaling section. For more information about these settings, see Enabling DynamoDB Auto Scaling on Existing Tables (p. 350).

To disable DynamoDB auto scaling, go to the Capacity tab for your table and clear Read capacity, Write capacity, or both.

Using the AWS CLI to Manage DynamoDB Auto Scaling

Instead of using the AWS Management Console, you can use the AWS Command Line Interface (AWS CLI) to manage Amazon DynamoDB auto scaling. The tutorial in this section demonstrates how to install and configure the AWS CLI for managing DynamoDB auto scaling. In this tutorial, you do the following:

- Create a DynamoDB table named TestTable. The initial throughput settings are 5 read capacity units and 5 write capacity units.
- Create an Application Auto Scaling policy for TestTable. The policy seeks to maintain a 50 percent target ratio between consumed write capacity and provisioned write capacity. The range for this metric is between 5 and 10 write capacity units. (Application Auto Scaling is not allowed to adjust the throughput beyond this range.)
- Run a Python program to drive write traffic to TestTable. When the target ratio exceeds 50 percent for a sustained period of time, Application Auto Scaling notifies DynamoDB to adjust the throughput of TestTable upward to maintain the 50 percent target utilization.
- Verify that DynamoDB has successfully adjusted the provisioned write capacity for TestTable.

Topics

- Before You Begin (p. 351)
- Step 1: Create a DynamoDB Table (p. 352)
- Step 2: Register a Scalable Target (p. 352)
- Step 3: Create a Scaling Policy (p. 353)
- Step 4: Drive Write Traffic to TestTable (p. 354)
- Step 5: View Application Auto Scaling Actions (p. 355)
- (Optional) Step 6: Clean Up (p. 356)

Before You Begin

Complete the following tasks before starting the tutorial.

Install the AWS CLI

If you haven't already done so, you must install and configure the AWS CLI. To do this, follow these instructions in the AWS Command Line Interface User Guide:
Install Python

Part of this tutorial requires you to run a Python program (see Step 4: Drive Write Traffic to TestTable (p. 354)). If you don't already have it installed, you can download Python.

Step 1: Create a DynamoDB Table

In this step, you use the AWS CLI to create TestTable. The primary key consists of pk (partition key) and sk (sort key). Both of these attributes are of type Number. The initial throughput settings are 5 read capacity units and 5 write capacity units.

1. Use the following AWS CLI command to create the table.

```
aws dynamodb create-table
  --table-name TestTable
  --attribute-definitions
    AttributeName=pk,AttributeType=N
    AttributeName=sk,AttributeType=N
  --key-schema
    AttributeName=pk,KeyType=HASH
    AttributeName=sk,KeyType=RANGE
  --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5
```

2. To check the status of the table, use the following command.

```
aws dynamodb describe-table
  --table-name TestTable
  --query "Table.[TableName,TableStatus,ProvisionedThroughput]"
```

The table is ready for use when its status is ACTIVE.

Step 2: Register a Scalable Target

Next you register the table's write capacity as a scalable target with Application Auto Scaling. This allows Application Auto Scaling to adjust the provisioned write capacity for TestTable, but only within the range of 5–10 capacity units.

**Note**

DynamoDB auto scaling requires the presence of a service linked role (AWSServiceRoleForApplicationAutoScaling_DynamoDBTable) that performs auto scaling actions on your behalf. This role is created automatically for you. For more information, see Service-Linked Roles for Application Auto Scaling in the Application Auto Scaling User Guide.

1. Enter the following command to register the scalable target.

```
aws application-autoscaling register-scalable-target
  --service-namespace dynamodb
  --resource-id "table/TestTable"
  --scalable-dimension "dynamodb:table:WriteCapacityUnits"
  --min-capacity 5
```
2. To verify the registration, use the following command.

```bash
aws application-autoscaling describe-scalable-targets
   --service-namespace dynamodb
   --resource-id "table/TestTable"
```

Note
You can also register a scalable target against a global secondary index. For example, for a
global secondary index ("test-index"), the resource ID and scalable dimension arguments are
updated appropriately.

```bash
aws application-autoscaling register-scalable-target
   --service-namespace dynamodb
   --resource-id "table/TestTable/index/test-index"
   --scalable-dimension "dynamodb:index:WriteCapacityUnits"
   --min-capacity 5
   --max-capacity 10
```

### Step 3: Create a Scaling Policy

In this step, you create a scaling policy for TestTable. The policy defines the details under which
Application Auto Scaling can adjust your table's provisioned throughput, and what actions to take when
it does so. You associate this policy with the scalable target that you defined in the previous step (write
capacity units for the TestTable table).

The policy contains the following elements:

- **PredefinedMetricSpecification**—The metric that Application Auto Scaling is allowed to adjust.
  For DynamoDB, the following values are valid values for PredefinedMetricType:
  - DynamoDBReadCapacityUtilization
  - DynamoDBWriteCapacityUtilization
- **ScaleOutCoolDown**—The minimum amount of time (in seconds) between each Application Auto
  Scaling event that increases provisioned throughput. This parameter allows Application Auto Scaling
  to continuously, but not aggressively, increase the throughput in response to real-world workloads.
  The default setting for ScaleOutCoolDown is 0.
- **ScaleInCoolDown**—The minimum amount of time (in seconds) between each Application Auto
  Scaling event that decreases provisioned throughput. This parameter allows Application Auto Scaling
  to decrease the throughput gradually and predictably. The default setting for ScaleInCoolDown is 0.
- **TargetValue**—Application Auto Scaling ensures that the ratio of consumed capacity to provisioned
capacity stays at or near this value. You define TargetValue as a percentage.

Note
To further understand how TargetValue works, suppose that you have a table with a
provisioned throughput setting of 200 write capacity units. You decide to create a scaling policy
for this table, with a TargetValue of 70 percent.
Now suppose that you begin driving write traffic to the table so that the actual write throughput
is 150 capacity units. The consumed-to-provisioned ratio is now (150 / 200), or 75 percent. This
ratio exceeds your target, so Application Auto Scaling increases the provisioned write capacity
to 215 so that the ratio is (150 / 215), or 69.77 percent—as close to your TargetValue as possible, but not exceeding it.

For TestTable, you set TargetValue to 50 percent. Application Auto Scaling adjusts the table's provisioned throughput within the range of 5–10 capacity units (see Step 2: Register a Scalable Target (p. 352)) so that the consumed-to-provisioned ratio remains at or near 50 percent. You set the values for ScaleOutCooldown and ScaleInCooldown to 60 seconds.

1. Create a file named `scaling-policy.json` with the following contents.

   ```json
   {
     "PredefinedMetricSpecification": {
       "PredefinedMetricType": "DynamoDBWriteCapacityUtilization"
     },
     "ScaleOutCooldown": 60,
     "ScaleInCooldown": 60,
     "TargetValue": 50.0
   }
   ```

2. Use the following AWS CLI command to create the policy.

   ```bash
   aws application-autoscaling put-scaling-policy \
   --service-namespace dynamodb \
   --resource-id "table/TestTable" \
   --scalable-dimension "dynamodb:table:WriteCapacityUnits" \
   --policy-name "MyScalingPolicy" \
   --policy-type "TargetTrackingScaling" \
   --target-tracking-scaling-policy-configuration file://scaling-policy.json
   ```

3. In the output, note that Application Auto Scaling has created two Amazon CloudWatch alarms—one each for the upper and lower boundary of the scaling target range.

4. Use the following AWS CLI command to view more details about the scaling policy.

   ```bash
   aws application-autoscaling describe-scaling-policies \
   --service-namespace dynamodb \
   --resource-id "table/TestTable" \
   --policy-name "MyScalingPolicy"
   ```

5. In the output, verify that the policy settings match your specifications from Step 2: Register a Scalable Target (p. 352) and Step 3: Create a Scaling Policy (p. 353).

**Step 4: Drive Write Traffic to TestTable**

Now you can test your scaling policy by writing data to TestTable. To do this, you run a Python program.

1. Create a file named `bulk-load-test-table.py` with the following contents.

   ```python
   import boto3
   dynamodb = boto3.resource('dynamodb')
   table = dynamodb.Table("TestTable")
   filler = "x" * 100000
   ```
i = 0
while (i < 10):
    j = 0
    while (j < 10):
        print (i, j)
        table.put_item(
            Item=
            {'pk':i,
             'sk':j,
             'filler':{'S':filler}
            }
        )
        j += 1
    i += 1

2. Enter the following command to run the program.

    python bulk-load-test-table.py

    The provisioned write capacity for TestTable is very low (5 write capacity units), so the program stalls occasionally due to write throttling. This is expected behavior.

    Let the program continue running while you move on to the next step.

**Step 5: View Application Auto Scaling Actions**

In this step, you view the Application Auto Scaling actions that are initiated on your behalf. You also verify that Application Auto Scaling has updated the provisioned write capacity for TestTable.

1. Enter the following command to view the Application Auto Scaling actions.

    aws application-autoscaling describe-scaling-activities \
    --service-namespace dynamodb

    Rerun this command occasionally, while the Python program is running. (It takes several minutes before your scaling policy is invoked.) You should eventually see the following output.

    ...
    {
        "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
        "Description": "Setting write capacity units to 10.",
        "ResourceId": "table/TestTable",
        "ActivityId": "0cc6eb03-2a7c-4b51-b67f-217224c6b656",
        "StartTime": 1489088210.175,
        "ServiceNamespace": "dynamodb",
        "EndTime": 1489088246.85,
        "Cause": "monitor alarm AutoScaling-table/TestTable-AlarmHigh-1bb3c8db-1b97-4353-baf1-4def76f4e1b9 in state ALARM triggered policy MyScalingPolicy",
        "StatusMessage": "Successfully set write capacity units to 10. Change successfully fulfilled by dynamodb.",
        "StatusCode": "Successful"
    },
    ...

    This indicates that Application Auto Scaling has issued an UpdateTable request to DynamoDB.

2. Enter the following command to verify that DynamoDB increased the table's write capacity.
aws dynamodb describe-table \
--table-name TestTable \
--query "Table.[TableName,TableStatus,ProvisionedThroughput]"

The WriteCapacityUnits should have been scaled from 5 to 10.

(Optional) Step 6: Clean Up

In this tutorial, you created several resources. You can delete these resources if you no longer need them.

1. Delete the scaling policy for TestTable.

aws application-autoscaling delete-scaling-policy \
--service-namespace dynamodb \
--resource-id "table/TestTable" \
--scalable-dimension "dynamodb:table:WriteCapacityUnits" \
--policy-name "MyScalingPolicy"

2. Deregister the scalable target.

aws application-autoscaling deregister-scalable-target \
--service-namespace dynamodb \
--resource-id "table/TestTable" \
--scalable-dimension "dynamodb:table:WriteCapacityUnits"

3. Delete the TestTable table.

aws dynamodb delete-table --table-name TestTable

Using the AWS SDK to Configure Auto Scaling on Amazon DynamoDB Tables

In addition to using the AWS Management Console and the AWS Command Line Interface (AWS CLI), you can write applications that interact with Amazon DynamoDB auto scaling. This section contains two Java programs that you can use to test this functionality:

• EnableDynamoDBAutoscaling.java
• DisableDynamoDBAutoscaling.java

Enabling Application Auto Scaling for a Table

The following program shows an example of setting up an auto scaling policy for a DynamoDB table (TestTable). It proceeds as follows:

• The program registers write capacity units as a scalable target for TestTable. The range for this metric is between 5 and 10 write capacity units.
• After the scalable target is created, the program builds a target tracking configuration. The policy seeks to maintain a 50 percent target ratio between consumed write capacity and provisioned write capacity.
• The program then creates the scaling policy, based on the target tracking configuration.

The program requires that you provide an Amazon Resource Name (ARN) for a valid Application Auto Scaling service linked role. (For example: arn:aws:iam::122517410325:role/AWSServiceRoleForApplicationAutoScaling_DynamoDBTable.) In the following program, replace SERVICE_ROLE_ARN_GOES_HERE with the actual ARN.

Adding Tags and Labels to Resources

You can label Amazon DynamoDB resources using tags. Tags let you categorize your resources in different ways, for example, by purpose, owner, environment, or other criteria. Tags can help you do the following:

- Quickly identify a resource based on the tags that you assigned to it.
- See AWS bills broken down by tags.
**Note**
Any local secondary indexes (LSI) and global secondary indexes (GSI) related to tagged tables are labeled with the same tags automatically. Currently, DynamoDB Streams usage cannot be tagged.

Tagging is supported by AWS services like Amazon EC2, Amazon S3, DynamoDB, and more. Efficient tagging can provide cost insights by enabling you to create reports across services that carry a specific tag.

To get started with tagging, do the following:

1. Understand [Tagging Restrictions in DynamoDB](#).  
2. Create tags by using [Tagging Resources in DynamoDB](#).  
3. Use [Cost Allocation Reports](#) to track your AWS costs per active tag.

Finally, it is good practice to follow optimal tagging strategies. For information, see [AWS Tagging Strategies](#).

**Tagging Restrictions in DynamoDB**

Each tag consists of a key and a value, both of which you define. The following restrictions apply:

- Each DynamoDB table can have only one tag with the same key. If you try to add an existing tag (same key), the existing tag value is updated to the new value.
- Tag keys and values are case sensitive.
- The maximum key length is 128 Unicode characters.
- The maximum value length is 256 Unicode characters.
- The allowed characters are letters, white space, and numbers, plus the following special characters: + = : / 
- The maximum number of tags per resource is 50.
- AWS-assigned tag names and values are automatically assigned the `aws:` prefix, which you can't assign. AWS-assigned tag names don't count toward the tag limit of 50. User-assigned tag names have the prefix `user:` in the cost allocation report.
- You can't backdate the application of a tag.

**Tagging Resources in DynamoDB**

You can use the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI) to add, list, edit, or delete tags. You can then activate these user-defined tags so that they appear on the AWS Billing and Cost Management console for cost allocation tracking. For more information, see [Cost Allocation Reports](#).

For bulk editing, you can also use Tag Editor on the AWS Management Console. For more information, see [Working with Tag Editor](#).

To use the DynamoDB API instead, see the following operations in the Amazon DynamoDB API Reference:

- TagResource
- UntagResource
- ListTagsOfResource
Adding Tags to New or Existing Tables (Console)

You can use the DynamoDB console to add tags to new tables when you create them, or to add, edit, or delete tags for existing tables.

To tag resources on creation (console)

2. In the navigation pane, choose Tables, and then choose Create table.
3. On the Create DynamoDB table page, provide a name and primary key. Choose Add tags and enter the tags that you want to use.

   For information about tag structure, see Tagging Restrictions in DynamoDB (p. 361).

   For more information about creating tables, see Basic Operations on DynamoDB Tables (p. 336).

To tag existing resources (console)

Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.

1. In the navigation pane, choose Tables.
2. Choose a table in the list, and then choose the Tags tab to add, edit, or delete your tags.

Adding Tags to New or Existing Tables (AWS CLI)

The following examples show how to use the AWS CLI to specify tags when you create tables and indexes, and to tag existing resources.

To tag resources on creation (AWS CLI)

- The following example creates a new Movies table and adds the Owner tag with a value of blueTeam:

```
aws dynamodb create-table \
  --table-name Movies \n  --attribute-definitions AttributeName=Title,AttributeType=S \n  --key-schema AttributeName=Title,KeyType=HASH \n  --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \n  --tags Key=Owner,Value=blueTeam
```

To tag existing resources (AWS CLI)

- The following example adds the Owner tag with a value of blueTeam for the Movies table:

```
aws dynamodb tag-resource \n  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/Movies \n  --tags Key=Owner,Value=blueTeam
```
To list all tags for a table (AWS CLI)

- The following example lists all the tags that are associated with the Movies table:

```bash
aws dynamodb list-tags-of-resource
--resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/Movies
```

Cost Allocation Reports

AWS uses tags to organize resource costs on your cost allocation report. AWS provides two types of cost allocation tags:

- An AWS-generated tag. AWS defines, creates, and applies this tag for you.
- User-defined tags. You define, create, and apply these tags.

You must activate both types of tags separately before they can appear in Cost Explorer or on a cost allocation report.

To activate AWS-generated tags:

2. In the navigation pane, choose Cost Allocation Tags.

To activate user-defined tags:

2. In the navigation pane, choose Cost Allocation Tags.

After you create and activate tags, AWS generates a cost allocation report with your usage and costs grouped by your active tags. The cost allocation report includes all of your AWS costs for each billing period. The report includes both tagged and untagged resources, so that you can clearly organize the charges for resources.

**Note**

Currently, any data transferred out from DynamoDB won't be broken down by tags on cost allocation reports.

For more information, see Using Cost Allocation Tags.

Working with DynamoDB Tables in Java

You can use the AWS SDK for Java to create, update, and delete Amazon DynamoDB tables, list all the tables in your account, or get information about a specific table.

**Topics**

- Creating a Table (p. 364)
- Updating a Table (p. 365)
- Deleting a Table (p. 365)
Creating a Table

To create a table, you must provide the table name, its primary key, and the provisioned throughput values. The following code snippet creates an example table that uses a numeric type attribute ID as its primary key.

To create a table using the AWS SDK for Java API

1. Create an instance of the DynamoDB class.
2. Instantiate a CreateTableRequest to provide the request information.
   
   You must provide the table name, attribute definitions, key schema, and provisioned throughput values.
3. Execute the createTable method by providing the request object as a parameter.

The following code example demonstrates the preceding steps.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

List<AttributeDefinition> attributeDefinitions = new ArrayList<AttributeDefinition>();
attributeDefinitions.add(new AttributeDefinition().withAttributeName("Id").withAttributeType("N"));

List<KeySchemaElement> keySchema = new ArrayList<KeySchemaElement>();
keySchema.add(new KeySchemaElement().withAttributeName("Id").withKeyType(KeyType.HASH));

CreateTableRequest request = new CreateTableRequest()
    .withTableName(tableName)
    .withKeySchema(keySchema)
    .withAttributeDefinitions(attributeDefinitions)
    .withProvisionedThroughput(new ProvisionedThroughput()
        .withReadCapacityUnits(5L)
        .withWriteCapacityUnits(6L));

Table table = dynamoDB.createTable(request);
table.waitForActive();
```

The table is not ready for use until DynamoDB creates it and sets its status to ACTIVE. The createTable request returns a Table object that you can use to obtain more information about the table.

Example

```java
TableDescription tableDescription =
    dynamoDB.getTable(tableName).describe();
System.out.printf("%s: %s \t ReadCapacityUnits: %d \t WriteCapacityUnits: %d",
    tableDescription.getTableStatus(),
    tableDescription.getTableName(),
    tableDescription.getProvisionedThroughput().getReadCapacityUnits(),
    tableDescription.getProvisionedThroughput().getWriteCapacityUnits());
```

You can call the describe method of the client to get table information at any time.
Updating a Table

You can update only the provisioned throughput values of an existing table. Depending on your application requirements, you might need to update these values.

**Note**
For more information about throughput increases and decreases per day, see Service, Account, and Table Limits in Amazon DynamoDB (p. 961).

To update a table using the AWS SDK for Java API

1. Create an instance of the Table class.
2. Create an instance of the ProvisionedThroughput class to provide the new throughput values.
3. Execute the updateTable method by providing the ProvisionedThroughput instance as a parameter.

The following code example demonstrates the preceding steps.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("ProductCatalog");
ProvisionedThroughput provisionedThroughput = new ProvisionedThroughput()
    .withReadCapacityUnits(15L)
    .withWriteCapacityUnits(12L);

table.updateTable(provisionedThroughput);

table.waitForActive();
```

Deleting a Table

To delete a table using the AWS SDK for Java API

1. Create an instance of the Table class.
2. Create an instance of the DeleteTableRequest class and provide the table name that you want to delete.
3. Execute the deleteTable method by providing the Table instance as a parameter.

The following code example demonstrates the preceding steps.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("ProductCatalog");

table.delete();
```
Listing Tables

To list tables in your account, create an instance of `DynamoDB` and execute the `listTables` method. The `ListTables` operation requires no parameters.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

TableCollection<ListTablesResult> tables = dynamoDB.listTables();
Iterator<Table> iterator = tables.iterator();

while (iterator.hasNext()) {
    Table table = iterator.next();
    System.out.println(table.getTableName());
}
```

Example: Create, Update, Delete, and List Tables Using the AWS SDK for Java Document API

The following code example uses the AWS SDK for Java Document API to create, update, and delete an Amazon DynamoDB table (ExampleTable). As part of the table update, it increases the provisioned throughput values. The example also lists all the tables in your account and gets the description of a specific table. For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

```java

}
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.

   For example, create a CreateTableRequest object to create a table and UpdateTableRequest object to update an existing table.

3. Execute the appropriate method provided by the client that you created in the preceding step.

   **Note**
   The examples in this section don't work with .NET core because it doesn't support synchronous methods. For more information, see AWS Asynchronous APIs for .NET.

**Topics**
- Creating a Table (p. 369)
- Updating a Table (p. 370)
- Deleting a Table (p. 371)
- Listing Tables (p. 371)
- Example: Create, Update, Delete, and List Tables Using the AWS SDK for .NET Low-Level API (p. 372)

### Creating a Table

To create a table, you must provide the table name, its primary key, and the provisioned throughput values.

**To create a table using the AWS SDK for .NET low-level API**

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the CreateTableRequest class to provide the request information.
   
   You must provide the table name, primary key, and the provisioned throughput values.
3. Execute the AmazonDynamoDBClient CreateTable method by providing the request object as a parameter.

The following C# example demonstrates the preceding steps. The sample creates a table (ProductCatalog) that uses Id as the primary key and set of provisioned throughput values. Depending on your application requirements, you can update the provisioned throughput values by using the UpdateTable API.

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";
var request = new CreateTableRequest
{
    TableName = tableName,
    AttributeDefinitions = new List<AttributeDefinition>()
    {
        new AttributeDefinition
        {
            AttributeName = "Id",
            AttributeType = "N"
        }
    },
    KeySchema = new List<KeySchemaElement>()
    {
        new KeySchemaElement
        {

            "Id"
        }
    }
};
```
**AttributeName = "Id",
KeyType = "HASH"  //Partition key
}
},
ProvisionedThroughput = new ProvisionedThroughput
{
ReadCapacityUnits = 10,
WriteCapacityUnits = 5
}
};
var response = client.CreateTable(request);

You must wait until DynamoDB creates the table and sets its status to ACTIVE. The CreateTable response includes the TableDescription property that provides the necessary table information.

Example

```csharp
var result = response.CreateTableResult;
var tableDescription = result.TableDescription;
Console.WriteLine("{1}: {0} 	 ReadCapacityUnits: {2} 	 WriteCapacityUnits: {3},",
tableDescription.TableStatus,
tableDescription.TableName,
tableDescription.ProvisionedThroughput.ReadCapacityUnits,
tableDescription.ProvisionedThroughput.WriteCapacityUnits);

string status = tableDescription.TableStatus;
Console.WriteLine(tableName + " - " + status);
```

You can also call the DescribeTable method of the client to get table information at any time.

Example

```csharp
var res = client.DescribeTable(new DescribeTableRequest{TableName = "ProductCatalog"});
```

**Updating a Table**

You can update only the provisioned throughput values of an existing table. Depending on your application requirements, you might need to update these values.

**Note**

You can increase throughput capacity as often as needed, and decrease it within certain constraints. For more information about throughput increases and decreases per day, see Service, Account, and Table Limits in Amazon DynamoDB (p. 961).

**To update a table using the AWS SDK for .NET low-level API**

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the UpdateTableRequest class to provide the request information.
   You must provide the table name and the new provisioned throughput values.
3. Execute the AmazonDynamoDBClient.UpdateTable method by providing the request object as a parameter.

The following C# example demonstrates the preceding steps.

Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
```
string tableName = "ExampleTable";

var request = new UpdateTableRequest()
{
    TableName = tableName,
    ProvisionedThroughput = new ProvisionedThroughput()
    {
        // Provide new values.
        ReadCapacityUnits = 20,
        WriteCapacityUnits = 10
    }
};
var response = client.UpdateTable(request);

### Deleting a Table

Follow these steps to delete a table using the .NET low-level API.

**To delete a table using the AWS SDK for .NET low-level API**

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `DeleteTableRequest` class, and provide the table name that you want to delete.
3. Execute the `AmazonDynamoDBClient.DeleteTable` method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps.

**Example**

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ExampleTable";
var request = new DeleteTableRequest { TableName = tableName };
var response = client.DeleteTable(request);
```

### Listing Tables

To list tables in your account using the AWS SDK for .NET low-level API, create an instance of the `AmazonDynamoDBClient` and execute the `ListTables` method.

The **ListTables** operation requires no parameters. However, you can specify optional parameters. For example, you can set the `Limit` parameter if you want to use paging to limit the number of table names per page. This requires you to create a `ListTablesRequest` object and provide optional parameters as shown in the following C# example. Along with the page size, the request sets the `ExclusiveStartTableName` parameter. Initially, `ExclusiveStartTableName` is null. However, after fetching the first page of results, to retrieve the next page of results, you must set this parameter value to the `LastEvaluatedTableName` property of the current result.

**Example**

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

// Initial value for the first page of table names.
string lastEvaluatedTableName = null;
do
{
    // Create a request object to specify optional parameters.
    var request = new ListTablesRequest
    {
    };
    var response = client.ListTables(request);
    lastEvaluatedTableName = response.LastEvaluatedTableName;
}
```
Example: Create, Update, Delete, and List Tables Using the AWS SDK for .NET Low-Level API

The following C# example creates, updates, and deletes a table (ExampleTable). It also lists all the tables in your account and gets the description of a specific table. The table update increases the provisioned throughput values. For step-by-step instructions to test the following example, see .NET Code Examples (p. 333).

```csharp
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;

Working with Items and Attributes

In Amazon DynamoDB, an item is a collection of attributes. Each attribute has a name and a value. An attribute value can be a scalar, a set, or a document type. For more information, see Amazon DynamoDB: How It Works (p. 2).

DynamoDB provides four operations for basic create, read, update, and delete (CRUD) functionality:

- **PutItem** — Create an item.
- **GetItem** — Read an item.
- **UpdateItem** — Update an item.
- **DeleteItem** — Delete an item.

Each of these operations requires that you specify the primary key of the item that you want to work with. For example, to read an item using GetItem, you must specify the partition key and sort key (if applicable) for that item.

In addition to the four basic CRUD operations, DynamoDB also provides the following:

- **BatchGetItem** — Read up to 100 items from one or more tables.
- **BatchWriteItem** — Create or delete up to 25 items in one or more tables.

These batch operations combine multiple CRUD operations into a single request. In addition, the batch operations read and write items in parallel to minimize response latencies.

This section describes how to use these operations and includes related topics, such as conditional updates and atomic counters. This section also includes example code that uses the AWS SDKs.

Topics
- **Reading an Item** (p. 376)
- **Writing an Item** (p. 376)
Reading an Item

To read an item from a DynamoDB table, use the `GetItem` operation. You must provide the name of the table, along with the primary key of the item you want.

Example

The following AWS CLI example shows how to read an item from the `ProductCatalog` table.

```
aws dynamodb get-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"1"}}'
```

Note
With `GetItem`, you must specify the *entire* primary key, not just part of it. For example, if a table has a composite primary key (partition key and sort key), you must supply a value for the partition key and a value for the sort key.

A `GetItem` request performs an eventually consistent read by default. You can use the `ConsistentRead` parameter to request a strongly consistent read instead. (This consumes additional read capacity units, but it returns the most up-to-date version of the item.)

`GetItem` returns all of the item's attributes. You can use a *projection expression* to return only some of the attributes. For more information, see Projection Expressions (p. 389).

To return the number of read capacity units consumed by `GetItem`, set the `ReturnConsumedCapacity` parameter to `TOTAL`.

Example

The following AWS Command Line Interface (AWS CLI) example shows some of the optional `GetItem` parameters.

```
aws dynamodb get-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"1"}}'
  --consistent-read
  --projection-expression "Description, Price, RelatedItems"
  --return-consumed-capacity TOTAL
```

Writing an Item

To create, update, or delete an item in a DynamoDB table, use one of the following operations:
PutItem

UpdateItem

DeleteItem

For each of these operations, you must specify the entire primary key, not just part of it. For example, if a table has a composite primary key (partition key and sort key), you must provide a value for the partition key and a value for the sort key.

To return the number of write capacity units consumed by any of these operations, set the ReturnConsumedCapacity parameter to one of the following:

- TOTAL — Returns the total number of write capacity units consumed.
- INDEXES — Returns the total number of write capacity units consumed, with subtotals for the table and any secondary indexes that were affected by the operation.
- NONE — No write capacity details are returned. (This is the default.)

**PutItem**

PutItem creates a new item. If an item with the same key already exists in the table, it is replaced with the new item.

**Example**

Write a new item to the Thread table. The primary key for Thread consists of ForumName (partition key) and Subject (sort key).

```bash
aws dynamodb put-item \\
--table-name Thread \\
--item file://item.json
```

The arguments for --item are stored in the item.json file.

```json
{
    "ForumName": {"S": "Amazon DynamoDB"},
    "Subject": {"S": "New discussion thread"},
    "Message": {"S": "First post in this thread"},
    "LastPostedBy": {"S": "fred@example.com"},
    "LastPostDateTime": {"S": "201603190422"}
}
```

**UpdateItem**

If an item with the specified key does not exist, UpdateItem creates a new item. Otherwise, it modifies an existing item's attributes.

You use an *update expression* to specify the attributes that you want to modify and their new values. For more information, see Update Expressions (p. 401).

Within the update expression, you use expression attribute values as placeholders for the actual values. For more information, see Expression Attribute Values (p. 392).
Example

Modify various attributes in the Thread item. The optional ReturnValues parameter shows the item as it appears after the update. For more information, see Return Values (p. 378).

```
aws dynamodb update-item \
  --table-name Thread \
  --key file://key.json \
  --update-expression "SET Answered = :zero, Replies = :zero, LastPostedBy = :lastpostedby" \
  --expression-attribute-values file://expression-attribute-values.json \
  --return-values ALL_NEW
```

The arguments for --key are stored in the key.json file.

```
{
    "ForumName": {"S": "Amazon DynamoDB"},
    "Subject": {"S": "New discussion thread"}
}
```

The arguments for --expression-attribute-values are stored in the expression-attribute-values.json file.

```
{
    "zero": {"N": "0"},
    "lastpostedby": {"S": "barney@example.com"}
}
```

DeleteItem

DeleteItem deletes the item with the specified key.

Example

The following AWS CLI example shows how to delete the Thread item.

```
aws dynamodb delete-item \
  --table-name Thread \
  --key file://key.json
```

Return Values

In some cases, you might want DynamoDB to return certain attribute values as they appeared before or after you modified them. The PutItem, UpdateItem, and DeleteItem operations have a ReturnValues parameter that you can use to return the attribute values before or after they are modified.

The default value for ReturnValues is NONE, meaning that DynamoDB does not return any information about attributes that were modified.

The following are the other valid settings for ReturnValues, organized by DynamoDB API operation.
PutItem

- **ReturnValues**: ALL_OLD
  - If you overwrite an existing item, ALL_OLD returns the entire item as it appeared before the overwrite.
  - If you write a nonexistent item, ALL_OLD has no effect.

UpdateItem

The most common usage for UpdateItem is to update an existing item. However, UpdateItem actually performs an **upsert**, meaning that it automatically creates the item if it doesn't already exist.

- **ReturnValues**: ALL_OLD
  - If you update an existing item, ALL_OLD returns the entire item as it appeared before the update.
  - If you update a nonexistent item (upsert), ALL_OLD has no effect.
- **ReturnValues**: ALL_NEW
  - If you update an existing item, ALL_NEW returns the entire item as it appeared after the update.
  - If you update a nonexistent item (upsert), ALL_NEW returns the entire item.
- **ReturnValues**: UPDATED_OLD
  - If you update an existing item, UPDATED_OLD returns only the updated attributes, as they appeared before the update.
  - If you update a nonexistent item (upsert), UPDATED_OLD has no effect.
- **ReturnValues**: UPDATED_NEW
  - If you update an existing item, UPDATED_NEW returns only the affected attributes, as they appeared after the update.
  - If you update a nonexistent item (upsert), UPDATED_NEW returns only the updated attributes, as they appear after the update.

DeleteItem

- **ReturnValues**: ALL_OLD
  - If you delete an existing item, ALL_OLD returns the entire item as it appeared before you deleted it.
  - If you delete a nonexistent item, ALL_OLD doesn't return any data.

Batch Operations

For applications that need to read or write multiple items, DynamoDB provides the **BatchGetItem** and **BatchWriteItem** operations. Using these operations can reduce the number of network round trips from your application to DynamoDB. In addition, DynamoDB performs the individual read or write operations in parallel. Your applications benefit from this parallelism without having to manage concurrency or threading.

The batch operations are essentially wrappers around multiple read or write requests. For example, if a BatchGetItem request contains five items, DynamoDB performs five GetItem operations on your behalf. Similarly, if a BatchWriteItem request contains two put requests and four delete requests, DynamoDB performs two PutItem and four DeleteItem requests.

In general, a batch operation does not fail unless all the requests in the batch fail. For example, suppose that you perform a BatchGetItem operation, but one of the individual GetItem requests in the batch
Batch Operations

BatchGetItem

A single BatchGetItem operation can contain up to 100 individual GetItem requests and can retrieve up to 16 MB of data. In addition, a BatchGetItem operation can retrieve items from multiple tables.

Example

Retrieve two items from the Thread table, using a projection expression to return only some of the attributes.

```bash
aws dynamodb batch-get-item \
  --request-items file://request-items.json
```

The arguments for `--request-items` are stored in the `request-items.json` file.

```json
{
  "Thread": {
    "Keys": [
      {
        "ForumName": {"S": "Amazon DynamoDB"},
        "Subject": {"S": "DynamoDB Thread 1"}
      },
      {
        "ForumName": {"S": "Amazon S3"},
        "Subject": {"S": "S3 Thread 1"}
      }
    ],
    "ProjectionExpression": "ForumName, Subject, LastPostedDateTime, Replies"
  }
}
```

BatchWriteItem

The BatchWriteItem operation can contain up to 25 individual PutItem and DeleteItem requests and can write up to 16 MB of data. (The maximum size of an individual item is 400 KB.) In addition, a BatchWriteItem operation can put or delete items in multiple tables.

Note

BatchWriteItem does not support UpdateItem requests.

Example

Write two items to the ProductCatalog table.

```bash
aws dynamodb batch-write-item \
  --request-items file://request-items.json
```

The arguments for `--request-items` are stored in the `request-items.json` file.

```json
{
  "ProductCatalog": [
    
  
}
```
Atomic Counters

You can use the UpdateItem operation to implement an atomic counter—a numeric attribute that is incremented, unconditionally, without interfering with other write requests. (All write requests are applied in the order in which they were received.) With an atomic counter, the updates are not idempotent. In other words, the numeric value increments each time you call UpdateItem.

You might use an atomic counter to track the number of visitors to a website. In this case, your application would increment a numeric value, regardless of its current value. If an UpdateItem operation fails, the application could simply retry the operation. This would risk updating the counter twice, but you could probably tolerate a slight overcounting or undercounting of website visitors.

An atomic counter would not be appropriate where overcounting or undercounting can't be tolerated (for example, in a banking application). In this case, it is safer to use a conditional update instead of an atomic counter.

For more information, see Incrementing and Decrementing Numeric Attributes (p. 405).

Example

The following AWS CLI example increments the Price of a product by 5. (Because UpdateItem is not idempotent, the Price increases every time you run this example.)

```
aws dynamodb update-item \
  --table-name ProductCatalog \
  --key '{"Id": { "N": "601" }}' \
  --update-expression "SET Price = Price + :incr" \
  --expression-attribute-values '{":incr":{"N":"5"}}' \
  --return-values UPDATED_NEW
```

Conditional Writes

By default, the DynamoDB write operations (PutItem, UpdateItem, DeleteItem) are unconditional: Each operation overwrites an existing item that has the specified primary key.

DynamoDB optionally supports conditional writes for these operations. A conditional write succeeds only if the item attributes meet one or more expected conditions. Otherwise, it returns an error. Conditional
writes are helpful in many situations. For example, you might want a `PutItem` operation to succeed only if there is not already an item with the same primary key. Or you could prevent an `UpdateItem` operation from modifying an item if one of its attributes has a certain value.

Conditional writes are helpful in cases where multiple users attempt to modify the same item. Consider the following diagram, in which two users (Alice and Bob) are working with the same item from a DynamoDB table.

Suppose that Alice uses the AWS CLI to update the `Price` attribute to 8.

```bash
aws dynamodb update-item \
    --table-name ProductCatalog \ 
    --key '{"Id":{"N":"1"}}' \ 
    --update-expression "SET Price = :newval" \ 
    --expression-attribute-values file://expression-attribute-values.json
```
The arguments for --expression-attribute-values are stored in the file expression-attribute-values.json:

```json
{
   "newval":{"N":"8"}
}
```

Now suppose that Bob issues a similar UpdateItem request later, but changes the Price to 12. For Bob, the --expression-attribute-values parameter looks like the following.

```json
{
   "newval":{"N":"12"}
}
```

Bob's request succeeds, but Alice's earlier update is lost.

To request a conditional PutItem, DeleteItem, or UpdateItem, you specify a condition expression. A condition expression is a string containing attribute names, conditional operators, and built-in functions. The entire expression must evaluate to true. Otherwise, the operation fails.

Now consider the following diagram, showing how conditional writes would prevent Alice's update from being overwritten.
Alice first tries to update `Price` to 8, but only if the current `Price` is 10.

```bash
aws dynamodb update-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"1"}}'
  --update-expression "SET Price = :newval"
  --condition-expression "Price = :currval"
  --expression-attribute-values file://expression-attribute-values.json
```

The arguments for `--expression-attribute-values` are stored in the `expression-attribute-values.json` file.

```json
{
  ":newval":{"N":"8"},
  ":currval":{"N":"10"}
}
```
Alice’s update succeeds because the condition evaluates to true.

Next, Bob attempts to update the **Price** to 12, but only if the current **Price** is 10. For Bob, the `expression-attribute-values` parameter looks like the following.

```json
{
  "newval":{"N":"12"},
  "currval":{"N":"10"}
}
```

Because Alice has previously changed the **Price** to 8, the condition expression evaluates to false, and Bob’s update fails.

For more information, see Condition Expressions (p. 393).

### Conditional Write Idempotence

Conditional writes can be **idempotent** if the conditional check is on the same attribute that is being updated. This means that DynamoDB performs a given write request only if certain attribute values in the item match what you expect them to be at the time of the request.

For example, suppose that you issue an `UpdateItem` request to increase the **Price** of an item by 3, but only if the **Price** is currently 20. After you send the request, but before you get the results back, a network error occurs, and you don’t know whether the request was successful. Because this conditional write is idempotent, you can retry the same `UpdateItem` request, and DynamoDB updates the item only if the **Price** is currently 20.

### Capacity Units Consumed by Conditional Writes

If a `ConditionExpression` evaluates to false during a conditional write, DynamoDB still consumes write capacity from the table:

- If the item does not currently exist in the table, DynamoDB consumes one write capacity unit.
- If the item does exist, the number of write capacity units consumed depends on the size of the item. For example, a failed conditional write of a 1 KB item would consume one write capacity unit. If the item were twice that size, the failed conditional write would consume two write capacity units.

**Note**

Write operations consume *write* capacity units only. They never consume *read* capacity units.

A failed conditional write returns a `ConditionalCheckFailedException`. When this occurs, you don’t receive any information in the response about the write capacity that was consumed. However, you can view the `ConsumedWriteCapacityUnits` metric for the table in Amazon CloudWatch. For more information, see DynamoDB Metrics (p. 859) in Logging and Monitoring in DynamoDB (p. 856).

To return the number of write capacity units consumed during a conditional write, you use the `ReturnConsumedCapacity` parameter:

- **TOTAL** — Returns the total number of write capacity units consumed.
- **INDEXES** — Returns the total number of write capacity units consumed, with subtotals for the table and any secondary indexes that were affected by the operation.
- **NONE** — No write capacity details are returned. (This is the default.)
Note
Unlike a global secondary index, a local secondary index shares its provisioned throughput capacity with its table. Read and write activity on a local secondary index consumes provisioned throughput capacity from the table.

Using Expressions in DynamoDB

In Amazon DynamoDB, you use expressions to denote the attributes that you want to read from an item. You also use expressions when writing an item to indicate any conditions that must be met (also known as a conditional update), and to indicate how the attributes are to be updated. This section describes the basic expression grammar and the available kinds of expressions.

Note
For backward compatibility, DynamoDB also supports conditional parameters that do not use expressions. For more information, see Legacy Conditional Parameters (p. 1036). New applications should use expressions rather than the legacy parameters.

A Sample Item: ProductCatalog

The following is a representation of an item in the ProductCatalog table. (This table is described in Example Tables and Data (p. 974).)

```json
{
  "Id": 123,
  "Title": "Bicycle 123",
  "Description": "123 description",
  "BicycleType": "Hybrid",
  "Brand": "Brand-Company C",
  "Price": 500,
  "Color": ["Red", "Black"],
  "ProductCategory": "Bicycle",
  "InStock": true,
  "QuantityOnHand": null,
  "RelatedItems": [
    341,
    472,
    649
  ]
}
```
"Pictures": {
    "FrontView": "http://example.com/products/123_front.jpg",
    "RearView": "http://example.com/products/123_rear.jpg",
    "SideView": "http://example.com/products/123_left_side.jpg"
  },
"ProductReviews": {
  "FiveStar": [
    "Excellent! Can't recommend it highly enough! Buy it!",
    "Do yourself a favor and buy this."
  ],
  "OneStar": [
    "Terrible product! Do not buy this."
  ],
  "Comment": "This product sells out quickly during the summer",
  "Safety.Warning": "Always wear a helmet"
}

Note the following:

- The partition key value (Id) is 123. There is no sort key.
- Most of the attributes have scalar data types, such as String, Number, Boolean, and Null.
- One attribute (Color) is a String Set.
- The following attributes are document data types:
  - A list of RelatedItems. Each element is an Id for a related product.
  - A map of Pictures. Each element is a short description of a picture, along with a URL for the corresponding image file.
  - A map of ProductReviews. Each element represents a rating and a list of reviews corresponding to that rating. Initially, this map is populated with five-star and one-star reviews.

**Top-Level Attributes**

An attribute is said to be top level if it is not embedded within another attribute. For the ProductCatalog item, the top-level attributes are as follows:

- Id
- Title
- Description
- BicycleType
- Brand
- Price
- Color
- ProductCategory
- InStock
- QuantityOnHand
- RelatedItems
- Pictures
- ProductReviews
- Comment
- Safety.Warning

All of these top-level attributes are scalars, except for Color (list), RelatedItems (list), Pictures (map), and ProductReviews (map).
Nested Attributes

An attribute is said to be *nested* if it is embedded within another attribute. To access a nested attribute, you use *dereference operators*:

- `[n]` — for list elements
- `. (dot)` — for map elements

Accessing List Elements

The dereference operator for a list element is `[n]`, where `n` is the element number. List elements are zero-based, so `[0]` represents the first element in the list, `[1]` represents the second, and so on. Here are some examples:

- `MyList[0]`
- `AnotherList[12]`
- `ThisList[5][11]`

The element `ThisList[5]` is itself a nested list. Therefore, `ThisList[5][11]` refers to the 12th element in that list.

The number within the square brackets must be a non-negative integer. Therefore, the following expressions are not valid:

- `MyList[-1]`
- `MyList[0.4]`

Accessing Map Elements

The dereference operator for a map element is `. (a dot). Use a dot as a separator between elements in a map:

- `MyMap.nestedField`
- `MyMap.nestedField.deeplyNestedField`

Document Paths

In an expression, you use a *document path* to tell DynamoDB where to find an attribute. For a top-level attribute, the document path is simply the attribute name. For a nested attribute, you construct the document path using dereference operators.

The following are some examples of document paths. (Refer to the item shown in Specifying Item Attributes When Using Expressions (p. 386).)

- A top-level scalar attribute.
  
  `ProductDescription`

- A top-level list attribute. (This returns the entire list, not just some of the elements.)
  
  `RelatedItems`

- The third element from the `RelatedItems` list. (Remember that list elements are zero-based.)
  
  `RelatedItems[2]`

- The front-view picture of the product.
• All of the five-star reviews.

ProductReviews.FiveStar
• The first of the five-star reviews.

ProductReviews.FiveStar[0]

**Note**
The maximum depth for a document path is 32. Therefore, the number of dereferences
operators in a path cannot exceed this limit.

You can use any attribute name in a document path, provided that the first character is a-z or A-Z
and the second character (if present) is a-z, A-Z, or 0-9. If an attribute name does not meet this
requirement, you must define an expression attribute name as a placeholder. For more information, see
Expression Attribute Names in DynamoDB (p. 390).

**Projection Expressions**

To read data from a table, you use operations such as GetItem, Query, or Scan. Amazon DynamoDB
returns all the item attributes by default. To get only some, rather than all of the attributes, use a
projection expression.

A *projection expression* is a string that identifies the attributes that you want. To retrieve a single
attribute, specify its name. For multiple attributes, the names must be comma-separated.

The following are some examples of projection expressions, based on the ProductCatalog item from
Specifying Item Attributes When Using Expressions (p. 386):

• A single top-level attribute.

  Title

• Three top-level attributes. DynamoDB retrieves the entire Color set.

  Title, Price, Color

• Four top-level attributes. DynamoDB returns the entire contents of RelatedItems and
  ProductReviews.

  Title, Description, RelatedItems, ProductReviews

You can use any attribute name in a projection expression, provided that the first character is a-z or
A-Z and the second character (if present) is a-z, A-Z, or 0-9. If an attribute name does not meet this
requirement, you must define an expression attribute name as a placeholder. For more information, see
Expression Attribute Names in DynamoDB (p. 390).

The following AWS CLI example shows how to use a projection expression with a GetItem operation.
This projection expression retrieves a top-level scalar attribute (Description), the first element in a list
(RelatedItems[0]), and a list nested within a map (ProductReviews.FiveStar).

```
aws dynamodb get-item \
  --table-name ProductCatalog \
  --key file://key.json \
  --projection-expression "Description, RelatedItems[0], ProductReviews.FiveStar"
```

The arguments for `--key` are stored in the `key.json` file.
Expression Attribute Names in DynamoDB

An expression attribute name is a placeholder that you use in an Amazon DynamoDB expression as an alternative to an actual attribute name. An expression attribute name must begin with a pound sign (#), and be followed by one or more alphanumeric characters.

This section describes several situations in which you must use expression attribute names.

**Note**
The examples in this section use the AWS Command Line Interface (AWS CLI). For programming language-specific code examples, see Getting Started with DynamoDB and AWS SDKs (p. 77).

**Topics**
- Reserved Words (p. 390)
- Attribute Names Containing Dots (p. 391)
- Nested Attributes (p. 391)
- Repeating Attribute Names (p. 392)

**Reserved Words**

Sometimes you might need to write an expression containing an attribute name that conflicts with a DynamoDB reserved word. (For a complete list of reserved words, see Reserved Words in DynamoDB (p. 1027).)

For example, the following AWS CLI example would fail because `Comment` is a reserved word.

```bash
aws dynamodb get-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"123"}}' \
  --projection-expression "Comment"
```

To work around this, you can replace `Comment` with an expression attribute name such as `#c`. The # (pound sign) is required and indicates that this is a placeholder for an attribute name. The AWS CLI example would now look like the following.

```bash
aws dynamodb get-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"123"}}' \
  --projection-expression "#c" \
  --expression-attribute-names '{"#c":"Comment"}'
```

**Note**
If an attribute name begins with a number or contains a space, a special character, or a reserved word, you must use an expression attribute name to replace that attribute's name in the expression.
Attribute Names Containing Dots

In an expression, a dot ("." ) is interpreted as a separator character in a document path. However, DynamoDB also allows you to use a dot character as part of an attribute name. This can be ambiguous in some cases. To illustrate, suppose that you wanted to retrieve the `Safety.Warning` attribute from a `ProductCatalog` item (see Specifying Item Attributes When Using Expressions (p. 386)).

Suppose that you wanted to access `Safety.Warning` using a projection expression.

```
aws dynamodb get-item \\
  --table-name ProductCatalog \\
  --key '{"Id":{"N":"123"}}' \\
  --projection-expression "Safety.Warning"
```

DynamoDB would return an empty result, rather than the expected string ("Always wear a helmet"). This is because DynamoDB interprets a dot in an expression as a document path separator. In this case, you must define an expression attribute name (such as `#sw`) as a substitute for `Safety.Warning`. You could then use the following projection expression.

```
aws dynamodb get-item \\
  --table-name ProductCatalog \\
  --key '{"Id":{"N":"123"}}' \\
  --projection-expression "#sw" \\
  --expression-attribute-names '{"#sw":"Safety.Warning"}''
```

DynamoDB would then return the correct result.

Nested Attributes

Suppose that you wanted to access the nested attribute `ProductReviews.OneStar`, using the following projection expression.

```
aws dynamodb get-item \\
  --table-name ProductCatalog \\
  --key '{"Id":{"N":"123"}}' \\
  --projection-expression "ProductReviews.OneStar"
```

The result would contain all of the one-star product reviews, which is expected.

But what if you decided to use an expression attribute name instead? For example, what would happen if you were to define `#pr1star` as a substitute for `ProductReviews.OneStar`?

```
aws dynamodb get-item \\
  --table-name ProductCatalog \\
  --key '{"Id":{"N":"123"}}' \\
  --projection-expression "#pr1star" \\
  --expression-attribute-names '{"#pr1star":"ProductReviews.OneStar"}''
```

DynamoDB would return an empty result instead of the expected map of one-star reviews. This is because DynamoDB interprets a dot in an expression attribute value as a character within an attribute's
name. When DynamoDB evaluates the expression attribute name #pr1star, it determines that ProductReviews.OneStar refers to a scalar attribute—which is not what was intended.

The correct approach would be to define an expression attribute name for each element in the document path:

- #pr - ProductReviews
- #1star - OneStar

You could then use #pr.#1star for the projection expression.

```bash
aws dynamodb get-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"123"}}'
  --projection-expression "#pr.#1star"
  --expression-attribute-names '{"#pr":"ProductReviews", "#1star":"OneStar"}'
```

DynamoDB would then return the correct result.

**Repeating Attribute Names**

Expression attribute names are helpful when you need to refer to the same attribute name repeatedly. For example, consider the following expression for retrieving some of the reviews from a ProductCatalog item.

```bash
aws dynamodb get-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"123"}}'
```

To make this more concise, you can replace ProductReviews with an expression attribute name such as #pr. The revised expression would now look like the following.

- #pr.FiveStar, #pr.ThreeStar, #pr.OneStar

```bash
aws dynamodb get-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"123"}}'
  --projection-expression '#pr.FiveStar, #pr.ThreeStar, #pr.OneStar'
  --expression-attribute-names '{"#pr":"ProductReviews"}'
```

If you define an expression attribute name, you must use it consistently throughout the entire expression. Also, you cannot omit the # symbol.

**Expression Attribute Values**

If you need to compare an attribute with a value, define an expression attribute value as a placeholder. *Expression attribute values* in Amazon DynamoDB are substitutes for the actual values that you want to
compare—values that you might not know until runtime. An expression attribute value must begin with a colon (:) and be followed by one or more alphanumeric characters.

For example, suppose that you wanted to return all of the ProductCatalog items that are available in Black and cost 500 or less. You could use a Scan operation with a filter expression, as in this AWS Command Line Interface (AWS CLI) example.

```
aws dynamodb scan \
  --table-name ProductCatalog \
  --filter-expression "contains(Color, :c) and Price <= :p" \
  --expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{
  ":c": { "S": "Black" },
  ":p": { "N": "500" }
}
```

**Note**

A Scan operation reads every item in a table. So you should avoid using Scan with large tables. The filter expression is applied to the Scan results, and items that don't match the filter expression are discarded.

If you define an expression attribute value, you must use it consistently throughout the entire expression. Also, you can't omit the : symbol.

Expression attribute values are used with condition expressions, update expressions, and filter expressions.

**Note**

For programming language-specific code examples, see Getting Started with DynamoDB and AWS SDKs (p. 77).

### Condition Expressions

To manipulate data in an Amazon DynamoDB table, you use the PutItem, UpdateItem, and DeleteItem operations. (You can also use BatchWriteItem to perform multiple PutItem or DeleteItem operations in a single call.)

For these data manipulation operations, you can specify a condition expression to determine which items should be modified. If the condition expression evaluates to true, the operation succeeds; otherwise, the operation fails.

The following are some AWS Command Line Interface (AWS CLI) examples of using condition expressions. These examples are based on the ProductCatalog table, which was introduced in Specifying Item Attributes When Using Expressions (p. 386). The partition key for this table is Id; there is no sort key. The following PutItem operation creates a sample ProductCatalog item that the examples refer to.

```
aws dynamodb put-item \
  --table-name ProductCatalog \
  --item file://item.json
```

The arguments for --item are stored in the item.json file. (For simplicity, only a few item attributes are used.)

- Preventing Overwrites of an Existing Item (p. 394)
- Checking for Attributes in an Item (p. 394)
- Conditional Deletes (p. 395)
- Conditional Updates (p. 396)
- Comparison Operator and Function Reference (p. 396)

Preventing Overwrites of an Existing Item

The `PutItem` operation overwrites an item with the same key (if it exists). If you want to avoid this, use a condition expression. This allows the write to proceed only if the item in question does not already have the same key.

```bash
aws dynamodb put-item
  --table-name ProductCatalog
  --item file://item.json
  --condition-expression "attribute_not_exists(Id)"
```

If the condition expression evaluates to false, DynamoDB returns the following error message: The conditional request failed.

**Note**

For more information about `attribute_not_exists` and other functions, see Comparison Operator and Function Reference (p. 396).

Checking for Attributes in an Item

You can check for the existence (or nonexistence) of any attribute. If the condition expression evaluates to true, the operation succeeds; otherwise, it fails.

The following example uses `attribute_not_exists` to delete a product only if it does not have a `Price` attribute.

```bash
aws dynamodb delete-item
  --table-name ProductCatalog
  --key '{{"Id": {"N": "456"}}}'
  --condition-expression "attribute_not_exists(Price)"
```

DynamoDB also provides an `attribute_exists` function. The following example deletes a product only if it has received poor reviews.

```bash
aws dynamodb delete-item
  --table-name ProductCatalog
  --key '{{"Id": {"N": "456"}}}'
```
Using Expressions

--condition-expression "attribute_exists(ProductReviews.OneStar)"

Note
For more information about attribute_not_exists, attribute_exists, and other functions, see Comparison Operator and Function Reference (p. 396).

Conditional Deletes
To perform a conditional delete, you use a DeleteItem operation with a condition expression. The condition expression must evaluate to true in order for the operation to succeed; otherwise, the operation fails.

Consider the item from Condition Expressions (p. 393).

```
{   
  "Id": {     
    "N": "456"   
  },  
  "Price": {     
    "N": "650"   
  },  
  "ProductCategory": {     
    "S": "Sporting Goods"   
  } 
}
```

Suppose that you wanted to delete the item, but only under the following conditions:

- The ProductCategory is either "Sporting Goods" or "Gardening Supplies."
- The Price is between 500 and 600.

The following example tries to delete the item.

```
aws dynamodb delete-item 
  --table-name ProductCatalog 
  --key '{"Id":{"N":"456"}}' 
  --condition-expression "(ProductCategory IN (:cat1, :cat2)) and (Price between :lo and :hi)" 
  --expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{  
  " :cat1": {"S": "Sporting Goods"},  
  " :cat2": {"S": "Gardening Supplies"},  
  " :lo": {"N": "500"},  
  " :hi": {"N": "600"}
}
```

Note
In the condition expression, the : (colon character) indicates an expression attribute value—a placeholder for an actual value. For more information, see Expression Attribute Values (p. 392). For more information about IN, AND, and other keywords, see Comparison Operator and Function Reference (p. 396).
In this example, the `ProductCategory` comparison evaluates to true, but the `Price` comparison evaluates to false. This causes the condition expression to evaluate to false and the `DeleteItem` operation to fail.

**Conditional Updates**

To perform a conditional update, you use an `UpdateItem` operation with a condition expression. The condition expression must evaluate to true in order for the operation to succeed; otherwise, the operation fails.

**Note**

`UpdateItem` also supports *update expressions*, where you specify the modifications you want to make to an item. For more information, see *Update Expressions* (p. 401).

Suppose that you started with the item shown in *Condition Expressions* (p. 393).

```json
{
  "Id": { "N": "456"},
  "Price": {"N": "650"},
  "ProductCategory": {"S": "Sporting Goods"}
}
```

The following example performs an `UpdateItem` operation. It tries to reduce the `Price` of a product by 75—but the condition expression prevents the update if the current `Price` is below 500.

```bash
aws dynamodb update-item
  --table-name ProductCatalog
  --key '{"Id": {"N": "456"}}'
  --update-expression "SET Price = Price - :discount"
  --condition-expression "Price > :limit"
  --expression-attribute-values file://values.json
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```json
{
  ":discount": { "N": "75"},
  ":limit": {"N": "500"}
}
```

If the starting `Price` is 650, the `UpdateItem` operation reduces the `Price` to 575. If you run the `UpdateItem` operation again, the `Price` is reduced to 500. If you run it a third time, the condition expression evaluates to false, and the update fails.

**Note**

In the condition expression, the `:` (colon character) indicates an *expression attribute value*—a placeholder for an actual value. For more information, see *Expression Attribute Values* (p. 392). For more information about `>` and other operators, see *Comparison Operator and Function Reference* (p. 396).

**Comparison Operator and Function Reference**

This section covers the built-in functions and keywords for writing condition expressions in Amazon DynamoDB.

**Topics**

- *Syntax for Condition Expressions* (p. 397)
- *Making Comparisons* (p. 397)
• Functions (p. 398)
• Logical Evaluations (p. 400)
• Parentheses (p. 401)
• Precedence in Conditions (p. 401)

Syntax for Condition Expressions

In the following syntax summary, an operand can be the following:

• A top-level attribute name, such as Id, Title, Description, or ProductCategory
• A document path that references a nested attribute

```plaintext
condition-expression ::= 
    operand comparator operand 
    | operand BETWEEN operand AND operand 
    | operand IN ( operand (',', operand (',', ...))) 
    | function 
    | condition AND condition 
    | condition OR condition 
    | NOT condition 
    | ( condition )

comparator ::= 
    = 
    | <> 
    | < 
    | <= 
    | > 
    | >=

function ::= 
    attribute_exists (path) 
    | attribute_not_exists (path) 
    | attribute_type (path, type) 
    | begins_with (path, substr) 
    | contains (path, operand) 
    | size (path)
```

Making Comparisons

Use these comparators to compare an operand against a range of values or an enumerated list of values:

• \( a = b \) — true if \( a \) is equal to \( b \)
• \( a <> b \) — true if \( a \) is not equal to \( b \)
• \( a < b \) — true if \( a \) is less than \( b \)
• \( a <= b \) — true if \( a \) is less than or equal to \( b \)
• \( a > b \) — true if \( a \) is greater than \( b \)
• \( a >= b \) — true if \( a \) is greater than or equal to \( b \)

Use the BETWEEN and IN keywords to compare an operand against a range of values or an enumerated list of values:

• \( a \) BETWEEN \( b \) AND \( c \) — true if \( a \) is greater than or equal to \( b \), and less than or equal to \( c \).
• \( a \) IN \( (b, c, d) \) — true if \( a \) is equal to any value in the list — for example, any of \( b \), \( c \) or \( d \). The list can contain up to 100 values, separated by commas.
## Functions

Use the following functions to determine whether an attribute exists in an item, or to evaluate the value of an attribute. These function names are case sensitive. For a nested attribute, you must provide its full document path.

<table>

</table>

**Logical Evaluations**

Use the **AND**, **OR**, and **NOT** keywords to perform logical evaluations. In the list following, **a** and **b** represent conditions to be evaluated.

- **a AND b** — true if **a** and **b** are both true.
- **a OR b** — true if either **a** or **b** (or both) are true.
NOT \( a \) — true if \( a \) is false; false if \( a \) is true.

Parentheses

Use parentheses to change the precedence of a logical evaluation. For example, suppose that conditions \( a \) and \( b \) are true, and that condition \( c \) is false. The following expression evaluates to true:

\[ a \ OR \ b \ AND \ c \]

However, if you enclose a condition in parentheses, it is evaluated first. For example, the following evaluates to false:

\[ (a \ OR \ b) \ AND \ c \]

Note
You can nest parentheses in an expression. The innermost ones are evaluated first.

Precedence in Conditions

DynamoDB evaluates conditions from left to right using the following precedence rules:

- \( = \) \(<>\) \(<\) \(<=\) \(>\) \(>=\)
- \(\text{IN}\)
- \(\text{BETWEEN}\)
- \(\text{attribute}\_\text{exists}\) \(\text{attribute}\_\text{not}\_\text{exists}\) \(\text{begins}\_\text{with}\) \(\text{contains}\)
- Parentheses
- \(\text{NOT}\)
- \(\text{AND}\)
- \(\text{OR}\)

Update Expressions

To update an existing item in an Amazon DynamoDB table, you use the \(\text{UpdateItem}\) operation. You must provide the key of the item that you want to update. You must also provide an update expression, indicating the attributes that you want to modify and the values that you want to assign to them.

An update expression specifies how \(\text{UpdateItem}\) will modify the attributes of an item—for example, setting a scalar value or removing elements from a list or a map.

The following is a syntax summary for update expressions.

```plaintext
update-expression ::= 
  [ SET action [, action] ... ]
  [ REMOVE action [, action] ... ]
  [ ADD action [, action] ... ]
  [ DELETE action [, action] ... ]
```

An update expression consists of one or more clauses. Each clause begins with a \(\text{SET}\), \(\text{REMOVE}\), \(\text{ADD}\), or \(\text{DELETE}\) keyword. You can include any of these clauses in an update expression, in any order. However, each action keyword can appear only once.

Within each clause, there are one or more actions separated by commas. Each action represents a data modification.
The examples in this section are based on the ProductCatalog item shown in Projection Expressions (p. 389).

Topics
- SET—Modifying or Adding Item Attributes (p. 402)
- REMOVE—Deleting Attributes from an Item (p. 407)
- ADD—Updating Numbers and Sets (p. 408)
- DELETE—Removing Elements from a Set (p. 409)

SET—Modifying or Adding Item Attributes

Use the SET action in an update expression to add one or more attributes to an item. If any of these attributes already exists, they are overwritten by the new values.

You can also use SET to add or subtract from an attribute that is of type Number. To perform multiple SET actions, separate them with commas.

In the following syntax summary:
- The path element is the document path to the item.
- An operand element can be either a document path to an item or a function.

```
set-action ::= path = value

value ::= operand
         | operand '+' operand
         | operand '-' operand

operand ::= path | function
```

The following PutItem operation creates a sample item that the examples refer to.

```
aws dynamodb put-item \
    --table-name ProductCatalog \
    --item file://item.json
```

The arguments for --item are stored in the item.json file. (For simplicity, only a few item attributes are used.)

```
{
    "Id": {"N": "789"},
    "ProductCategory": {"S": "Home Improvement"},
    "Price": {"N": "52"},
    "InStock": {"BOOL": true},
    "Brand": {"S": "Acme"}
}
```

Modifying Attributes

Example

Update the `ProductCategory` and `Price` attributes.

```bash
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "SET ProductCategory = :c, Price = :p" \
--expression-attribute-values file://values.json \
--return-values ALL_NEW
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```json
{
  "c": { "S": "Hardware" },
  "p": { "N": "60" }
}
```

Note

In the UpdateItem operation, `--return-values ALL_NEW` causes DynamoDB to return the item as it appears after the update.

Adding Lists and Maps

Example

Add a new list and a new map.

```bash
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "SET RelatedItems = :ri, ProductReviews = :pr" \
--expression-attribute-values file://values.json \
--return-values ALL_NEW
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```json
{
  "ri": {
    "L": [
      { "S": "Hammer" }
    ]
  }
}
```
Adding Elements to a List

Example

Add a new attribute to the RelatedItems list. (Remember that list elements are zero-based, so [0] represents the first element in the list, [1] represents the second, and so on.)

```
aws dynamodb update-item \
    --table-name ProductCatalog \
    --key '{"Id":{"N":"789"}}' \
    --update-expression "SET RelatedItems[1] = :ri" \
    --expression-attribute-values file://values.json \
    --return-values ALL_NEW
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```
{   "ri": { "S": "Nails" } }
```

Note

When you use `SET` to update a list element, the contents of that element are replaced with the new data that you specify. If the element doesn't already exist, `SET` appends the new element at the end of the list.

If you add multiple elements in a single `SET` operation, the elements are sorted in order by element number.

Adding Nested Map Attributes

Example

Add some nested map attributes.

```
aws dynamodb update-item \
    --table-name ProductCatalog \
    --key '{"Id":{"N":"789"}}' \
    --update-expression "SET #pr.#5star[1] = :r5, #pr.#3star = :r3" \
    --expression-attribute-names file://names.json \
    --expression-attribute-values file://values.json \
    --return-values ALL_NEW
```

The arguments for `--expression-attribute-names` are stored in the `names.json` file.
The arguments for \texttt{--expression-attribute-values} are stored in the \texttt{values.json} file.

```
{
  ":r5": { "S": "Very happy with my purchase" },
  ":r3": {
    "L": [
      { "S": "Just OK - not that great" }
    ]
  }
}
```

**Incrementing and Decrementing Numeric Attributes**

You can add to or subtract from an existing numeric attribute. To do this, use the + (plus) and - (minus) operators.

**Example**

Decrease the Price of an item.

```
aws dynamodb update-item \
  --table-name ProductCatalog \ 
  --key '{"Id": "789"}' \ 
  --update-expression "SET Price = Price - :p" \ 
  --expression-attribute-values '{":p": {"N": "15"}}' \ 
  --return-values ALL_NEW
```

To increase the Price, you would use the + operator in the update expression.

**Appending Elements to a List**

You can add elements to the end of a list. To do this, use \texttt{SET} with the \texttt{list_append} function. (The function name is case sensitive.) The \texttt{list_append} function is specific to the \texttt{SET} action and can only be used in an update expression. The syntax is as follows.

- \texttt{list_append (list1, list2)}

The function takes two lists as input and appends all elements from \texttt{list2} to \texttt{list1}.

**Example**

In Adding Elements to a List (p. 404), you create the \texttt{RelatedItems} list and populate it with two elements: Hammer and Nails. Now you append two more elements to the end of \texttt{RelatedItems}.

```
aws dynamodb update-item \
  --table-name ProductCatalog \ 
  --key '{"Id": "789"}' \ 
  --update-expression "SET #ri = list_append(#ri, :vals)" \
```

API Version 2012-08-10
The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```json
{
  "vals": {
    "L": [
      { "S": "Screwdriver" },
      { "S": "Hacksaw" }
    ]
  }
}
```

Finally, you append one more element to the `beginning` of `RelatedItems`. To do this, swap the order of the `list_append` elements. (Remember that `list_append` takes two lists as input and appends the second list to the first.)

```bash/aws dynamodb update-item \\
--table-name ProductCatalog \\
--key '{"Id":{"N":"789"}}' \\
--update-expression "SET #ri = list_append(:vals, #ri)" \\
--expression-attribute-names '({"#ri": "RelatedItems"})' \\
--expression-attribute-values '({"vals": {"L": [ { "S": "Chisel" }]}})' \\
--return-values ALL_NEW
```

The resulting `RelatedItems` attribute now contains five elements, in the following order: Chisel, Hammer, Nails, Screwdriver, Hacksaw.

### Preventing Overwrites of an Existing Attribute

If you want to avoid overwriting an existing attribute, you can use `SET` with the `if_not_exists` function. (The function name is case sensitive.) The `if_not_exists` function is specific to the `SET` action and can only be used in an update expression. The syntax is as follows.

* `if_not_exists (path, value)`

If the item does not contain an attribute at the specified `path`, `if_not_exists` evaluates to `value`; otherwise, it evaluates to `path`.

#### Example

Set the `Price` of an item, but only if the item does not already have a `Price` attribute. (If `Price` already exists, nothing happens.)

```bash/aws dynamodb update-item \\
--table-name ProductCatalog \\
--key '{"Id":{"N":"789"}}' \\
--update-expression "SET Price = if_not_exists(Price, :p)" \\
--expression-attribute-values '({":p": {"N": "100"}})' \\
--return-values ALL_NEW
```
REMOVE—Deleting Attributes from an Item

Use the REMOVE action in an update expression to remove one or more attributes from an item in Amazon DynamoDB. To perform multiple REMOVE actions, separate them with commas.

The following is a syntax summary for REMOVE in an update expression. The only operand is the document path for the attribute that you want to remove.

```
remove-action ::= path
```

Example

Remove some attributes from an item. (If the attributes don't exist, nothing happens.)

```
aws dynamodb update-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"789"}}'
  --update-expression "REMOVE Brand, InStock, QuantityOnHand"
  --return-values ALL_NEW
```

Removing Elements from a List

You can use REMOVE to delete individual elements from a list.

Example

In Appending Elements to a List (p. 405), you modify a list attribute (RelatedItems) so that it contained five elements:

- [0]—Chisel
- [1]—Hammer
- [2]—Nails
- [3]—Screwdriver
- [4]—Hacksaw

The following AWS Command Line Interface (AWS CLI) example deletes Hammer and Nails from the list.

```
aws dynamodb update-item
  --table-name ProductCatalog
  --key '{"Id":{"N":"789"}}'
  --update-expression "REMOVE RelatedItems[1], RelatedItems[2]"
  --return-values ALL_NEW
```

After Hammer and Nails are removed, the remaining elements are shifted. The list now contains the following:

- [0]—Chisel
- [1]—Screwdriver
- [2]—Hacksaw
ADD—Updating Numbers and Sets

**Note**
In general, we recommend using SET rather than ADD.

Use the ADD action in an update expression to add a new attribute and its values to an item.

If the attribute already exists, the behavior of ADD depends on the attribute's data type:

- If the attribute is a number, and the value you are adding is also a number, the value is mathematically added to the existing attribute. (If the value is a negative number, it is subtracted from the existing attribute.)
- If the attribute is a set, and the value you are adding is also a set, the value is appended to the existing set.

**Note**
The ADD action supports only number and set data types.

To perform multiple ADD actions, separate them with commas.

In the following syntax summary:

- The **path** element is the document path to an attribute. The attribute must be either a Number or a set data type.
- The **value** element is a number that you want to add to the attribute (for Number data types), or a set to append to the attribute (for set types).

```
add-action ::= path value
```

**Adding a Number**

Assume that the **QuantityOnHand** attribute does not exist. The following AWS CLI example sets **QuantityOnHand** to 5.

```
aws dynamodb update-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"789"}}' \
  --update-expression "ADD QuantityOnHand :q" \
  --expression-attribute-values '{":q": {"N": "5"}}' \
  --return-values ALL_NEW
```

Now that **QuantityOnHand** exists, you can rerun the example to increment **QuantityOnHand** by 5 each time.

**Adding Elements to a Set**

Assume that the **Color** attribute does not exist. The following AWS CLI example sets **Color** to a string set with two elements.

```
aws dynamodb update-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"789"}}' \
  --update-expression "ADD Color #1, #2" \
  --expression-attribute-values '{"#1": "red", 
```
Now that Color exists, you can add more elements to it.

```
aws dynamodb update-item
  --table-name ProductCatalog 
  --key '{"Id":{"N":"789"}}'
  --update-expression "ADD Color :c" 
  --expression-attribute-values '{":c": {"SS": ["Orange", "Purple"]}}'
  --return-values ALL_NEW
```

---

### DELETE—Removing Elements from a Set

**Important**  
The DELETE action supports only Set data types.

Use the DELETE action in an update expression to remove one or more elements from a set. To perform multiple DELETE actions, separate them with commas.

In the following syntax summary:

- The `path` element is the document path to an attribute. The attribute must be a set data type.
- The `subset` is one or more elements that you want to delete from `path`. You must specify `subset` as a set type.

```
delete-action ::=  
    path value
```

### Example

In Adding Elements to a Set (p. 408), you create the `Colors` string set. This example removes some of the elements from that set.

```
aws dynamodb update-item 
  --table-name ProductCatalog 
  --key '{"Id":{"N":"789"}}'
  --update-expression "DELETE Color :p" 
  --expression-attribute-values '{":p": {"SS": ["Yellow", "Purple"]}}'
  --return-values ALL_NEW
```

### Expiring Items By Using DynamoDB Time to Live (TTL)

Amazon DynamoDB Time to Live (TTL) allows you to define a per-item timestamp to determine when an item is no longer needed. Shortly after the date and time of the specified timestamp, DynamoDB deletes
the item from your table without consuming any write throughput. TTL is provided at no extra cost as a means to reduce stored data volumes by retaining only the items that remain current for your workload’s needs.

TTL is useful if you store items that lose relevance after a specific time. The following are example TTL use cases:

- Remove user or sensor data after one year of inactivity in an application.
- Archive expired items to an Amazon S3 data lake via DynamoDB Streams and AWS Lambda.
- Retain sensitive data for a certain amount of time according to contractual or regulatory obligations.

For more information about TTL, see these topics:

- Using Time to Live.
- Time to Live: How It Works.
- Enabling Time to Live.

How It Works: DynamoDB Time to Live (TTL)

When enabling TTL on a DynamoDB table, you must identify a specific attribute name that the service will look for when determining if an item is eligible for expiration. After you enable TTL on a table, a per-partition scanner background process automatically and continuously evaluates the expiry status of items in the table.

The scanner background process compares the current time, in Unix epoch time format in seconds, to the value stored in the user-defined attribute of an item. If the attribute is a Number data type, the attribute's value is a timestamp in Unix epoch time format in seconds, is older than the current time, but not five years or older, then the item is set to expired. For specifics about formatting TTL attributes, see Formatting the item’s TTL attribute. A second background process scans for expired items and deletes them. Both processes take place automatically in the background, do not affect read or write traffic to the table, and do not have a monetary cost.

As items are deleted from the table, two background operations happen simultaneously:

- Items are removed from any local secondary index and global secondary index in the same way as a DeleteItem operation.
- A delete operation for each item enters the DynamoDB Stream, but is tagged as a system delete and not a regular delete. For more information about how to use this system delete, see DynamoDB Streams and Time to Live.

Important

- Depending on the size and activity level of a table, the actual delete operation of an expired item can vary. Because TTL is meant to be a background process, the nature of the capacity used to expire and delete items via TTL is variable (but free of charge). Deletion of an item can take up to 48 hours.
- Items that have expired, but haven’t yet been deleted by TTL, still appear in reads, queries, and scans. If you do not want expired items in the result set, you must filter them out. To do this, use a filter expression that returns only items where the Time to Live expiration value is greater than the current time in epoch format. For more information, see Filter Expressions for Scan.
- Items that are past their expiration, but have not yet been deleted can still be updated, and successful updates to change or remove the expiration attribute will be honored.
You can monitor TTL rates on the CloudWatch metrics tab for a table, and see when and the rate at which items are deleted.

Time to Live Example

For example, consider a table named SessionData that tracks the session history of users. Each item in SessionData is identified by the partition key (UserName) and the sort key (SessionId). Additional attributes like UserName, SessionId, CreationTime, and ExpirationTime track the session information. The ExpirationTime attribute is set as the TTL attribute on the table (not all of the attributes on each item are shown).

<table>
<thead>
<tr>
<th>UserName</th>
<th>SessionId</th>
<th>CreationTime</th>
<th>ExpirationTime (TTL)</th>
<th>SessionInfo</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>user1</td>
<td>746865726527731571820360</td>
<td>1571827560</td>
<td>1571827560</td>
<td>{JSON Document}</td>
<td>...</td>
</tr>
<tr>
<td>user2</td>
<td>6e6f7468696e671571820180</td>
<td>1571827380</td>
<td>1571827380</td>
<td>{JSON Document}</td>
<td>...</td>
</tr>
<tr>
<td>user3</td>
<td>746f20736565201571820923</td>
<td>1571828123</td>
<td>1571828123</td>
<td>{JSON Document}</td>
<td>...</td>
</tr>
<tr>
<td>user4</td>
<td>686572652121211571820683</td>
<td>1571827883</td>
<td>1571827883</td>
<td>{JSON Document}</td>
<td>...</td>
</tr>
<tr>
<td>user5</td>
<td>6e6572642e2e2e1571820743</td>
<td>1571831543</td>
<td>1571831543</td>
<td>{JSON Document}</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
In this example, each item has an ExpirationTime attribute value set when it is created. Consider the following table item.

**SessionData**

<table>
<thead>
<tr>
<th>UserName</th>
<th>SessionId</th>
<th>CreationTime</th>
<th>ExpirationTime (TTL)</th>
<th>SessionInfo</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>user1</td>
<td>74686526527731571820360</td>
<td>1571827560</td>
<td></td>
<td>(JSON Document)</td>
<td>...</td>
</tr>
</tbody>
</table>

In this example, the item CreationTime is set to Wednesday, October 23 08:46 AM UTC 2019, and the ExpirationTime is set 2 hours later at Wednesday, October 23 10:46 AM UTC 2019. The item expires when the current time, in epoch format, is greater than the time in the ExpirationTime attribute. In this case, the item with the key { Username: user1, SessionId: 7468652652773} expires 10:00 AM (1571827560).

**Using DynamoDB Time to Live (TTL)**

When using TTL, most of the hard work is done behind the scenes by DynamoDB on your behalf. You should, though, be aware of a few considerations to help your implementation proceed smoothly.

**Topics**

- Formatting an item’s TTL attribute (p. 412)
- Usage Notes (p. 412)
- Troubleshooting TTL (p. 413)

**Formatting an item’s TTL attribute**

When enabling TTL on a table, DynamoDB requires you to identify a specific attribute name that the service will look for when determining if an item is eligible for expiration. In addition, further requirements ensure that the background TTL processes uses the value of the TTL attribute. If an item is to be eligible for expiration via TTL:

- The item must contain the attribute specified when TTL was enabled on the table. For example, if you specify for a table to use the attribute name expdate as the TTL attribute, but an item does not have an attribute with that name, the TTL process ignores the item.
- The TTL attribute's value must be a **Number** data type. For example, if you specify for a table to use the attribute name expdate as the TTL attribute, but the attribute on an item is a **String** data type, the TTL processes ignore the item.
- The TTL attribute's value must be a timestamp in **Unix epoch time format** in seconds. If you use any other format, the TTL processes ignore the item. For example, if you set the value of the attribute to 1645119622, that is Thursday, February 17, 2022 17:40:22 (GMT), the item will be expired after that time. For a visual web form to test values and see code examples for different languages for epoch time format, see **Epoch Converter**.
- The TTL attribute value must be a datetimestamp with an expiration of no more than five years in the past. For example, if you set the value of the attribute to 1171734022, that is February 17, 2007 17:40:22 (GMT) and older than five years. As a results the TTL processes do not expire the item.

**Usage Notes**

When using TTL, consider the following:
Enabling, disabling, or changing TTL settings on a table can take approximately one hour for the settings to propagate and to allow the execution of any further TTL related actions.

You cannot reconfigure TTL to look for a different attribute. You must disable TTL, and then reenable TTL with the new attribute going forward.

When you use AWS CloudFormation, you can enable TTL when creating a DynamoDB table. For more information, see the AWS CloudFormation User Guide.

You can use AWS Identity and Access Management (IAM) policies to prevent unauthorized updates to the TTL attribute on an item or the configuration of TTL. If you allow access to only specified actions in your existing IAM policies, ensure that your policies are updated to allow dynamodb:UpdateTimeToLive for roles that need to enable or disable TTL on tables. For more information, see Using Identity-Based Policies (IAM Policies) for Amazon DynamoDB.

Consider whether you need to do any post processing of deleted items via DynamoDB Streams, such as archiving items to an Amazon S3 data lake. The streams records of TTL deletes are marked as system deletes and as normal deletes, and you can filter for system deletes by using an AWS Lambda function. For more information about the additions to the streams records, see DynamoDB Streams and Time to Live.

If data recovery is a concern, we recommend that you back up your tables. For fully managed table backups, use DynamoDB on-demand backups or continuous backups with point-in-time recovery. For a 24-hour recovery window, you can use DynamoDB Streams. For more information, see DynamoDB Streams and Time to Live.

Troubleshooting TTL

If DynamoDB TTL is not working, check the following:

- Confirm that you have enabled TTL on the table, and the name of the attribute selected for TTL is set to what your code is writing into items. You can confirm this information on a table's Overview tab on the DynamoDB console.
- Look at Amazon CloudWatch metrics on the Metrics tab of the DynamoDB console to confirm that TTL is deleting items as you expect them to be deleted.
- Confirm that the TTL attribute value is properly formatted. For more information see, Formatting an item's TTL attribute (p. 412).

Enabling Time to Live (TTL)

You can use the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI) to enable Time to Live. To use the API instead, see Amazon DynamoDB API Reference.

Topics
- Enable Time to Live (Console) (p. 413)
- Enable Time to Live (AWS CLI) (p. 415)

Enable Time to Live (Console)

Follow these steps to enable Time to Live using the DynamoDB console:

2. Choose Tables, and then choose the table that you want to modify.
3. In Table details, next to TTL attribute, choose Manage TTL.
4. In the Manage TTL dialog box, choose Enable TTL, and then enter the TTL attribute name.

There are three settings in Manage TTL:

- **Enable TTL** – Choose this to either enable or disable TTL on the table. It can take up to one hour for the change to fully process.

- **TTL Attribute** – The name of the DynamoDB attribute to store the TTL timestamp for items.

- **24-hour backup streams** – Choose this setting to enable Amazon DynamoDB Streams on the table. For more information about how you can use DynamoDB Streams for backup, see DynamoDB Streams and Time to Live (p. 579).

5. (Optional) To preview some of the items that will be deleted when TTL is enabled, choose Run preview.

   **Warning**
   This provides you with a sample list of items. It does not provide you with a complete list of items that will be deleted by TTL.

6. Choose Continue to save the settings and enable TTL.
Now that TTL is enabled, the TTL attribute is marked **TTL** when you view items on the DynamoDB console.

You can view the date and time that an item expires by hovering your pointer over the attribute.

<table>
<thead>
<tr>
<th>id</th>
<th>ttl (TTL)</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1460232057</td>
</tr>
<tr>
<td>10</td>
<td>1459760753</td>
</tr>
<tr>
<td>3</td>
<td>1459221815</td>
</tr>
<tr>
<td>2</td>
<td>1459921806</td>
</tr>
<tr>
<td>21</td>
<td>1459703052</td>
</tr>
</tbody>
</table>

**Enable Time to Live (AWS CLI)**

1. Enable TTL on the **TTLExample** table.

   ```shell
   aws dynamodb update-time-to-live --table-name TTLExample --time-to-live-specification "Enabled=true, AttributeName=ttl"
   ```

2. Describe TTL on the **TTLExample** table.

   ```shell
  aws dynamodb describe-time-to-live --table-name TTLExample
   {
     "TimeToLiveDescription": {
       "AttributeName": "ttl",
       "TimeToLiveStatus": "ENABLED"
     }
   }
   ```

3. Add an item to the **TTLExample** table with the Time to Live attribute set using the BASH shell and the AWS CLI.

   ```bash
   EXP=`date -d '+5 days' +%s`
   aws dynamodb put-item --table-name "TTLExample" --item '{"id": {"N": "1"}, "ttl": {"N": "$EXP"}}'
   ```

   This example starts with the current date and adds 5 days to it to create an expiration time. Then, it converts the expiration time to epoch time format to finally add an item to the "**TTLExample**" table.

   **Note**
   One way to set expiration values for Time to Live is to calculate the number of seconds to add to the expiration time. For example, 5 days is 432,000 seconds. However, it is often preferable to start with a date and work from there.

   It is fairly simple to get the current time in epoch time format, as in the following examples.

   - **Linux Terminal:** `date +%s`
   - **Python:** `import time; int(time.time())`
   - **Java:** `System.currentTimeMillis() / 1000L`
   - **JavaScript:** `Math.floor(Date.now() / 1000)`
Working with Items: Java

You can use the AWS SDK for Java Document API to perform typical create, read, update, and delete (CRUD) operations on Amazon DynamoDB items in a table.

**Note**
The SDK for Java also provides an object persistence model, allowing you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see Java: DynamoDBMapper (p. 226).

This section contains Java examples to perform several Java Document API item actions and several complete working examples.

**Putting an Item**

The `putItem` method stores an item in a table. If the item exists, it replaces the entire item. Instead of replacing the entire item, if you want to update only specific attributes, you can use the `updateItem` method. For more information, see [Updating an Item (p. 423)](#).  

Follow these steps:

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `Table` class to represent the table you want to work with.
3. Create an instance of the `Item` class to represent the new item. You must specify the new item's primary key and its attributes.
4. Call the `putItem` method of the `Table` object, using the `Item` that you created in the preceding step.

The following Java code example demonstrates the preceding tasks. The code writes a new item to the `ProductCatalog` table.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("ProductCatalog");

// Build a list of related items
List<Number> relatedItems = new ArrayList<Number>();
relatedItems.add(341);
relatedItems.add(472);
relatedItems.add(649);
```
// Build a map of product pictures
Map<String, String> pictures = new HashMap<String, String>(){
    pictures.put("FrontView", "http://example.com/products/123_front.jpg");
    pictures.put("RearView", "http://example.com/products/123_rear.jpg");
    pictures.put("SideView", "http://example.com/products/123_left_side.jpg");
}

// Build a map of product reviews
Map<String, List<String>> reviews = new HashMap<String, List<String>>(){
    List<String> fiveStarReviews = new ArrayList<String>();
    fiveStarReviews.add("Excellent! Can't recommend it highly enough! Buy it!");
    reviews.put("FiveStar", fiveStarReviews);
    List<String> oneStarReviews = new ArrayList<String>();
    oneStarReviews.add("Terrible product! Do not buy this.");
    reviews.put("OneStar", oneStarReviews);
}

// Build the item
Item item = new Item()
    .withPrimaryKey("Id", 123)
    .withString("Title", "Bicycle 123")
    .withString("Description", "123 description")
    .withString("BicycleType", "Hybrid")
    .withString("Brand", "Brand-Company C")
    .withNumber("Price", 500)
    .withStringSet("Color", new HashSet<String>(Arrays.asList("Red", "Black")))
    .withString("ProductCategory", "Bicycle")
    .withBoolean("InStock", true)
    .withNull("QuantityOnHand")
    .withList("RelatedItems", relatedItems)
    .withMap("Pictures", pictures)
    .withMap("Reviews", reviews);

// Write the item to the table
PutItemOutcome outcome = table.putItem(item);

In the preceding example, the item has attributes that are scalars (String, Number, Boolean, Null),
sets (String Set), and document types (List, Map).

**Specifying Optional Parameters**

Along with the required parameters, you can also specify optional parameters to the putItem
method. For example, the following Java code example uses an optional parameter to specify a
condition for uploading the item. If the condition you specify is not met, the AWS SDK for Java throws a
ConditionalCheckFailedException. The code example specifies the following optional parameters
in the putItem method:

- A ConditionExpression that defines the conditions for the request. The code defines the condition
  that the existing item with the same primary key is replaced only if it has an ISBN attribute that equals
  a specific value.
- A map for ExpressionAttributeValues that is used in the condition. In this case, there is only one
  substitution required: The placeholder :val in the condition expression is replaced at runtime with the
  actual ISBN value to be checked.

The following example adds a new book item using these optional parameters.

**Example**

Item item = new Item()}
PutItem and JSON Documents

You can store a JSON document as an attribute in a DynamoDB table. To do this, use the `withJSON` method of `Item`. This method parses the JSON document and maps each element to a native DynamoDB data type.

Suppose that you wanted to store the following JSON document, containing vendors that can fulfill orders for a particular product.

**Example**

```java
{
  "V01": {
    "Name": "Acme Books",
    "Offices": [ "Seattle" ]
  },
  "V02": {
    "Name": "New Publishers, Inc.",
    "Offices": [ "London", "New York"
  },
  "V03": {
    "Name": "Better Buy Books",
    "Offices": [ "Tokyo", "Los Angeles", "Sydney"
  }
}
```

You can use the `withJSON` method to store this in the `ProductCatalog` table, in a `Map` attribute named `VendorInfo`. The following Java code example demonstrates how to do this.

```java
String vendorDocument = "{" + "  "V01": {" + "    "Name": "Acme Books"," + "    "Offices": [ "Seattle" ]" + "  }," + "  "V02": {
    "Name": "New Publishers, Inc.",
    "Offices": [ "London", "New York"
  },
  "V03": {
    "Name": "Better Buy Books",
    "Offices": [ "Tokyo", "Los Angeles", "Sydney"
    ]
  }
}"
```

API Version 2012-08-10

418
Item item = new Item()
    .withPrimaryKey("Id", 210)
    .withString("Title", "Book 210 Title")
    .withString("ISBN", "210-2102102102")
    .withNumber("Price", 30)
    .withJSON("VendorInfo", vendorDocument);
PutItemOutcome outcome = table.putItem(item);

Getting an Item

To retrieve a single item, use the getItem method of a Table object. Follow these steps:

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class to represent the table you want to work with.
3. Call the getItem method of the Table instance. You must specify the primary key of the item that you want to retrieve.

The following Java code example demonstrates the preceding steps. The code gets the item that has the specified partition key.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("ProductCatalog");
Item item = table.getItem("Id", 101);
```

Specifying Optional Parameters

Along with the required parameters, you can also specify optional parameters for the getItem method. For example, the following Java code example uses an optional method to retrieve only a specific list of attributes and to specify strongly consistent reads. (To learn more about read consistency, see Read Consistency (p. 16).)

You can use a ProjectionExpression to retrieve only specific attributes or elements, rather than an entire item. A ProjectionExpression can specify top-level or nested attributes using document paths. For more information, see Projection Expressions (p. 389).

The parameters of the getItem method don't let you specify read consistency. However, you can create a GetItemSpec, which provides full access to all of the inputs to the low-level GetItem operation. The following code example creates a GetItemSpec and uses that spec as input to the getItem method.

Example

```java
GetItemSpec spec = new GetItemSpec()
    .withPrimaryKey("Id", 206)
    .withProjectionExpression("Id, Title, RelatedItems[0], Reviews.FiveStar")
    .withConsistentRead(true);
Item item = table.getItem(spec);
System.out.println(item.toJSONPretty());
```
To print an Item in a human-readable format, use the `toJSONPretty` method. The output from the previous example looks like the following.

```json
{
  "RelatedItems" : [ 341 ],
  "Reviews" : {
    "FiveStar" : [ "Excellent! Can't recommend it highly enough! Buy it!", "Do yourself a favor and buy this" ]
  },
  "Id" : 123,
  "Title" : "20-Bicycle 123"
}
```

### GetItem and JSON Documents

In the PutItem and JSON Documents (p. 418) section, you store a JSON document in a `Map` attribute named `VendorInfo`. You can use the `getItem` method to retrieve the entire document in JSON format. Or you can use document path notation to retrieve only some of the elements in the document. The following Java code example demonstrates these techniques.

```java
GetItemSpec spec = new GetItemSpec()
  .withPrimaryKey("Id", 210);
System.out.println("All vendor info:");
spec.withProjectionExpression("VendorInfo");
System.out.println(table.getItem(spec).toJSON());

System.out.println("A single vendor:");
spec.withProjectionExpression("VendorInfo.V03");
System.out.println(table.getItem(spec).toJSON());

System.out.println("First office location for this vendor:");
spec.withProjectionExpression("VendorInfo.V03.Offices[0]" );
System.out.println(table.getItem(spec).toJSON());
```

The output from the previous example looks like the following.

```plaintext
All vendor info:
{
  "VendorInfo":{
    "V03":{"Name":"Better Buy Books","Offices":["Tokyo","Los Angeles","Sydney"]},
    "V02":{"Name":"New Publishers, Inc.","Offices":["London","New York"]},
    "V01":{"Name":"Acme Books","Offices":["Seattle"]}
  }
}
A single vendor:
{
  "VendorInfo":{
    "V03":{"Name":"Better Buy Books","Offices":["Tokyo","Los Angeles","Sydney"]}
  }
}
First office location for a single vendor:
{
  "VendorInfo":{
    "V03":{"Offices":["Tokyo"]}
  }
}
```

**Note**

You can use the `toJSON` method to convert any item (or its attributes) to a JSON-formatted string. The following code retrieves several top-level and nested attributes and prints the results as JSON.

```java
GetItemSpec spec = new GetItemSpec()
  .withPrimaryKey("Id", 210)
  .withProjectionExpression("VendorInfo.V01, Title, Price");
Item item = table.getItem(spec);
System.out.println(item.toJSONString());
```
Batch Write: Putting and Deleting Multiple Items

**Batch write** refers to putting and deleting multiple items in a batch. The `batchWriteItem` method enables you to put and delete multiple items from one or more tables in a single call. The following are the steps to put or delete multiple items using the AWS SDK for Java Document API.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `TableWriteItems` class that describes all the put and delete operations for a table. If you want to write to multiple tables in a single batch write operation, you must create one `TableWriteItems` instance per table.
3. Call the `batchWriteItem` method by providing the `TableWriteItems` objects that you created in the preceding step.
4. Process the response. You should check if there were any unprocessed request items returned in the response. This could happen if you reach the provisioned throughput limit or some other transient error. Also, DynamoDB limits the request size and the number of operations you can specify in a request. If you exceed these limits, DynamoDB rejects the request. For more information, see Service, Account, and Table Limits in Amazon DynamoDB (p. 961).

The following Java code example demonstrates the preceding steps. The example performs a `batchWriteItem` operation on two tables: `Forum` and `Thread`. The corresponding `TableWriteItems` objects define the following actions:

- Put an item in the `Forum` table.
- Put and delete an item in the `Thread` table.

The code then calls `batchWriteItem` to perform the operation.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

TableWriteItems forumTableWriteItems = new TableWriteItems("Forum")
    .withItemsToPut(
        new Item()
            .withPrimaryKey("Name", "Amazon RDS")
            .withNumber("Threads", 0));

TableWriteItems threadTableWriteItems = new TableWriteItems("Thread")
    .withItemsToPut(
        new Item()
            .withPrimaryKey("ForumName","Amazon RDS","Subject","Amazon RDS Thread 1")
            .withHashAndRangeKeysToDelete("ForumName","Some partition key value", "Amazon S3", "Some sort key value");

BatchWriteItemOutcome outcome = dynamoDB.batchWriteItem(forumTableWriteItems, threadTableWriteItems);

// Code for checking unprocessed items is omitted in this example
```

For a working example, see Example: Batch Write Operation Using the AWS SDK for Java Document API (p. 429).
Batch Get: Getting Multiple Items

The `batchGetItem` method enables you to retrieve multiple items from one or more tables. To retrieve a single item, you can use the `getItem` method.

Follow these steps:

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `TableKeysAndAttributes` class that describes a list of primary key values to retrieve from a table. If you want to read from multiple tables in a single batch get operation, you must create one `TableKeysAndAttributes` instance per table.
3. Call the `batchGetItem` method by providing the `TableKeysAndAttributes` objects that you created in the preceding step.

The following Java code example demonstrates the preceding steps. The example retrieves two items from the `Forum` table and three items from the `Thread` table.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

TableKeysAndAttributes forumTableKeysAndAttributes = new TableKeysAndAttributes(forumTableName);
forumTableKeysAndAttributes.addHashOnlyPrimaryKeys("Name", "Amazon S3", "Amazon DynamoDB");

TableKeysAndAttributes threadTableKeysAndAttributes = new TableKeysAndAttributes(threadTableName);
threadTableKeysAndAttributes.addHashAndRangePrimaryKeys("ForumName", "Subject", "Amazon DynamoDB","DynamoDB Thread 1", "Amazon DynamoDB","DynamoDB Thread 2", "Amazon S3","S3 Thread 1");

BatchGetItemOutcome outcome = dynamoDB.batchGetItem(
    forumTableKeysAndAttributes, threadTableKeysAndAttributes);

for (String tableName : outcome.getTableItems().keySet()) {
    System.out.println("Items in table " + tableName);
    List<Item> items = outcome.getTableItems().get(tableName);
    for (Item item : items) {
        System.out.println(item);
    }
}
```

Specifying Optional Parameters

Along with the required parameters, you can also specify optional parameters when using `batchGetItem`. For example, you can provide a `ProjectionExpression` with each `TableKeysAndAttributes` you define. This allows you to specify the attributes that you want to retrieve from the table.

The following code example retrieves two items from the `Forum` table. The `withProjectionExpression` parameter specifies that only the `Threads` attribute is to be retrieved.

Example

```java
TableKeysAndAttributes forumTableKeysAndAttributes = new TableKeysAndAttributes("Forum")
    .withProjectionExpression("Threads");
```
Updating an Item

The updateItem method of a Table object can update existing attribute values, add new attributes, or delete attributes from an existing item.

The updateItem method behaves as follows:

- If an item does not exist (no item in the table with the specified primary key), updateItem adds a new item to the table.
- If an item exists, updateItem performs the update as specified by the UpdateExpression parameter.

**Note**

It is also possible to "update" an item using putItem. For example, if you call putItem to add an item to the table, but there is already an item with the specified primary key, putItem replaces the entire item. If there are attributes in the existing item that are not specified in the input, putItem removes those attributes from the item.

In general, we recommend that you use updateItem whenever you want to modify any item attributes. The updateItem method only modifies the item attributes that you specify in the input, and the other attributes in the item remain unchanged.

Follow these steps:

1. Create an instance of the Table class to represent the table that you want to work with.
2. Call the updateTable method of the Table instance. You must specify the primary key of the item that you want to retrieve, along with an UpdateExpression that describes the attributes to modify and how to modify them.

The following Java code example demonstrates the preceding tasks. The code updates a book item in the ProductCatalog table. It adds a new author to the set of Authors and deletes the existing ISBN attribute. It also reduces the price by one.

An ExpressionAttributeValues map is used in the UpdateExpression. The placeholders :val1 and :val2 are replaced at runtime with the actual values for Authors and Price.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("ProductCatalog");

Map<String, String> expressionAttributeNames = new HashMap<String, String>();
expressionAttributeNames.put("#A", "Authors");
expressionAttributeNames.put("#P", "Price");
expressionAttributeNames.put("#I", "ISBN");

Map<String, Object> expressionAttributeValueValues = new HashMap<String, Object>;
expressionAttributeValueValues.put(":val1",
    new HashSet<String>(Arrays.asList("Author YY","Author ZZ")));
expressionAttributeValueValues.put(":val2", 1); //Price

UpdateItemOutcome outcome = table.updateItem("Id", // key attribute name
```
Specifying Optional Parameters

Along with the required parameters, you can also specify optional parameters for the `updateItem` method, including a condition that must be met in order for the update to occur. If the condition you specify is not met, the AWS SDK for Java throws a `ConditionalCheckFailedException`. For example, the following Java code example conditionally updates a book item price to 25. It specifies a `ConditionExpression` stating that the price should be updated only if the existing price is 20.

Example

```java
Table table = dynamoDB.getTable("ProductCatalog");
Map<String, String> expressionAttributeNames = new HashMap<String, String>();
expressionAttributeNames.put("#P", "Price");

Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val1", 25);  // update Price to 25...
expressionAttributeValues.put(":val2", 20);  //...but only if existing Price is 20

UpdateItemOutcome outcome = table.updateItem(
    new PrimaryKey("Id", 101),
    "set #P = :val1", // UpdateExpression
    "#P = :val2",     // ConditionExpression
    expressionAttributeNames,
    expressionAttributeValues);
```

Atomic Counter

You can use `updateItem` to implement an atomic counter, where you increment or decrement the value of an existing attribute without interfering with other write requests. To increment an atomic counter, use an `UpdateExpression` with a `set` action to add a numeric value to an existing attribute of type `Number`.

The following example demonstrates this, incrementing the `Quantity` attribute by one. It also demonstrates the use of the `ExpressionAttributeNames` parameter in an `UpdateExpression`.

```java
Table table = dynamoDB.getTable("ProductCatalog");
Map<String, String> expressionAttributeNames = new HashMap<String, String>();
expressionAttributeNames.put("#p", "PageCount");

Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val", 1);

UpdateItemOutcome outcome = table.updateItem(
    "Id", 121,
    "set #p = #p + :val",
    expressionAttributeNames,
    expressionAttributeValues);
```

Deleting an Item

The `deleteItem` method deletes an item from a table. You must provide the primary key of the item that you want to delete.
Follow these steps:

2. Call the deleteItem method by providing the key of the item you want to delete.

The following Java example demonstrates these tasks.

Example

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("ProductCatalog");
DeleteItemOutcome outcome = table.deleteItem("Id", 101);
```

Specifying Optional Parameters

You can specify optional parameters for deleteItem. For example, the following Java code example specifies a ConditionExpression, stating that a book item in ProductCatalog can only be deleted if the book is no longer in publication (the InPublication attribute is false).

Example

```java
Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val", false);
DeleteItemOutcome outcome = table.deleteItem("Id", 103,
    "InPublication = :val",
    null, // ExpressionAttributeNames - not used in this example
    expressionAttributeValues);
```

Example: CRUD Operations Using the AWS SDK for Java Document API

The following code example illustrates CRUD operations on an Amazon DynamoDB item. The example creates an item, retrieves it, performs various updates, and finally deletes the item.

**Note**
The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see Java: DynamoDBMapper (p. 226).

**Note**
This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section.
For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

Example: Batch Write Operation Using the AWS SDK for Java Document API

The following Java code example uses the \texttt{batchWriteItem} method to perform the following put and delete operations:

- Put one item in the \texttt{Forum} table.
- Put one item and delete one item from the \texttt{Thread} table.

You can specify any number of put and delete requests against one or more tables when creating your batch write request. However, \texttt{batchWriteItem} limits the size of a batch write request and the number of put and delete operations in a single batch write operation. If your request exceeds these limits, your request is rejected. If your table does not have sufficient provisioned throughput to serve this request, the unprocessed request items are returned in the response.

The following example checks the response to see if it has any unprocessed request items. If it does, it loops back and resends the \texttt{batchWriteItem} request with unprocessed items in the request. If you followed the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section, you should already have created the \texttt{Forum} and \texttt{Thread} tables. You can also create these tables and upload sample data programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for Java (p. 983).

For step-by-step instructions for testing the following sample, see Java Code Examples (p. 331).

Example: Batch Get Operation Using the AWS SDK for Java Document API

The following Java code example uses the batchGetItem method to retrieve multiple items from the
Forum and the Thread tables. The BatchGetItemRequest specifies the table names and a list of keys
for each item to get. The example processes the response by printing the items retrieved.

Note
This code example assumes that you have already loaded data into DynamoDB for your account
by following the instructions in the Creating Tables and Loading Data for Code Examples in
DynamoDB (p. 326) section.
For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

Example: Handling Binary Type Attributes Using the AWS SDK for Java Document API

The following Java code example illustrates handling binary type attributes. The example adds an item to the Reply table. The item includes a binary type attribute (ExtendedMessage) that stores compressed data. The example then retrieves the item and prints all the attribute values. For illustration, the example uses the GZIPOutputStream class to compress a sample stream and assign it to the ExtendedMessage attribute. When the binary attribute is retrieved, it is decompressed using the GZIPInputStream class.

Note
The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see Java: DynamoDBMapper (p. 226).

If you followed the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section, you should already have created the Reply table. You can also create this table programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for Java (p. 983).

Working with Items: .NET

You can use the AWS SDK for .NET low-level API to perform typical create, read, update, and delete (CRUD) operations on an item in a table. The following are the common steps that you follow to perform data CRUD operations using the .NET low-level API:

1. Create an instance of the `AmazonDynamoDBClient` class (the client).
2. Provide the operation-specific required parameters in a corresponding request object.
   
   For example, use the `PutItemRequest` request object when uploading an item and use the `GetItemRequest` request object when retrieving an existing item.
   
   You can use the request object to provide both the required and optional parameters.
3. Execute the appropriate method provided by the client by passing in the request object that you created in the preceding step.
   
   The `AmazonDynamoDBClient` client provides `PutItem`, `GetItem`, `UpdateItem`, and `DeleteItem` methods for the CRUD operations.

Putting an Item

The `PutItem` method uploads an item to a table. If the item exists, it replaces the entire item.

**Note**

Instead of replacing the entire item, if you want to update only specific attributes, you can use the `UpdateItem` method. For more information, see Updating an Item (p. 439).

The following are the steps to upload an item using the low-level .NET SDK API:

1. Create an instance of the `AmazonDynamoDBClient` class.
2. **Provide the required parameters by creating an instance of the** PutItemRequest **class.**

   To put an item, you must provide the table name and the item.

3. **Execute the** PutItem **method by providing the** PutItemRequest **object that you created in the preceding step.**

   The following C# example demonstrates the preceding steps. The example uploads an item to the ProductCatalog table.

   **Example**

   ```csharp
   AmazonDynamoDBClient client = new AmazonDynamoDBClient();
   string tableName = "ProductCatalog";

   var request = new PutItemRequest
   {
      TableName = tableName,
      Item = new Dictionary<string, AttributeValue>()
      {
         { "Id", new AttributeValue { N = "201" } },
         { "Title", new AttributeValue { S = "Book 201 Title" } },
         { "ISBN", new AttributeValue { S = "11-11-11-11" } },
         { "Price", new AttributeValue { S = "20.00" } },
         { "Authors",
            new AttributeValue
            { SS = new List<string> { "Author1", "Author2" } }
         }
      }
   };
   client.PutItem(request);
   
   In the preceding example, you upload a book item that has the Id, Title, ISBN, and Authors attributes. Note that Id is a numeric type attribute, and all other attributes are of the string type. Authors is a String set.

   **Specifying Optional Parameters**

   You can also provide optional parameters using the PutItemRequest object as shown in the following C# example. The example specifies the following optional parameters:

   • ExpressionAttributeNames, ExpressionAttributeValues, and ConditionExpression specify that the item can be replaced only if the existing item has the ISBN attribute with a specific value.

   • ReturnValues parameter to request the old item in the response.

   **Example**

   ```csharp
   var request = new PutItemRequest
   {
      TableName = tableName,
      Item = new Dictionary<string, AttributeValue>()
      {
         { "Id", new AttributeValue { N = "104" } },
         { "Title", new AttributeValue { S = "Book 104 Title" } },
         { "ISBN", new AttributeValue { S = "444-4444444444" } },
         { "Authors",
            new AttributeValue
            { SS = new List<string> { "Author3" } }
         }
      },
   };
   client.PutItem(request);
   ```
// Optional parameters.
ExpressionAttributeNames = new Dictionary<string,string>()
{
    {"#I", "ISBN"}
},
ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
{
    {":isbn", new AttributeValue {S = "444-4444444444"}}
},
ConditionExpression = "#I = :isbn"
};
var response = client.PutItem(request);

For more information, see PutItem.

Getting an Item

The GetItem method retrieves an item.

**Note**
To retrieve multiple items, you can use the BatchGetItem method. For more information, see Batch Get: Getting Multiple Items (p. 444).

The following are the steps to retrieve an existing item using the low-level AWS SDK for .NET API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Provide the required parameters by creating an instance of the GetItemRequest class.
   
   To get an item, you must provide the table name and primary key of the item.
3. Execute the GetItem method by providing the GetItemRequest object that you created in the preceding step.

The following C# example demonstrates the preceding steps. The example retrieves an item from the ProductCatalog table.

AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";
var request = new GetItemRequest
{
    TableName = tableName,
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N = "202" } } },
};
var response = client.GetItem(request);

// Check the response.
var result = response.GetItemResult;
var attributeMap = result.Item; // Attribute list in the response.

Specifying Optional Parameters

You can also provide optional parameters using the GetItemRequest object, as shown in the following C# example. The sample specifies the following optional parameters:

- **ProjectionExpression** parameter to specify the attributes to retrieve.
- **ConsistentRead** parameter to perform a strongly consistent read. To learn more read consistency, see Read Consistency (p. 16).
Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new GetItemRequest
{
    TableName = tableName,
    Key = new Dictionary<string,AttributeValue>() { {"Id", new AttributeValue { N = "202" } } },
    // Optional parameters.
    ProjectionExpression = "Id, ISBN, Title, Authors",
    ConsistentRead = true
};

var response = client.GetItem(request);

// Check the response.
var result = response.GetItemResult;
var attributeMap = result.Item;
```

For more information, see GetItem.

Updating an Item

The UpdateItem method updates an existing item if it is present. You can use the UpdateItem operation to update existing attribute values, add new attributes, or delete attributes from the existing collection. If the item that has the specified primary key is not found, it adds a new item.

The UpdateItem operation uses the following guidelines:

- If the item does not exist, UpdateItem adds a new item using the primary key that is specified in the input.
- If the item exists, UpdateItem applies the updates as follows:
  - Replaces the existing attribute values by the values in the update.
  - If the attribute that you provide in the input does not exist, it adds a new attribute to the item.
  - If the input attribute is null, it deletes the attribute, if it is present.
  - If you use ADD for the Action, you can add values to an existing set (string or number set), or mathematically add (use a positive number) or subtract (use a negative number) from the existing numeric attribute value.

Note

The PutItem operation also can perform an update. For more information, see Putting an Item (p. 436). For example, if you call PutItem to upload an item and the primary key exists, the PutItem operation replaces the entire item. If there are attributes in the existing item and those attributes are not specified in the input, the PutItem operation deletes those attributes. However, UpdateItem updates only the specified input attributes. Any other existing attributes of that item remain unchanged.

The following are the steps to update an existing item using the low-level .NET SDK API:

1. Create an instance of the AmazonDynamoDBClient class.
2. Provide the required parameters by creating an instance of the UpdateItemRequest class.

   This is the request object in which you describe all the updates, such as add attributes, update existing attributes, or delete attributes. To delete an existing attribute, specify the attribute name with null value.
3. Execute the `UpdateItem` method by providing the `UpdateItemRequest` object that you created in the preceding step.

The following C# code example demonstrates the preceding steps. The example updates a book item in the `ProductCatalog` table. It adds a new author to the `Authors` collection, and deletes the existing `ISBN` attribute. It also reduces the price by one.

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new UpdateItemRequest
{
    TableName = tableName,
    Key = new Dictionary<string, AttributeValue>() { { "Id", new AttributeValue { N = "202" } } },
    ExpressionAttributeNames = new Dictionary<string, string>()
    {
        {"#A", "Authors"},
        {"#P", "Price"},
        {"#NA", "NewAttribute"},
        {"#I", "ISBN"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
    {
        {":auth", new AttributeValue { SS = {"Author YY", "Author ZZ"} }},
        {":p", new AttributeValue { N = "1" }},
        {":newattr", new AttributeValue { S = "someValue" }},
    },
    // This expression does the following:
    // 1) Adds two new authors to the list
    // 2) Reduces the price
    // 3) Adds a new attribute to the item
    // 4) Removes the ISBN attribute from the item
    UpdateExpression = "ADD #A :auth SET #P = #P - :p, #NA = :newattr REMOVE #I"
};
var response = client.UpdateItem(request);
```

### Specifying Optional Parameters

You can also provide optional parameters using the `UpdateItemRequest` object, as shown in the following C# example. It specifies the following optional parameters:

- `ExpressionAttributeValues` and `ConditionExpression` to specify that the price can be updated only if the existing price is 20.00.
- `ReturnValues` parameter to request the updated item in the response.

#### Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new UpdateItemRequest
{
    Key = new Dictionary<string, AttributeValue>() { { "Id", new AttributeValue { N = "202" } } },
    // Update price only if the current price is 20.00.
    ExpressionAttributeNames = new Dictionary<string, string>()
    {
```
For more information, see UpdateItem.

**Atomic Counter**

You can use updateItem to implement an atomic counter, where you increment or decrement the value of an existing attribute without interfering with other write requests. To update an atomic counter, use updateItem with an attribute of type Number in the UpdateExpression parameter, and ADD as the Action.

The following example demonstrates this, incrementing the Quantity attribute by one.

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new UpdateItemRequest
{
    Key = new Dictionary<string, AttributeValue>() { { "Id", new AttributeValue { N = "121" } } },
    ExpressionAttributeNames = new Dictionary<string, string>()
    {
        {"#Q", "Quantity"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
    {
        {":incr",new AttributeValue {N = "1"}}
    },
    UpdateExpression = "SET #Q = #Q + :incr",
    TableName = tableName
};
var response = client.UpdateItem(request);
```

**Deleting an Item**

The DeleteItem method deletes an item from a table.

The following are the steps to delete an item using the low-level .NET SDK API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Provide the required parameters by creating an instance of the DeleteItemRequest class.
   
   To delete an item, the table name and item's primary key are required.
3. Execute the DeleteItem method by providing the DeleteItemRequest object that you created in the preceding step.
Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new DeleteItemRequest{
  TableName = tableName,
  Key = new Dictionary<string, AttributeValue>(){ { "Id", new AttributeValue{ N = "201" } } },
};

var response = client.DeleteItem(request);
```

Specifying Optional Parameters

You can also provide optional parameters using the `DeleteItemRequest` object as shown in the following C# code example. It specifies the following optional parameters:

- `ExpressionAttributeValues` and `ConditionExpression` to specify that the book item can be deleted only if it is no longer in publication (the InPublication attribute value is false).
- `ReturnValues` parameter to request the deleted item in the response.

Example

```csharp
var request = new DeleteItemRequest{
  TableName = tableName,
  Key = new Dictionary<string, AttributeValue>(){ { "Id", new AttributeValue{ N = "201" } } },

  // Optional parameters.
  ReturnValues = "ALL_OLD",
  ExpressionAttributeNames = new Dictionary<string, string>(){
    {"#IP", "InPublication"}
  },
  ExpressionAttributeValues = new Dictionary<string, AttributeValue>(){
    {":inpub", new AttributeValue{BOOL = false}}
  },
  ConditionExpression = "#IP = :inpub"
};

var response = client.DeleteItem(request);
```

For more information, see `DeleteItem`.

Batch Write: Putting and Deleting Multiple Items

*Batch write* refers to putting and deleting multiple items in a batch. The `BatchWriteItem` method enables you to put and delete multiple items from one or more tables in a single call. The following are the steps to retrieve multiple items using the low-level .NET SDK API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Describe all the put and delete operations by creating an instance of the `BatchWriteItemRequest` class.
3. Execute the `BatchWriteItem` method by providing the `BatchWriteItemRequest` object that you created in the preceding step.
4. Process the response. You should check if there were any unprocessed request items returned in the response. This could happen if you reach the provisioned throughput limit or some other transient error. Also, DynamoDB limits the request size and the number of operations you can specify in a request. If you exceed these limits, DynamoDB rejects the request. For more information, see BatchWriteItem.

The following C# code example demonstrates the preceding steps. The example creates a BatchWriteItemRequest to perform the following write operations:

- Put an item in Forum table.
- Put and delete an item from Thread table.

The code then executes BatchWriteItem to perform a batch operation.

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

string table1Name = "Forum";
string table2Name = "Thread";

var request = new BatchWriteItemRequest
{
    RequestItems = new Dictionary<string, List<WriteRequest>>
    {
        { table1Name, new List<WriteRequest>
        {
            new WriteRequest
            {
                PutRequest = new PutRequest
                {
                    Item = new Dictionary<string, AttributeValue>
                    {
                        { "Name", new AttributeValue { S = "Amazon S3 forum" } },
                        { "Threads", new AttributeValue { N = "0" } }
                    }
                }
            }
        } },
        { table2Name, new List<WriteRequest>
        {
            new WriteRequest
            {
                PutRequest = new PutRequest
                {
                    Item = new Dictionary<string, AttributeValue>
                    {
                        { "ForumName", new AttributeValue { S = "Amazon S3 forum" } },
                        { "Subject", new AttributeValue { S = "My sample question" } },
                        { "Message", new AttributeValue { S = "Message Text." } },
                        { "KeywordTags", new AttributeValue { SS = new List<string> { "Amazon S3", "Bucket" } } }
                    }
                }
            },
            new WriteRequest
            {
                DeleteRequest = new DeleteRequest
                {
                    Key = new Dictionary<string, AttributeValue>()
                    {
                        { "Bucket", new AttributeValue() }
                    }
                }
            }
        } }
    }
};
```
Batch Get: Getting Multiple Items

The `BatchGetItem` method enables you to retrieve multiple items from one or more tables.

**Note**
To retrieve a single item, you can use the `GetItem` method.

The following are the steps to retrieve multiple items using the low-level AWS SDK for .NET API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Provide the required parameters by creating an instance of the `BatchGetItemRequest` class.
   
   To retrieve multiple items, the table name and a list of primary key values are required.
3. Execute the `BatchGetItem` method by providing the `BatchGetItemRequest` object that you created in the preceding step.
4. Process the response. You should check if there were any unprocessed keys, which could happen if you reach the provisioned throughput limit or some other transient error.

The following C# code example demonstrates the preceding steps. The example retrieves items from two tables, `Forum` and `Thread`. The request specifies two items in the `Forum` and three items in the `Thread` table. The response includes items from both of the tables. The code shows how you can process the response.

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string table1Name = "Forum";
string table2Name = "Thread";
var request = new BatchGetItemRequest
{
    RequestItems = new Dictionary<string, KeysAndAttributes>()
    {
        { table1Name,
            new KeysAndAttributes
            {
                Keys = new List<Dictionary<string, AttributeValue>>()
                {
                    new Dictionary<string, AttributeValue>()
                    {
                        { "Name", new AttributeValue { S = "DynamoDB" } }
                    },
                    new Dictionary<string, AttributeValue>()
                    {
                        { "Name", new AttributeValue { S = "Amazon S3" } }
                    }
                }
            }
        }
    }
};
response = client.BatchGetItem(request);
```

For a working example, see Example: Batch Operations Using the AWS SDK for .NET Low-Level API (p. 450).
```csharp
    },
    },
    {  
      table2Name,
      new KeysAndAttributes
      {
        Keys = new List<Dictionary<string, AttributeValue>>()
        {
          new Dictionary<string, AttributeValue>()
          {
            {"ForumName", new AttributeValue { S = "DynamoDB" } },
            {"Subject", new AttributeValue { S = "DynamoDB Thread 1" } }
          },
          new Dictionary<string, AttributeValue>()
          {
            {"ForumName", new AttributeValue { S = "DynamoDB" } },
            {"Subject", new AttributeValue { S = "DynamoDB Thread 2" } }
          },
          new Dictionary<string, AttributeValue>()
          {
            {"ForumName", new AttributeValue { S = "Amazon S3" } },
            {"Subject", new AttributeValue { S = "Amazon S3 Thread 1" } }
          }
        }
      }
    }
  }
}  

var response = client.BatchGetItem(request);

// Check the response.
var result = response.BatchGetItemResult;
var responses = result.Responses; // The attribute list in the response.

var table1Results = responses[table1Name];
Console.WriteLine("Items in table {0}" + table1Name);
foreach (var item1 in table1Results.Items)
{
  PrintItem(item1);
}

var table2Results = responses[table2Name];
Console.WriteLine("Items in table {1}" + table2Name);
foreach (var item2 in table2Results.Items)
{
  PrintItem(item2);
}

// Any unprocessed keys? could happen if you exceed ProvisionedThroughput or some other error.
Dictionary<string, KeysAndAttributes> unprocessedKeys = result.UnprocessedKeys;
foreach (KeyValuePair<string, KeysAndAttributes> pair in unprocessedKeys)
{
  Console.WriteLine(pair.Key, pair.Value);
}
```

### Specifying Optional Parameters

You can also provide optional parameters using the `BatchGetItemRequest` object as shown in the following C# code example. The example retrieves two items from the `Forum` table. It specifies the following optional parameter:

- **ProjectionExpression** parameter to specify the attributes to retrieve.
Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "Forum";
var request = new BatchGetItemRequest
{
  RequestItems = new Dictionary<string, KeysAndAttributes>()
  {
    { tableName,
      new KeysAndAttributes
      {
        Keys = new List<Dictionary<string, AttributeValue>>()
        {
          new Dictionary<string, AttributeValue>()
          {
            "Name", new AttributeValue { S = "DynamoDB" } }
        },
        new Dictionary<string, AttributeValue>()
        {
          "Name", new AttributeValue { S = "Amazon S3" } }
        }
      }
    },
    // Optional - name of an attribute to retrieve.
    ProjectionExpression = "Title"
  }
};
var response = client.BatchGetItem(request);
```

For more information, see BatchGetItem.

Example: CRUD Operations Using the AWS SDK for .NET Low-Level API

The following C# code example illustrates CRUD operations on an Amazon DynamoDB item. The example adds an item to the ProductCatalog table, retrieves it, performs various updates, and finally deletes the item. If you followed the steps in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), you already have the ProductCatalog table created. You can also create these sample tables programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for .NET (p. 990).

For step-by-step instructions for testing the following sample, see .NET Code Examples (p. 333).

Example: Batch Operations Using the AWS SDK for .NET Low-Level API

Topics
- Example: Batch Write Operation Using the AWS SDK for .NET Low-Level API (p. 450)
- Example: Batch Get Operation Using the AWS SDK for .NET Low-Level API (p. 453)

This section provides examples of batch operations, batch write and batch get, that Amazon DynamoDB supports.

Example: Batch Write Operation Using the AWS SDK for .NET Low-Level API

The following C# code example uses the BatchWriteItem method to perform the following put and delete operations:
- Put one item in the Forum table.
- Put one item and delete one item from the Thread table.

You can specify any number of put and delete requests against one or more tables when creating your batch write request. However, DynamoDB BatchWriteItem limits the size of a batch write request and
the number of put and delete operations in a single batch write operation. For more information, see BatchWriteItem. If your request exceeds these limits, your request is rejected. If your table does not have sufficient provisioned throughput to serve this request, the unprocessed request items are returned in the response.

The following example checks the response to see if it has any unprocessed request items. If it does, it loops back and resends the BatchWriteItem request with unprocessed items in the request. If you followed the steps in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), you already have the Forum and Thread tables created. You can also create these sample tables and upload sample data programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for .NET (p. 990).

For step-by-step instructions for testing the following sample, see .NET Code Examples (p. 333).

Example: Batch Get Operation Using the AWS SDK for .NET Low-Level API

The following C# code example uses the BatchGetItem method to retrieve multiple items from the Forum and the Thread tables in Amazon DynamoDB. The BatchGetItemRequest specifies the table names and a list of primary keys for each table. The example processes the response by printing the items retrieved.

If you followed the steps in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), you already have these tables created with sample data. You can also create these sample tables and upload sample data programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for .NET (p. 990).

For step-by-step instructions for testing the following sample, see .NET Code Examples (p. 333).

Example: Handling Binary Type Attributes Using the AWS SDK for .NET Low-Level API

The following C# code example illustrates the handling of binary type attributes. The example adds an item to the Reply table. The item includes a binary type attribute (ExtendedMessage) that stores compressed data. The example then retrieves the item and prints all the attribute values. For illustration, the example uses the GZipStream class to compress a sample stream and assigns it to the ExtendedMessage attribute, and decompresses it when printing the attribute value.

If you followed the steps in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), you already have the Reply table created. You can also create these sample tables programmatically. For more information, see Creating Example Tables and Uploading Data Using the AWS SDK for .NET (p. 990).

For step-by-step instructions for testing the following example, see .NET Code Examples (p. 333).

Working with Queries in DynamoDB

The `Query` operation in Amazon DynamoDB finds items based on primary key values.

You must provide the name of the partition key attribute and a single value for that attribute. `Query` returns all items with that partition key value. Optionally, you can provide a sort key attribute and use a comparison operator to refine the search results.

**Topics**

- Key Condition Expression (p. 459)
- Filter Expressions for Query (p. 461)
- Limiting the Number of Items in the Result Set (p. 462)
- Paginating Table Query Results (p. 462)
- Counting the Items in the Results (p. 463)
- Capacity Units Consumed by Query (p. 464)
- Read Consistency for Query (p. 464)
- Querying Tables and Indexes: Java (p. 464)
- Querying Tables and Indexes: .NET (p. 470)

**Key Condition Expression**

To specify the search criteria, you use a [*key condition expression*]—a string that determines the items to be read from the table or index.

You must specify the partition key name and value as an equality condition.

You can optionally provide a second condition for the sort key (if present). The sort key condition must use one of the following comparison operators:

- \( a = b \) — true if the attribute \( a \) is equal to the value \( b \)
- \( a < b \) — true if \( a \) is less than \( b \)
- \( a \leq b \) — true if \( a \) is less than or equal to \( b \)
• \( a > b \) — true if \( a \) is greater than \( b \)
• \( a \geq b \) — true if \( a \) is greater than or equal to \( b \)
• \( a \) BETWEEN \( b \) AND \( c \) — true if \( a \) is greater than or equal to \( b \), and less than or equal to \( c \).

The following function is also supported:
• \( \text{begins}_\text{with} (a, \text{substr}) \) — true if the value of attribute \( a \) begins with a particular substring.

The following AWS Command Line Interface (AWS CLI) examples demonstrate the use of key condition expressions. These expressions use placeholders (such as \( :name \) and \( :sub \)) instead of actual values. For more information, see Expression Attribute Names in DynamoDB (p. 390) and Expression Attribute Values (p. 392).

Example
Query the Thread table for a particular ForumName (partition key). All of the items with that ForumName value are read by the query because the sort key (Subject) is not included in KeyConditionExpression.

```
aws dynamodb query \
  --table-name Thread \n  --key-condition-expression "ForumName = :name" \n  --expression-attribute-values '{":name":{"S":"Amazon DynamoDB"}}'
```

Example
Query the Thread table for a particular ForumName (partition key), but this time return only the items with a given Subject (sort key).

```
aws dynamodb query \
  --table-name Thread \n  --key-condition-expression "ForumName = :name and Subject = :sub" \n  --expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```json
{
  "name":{"S":"Amazon DynamoDB"},
  "sub":{"S":"DynamoDB Thread 1"}
}
```

Example
Query the Reply table for a particular Id (partition key), but return only those items whose ReplyDateTime (sort key) begins with certain characters.

```
aws dynamodb query \
  --table-name Reply \n  --key-condition-expression "Id = :id and begins_with(ReplyDateTime, :dt)" \n  --expression-attribute-values file://values.json
```
The arguments for --expression-attribute-values are stored in the values.json file.

```
{
  "id":{"S":"Amazon DynamoDB#DynamoDB Thread 1"},
  "dt":{"S":"2015-09"}
}
```

You can use any attribute name in a key condition expression, provided that the first character is a-z or A-Z and the second character (if present) is a-z, A-Z, or 0-9. In addition, the attribute name must not be a DynamoDB reserved word. (For a complete list of these, see Reserved Words in DynamoDB (p. 1027).) If an attribute name does not meet these requirements, you must define an expression attribute name as a placeholder. For more information, see Expression Attribute Names in DynamoDB (p. 390).

For items with a given partition key value, DynamoDB stores these items close together, in sorted order by sort key value. In a Query operation, DynamoDB retrieves the items in sorted order, and then processes the items using KeyConditionExpression and any FilterExpression that might be present. Only then are the Query results sent back to the client.

A Query operation always returns a result set. If no matching items are found, the result set is empty. Query results are always sorted by the sort key value. If the data type of the sort key is Number, the results are returned in numeric order. Otherwise, the results are returned in order of UTF-8 bytes. By default, the sort order is ascending. To reverse the order, set the ScanIndexForward parameter to false.

A single Query operation can retrieve a maximum of 1 MB of data. This limit applies before any FilterExpression is applied to the results. If LastEvaluatedKey is present in the response and is non-null, you must paginate the result set (see Paginating Table Query Results (p. 462)).

**Filter Expressions for Query**

If you need to further refine the Query results, you can optionally provide a filter expression. A filter expression determines which items within the Query results should be returned to you. All of the other results are discarded.

A filter expression is applied after a Query finishes, but before the results are returned. Therefore, a Query consumes the same amount of read capacity, regardless of whether a filter expression is present.

A Query operation can retrieve a maximum of 1 MB of data. This limit applies before the filter expression is evaluated.

A filter expression cannot contain partition key or sort key attributes. You need to specify those attributes in the key condition expression, not the filter expression.

The syntax for a filter expression is identical to that of a condition expression. Filter expressions can use the same comparators, functions, and logical operators as a condition expression. For more information, Condition Expressions (p. 395).

**Example**

The following AWS CLI example queries the Thread table for a particular ForumName (partition key) and Subject (sort key). Of the items that are found, only the most popular discussion threads are returned—in other words, only those threads with more than a certain number of Views.

```
aws dynamodb query \
```
Limiting the Number of Items in the Result Set

```
--table-name Thread 
--key-condition-expression "ForumName = :fn and Subject = :sub" 
--filter-expression "#v >= :num" 
--expression-attribute-names '{"#v": "Views"}' 
--expression-attribute-values file://values.json
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```json
{
  ":fn": "Amazon DynamoDB",
  ":sub": "DynamoDB Thread 1",
  ":num": {"N": "3"}
}
```

Note that `Views` is a reserved word in DynamoDB (see Reserved Words in DynamoDB (p. 1027)), so this example uses `#v` as a placeholder. For more information, see Expression Attribute Names in DynamoDB (p. 390).

**Note**
A filter expression removes items from the Query result set. If possible, avoid using Query where you expect to retrieve a large number of items but also need to discard most of those items.

**Limiting the Number of Items in the Result Set**

The Query operation allows you to limit the number of items that it reads. To do this, set the Limit parameter to the maximum number of items that you want.

For example, suppose that you Query a table, with a Limit value of 6, and without a filter expression. The Query result contains the first six items from the table that match the key condition expression from the request.

Now suppose that you add a filter expression to the Query. In this case, DynamoDB reads up to six items, and then returns only those that match the filter expression. The final Query result contains six items or fewer, even if more items would have matched the filter expression if DynamoDB had kept reading more items.

**Paginating Table Query Results**

DynamoDB paginates the results from Query operations. With pagination, the Query results are divided into "pages" of data that are 1 MB in size (or less). An application can process the first page of results, then the second page, and so on.

A single Query only returns a result set that fits within the 1 MB size limit. To determine whether there are more results, and to retrieve them one page at a time, applications should do the following:

1. Examine the low-level Query result:
   - If the result contains a LastEvaluatedKey element, proceed to step 2.
   - If there is not a LastEvaluatedKey in the result, there are no more items to be retrieved.
2. Construct a new Query request, with the same parameters as the previous one. However, this time, take the LastEvaluatedKey value from step 1 and use it as the ExclusiveStartKey parameter in the new Query request.
3. Run the new Query request.
4. Go to step 1.
In other words, the \texttt{LastEvaluatedKey} from a \texttt{Query} response should be used as the \texttt{ExclusiveStartKey} for the next \texttt{Query} request. If there is not a \texttt{LastEvaluatedKey} element in a \texttt{Query} response, then you have retrieved the final page of results. If \texttt{LastEvaluatedKey} is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when \texttt{LastEvaluatedKey} is empty.

You can use the AWS CLI to view this behavior. The AWS CLI sends low-level \texttt{Query} requests to DynamoDB repeatedly, until \texttt{LastEvaluatedKey} is no longer present in the results. Consider the following AWS CLI example that retrieves movie titles from a particular year.

\begin{verbatim}
aws dynamodb query --table-name Movies \\
    --projection-expression "title" \\
    --key-condition-expression "#y = :yyyy" \\
    --expression-attribute-names '("#y":"year")' \\
    --expression-attribute-values '("yyyy":{"N":"1993"})' \\
    --page-size 5 \\
    --debug
\end{verbatim}

Ordinarily, the AWS CLI handles pagination automatically. However, in this example, the AWS CLI --page-size parameter limits the number of items per page. The --debug parameter prints low-level information about requests and responses.

If you run the example, the first response from DynamoDB looks similar to the following.

\begin{verbatim}
\end{verbatim}

The \texttt{LastEvaluatedKey} in the response indicates that not all of the items have been retrieved. The AWS CLI then issues another \texttt{Query} request to DynamoDB. This request and response pattern continues, until the final response.

\begin{verbatim}
\end{verbatim}

The absence of \texttt{LastEvaluatedKey} indicates that there are no more items to retrieve.

\textbf{Note}

The AWS SDKs handle the low-level DynamoDB responses (including the presence or absence of \texttt{LastEvaluatedKey}) and provide various abstractions for paginating \texttt{Query} results. For example, the SDK for Java document interface provides \texttt{java.util.Iterator} support so that you can walk through the results one at a time.

For code examples in various programming languages, see the Amazon DynamoDB Getting Started Guide and the AWS SDK documentation for your language.

For more information about querying with DynamoDB, see Working with Queries in DynamoDB (p. 459).

\section*{Counting the Items in the Results}

In addition to the items that match your criteria, the \texttt{Query} response contains the following elements:

- \texttt{ScannedCount} — The number of items that matched the key condition expression \textit{before} a filter expression (if present) was applied.
- \texttt{Count} — The number of items that remain \textit{after} a filter expression (if present) was applied.
Note
If you don’t use a filter expression, ScannedCount and Count have the same value.

If the size of the Query result set is larger than 1 MB, ScannedCount and Count represent only a partial count of the total items. You need to perform multiple Query operations to retrieve all the results (see Paginating Table Query Results (p. 462)).

Each Query response contains the ScannedCount and Count for the items that were processed by that particular Query request. To obtain grand totals for all of the Query requests, you could keep a running tally of both ScannedCount and Count.

Capacity Units Consumed by Query

You can Query any table or secondary index, provided that it has a composite primary key (partition key and sort key). Query operations consume read capacity units, as follows.

<table>
<thead>
<tr>
<th>If you Query a...</th>
<th>DynamoDB consumes read capacity units from...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table’s provisioned read capacity.</td>
</tr>
<tr>
<td>Global secondary index</td>
<td>The index’s provisioned read capacity.</td>
</tr>
<tr>
<td>Local secondary index</td>
<td>The base table’s provisioned read capacity.</td>
</tr>
</tbody>
</table>

By default, a Query operation does not return any data on how much read capacity it consumes. However, you can specify the ReturnConsumedCapacity parameter in a Query request to obtain this information. The following are the valid settings for ReturnConsumedCapacity:

- **NONE** — No consumed capacity data is returned. (This is the default.)
- **TOTAL** — The response includes the aggregate number of read capacity units consumed.
- **INDEXES** — The response shows the aggregate number of read capacity units consumed, together with the consumed capacity for each table and index that was accessed.

DynamoDB calculates the number of read capacity units consumed based on item size, not on the amount of data that is returned to an application. For this reason, the number of capacity units consumed is the same whether you request all of the attributes (the default behavior) or just some of them (using a projection expression). The number is also the same whether or not you use a filter expression.

Read Consistency for Query

A Query operation performs eventually consistent reads, by default. This means that the Query results might not reflect changes due to recently completed PutItem or UpdateItem operations. For more information, see Read Consistency (p. 16).

If you require strongly consistent reads, set the ConsistentRead parameter to true in the Query request.

Querying Tables and Indexes: Java

The Query operation enables you to query a table or a secondary index in Amazon DynamoDB. You must provide a partition key value and an equality condition. If the table or index has a sort key, you can refine the results by providing a sort key value and a condition.
Note
The AWS SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code you have to write. For more information, see Java: DynamoDBMapper (p. 226).

The following are the steps to retrieve an item using the AWS SDK for Java Document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class to represent the table you want to work with.
3. Call the query method of the Table instance. You must specify the partition key value of the items that you want to retrieve, along with any optional query parameters.

The response includes an ItemCollection object that provides all items returned by the query.

The following Java code example demonstrates the preceding tasks. The example assumes that you have a Reply table that stores replies for forum threads. For more information, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

```
Reply ( Id, ReplyDateTime, ... )
```

Each forum thread has a unique ID and can have zero or more replies. Therefore, the Id attribute of the Reply table is composed of both the forum name and forum subject. Id (partition key) and ReplyDateTime (sort key) make up the composite primary key for the table.

The following query retrieves all replies for a specific thread subject. The query requires both the table name and the Subject value.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
   .withRegion(Regions.US_WEST_2).build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("Reply");

QuerySpec spec = new QuerySpec()
   .withKeyConditionExpression("Id = :v_id")
   .withValueMap(new ValueMap()
      .withString(":v_id", "Amazon DynamoDB#DynamoDB Thread 1");

ItemCollection<QueryOutcome> items = table.query(spec);

Iterator<Item> iterator = items.iterator();
Item item = null;
while (iterator.hasNext()) {
   item = iterator.next();
   System.out.println(item.toJSONPretty());
}
```

Specifying Optional Parameters

The query method supports several optional parameters. For example, you can optionally narrow the results from the preceding query to return replies in the past two weeks by specifying a condition. The condition is called a sort key condition, because DynamoDB evaluates the query condition that you specify against the sort key of the primary key. You can specify other optional parameters to retrieve only a specific list of attributes from items in the query result.

The following Java code example retrieves forum thread replies posted in the past 15 days. The example specifies optional parameters using the following:
• A KeyConditionExpression to retrieve the replies from a specific discussion forum (partition key) and, within that set of items, replies that were posted within the last 15 days (sort key).
• A FilterExpression to return only the replies from a specific user. The filter is applied after the query is processed, but before the results are returned to the user.
• A ValueMap to define the actual values for the KeyConditionExpression placeholders.
• A ConsistentRead setting of true, to request a strongly consistent read.

This example uses a QuerySpec object that gives access to all of the low-level Query input parameters.

```
Example

Table table = dynamoDB.getTable("Reply");

long twoWeeksAgoMilli = (new Date()).getTime() - (15L*24L*60L*60L*1000L);
Date twoWeeksAgo = new Date();
twoWeeksAgo.setTime(twoWeeksAgoMilli);
SimpleDateFormat df = new SimpleDateFormat("yyyy-MM-dd'T'HH:mm:ss.SSS'Z'");
String twoWeeksAgoStr = df.format(twoWeeksAgo);

QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("Id = :v_id and ReplyDateTime > :v_reply_dt_tm")
    .withFilterExpression("PostedBy = :v_posted_by")
    .withValueMap(new ValueMap()
        .withString(":v_id", "Amazon DynamoDB#DynamoDB Thread 1")
        .withString(":v_reply_dt_tm", twoWeeksAgoStr)
        .withString(":v_posted_by", "User B")
    .withConsistentRead(true);

ItemCollection<QueryOutcome> items = table.query(spec);
Iterator<Item> iterator = items.iterator();
while (iterator.hasNext()) {
    System.out.println(iterator.next().toJSONPretty());
}
```

You can also optionally limit the number of items per page by using the withMaxPageSize method. When you call the query method, you get an ItemCollection that contains the resulting items. You can then step through the results, processing one page at a time, until there are no more pages.

The following Java code example modifies the query specification shown previously. This time, the query spec uses the withMaxPageSize method. The Page class provides an iterator that allows the code to process the items on each page.

```
Example

spec.withMaxPageSize(10);
ItemCollection<QueryOutcome> items = table.query(spec);

// Process each page of results
int pageNum = 0;
for (Page<Item, QueryOutcome> page : items.pages()) {
    System.out.println("\nPage: " + ++pageNum);
    // Process each item on the current page
    Iterator<Item> item = page.iterator();
    while (item.hasNext()) {
        System.out.println(item.next().toJSONPretty());
    }
}
```
Example - Query Using Java

The following tables store information about a collection of forums. For more information, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

**Note**
The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code you have to write. For more information, see Java: DynamoDBMapper (p. 226).

Example

```
Forum ( Name, ... )
Thread ( ForumName, Subject, Message, LastPostedBy, LastPostDateTime, ...)
Reply ( Id, ReplyDateTime, Message, PostedBy, ...)
```

In this Java code example, you execute variations of finding replies for a thread "DynamoDB Thread 1" in forum "DynamoDB".

- Find replies for a thread.
- Find replies for a thread, specifying a limit on the number of items per page of results. If the number of items in the result set exceeds the page size, you get only the first page of results. This coding pattern ensures that your code processes all the pages in the query result.
- Find replies in the last 15 days.
- Find replies in a specific date range.

The preceding two queries show how you can specify sort key conditions to narrow the query results and use other optional query parameters.

**Note**
This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section.

For step-by-step instructions to run the following example, see Java Code Examples (p. 331).

Querying Tables and Indexes: .NET

The Query operation enables you to query a table or a secondary index in Amazon DynamoDB. You must provide a partition key value and an equality condition. If the table or index has a sort key, you can refine the results by providing a sort key value and a condition.

The following are the steps to query a table using the low-level AWS SDK for .NET API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the QueryRequest class and provide query operation parameters.
3. Execute the Query method and provide the QueryRequest object that you created in the preceding step.

    The response includes the QueryResult object that provides all items returned by the query.

The following C# code example demonstrates the preceding tasks. The code assumes that you have a Reply table that stores replies for forum threads. For more information, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

Example

```
Reply Id, ReplyDateTime, ...
```

Each forum thread has a unique ID and can have zero or more replies. Therefore, the primary key is composed of both the Id (partition key) and ReplyDateTime (sort key).
The following query retrieves all replies for a specific thread subject. The query requires both the table name and the Subject value.

Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

var request = new QueryRequest
{
    TableName = "Reply",
    KeyConditionExpression = "Id = :v_Id",
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":v_Id", new AttributeValue { S = "Amazon DynamoDB#DynamoDB Thread 1" }}
    }
};

var response = client.Query(request);

foreach (Dictionary<string, AttributeValue> item in response.Items)
{
    // Process the result.
    PrintItem(item);
}
```

Specifying Optional Parameters

The `Query` method supports several optional parameters. For example, you can optionally narrow the query result in the preceding query to return replies in the past two weeks by specifying a condition. The condition is called a sort key condition, because DynamoDB evaluates the query condition that you specify against the sort key of the primary key. You can specify other optional parameters to retrieve only a specific list of attributes from items in the query result. For more information, see `Query`.

The following C# code example retrieves forum thread replies posted in the past 15 days. The example specifies the following optional parameters:

- A `KeyConditionExpression` to retrieve only the replies in the past 15 days.
- A `ProjectionExpression` parameter to specify a list of attributes to retrieve for items in the query result.
- A `ConsistentRead` parameter to perform a strongly consistent read.

Example

```csharp
DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);
string twoWeeksAgoString = twoWeeksAgoDate.ToString(AWSSDKUtils.ISO8601DateFormat);

var request = new QueryRequest
{
    TableName = "Reply",
    KeyConditionExpression = "Id = :v_Id and ReplyDateTime > :v_twoWeeksAgo",
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":v_Id", new AttributeValue { S = "Amazon DynamoDB#DynamoDB Thread 2"}},
        {":v_twoWeeksAgo", new AttributeValue { S = twoWeeksAgoString }}
    },
    ProjectionExpression = "Subject, ReplyDateTime, PostedBy",
    ConsistentRead = true
};

var response = client.Query(request);

foreach (Dictionary<string, AttributeValue> item in response.Items)
{
    // Process the result.
    PrintItem(item);
}
```
You can also optionally limit the page size, or the number of items per page, by adding the optional `Limit` parameter. Each time you execute the `Query` method, you get one page of results that has the specified number of items. To fetch the next page, you execute the `Query` method again by providing the primary key value of the last item in the previous page so that the method can return the next set of items. You provide this information in the request by setting the `ExclusiveStartKey` property. Initially, this property can be null. To retrieve subsequent pages, you must update this property value to the primary key of the last item in the preceding page.

The following C# example queries the `Reply` table. In the request, it specifies the `Limit` and `ExclusiveStartKey` optional parameters. The `do/while` loop continues to scan one page at a time until the `LastEvaluatedKey` returns a null value.

**Example**

```csharp
Dictionary<string, AttributeValue> lastKeyEvaluated = null;

do {
    var request = new QueryRequest
    {
        TableName = "Reply",
        KeyConditionExpression = "Id = :v_Id",
        ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
            {":v_Id", new AttributeValue { S = "Amazon DynamoDB#DynamoDB Thread 2" }}
        },
        // Optional parameters.
        Limit = 1,
        ExclusiveStartKey = lastKeyEvaluated
    };
    var response = client.Query(request);
    // Process the query result.
    foreach (Dictionary<string, AttributeValue> item in response.Items)
    {
        PrintItem(item);
    }
    lastKeyEvaluated = response.LastEvaluatedKey;
} while (lastKeyEvaluated != null && lastKeyEvaluated.Count != 0);
```

**Example - Querying Using the AWS SDK for .NET**

The following tables store information about a collection of forums. For more information, see Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

**Example**

<table>
<thead>
<tr>
<th>Forum ( Name, ... )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread ( ForumName, Subject, Message, LastPostedBy, LastPostDateTime, ... )</td>
</tr>
<tr>
<td>Reply ( Id, ReplyDateTime, Message, PostedBy, ... )</td>
</tr>
</tbody>
</table>

In this example, you execute variations of “Find replies for a thread “DynamoDB Thread 1” in forum “DynamoDB”.

API Version 2012-08-10
472
• Find replies for a thread.
• Find replies for a thread. Specify the Limit query parameter to set page size.

This function illustrates the use of pagination to process multipage result. DynamoDB has a page size limit and if your result exceeds the page size, you get only the first page of results. This coding pattern ensures your code processes all the pages in the query result.

• Find replies in the last 15 days.
• Find replies in a specific date range.

The preceding two queries show how you can specify sort key conditions to narrow query results and use other optional query parameters.

For step-by-step instructions for testing the following example, see .NET Code Examples (p. 333).

Working with Scans in DynamoDB

A Scan operation in Amazon DynamoDB reads every item in a table or a secondary index. By default, a Scan operation returns all of the data attributes for every item in the table or index. You can use the
ProjectionExpression parameter so that Scan only returns some of the attributes, rather than all of them.

Scan always returns a result set. If no matching items are found, the result set is empty.

A single Scan request can retrieve a maximum of 1 MB of data. Optionally, DynamoDB can apply a filter expression to this data, narrowing the results before they are returned to the user.

**Topics**
- Filter Expressions for Scan (p. 477)
- Limiting the Number of Items in the Result Set (p. 477)
- Paginating the Results (p. 478)
- Counting the Items in the Results (p. 479)
- Capacity Units Consumed by Scan (p. 479)
- Read Consistency for Scan (p. 480)
- Parallel Scan (p. 480)
- Scanning Tables and Indexes: Java (p. 482)
- Scanning Tables and Indexes: .NET (p. 489)

**Filter Expressions for Scan**

If you need to further refine the Scan results, you can optionally provide a filter expression. A filter expression determines which items within the Scan results should be returned to you. All of the other results are discarded.

A filter expression is applied after a Scan finishes but before the results are returned. Therefore, a Scan consumes the same amount of read capacity, regardless of whether a filter expression is present.

A Scan operation can retrieve a maximum of 1 MB of data. This limit applies before the filter expression is evaluated.

With Scan, you can specify any attributes in a filter expression—including partition key and sort key attributes.

The syntax for a filter expression is identical to that of a condition expression. Filter expressions can use the same comparators, functions, and logical operators as a condition expression. For more information, see *Condition Expressions* (p. 393).

**Example**

The following AWS Command Line Interface (AWS CLI) example scans the Thread table and returns only the items that were last posted to by a particular user.

```bash
aws dynamodb scan \
  --table-name Thread \
  --filter-expression "LastPostedBy = :name" \
  --expression-attribute-values '{"name":{"S":"User A"}}'
```

**Limiting the Number of Items in the Result Set**

The Scan operation enables you to limit the number of items that it returns in the result. To do this, set the Limit parameter to the maximum number of items that you want the Scan operation to return, prior to filter expression evaluation.
For example, suppose that you scan a table with a limit value of 6 and without a filter expression. The scan result contains the first six items from the table that match the key condition expression from the request.

Now suppose that you add a filter expression to the scan. In this case, DynamoDB applies the filter expression to the six items that were returned, discarding those that do not match. The final scan result contains six items or fewer, depending on the number of items that were filtered.

Paginating the Results

DynamoDB paginates the results from scan operations. With pagination, the scan results are divided into “pages” of data that are 1 MB in size (or less). An application can process the first page of results, then the second page, and so on.

A single scan only returns a result set that fits within the 1 MB size limit. To determine whether there are more results and to retrieve them one page at a time, applications should do the following:

1. Examine the low-level scan result:
   - If the result contains a LastEvaluatedKey element, proceed to step 2.
   - If there is not a LastEvaluatedKey in the result, then there are no more items to be retrieved.

2. Construct a new scan request, with the same parameters as the previous one. However, this time, take the LastEvaluatedKey value from step 1 and use it as the ExclusiveStartKey parameter in the new scan request.

3. Run the new scan request.

4. Go to step 1.

In other words, the LastEvaluatedKey from a scan response should be used as the ExclusiveStartKey for the next scan request. If there is not a LastEvaluatedKey element in a scan response, you have retrieved the final page of results. (The absence of LastEvaluatedKey is the only way to know that you have reached the end of the result set.)

You can use the AWS CLI to view this behavior. The AWS CLI sends low-level scan requests to DynamoDB, repeatedly, until LastEvaluatedKey is no longer present in the results. Consider the following AWS CLI example that scans the entire movies table but returns only the movies from a particular genre.

```
aws dynamodb scan
   --table-name Movies
   --projection-expression "title"
   --filter-expression 'contains(info.genres,:gen)' 
   --expression-attribute-values '{":gen":{"S":"Sci-Fi"}}' 
   --page-size 100
   --debug
```

Ordinarily, the AWS CLI handles pagination automatically. However, in this example, the AWS CLI --page-size parameter limits the number of items per page. The --debug parameter prints low-level information about requests and responses.

If you run the example, the first response from DynamoDB looks similar to the following.

```
2017-07-07 12:19:14,389 - MainThread - botocore.parsers - DEBUG - Response body:
b'"Count":7,"Items":[["title":{"S":"Monster on the Campus"}},"title":{"S":"+1"}},
{"title":{"S":"100 Degrees Below Zero"}},{"title":{"S":"About Time"}},{"title":{"S":"After Earth"}},
{"title":{"S":"Age of Dinosaurs"}},{"title":{"S":"Cloudy with a Chance of Meatballs 2"}}]
```
The `LastEvaluatedKey` in the response indicates that not all of the items have been retrieved. The AWS CLI then issues another Scan request to DynamoDB. This request and response pattern continues, until the final response.

```
2017-07-07 12:19:17,830 - MainThread - botocore.parsers - DEBUG - Response body:
'b{"Count":1,"Items":[["title":{"S":"WarGames"}]],"ScannedCount":6}''
```

The absence of `LastEvaluatedKey` indicates that there are no more items to retrieve.

**Note**
The AWS SDKs handle the low-level DynamoDB responses (including the presence or absence of `LastEvaluatedKey`) and provide various abstractions for paginating Scan results. For example, the SDK for Java document interface provides `java.util.Iterator` support so that you can walk through the results one at a time. For code examples in various programming languages, see the Amazon DynamoDB Getting Started Guide and the AWS SDK documentation for your language.

**Counting the Items in the Results**

In addition to the items that match your criteria, the Scan response contains the following elements:

- **ScannedCount** — The number of items evaluated, before any ScanFilter is applied. A high ScannedCount value with few, or no, Count results indicates an inefficient Scan operation. If you did not use a filter in the request, ScannedCount is the same as Count.
- **Count** — The number of items that remain, after a filter expression (if present) was applied.

**Note**
If you do not use a filter expression, ScannedCount and Count have the same value.

If the size of the Scan result set is larger than 1 MB, ScannedCount and Count represent only a partial count of the total items. You need to perform multiple Scan operations to retrieve all the results (see *Paginating the Results* (p. 478)).

Each Scan response contains the ScannedCount and Count for the items that were processed by that particular Scan request. To get grand totals for all of the Scan requests, you could keep a running tally of both ScannedCount and Count.

**Capacity Units Consumed by Scan**

You can Scan any table or secondary index. Scan operations consume read capacity units, as follows.

<table>
<thead>
<tr>
<th>If you Scan a...</th>
<th>DynamoDB consumes read capacity units from...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table’s provisioned read capacity.</td>
</tr>
<tr>
<td>Global secondary index</td>
<td>The index’s provisioned read capacity.</td>
</tr>
<tr>
<td>Local secondary index</td>
<td>The base table’s provisioned read capacity.</td>
</tr>
</tbody>
</table>

By default, a Scan operation does not return any data on how much read capacity it consumes. However, you can specify the `ReturnConsumedCapacity` parameter in a Scan request to obtain this information. The following are the valid settings for ReturnConsumedCapacity:
Read Consistency for Scan

A Scan operation performs eventually consistent reads, by default. This means that the Scan results might not reflect changes due to recently completed PutItem or UpdateItem operations. For more information, see Read Consistency (p. 16).

If you require strongly consistent reads, as of the time that the Scan begins, set the ConsistentRead parameter to true in the Scan request. This ensures that all of the write operations that completed before the Scan began are included in the Scan response.

Setting ConsistentRead to true can be useful in table backup or replication scenarios, in conjunction with DynamoDB Streams. You first use Scan with ConsistentRead set to true to obtain a consistent copy of the data in the table. During the Scan, DynamoDB Streams records any additional write activity that occurs on the table. After the Scan is complete, you can apply the write activity from the stream to the table.

**Note**

A Scan operation with ConsistentRead set to true consumes twice as many read capacity units as compared to leaving ConsistentRead at its default value (false).

Parallel Scan

By default, the Scan operation processes data sequentially. Amazon DynamoDB returns data to the application in 1 MB increments, and an application performs additional Scan operations to retrieve the next 1 MB of data.

The larger the table or index being scanned, the more time the Scan takes to complete. In addition, a sequential Scan might not always be able to fully use the provisioned read throughput capacity: Even though DynamoDB distributes a large table's data across multiple physical partitions, a Scan operation can only read one partition at a time. For this reason, the throughput of a Scan is constrained by the maximum throughput of a single partition.

To address these issues, the Scan operation can logically divide a table or secondary index into multiple segments, with multiple application workers scanning the segments in parallel. Each worker can be a thread (in programming languages that support multithreading) or an operating system process. To perform a parallel scan, each worker issues its own Scan request with the following parameters:

- **Segment** — A segment to be scanned by a particular worker. Each worker should use a different value for Segment.
- **TotalSegments** — The total number of segments for the parallel scan. This value must be the same as the number of workers that your application will use.

The following diagram shows how a multithreaded application performs a parallel Scan with three degrees of parallelism.
In this diagram, the application spawns three threads and assigns each thread a number. (Segments are zero-based, so the first number is always 0.) Each thread issues a Scan request, setting Segment to its designated number and setting TotalSegments to 3. Each thread scans its designated segment, retrieving data 1 MB at a time, and returns the data to the application's main thread.

The values for Segment and TotalSegments apply to individual Scan requests, and you can use different values at any time. You might need to experiment with these values, and the number of workers you use, until your application achieves its best performance.

**Note**
A parallel scan with a large number of workers can easily consume all of the provisioned throughput for the table or index being scanned. It is best to avoid such scans if the table or index is also incurring heavy read or write activity from other applications.
To control the amount of data returned per request, use the `Limit` parameter. This can help prevent situations where one worker consumes all of the provisioned throughput, at the expense of all other workers.

**Scanning Tables and Indexes: Java**

The `Scan` operation reads all of the items in a table or index in Amazon DynamoDB.

The following are the steps to scan a table using the AWS SDK for Java Document API.

1. Create an instance of the `AmazonDynamoDB` class.
2. Create an instance of the `ScanRequest` class and provide scan parameter.
   - The only required parameter is the table name.
3. Execute the `scan` method and provide the `ScanRequest` object that you created in the preceding step.

The following `Reply` table stores replies for forum threads.

**Example**

<table>
<thead>
<tr>
<th>Reply ( Id, ReplyDateTime, Message, PostedBy )</th>
</tr>
</thead>
</table>

The table maintains all the replies for various forum threads. Therefore, the primary key is composed of both the `Id` (partition key) and `ReplyDateTime` (sort key). The following Java code example scans the entire table. The `ScanRequest` instance specifies the name of the table to scan.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
ScanRequest scanRequest = new ScanRequest()
    .withTableName("Reply");
ScanResult result = client.scan(scanRequest);
for (Map<String, AttributeValue> item : result.getItems()){
    printItem(item);
}
```

**Specifying Optional Parameters**

The `scan` method supports several optional parameters. For example, you can optionally use a filter expression to filter the scan result. In a filter expression, you can specify a condition and attribute names and values on which you want the condition evaluated. For more information, see `Scan`.

The following Java example scans the `ProductCatalog` table to find items that are priced less than 0. The example specifies the following optional parameters:

- A filter expression to retrieve only the items priced less than 0 (error condition).
- A list of attributes to retrieve for items in the query results.

**Example**

```java
Map<String, AttributeValue> expressionAttributeValues =
    new HashMap<String, AttributeValue>();
expressionAttributeValues.put(":val", new AttributeValue().withN("0"));
```
ScanRequest scanRequest = new ScanRequest()
  .withTableName("ProductCatalog")
  .withFilterExpression("Price < :val")
  .withProjectionExpression("Id")
  .withExpressionAttributeValues(expressionAttributeValues);

ScanResult result = client.scan(scanRequest);
for (Map<String, AttributeValue> item : result.getItems()) {
    printItem(item);
}

You can also optionally limit the page size, or the number of items per page, by using the withLimit
method of the scan request. Each time you execute the scan method, you get one page of results
that has the specified number of items. To fetch the next page, you execute the scan method
again by providing the primary key value of the last item in the previous page so that the scan
method can return the next set of items. You provide this information in the request by using the
withExclusiveStartKey method. Initially, the parameter of this method can be null. To retrieve
subsequent pages, you must update this property value to the primary key of the last item in the
preceding page.

The following Java code example scans the ProductCatalog table. In the request, the withLimit and
withExclusiveStartKey methods are used. The do/while loop continues to scan one page at time
until the getLastEvaluatedKey method of the result returns a value of null.

Example

Map<String, AttributeValue> lastKeyEvaluated = null;
do {
    ScanRequest scanRequest = new ScanRequest()
        .withTableName("ProductCatalog")
        .withLimit(10)
        .withExclusiveStartKey(lastKeyEvaluated);

    ScanResult result = client.scan(scanRequest);
    for (Map<String, AttributeValue> item : result.getItems()){
        printItem(item);
    }
    lastKeyEvaluated = result.getLastEvaluatedKey();
} while (lastKeyEvaluated != null);

Example - Scan Using Java

The following Java code example provides a working sample that scans the ProductCatalog table to
find items that are priced less than 100.

Note
The SDK for Java also provides an object persistence model, enabling you to map your client-
side classes to DynamoDB tables. This approach can reduce the amount of code that you have to
write. For more information, see Java: DynamoDBMapper (p. 226).

Note
This code example assumes that you have already loaded data into DynamoDB for your account
by following the instructions in the Creating Tables and Loading Data for Code Examples in
DynamoDB (p. 326) section.
For step-by-step instructions to run the following example, see Java Code Examples (p. 331).
Example - Parallel Scan Using Java

The following Java code example demonstrates a parallel scan. The program deletes and re-creates a table named ParallelScanTest, and then loads the table with data. When the data load is finished,
the program spawns multiple threads and issues parallel Scan requests. The program prints runtime statistics for each parallel request.

**Note**
The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see Java: DynamoDBMapper (p. 226).

Scanning Tables and Indexes: .NET

The Scan operation reads all of the items in a table or index in Amazon DynamoDB.

The following are the steps to scan a table using the AWS SDK for .NET low-level API:

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the ScanRequest class and provide scan operation parameters.
   - The only required parameter is the table name.
3. Execute the Scan method and provide the QueryRequest object that you created in the preceding step.

The following Reply table stores replies for forum threads.

Example

```csharp
>Reply ( <emphasis role="underline">Id</emphasis>, <emphasis role="underline">ReplyDateTime</emphasis>, Message, PostedBy )
```

The table maintains all the replies for various forum threads. Therefore, the primary key is composed of both the Id (partition key) and ReplyDateTime (sort key). The following C# code example scans the entire table. The ScanRequest instance specifies the name of the table to scan.

Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
var request = new ScanRequest
```
Specifying Optional Parameters

The Scan method supports several optional parameters. For example, you can optionally use a scan filter to filter the scan result. In a scan filter, you can specify a condition and an attribute name on which you want the condition evaluated. For more information, see Scan.

The following C# code scans the ProductCatalog table to find items that are priced less than 0. The sample specifies the following optional parameters:

- A FilterExpression parameter to retrieve only the items priced less than 0 (error condition).
- A ProjectionExpression parameter to specify the attributes to retrieve for items in the query results.

The following C# example scans the ProductCatalog table to find all items priced less than 0.

Example

```csharp
var forumScanRequest = new ScanRequest
{
    TableName = "ProductCatalog",
    // Optional parameters.
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":val", new AttributeValue { N = "0" }}
    },
    FilterExpression = "Price < :val",
    ProjectionExpression = "Id"
};
```

You can also optionally limit the page size or the number of items per page, by adding the optional Limit parameter. Each time you execute the Scan method, you get one page of results that has the specified number of items. To fetch the next page, you execute the Scan method again by providing the primary key value of the last item in the previous page so that the Scan method can return the next set of items. You provide this information in the request by setting the ExclusiveStartKey property. Initially, this property can be null. To retrieve subsequent pages, you must update this property value to the primary key of the last item in the preceding page.

The following C# code example scans the ProductCatalog table. In the request, it specifies the Limit and ExclusiveStartKey optional parameters. The do/while loop continues to scan one page at a time until the LastEvaluatedKey returns a null value.

Example

```csharp
Dictionary<string, AttributeValue> lastKeyEvaluated = null;

do
{
    var request = new ScanRequest
```

}
program spawns multiple threads and issues parallel Scan requests. Finally, the program prints a summary of runtime statistics.

Improving Data Access with Secondary Indexes

Topics
- Using Global Secondary Indexes in DynamoDB (p. 500)
- Local Secondary Indexes (p. 537)

Amazon DynamoDB provides fast access to items in a table by specifying primary key values. However, many applications might benefit from having one or more secondary (or alternate) keys available, to allow efficient access to data with attributes other than the primary key. To address this, you can create one or more secondary indexes on a table and issue `Query` or `Scan` requests against these indexes.

A secondary index is a data structure that contains a subset of attributes from a table, along with an alternate key to support `Query` operations. You can retrieve data from the index using a `Query`, in much the same way as you use `Query` with a table. A table can have multiple secondary indexes, which give your applications access to many different query patterns.

**Note**
You can also `Scan` an index, in much the same way as you would `Scan` a table.

Every secondary index is associated with exactly one table, from which it obtains its data. This is called the base table for the index. When you create an index, you define an alternate key for the index (partition key and sort key). You also define the attributes that you want to be projected, or copied, from the base table into the index. DynamoDB copies these attributes into the index, along with the primary key attributes from the base table. You can then query or scan the index just as you would query or scan a table.

Every secondary index is automatically maintained by DynamoDB. When you add, modify, or delete items in the base table, any indexes on that table are also updated to reflect these changes.

DynamoDB supports two types of secondary indexes:

- **Global secondary index** — An index with a partition key and a sort key that can be different from those on the base table. A global secondary index is considered "global" because queries on the index can span all of the data in the base table, across all partitions. A global secondary index is stored in its own partition space away from the base table and scales separately from the base table.

- **Local secondary index** — An index that has the same partition key as the base table, but a different sort key. A local secondary index is "local" in the sense that every partition of a local secondary index is scoped to a base table partition that has the same partition key value.
You should consider your application's requirements when you determine which type of index to use. The following table shows the main differences between a global secondary index and a local secondary index.

Working with Indexes

</thead>
<tbody>
<tr>
<td>are projected into the index. DynamoDB does not fetch any attributes from the table.</td>
<td>not projected in to the index. DynamoDB automatically fetches those attributes from the table.</td>
<td></td>
</tr>
</tbody>
</table>

If you want to create more than one table with secondary indexes, you must do so sequentially. For example, you would create the first table and wait for it to become active, create the next table and wait for it to become active, and so on. If you try to concurrently create more than one table with a secondary index, DynamoDB returns a LimitExceededException.

For each secondary index, you must specify the following:

- The type of index to be created – either a global secondary index or a local secondary index.
- A name for the index. The naming rules for indexes are the same as those for tables, as listed in Service, Account, and Table Limits in Amazon DynamoDB (p. 961). The name must be unique for the base table it is associated with, but you can use the same name for indexes that are associated with different base tables.
- The key schema for the index. Every attribute in the index key schema must be a top-level attribute of type String, Number, or Binary. Other data types, including documents and sets, are not allowed. Other requirements for the key schema depend on the type of index:
  - For a global secondary index, the partition key can be any scalar attribute of the base table. A sort key is optional, and it too can be any scalar attribute of the base table.
  - For a local secondary index, the partition key must be the same as the base table's partition key, and the sort key must be a non-key base table attribute.
- Additional attributes, if any, to project from the base table into the index. These attributes are in addition to the table's key attributes, which are automatically projected into every index. You can project attributes of any data type, including scalars, documents, and sets.
- The provisioned throughput settings for the index, if necessary:
  - For a global secondary index, you must specify read and write capacity unit settings. These provisioned throughput settings are independent of the base table's settings.
  - For a local secondary index, you do not need to specify read and write capacity unit settings. Any read and write operations on a local secondary index draw from the provisioned throughput settings of its base table.

For maximum query flexibility, you can create up to 20 global secondary indexes (default limit) and up to 5 local secondary indexes per table.

The limit of global secondary indexes per table is five for the following AWS Regions:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
- Europe (Stockholm)

To get a detailed listing of secondary indexes on a table, use the DescribeTable operation. DescribeTable returns the name, storage size, and item counts for every secondary index on the table. These values are not updated in real time, but they are refreshed approximately every six hours.

You can access the data in a secondary index using either the Query or Scan operation. You must specify the name of the base table and the name of the index that you want to use, the attributes to be returned in the results, and any condition expressions or filters that you want to apply. DynamoDB can return the results in ascending or descending order.
When you delete a table, all of the indexes associated with that table are also deleted.

For best practices, see Best Practices for Using Secondary Indexes in DynamoDB (p. 907).

**Using Global Secondary Indexes in DynamoDB**

Some applications might need to perform many kinds of queries, using a variety of different attributes as query criteria. To support these requirements, you can create one or more *global secondary indexes* and issue *Query* requests against these indexes in Amazon DynamoDB.

API Version 2012-08-10
Now suppose that you wanted to write a leaderboard application to display top scores for each game. A query that specified the key attributes (UserId and GameTitle) would be very efficient. However, if the application needed to retrieve data from GameScores based on GameTitle only, it would need to use a Scan operation. As more items are added to the table, scans of all the data would become slow and inefficient. This makes it difficult to answer questions such as the following:

- What is the top score ever recorded for the game Meteor Blasters?
- Which user had the highest score for Galaxy Invaders?
- What was the highest ratio of wins vs. losses?

To speed up queries on non-key attributes, you can create a global secondary index. A global secondary index contains a selection of attributes from the base table, but they are organized by a primary key that is different from that of the table. The index key does not need to have any of the key attributes from the table. It doesn't even need to have the same key schema as a table.

For example, you could create a global secondary index named GameTitleIndex, with a partition key of GameTitle and a sort key of TopScore. The base table's primary key attributes are always projected into an index, so the UserId attribute is also present. The following diagram shows what GameTitleIndex index would look like.

Now you can query GameTitleIndex and easily obtain the scores for Meteor Blasters. The results are ordered by the sort key values, TopScore. If you set the ScanIndexForward parameter to false, the results are returned in descending order, so the highest score is returned first.
Every global secondary index must have a partition key, and can have an optional sort key. The index key schema can be different from the base table schema. You could have a table with a simple primary key (partition key), and create a global secondary index with a composite primary key (partition key and sort key)—or vice versa. The index key attributes can consist of any top-level String, Number, or Binary attributes from the base table. Other scalar types, document types, and set types are not allowed.

You can project other base table attributes into the index if you want. When you query the index, DynamoDB can retrieve these projected attributes efficiently. However, global secondary index queries cannot fetch attributes from the base table. For example, if you query GameTitleIndex as shown in the previous diagram, the query could not access any non-key attributes other than TopScore (although the key attributes GameTitle and UserId would automatically be projected).

In a DynamoDB table, each key value must be unique. However, the key values in a global secondary index do not need to be unique. To illustrate, suppose that a game named Comet Quest is especially difficult, with many new users trying but failing to get a score above zero. The following is some data that could represent this.

<table>
<thead>
<tr>
<th>UserId</th>
<th>GameTitle</th>
<th>TopScore</th>
</tr>
</thead>
<tbody>
<tr>
<td>123</td>
<td>Comet Quest</td>
<td>0</td>
</tr>
<tr>
<td>201</td>
<td>Comet Quest</td>
<td>0</td>
</tr>
<tr>
<td>301</td>
<td>Comet Quest</td>
<td>0</td>
</tr>
</tbody>
</table>

When this data is added to the GameScores table, DynamoDB propagates it to GameTitleIndex. If we then query the index using Comet Quest for GameTitle and 0 for TopScore, the following data is returned.

<table>
<thead>
<tr>
<th>GameTitle</th>
<th>TopScore</th>
<th>UserId</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comet Quest</td>
<td>0</td>
<td>123</td>
</tr>
<tr>
<td>Comet Quest</td>
<td>0</td>
<td>201</td>
</tr>
<tr>
<td>Comet Quest</td>
<td>0</td>
<td>301</td>
</tr>
</tbody>
</table>

Only the items with the specified key values appear in the response. Within that set of data, the items are in no particular order.

A global secondary index only tracks data items where its key attributes actually exist. For example, suppose that you added another new item to the GameScores table, but only provided the required primary key attributes.

<table>
<thead>
<tr>
<th>UserId</th>
<th>GameTitle</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>Comet Quest</td>
</tr>
</tbody>
</table>

Because you didn't specify the TopScore attribute, DynamoDB would not propagate this item to GameTitleIndex. Thus, if you queried GameScores for all the Comet Quest items, you would get the following four items.
A similar query on GameTitleIndex would still return three items, rather than four. This is because the item with the nonexistent TopScore is not propagated to the index.

Attribute Projections

A *projection* is the set of attributes that is copied from a table into a secondary index. The partition key and sort key of the table are always projected into the index; you can project other attributes to support your application's query requirements. When you query an index, Amazon DynamoDB can access any attribute in the projection as if those attributes were in a table of their own.

When you create a secondary index, you need to specify the attributes that will be projected into the index. DynamoDB provides three different options for this:

- **KEYS_ONLY** – Each item in the index consists only of the table partition key and sort key values, plus the index key values. The KEYS_ONLY option results in the smallest possible secondary index.
- **INCLUDE** – In addition to the attributes described in KEYS_ONLY, the secondary index will include other non-key attributes that you specify.
- **ALL** – The secondary index includes all of the attributes from the source table. Because all of the table data is duplicated in the index, an ALL projection results in the largest possible secondary index.

In the previous diagram, GameTitleIndex has only one projected attribute: UserId. So while an application can efficiently determine the UserId of the top scorers for each game using GameTitle and TopScore in queries, it can't efficiently determine the highest ratio of wins vs. losses for the top scorers. To do so, it would have to perform an additional query on the base table to fetch the wins and losses for each of the top scorers. A more efficient way to support queries on this data would be to project these attributes from the base table into the global secondary index, as shown in this diagram.
Because the non-key attributes \texttt{Wins} and \texttt{Losses} are projected into the index, an application can determine the wins vs. losses ratio for any game, or for any combination of game and user ID.

When you choose the attributes to project into a global secondary index, you must consider the tradeoff between provisioned throughput costs and storage costs:

- If you need to access just a few attributes with the lowest possible latency, consider projecting only those attributes into a global secondary index. The smaller the index, the less that it costs to store it, and the less your write costs are.
- If your application frequently accesses some non-key attributes, you should consider projecting those attributes into a global secondary index. The additional storage costs for the global secondary index offset the cost of performing frequent table scans.
- If you need to access most of the non-key attributes on a frequent basis, you can project these attributes—or even the entire base table—into a global secondary index. This gives you maximum flexibility. However, your storage cost would increase, or even double.
- If your application needs to query a table infrequently, but must perform many writes or updates against the data in the table, consider projecting \texttt{KEYS\_ONLY}. The global secondary index would be of minimal size, but would still be available when needed for query activity.

\textbf{Querying a Global Secondary Index}

You can use the \texttt{Query} operation to access one or more items in a global secondary index. The query must specify the name of the base table and the name of the index that you want to use, the attributes
to be returned in the query results, and any query conditions that you want to apply. DynamoDB can return the results in ascending or descending order.

Consider the following data returned from a Query that requests gaming data for a leaderboard application.

```json
{
"TableName": "GameScores",
"IndexName": "GameTitleIndex",
"KeyConditionExpression": "GameTitle = :v_title",
"ExpressionAttributeValues": {
":v_title": {"S": "Meteor Blasters"}
},
"ProjectionExpression": "UserId, TopScore",
"ScanIndexForward": false
}
```

In this query:

- DynamoDB accesses GameTitleIndex, using the GameTitle partition key to locate the index items for Meteor Blasters. All of the index items with this key are stored adjacent to each other for rapid retrieval.
- Within this game, DynamoDB uses the index to access all of the user IDs and top scores for this game.
- The results are returned, sorted in descending order because the ScanIndexForward parameter is set to false.

### Scanning a Global Secondary Index

You can use the Scan operation to retrieve all of the data from a global secondary index. You must provide the base table name and the index name in the request. With a Scan, DynamoDB reads all of the data in the index and returns it to the application. You can also request that only some of the data be returned, and that the remaining data should be discarded. To do this, use the FilterExpression parameter of the Scan operation. For more information, see Filter Expressions for Scan (p. 477).

### Data Synchronization Between Tables and Global Secondary Indexes

DynamoDB automatically synchronizes each global secondary index with its base table. When an application writes or deletes items in a table, any global secondary indexes on that table are updated asynchronously, using an eventually consistent model. Applications never write directly to an index. However, it is important that you understand the implications of how DynamoDB maintains these indexes.

Global secondary indexes inherit the read/write capacity mode from the base table. For more information, see Considerations When Changing Read/Write Capacity Mode (p. 341).

When you create a global secondary index, you specify one or more index key attributes and their data types. This means that whenever you write an item to the base table, the data types for those attributes must match the index key schema's data types. In the case of GameTitleIndex, the GameTitle partition key in the index is defined as a String data type. The TopScore sort key in the index is of type Number. If you try to add an item to the GameScores table and specify a different data type for either GameTitle or TopScore, DynamoDB returns a ValidationException because of the data type mismatch.

When you put or delete items in a table, the global secondary indexes on that table are updated in an eventually consistent fashion. Changes to the table data are propagated to the global secondary indexes
Global Secondary Indexes

within a fraction of a second, under normal conditions. However, in some unlikely failure scenarios, longer propagation delays might occur. Because of this, your applications need to anticipate and handle situations where a query on a global secondary index returns results that are not up to date.

If you write an item to a table, you don't have to specify the attributes for any global secondary index sort key. Using GameTitleIndex as an example, you would not need to specify a value for the TopScore attribute to write a new item to the GameScores table. In this case, DynamoDB does not write any data to the index for this particular item.

A table with many global secondary indexes incurs higher costs for write activity than tables with fewer indexes. For more information, see Provisioned Throughput Considerations for Global Secondary Indexes (p. 506).

Provisioned Throughput Considerations for Global Secondary Indexes

When you create a global secondary index on a provisioned mode table, you must specify read and write capacity units for the expected workload on that index. The provisioned throughput settings of a global secondary index are separate from those of its base table. A Query operation on a global secondary index consumes read capacity units from the index, not the base table. When you put, update or delete items in a table, the global secondary indexes on that table are also updated. These index updates consume write capacity units from the index, not from the base table.

For example, if you Query a global secondary index and exceed its provisioned read capacity, your request will be throttled. If you perform heavy write activity on the table, but a global secondary index on that table has insufficient write capacity, the write activity on the table will be throttled.

Note

To avoid potential throttling, the provisioned write capacity for a global secondary index should be equal or greater than the write capacity of the base table because new updates write to both the base table and global secondary index.

To view the provisioned throughput settings for a global secondary index, use the DescribeTable operation. Detailed information about all of the table's global secondary indexes is returned.

Read Capacity Units

Global secondary indexes support eventually consistent reads, each of which consume one half of a read capacity unit. This means that a single global secondary index query can retrieve up to \(2 \times 4 \text{ KB} = 8 \text{ KB}\) per read capacity unit.

For global secondary index queries, DynamoDB calculates the provisioned read activity in the same way as it does for queries against tables. The only difference is that the calculation is based on the sizes of the index entries, rather than the size of the item in the base table. The number of read capacity units is the sum of all projected attribute sizes across all of the items returned. The result is then rounded up to the next 4 KB boundary. For more information about how DynamoDB calculates provisioned throughput usage, see Managing Settings on DynamoDB Provisioned Capacity Tables (p. 342).

The maximum size of the results returned by a query operation is 1 MB. This includes the sizes of all the attribute names and values across all of the items returned.

For example, consider a global secondary index where each item contains 2,000 bytes of data. Now suppose that you Query this index and that the query returns eight items. The total size of the matching items is 2,000 bytes \(\times 8\) items = 16,000 bytes. This result is then rounded up to the nearest 4 KB boundary. Because global secondary index queries are eventually consistent, the total cost is \(0.5 \times (16 \text{ KB} / 4 \text{ KB})\), or 2 read capacity units.
Write Capacity Units

When an item in a table is added, updated, or deleted, and a global secondary index is affected by this, the global secondary index consumes provisioned write capacity units for the operation. The total provisioned throughput cost for a write consists of the sum of write capacity units consumed by writing to the base table and those consumed by updating the global secondary indexes. If a write to a table does not require a global secondary index update, no write capacity is consumed from the index.

For a table write to succeed, the provisioned throughput settings for the table and all of its global secondary indexes must have enough write capacity to accommodate the write. Otherwise, the write to the table is throttled.

The cost of writing an item to a global secondary index depends on several factors:

- If you write a new item to the table that defines an indexed attribute, or you update an existing item to define a previously undefined indexed attribute, one write operation is required to put the item into the index.
- If an update to the table changes the value of an indexed key attribute (from A to B), two writes are required, one to delete the previous item from the index and another write to put the new item into the index.
- If an item was present in the index, but a write to the table caused the indexed attribute to be deleted, one write is required to delete the old item projection from the index.
- If an item is not present in the index before or after the item is updated, there is no additional write cost for the index.
- If an update to the table only changes the value of projected attributes in the index key schema, but does not change the value of any indexed key attribute, one write is required to update the values of the projected attributes into the index.

All of these factors assume that the size of each item in the index is less than or equal to the 1 KB item size for calculating write capacity units. Larger index entries require additional write capacity units.

You can minimize your write costs by considering which attributes your queries will need to return and projecting only those attributes into the index.

Storage Considerations for Global Secondary Indexes

When an application writes an item to a table, DynamoDB automatically copies the correct subset of attributes to any global secondary indexes in which those attributes should appear. Your AWS account is charged for storage of the item in the base table and also for storage of attributes in any global secondary indexes on that table.

The amount of space used by an index item is the sum of the following:

- The size in bytes of the base table primary key (partition key and sort key)
- The size in bytes of the index key attribute
- The size in bytes of the projected attributes (if any)
- 100 bytes of overhead per index item

To estimate the storage requirements for a global secondary index, you can estimate the average size of an item in the index and then multiply by the number of items in the base table that have the global secondary index key attributes.

If a table contains an item where a particular attribute is not defined, but that attribute is defined as an index partition key or sort key, DynamoDB doesn't write any data for that item to the index.
Managing Global Secondary Indexes

This section describes how to create, modify, and delete global secondary indexes in Amazon DynamoDB.

Creating a Table with Global Secondary Indexes

To create a table with one or more global secondary indexes, use the `CreateTable` operation with the `GlobalSecondaryIndexes` parameter. For maximum query flexibility, you can create up to 20 global secondary indexes (default limit) per table.

You must specify one attribute to act as the index partition key. You can optionally specify another attribute for the index sort key. It is not necessary for either of these key attributes to be the same as a key attribute in the table. For example, in the `GameScores` table (see Using Global Secondary Indexes in DynamoDB (p. 500)), neither `TopScore` nor `TopScoreDateTime` are key attributes. You could create a global secondary index with a partition key of `TopScore` and a sort key of `TopScoreDateTime`. You might use such an index to determine whether there is a correlation between high scores and the time of day a game is played.

Each index key attribute must be a scalar of type `String`, `Number`, or `Binary`. (It cannot be a document or a set.) You can project attributes of any data type into a global secondary index. This includes scalars, documents, and sets. For a complete list of data types, see Data Types (p. 13).

If using provisioned mode, you must provide `ProvisionedThroughput` settings for the index, consisting of `ReadCapacityUnits` and `WriteCapacityUnits`. These provisioned throughput settings are separate from those of the table, but behave in similar ways. For more information, see Provisioned Throughput Considerations for Global Secondary Indexes (p. 506).

Global secondary indexes inherit the read/write capacity mode from the base table. For more information, see Considerations When Changing Read/Write Capacity Mode (p. 341).

Describing the Global Secondary Indexes on a Table

To view the status of all the global secondary indexes on a table, use the `DescribeTable` operation. The `GlobalSecondaryIndexes` portion of the response shows all of the indexes on the table, along with the current status of each (`IndexStatus`).

The `IndexStatus` for a global secondary index will be one of the following:

- **CREATING** — The index is currently being created, and is not yet available for use.
- **ACTIVE** — The index is ready for use, and applications can perform `Query` operations on the index.
- **UPDATING** — The provisioned throughput settings of the index are being changed.
- **DELETING** — The index is currently being deleted, and can no longer be used.

When DynamoDB has finished building a global secondary index, the index status changes from **CREATING** to **ACTIVE**.
Adding a Global Secondary Index to an Existing Table

To add a global secondary index to an existing table, use the `UpdateTable` operation with the `GlobalSecondaryIndexUpdates` parameter. You must provide the following:

- An index name. The name must be unique among all the indexes on the table.
- The key schema of the index. You must specify one attribute for the index partition key; you can optionally specify another attribute for the index sort key. It is not necessary for either of these key attributes to be the same as a key attribute in the table. The data types for each schema attribute must be scalar: `String`, `Number`, or `Binary`.
- The attributes to be projected from the table into the index:
  - `KEYS_ONLY` — Each item in the index consists only of the table partition key and sort key values, plus the index key values.
  - `INCLUDE` — In addition to the attributes described in `KEYS_ONLY`, the secondary index includes other non-key attributes that you specify.
  - `ALL` — The index includes all of the attributes from the source table.
- The provisioned throughput settings for the index, consisting of `ReadCapacityUnits` and `WriteCapacityUnits`. These provisioned throughput settings are separate from those of the table.

You can only create one global secondary index per `UpdateTable` operation.

Phases of Index Creation

When you add a new global secondary index to an existing table, the table continues to be available while the index is being built. However, the new index is not available for Query operations until its status changes from `CREATING` to `ACTIVE`.

Behind the scenes, DynamoDB builds the index in two phases:

Resource Allocation

DynamoDB allocates the compute and storage resources that are needed for building the index.

During the resource allocation phase, the `IndexStatus` attribute is `CREATING` and the `Backfilling` attribute is false. Use the `DescribeTable` operation to retrieve the status of a table and all of its secondary indexes.

While the index is in the resource allocation phase, you can't delete the index or delete its parent table. You also can't modify the provisioned throughput of the index or the table. You cannot add or delete other indexes on the table. However, you can modify the provisioned throughput of these other indexes.

Backfilling

For each item in the table, DynamoDB determines which set of attributes to write to the index based on its projection (`KEYS_ONLY`, `INCLUDE`, or `ALL`). It then writes these attributes to the index. During the backfill phase, DynamoDB tracks the items that are being added, deleted, or updated in the table. The attributes from these items are also added, deleted, or updated in the index as appropriate.

During the backfilling phase, the `IndexStatus` attribute is set to `CREATING`, and the `Backfilling` attribute is true. Use the `DescribeTable` operation to retrieve the status of a table and all of its secondary indexes.

While the index is backfilling, you cannot delete its parent table. However, you can still delete the index or modify the provisioned throughput of the table and any of its global secondary indexes.
Note
During the backfilling phase, some writes of violating items might succeed while others are rejected. After backfilling, all writes to items that violate the new index's key schema are rejected. We recommend that you run the Violation Detector tool after the backfill phase finishes to detect and resolve any key violations that might have occurred. For more information, see Detecting and Correcting Index Key Violations (p. 511).

While the resource allocation and backfilling phases are in progress, the index is in the CREATING state. During this time, DynamoDB performs read operations on the table. You are not charged for this read activity.

When the index build is complete, its status changes to ACTIVE. You can't Query or Scan the index until it is ACTIVE.

Note
In some cases, DynamoDB can't write data from the table to the index because of index key violations. This can occur if:

- The data type of an attribute value does not match the data type of an index key schema data type.
- The size of an attribute exceeds the maximum length for an index key attribute.
- An index key attribute has an empty String or empty Binary attribute value.

Index key violations do not interfere with global secondary index creation. However, when the index becomes ACTIVE, the violating keys are not present in the index. DynamoDB provides a standalone tool for finding and resolving these issues. For more information, see Detecting and Correcting Index Key Violations (p. 511).

Adding a Global Secondary Index to a Large Table

The time required for building a global secondary index depends on several factors, such as the following:

- The size of the table
- The number of items in the table that qualify for inclusion in the index
- The number of attributes projected into the index
- The provisioned write capacity of the index
- Write activity on the main table during index builds

If you are adding a global secondary index to a very large table, it might take a long time for the creation process to complete. To monitor progress and determine whether the index has sufficient write capacity, consult the following Amazon CloudWatch metrics:

- OnlineIndexPercentageProgress
- OnlineIndexConsumedWriteCapacity
- OnlineIndexThrottleEvents

Note
For more information about CloudWatch metrics related to DynamoDB, see DynamoDB Metrics (p. 859).

If the provisioned write throughput setting on the index is too low, the index build will take longer to complete. To shorten the time it takes to build a new global secondary index, you can increase its provisioned write capacity temporarily.
Global Secondary Indexes

**Note**
As a general rule, we recommend setting the provisioned write capacity of the index to 1.5 times the write capacity of the table. This is a good setting for many use cases. However, your actual requirements might be higher or lower.

While an index is being backfilled, DynamoDB uses internal system capacity to read from the table. This is to minimize the impact of the index creation and to assure that your table does not run out of read capacity.

However, it is possible that the volume of incoming write activity might exceed the provisioned write capacity of the index. This is a bottleneck scenario, in which the index creation takes more time because the write activity to the index is throttled. During the index build, we recommend that you monitor the Amazon CloudWatch metrics for the index to determine whether its consumed write capacity is exceeding its provisioned capacity. In a bottleneck scenario, you should increase the provisioned write capacity on the index to avoid write throttling during the backfill phase.

After the index has been created, you should set its provisioned write capacity to reflect the normal usage of your application.

**Deleting a Global Secondary Index**

If you no longer need a global secondary index, you can delete it using the `UpdateTable` operation.

You can delete only one global secondary index per `UpdateTable` operation.

While the global secondary index is being deleted, there is no effect on any read or write activity in the parent table. While the deletion is in progress, you can still modify the provisioned throughput on other indexes.

**Note**
When you delete a table using the `DeleteTable` action, all of the global secondary indexes on that table are also deleted.

**Modifying a Global Secondary Index during Creation**

While an index is being built, you can use the `DescribeTable` operation to determine what phase it is in. The description for the index includes a Boolean attribute, `Backfilling`, to indicate whether DynamoDB is currently loading the index with items from the table. If `Backfilling` is true, the resource allocation phase is complete and the index is now backfilling.

While the backfill is proceeding, you can update the provisioned throughput parameters for the index. You might decide to do this in order to speed up the index build: You can increase the write capacity of the index while it is being built, and then decrease it afterward. To modify the provisioned throughput settings of the index, use the `UpdateTable` operation. The index status changes to `UPDATING`, and Backfilling is true until the index is ready for use.

During the backfilling phase, you can delete the index that is being created. During this phase, you can't add or delete other indexes on the table.

**Note**
For indexes that were created as part of a `CreateTable` operation, the `Backfilling` attribute does not appear in the `DescribeTable` output. For more information, see Phases of Index Creation (p. 509).

**Detecting and Correcting Index Key Violations**

During the backfill phase of global secondary index creation, Amazon DynamoDB examines each item in the table to determine whether it is eligible for inclusion in the index. Some items might not be eligible because they would cause index key violations. In these cases, the items remain in the table, but the index doesn't have a corresponding entry for that item.
An index key violation occurs in the following situations:

- There is a data type mismatch between an attribute value and the index key schema data type. For example, suppose that one of the items in the GameScores table had a TopScore value of type String. If you added a global secondary index with a partition key of TopScore, of type Number, the item from the table would violate the index key.

- An attribute value from the table exceeds the maximum length for an index key attribute. The maximum length of a partition key is 2048 bytes, and the maximum length of a sort key is 1024 bytes. If any of the corresponding attribute values in the table exceed these limits, the item from the table would violate the index key.

**Note**
If a String or Binary attribute value is set for an attribute that is used as an index key, then the attribute value must have a length greater than zero; otherwise, the item from the table would violate the index key.

This tool does not flag this index key violation, at this time.

If an index key violation occurs, the backfill phase continues without interruption. However, any violating items are not included in the index. After the backfill phase completes, all writes to items that violate the new index's key schema will be rejected.

To identify and fix attribute values in a table that violate an index key, use the Violation Detector tool. To run Violation Detector, you create a configuration file that specifies the name of a table to be scanned, the names and data types of the global secondary index partition key and sort key, and what actions to take if any index key violations are found. Violation Detector can run in one of two different modes:

- **Detection mode** — Detect index key violations. Use detection mode to report the items in the table that would cause key violations in a global secondary index. (You can optionally request that these violating table items be deleted immediately when they are found.) The output from detection mode is written to a file, which you can use for further analysis.

- **Correction mode** — Correct index key violations. In correction mode, Violation Detector reads an input file with the same format as the output file from detection mode. Correction mode reads the records from the input file and, for each record, it either deletes or updates the corresponding items in the table. (Note that if you choose to update the items, you must edit the input file and set appropriate values for these updates.)

### Downloading and Running Violation Detector

Violation Detector is available as an executable Java Archive (.jar file), and runs on Windows, macOS, or Linux computers. Violation Detector requires Java 1.7 (or later) and Apache Maven.

- Download Violation Detector from GitHub

Follow the instructions in the README.md file to download and install Violation Detector using Maven.

To start Violation Detector, go to the directory where you have built ViolationDetector.java and enter the following command.

```
java -jar ViolationDetector.jar [options]
```

The Violation Detector command line accepts the following options:

- `-h | --help` — Prints a usage summary and options for Violation Detector.
- `-p | --configFilePath value` — The fully qualified name of a Violation Detector configuration file. For more information, see The Violation Detector Configuration File (p. 513).
• `-t | --detect value` — Detect index key violations in the table, and write them to the Violation Detector output file. If the value of this parameter is set to `keep`, items with key violations are not modified. If the value is set to `delete`, items with key violations are deleted from the table.

• `-c | --correct value` — Read index key violations from an input file, and take corrective actions on the items in the table. If the value of this parameter is set to `update`, items with key violations are updated with new, non-violating values. If the value is set to `delete`, items with key violations are deleted from the table.

### The Violation Detector Configuration File

At runtime, the Violation Detector tool requires a configuration file. The parameters in this file determine which DynamoDB resources that Violation Detector can access, and how much provisioned throughput it can consume. The following table describes these parameters.

**Detection**

To detect index key violations, use Violation Detector with the --detect command line option. To show how this option works, consider the ProductCatalog table shown in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326). The following is a list of items in the table. Only the primary key (Id) and the Price attribute are shown.

<table>
<thead>
<tr>
<th>Id (Primary Key)</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>5</td>
</tr>
<tr>
<td>102</td>
<td>20</td>
</tr>
</tbody>
</table>
All of the values for Price are of type Number. However, because DynamoDB is schemaless, it is possible to add an item with a non-numeric Price. For example, suppose that you add another item to the ProductCatalog table.

<table>
<thead>
<tr>
<th>Id (Primary Key)</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>999</td>
<td>&quot;Hello&quot;</td>
</tr>
</tbody>
</table>

The table now has a total of nine items.

Now you add a new global secondary index to the table: PriceIndex. The primary key for this index is a partition key, Price, which is of type Number. After the index has been built, it will contain eight items—but the ProductCatalog table has nine items. The reason for this discrepancy is that the value "Hello" is of type String, but PriceIndex has a primary key of type Number. The String value violates the global secondary index key, so it is not present in the index.

To use Violation Detector in this scenario, you first create a configuration file such as the following.

```python
# Properties file for violation detection tool configuration.
# Parameters that are not specified will use default values.

awsCredentialsFile = /home/alice/credentials.txt
dynamoDBRegion = us-west-2
tableName = ProductCatalog
gsiHashKeyName = Price
gsiHashKeyType = N
recordDetails = true
recordGsiValueInViolationRecord = true
detectionOutputPath = ./gsi_violation_check.csv
correctionInputPath = ./gsi_violation_check.csv
numOfSegments = 1
readWriteIOPSPercent = 40
```

Next, you run Violation Detector as in the following example.

```bash
$ java -jar ViolationDetector.jar --configFilePath config.txt --detect keep
Violation detection started: sequential scan, Table name: ProductCatalog, GSI name: PriceIndex
Progress: Items scanned in total: 9, Items scanned by this thread: 9, Violations found by this thread: 1, Violations deleted by this thread: 0
Violation detection finished: Records scanned: 9, Violations found: 1, Violations deleted: 0, see results at: ./gsi_violation_check.csv
```
If the `recordDetails` config parameter is set to `true`, Violation Detector writes details of each violation to the output file, as in the following example.

<table>
<thead>
<tr>
<th>Table Hash Key, GSI Hash Key Value, GSI Hash Key Violation Type, GSI Hash Key Violation Description, GSI Hash Key Update Value (FOR USER), Delete Blank Attributes When Updating? (Y/N)</th>
</tr>
</thead>
<tbody>
<tr>
<td>999, &quot;{&quot;S&quot;: &quot;Hello&quot;&quot;}&quot; , Type Violation, Expected: N Found: S,</td>
</tr>
</tbody>
</table>

The output file is in CSV format. The first line in the file is a header, followed by one record per item that violates the index key. The fields of these violation records are as follows:

- **Table Hash Key** — The partition key value of the item in the table.
- **Table Range Key** — The sort key value of the item in the table.
- **GSI Hash Key Value** — The partition key value of the global secondary index.
- **GSI Hash Key Violation Type** — Either **Type Violation** or **Size Violation**.
- **GSI Hash Key Violation Description** — The cause of the violation.
- **GSI Hash Key Update Value (FOR USER)** — In correction mode, a new user-supplied value for the attribute.
- **GSI Range Key Value** — The sort key value of the global secondary index.
- **GSI Range Key Violation Type** — Either **Type Violation** or **Size Violation**.
- **GSI Range Key Violation Description** — The cause of the violation.
- **GSI Range Key Update Value (FOR USER)** — In correction mode, a new user-supplied value for the attribute.
- **Delete Blank Attribute When Updating? (Y/N)** — In correction mode, determines whether to delete (Y) or keep (N) the violating item in the table—but only if either of the following fields are blank:
  - **GSI Hash Key Update Value (FOR USER)**
  - **GSI Range Key Update Value (FOR USER)**

If either of these fields are non-blank, then Delete Blank Attribute When Updating? (Y/N) has no effect.

**Note**
The output format might vary, depending on the configuration file and command line options. For example, if the table has a simple primary key (without a sort key), no sort key fields will be present in the output.
The violation records in the file might not be in sorted order.

**Correction**
To correct index key violations, use Violation Detector with the `--correct` command line option. In correction mode, Violation Detector reads the input file specified by the `correctionInputPath` parameter. This file has the same format as the `detectionOutputPath` file, so that you can use the output from detection as input for correction.

Violation Detector provides two different ways to correct index key violations:

- **Delete violations** — Delete the table items that have violating attribute values.
- **Update violations** — Update the table items, replacing the violating attributes with non-violating values.

In either case, you can use the output file from detection mode as input for correction mode.
Continuing with the ProductCatalog example, suppose that you want to delete the violating item from the table. To do this, you use the following command line.

```bash
$ java -jar ViolationDetector.jar --configFilePath config.txt --correct delete
```

At this point, you are asked to confirm whether you want to delete the violating items.

```
Are you sure to delete all violations on the table? y/n
y
Confirmed, will delete violations on the table...
Violation correction from file started: Reading records from file: ./
gsi_violation_check.csv, will delete these records from table.
Violation correction from file finished: Violations delete: 1, Violations Update: 0
```

Now both ProductCatalog and PriceIndex have the same number of items.

**Working with Global Secondary Indexes: Java**

You can use the AWS SDK for Java Document API to create an Amazon DynamoDB table with one or more global secondary indexes, describe the indexes on the table, and perform queries using the indexes.

The following are the common steps for table operations.

1. Create an instance of the `DynamoDB` class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.
3. Call the appropriate method provided by the client that you created in the preceding step.

**Topics**

- Create a Table with a Global Secondary Index (p. 519)
- Describe a Table with a Global Secondary Index (p. 521)
- Query a Global Secondary Index (p. 521)
- Example: Global Secondary Indexes Using the AWS SDK for Java Document API (p. 522)

**Create a Table with a Global Secondary Index**

You can create global secondary indexes at the same time that you create a table. To do this, use `CreateTable` and provide your specifications for one or more global secondary indexes. The following Java code example creates a table to hold information about weather data. The partition key is `Location` and the sort key is `Date`. A global secondary index named `PrecipIndex` allows fast access to precipitation data for various locations.

The following are the steps to create a table with a global secondary index, using the DynamoDB document API.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.
   
   You must provide the table name, its primary key, and the provisioned throughput values. For the global secondary index, you must provide the index name, its provisioned throughput settings, the attribute definitions for the index sort key, the key schema for the index, and the attribute projection.
3. Call the `createTable` method by providing the request object as a parameter.
The following Java code example demonstrates the preceding steps. The code creates a table (WeatherData) with a global secondary index (PrecipIndex). The index partition key is Date and its sort key is Precipitation. All of the table attributes are projected into the index. Users can query this index to obtain weather data for a particular date, optionally sorting the data by precipitation amount.

Because Precipitation is not a key attribute for the table, it is not required. However, WeatherData items without Precipitation do not appear in PrecipIndex.

```java
AmazonDynamoDBClient client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

// Attribute definitions
ArrayList<AttributeDefinition> attributeDefinitions = new ArrayList<AttributeDefinition>();
attributeDefinitions.add(new AttributeDefinition()
    .withAttributeName("Location")
    .withAttributeType("S"));
attributeDefinitions.add(new AttributeDefinition()
    .withAttributeName("Date")
    .withAttributeType("S"));
attributeDefinitions.add(new AttributeDefinition()
    .withAttributeName("Precipitation")
    .withAttributeType("N"));

// Table key schema
ArrayList<KeySchemaElement> tableKeySchema = new ArrayList<KeySchemaElement>();
tableKeySchema.add(new KeySchemaElement()
    .withAttributeName("Location")
    .withKeyType(KeyType.HASH)); //Partition key
tableKeySchema.add(new KeySchemaElement()
    .withAttributeName("Date")
    .withKeyType(KeyType.RANGE)); //Sort key

// PrecipIndex
GlobalSecondaryIndex precipIndex = new GlobalSecondaryIndex()
    .withIndexName("PrecipIndex")
    .withProvisionedThroughput(new ProvisionedThroughput()
        .withReadCapacityUnits((long) 10)
        .withWriteCapacityUnits((long) 1))
    .withProjection(new Projection().withProjectionType(ProjectionType.ALL));

ArrayList<KeySchemaElement> indexKeySchema = new ArrayList<KeySchemaElement>();
indexKeySchema.add(new KeySchemaElement()
    .withAttributeName("Date")
    .withKeyType(KeyType.HASH)); //Partition key
indexKeySchema.add(new KeySchemaElement()
    .withAttributeName("Precipitation")
    .withKeyType(KeyType.RANGE)); //Sort key
precipIndex.setKeySchema(indexKeySchema);

CreateTableRequest createTableRequest = new CreateTableRequest()
    .withTableName("WeatherData")
    .withProvisionedThroughput(new ProvisionedThroughput()
        .withReadCapacityUnits((long) 5)
        .withWriteCapacityUnits((long) 1))
    .withAttributeDefinitions(attributeDefinitions)
    .withKeySchema(tableKeySchema)
    .withGlobalSecondaryIndexes(precipIndex);

Table table = dynamoDB.createTable(createTableRequest);
System.out.println(table.getDescription());
```
You must wait until DynamoDB creates the table and sets the table status to **ACTIVE**. After that, you can begin putting data items into the table.

### Describe a Table with a Global Secondary Index

To get information about global secondary indexes on a table, use `DescribeTable`. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access global secondary index information a table.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `Table` class to represent the index you want to work with.
3. Call the `describe` method on the `Table` object.

The following Java code example demonstrates the preceding steps.

#### Example

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("WeatherData");
TableDescription tableDesc = table.describe();

Iterator<GlobalSecondaryIndexDescription> gsiIter =
    tableDesc.getGlobalSecondaryIndexes().iterator();
while (gsiIter.hasNext()) {
    GlobalSecondaryIndexDescription gsiDesc = gsiIter.next();
    System.out.println("Info for index ",
                      gsiDesc.getIndexName() + ":");

    Iterator<KeySchemaElement> kseIter = gsiDesc.getKeySchema().iterator();
    while (kseIter.hasNext()) {
        KeySchemaElement kse = kseIter.next();
        System.out.printf("%s: %s
\t\n", kse.getAttributeName(), kse.getKeyType());
    }
    Projection projection = gsiDesc.getProjection();
    System.out.println("\nThe projection type is: ",
                      projection.getProjectionType());
    if (projection.getProjectionType().toString().equals("INCLUDE")) {
        System.out.println("\n\tThe non-key projected attributes are: ",
                          projection.getNonKeyAttributes());
    }
}
```

### Query a Global Secondary Index

You can use `query` on a global secondary index, in much the same way you `query` a table. You need to specify the index name, the query criteria for the index partition key and sort key (if present), and the attributes that you want to return. In this example, the index is `PrecipIndex`, which has a partition key of `Date` and a sort key of `Precipitation`. The index query returns all of the weather data for a particular date, where the precipitation is greater than zero.

The following are the steps to query a global secondary index using the AWS SDK for Java Document API.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `Table` class to represent the index you want to work with.
3. Create an instance of the `Index` class for the index you want to query.
4. Call the query method on the `Index` object.

The attribute name `Date` is a DynamoDB reserved word. Therefore, you must use an expression attribute name as a placeholder in the `KeyConditionExpression`.

The following Java code example demonstrates the preceding steps.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);
Table table = dynamoDB.getTable("WeatherData");
Index index = table.getIndex("PrecipIndex");
QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("#d = :v_date and Precipitation = :v_precip")
    .withNameMap(new NameMap()
        .with("#d","Date")
    )
    .withValueMap(new ValueMap()
        .withString(":v_date","2013-08-10")
        .withNumber(":v_precip",0));
ItemCollection<QueryOutcome> items = index.query(spec);
Iterator<Item> iter = items.iterator();
while (iter.hasNext()) {
    System.out.println(iter.next().toJSONPretty());
}
```

**Example: Global Secondary Indexes Using the AWS SDK for Java Document API**

The following Java code example shows how to work with global secondary indexes. The example creates a table named `Issues`, which might be used in a simple bug tracking system for software development. The partition key is `IssueId` and the sort key is `Title`. There are three global secondary indexes on this table:

- **CreateDateIndex** — The partition key is `CreateDate` and the sort key is `IssueId`. In addition to the table keys, the attributes `Description` and `Status` are projected into the index.
- **TitleIndex** — The partition key is `Title` and the sort key is `IssueId`. No attributes other than the table keys are projected into the index.
- **DueDateIndex** — The partition key is `DueDate`, and there is no sort key. All of the table attributes are projected into the index.

After the `Issues` table is created, the program loads the table with data representing software bug reports. It then queries the data using the global secondary indexes. Finally, the program deletes the `Issues` table.

Working with Global Secondary Indexes: .NET

You can use the AWS SDK for .NET low-level API to create an Amazon DynamoDB table with one or more global secondary indexes, describe the indexes on the table, and perform queries using the indexes. These operations map to the corresponding DynamoDB operations. For more information, see the Amazon DynamoDB API Reference.

The following are the common steps for table operations using the .NET low-level API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.
   For example, create a CreateTableRequest object to create a table and QueryRequest object to query a table or an index.
3. Execute the appropriate method provided by the client that you created in the preceding step.

Topics

- Create a Table with a Global Secondary Index (p. 527)
- Describe a Table with a Global Secondary Index (p. 529)
- Query a Global Secondary Index (p. 529)
- Example: Global Secondary Indexes Using the AWS SDK for .NET Low-Level API (p. 530)

Create a Table with a Global Secondary Index

You can create global secondary indexes at the same time that you create a table. To do this, use CreateTable and provide your specifications for one or more global secondary indexes. The following C# code example creates a table to hold information about weather data. The partition key is Location and the sort key is Date. A global secondary index named PrecipIndex allows fast access to precipitation data for various locations.

The following are the steps to create a table with a global secondary index, using the .NET low-level API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the CreateTableRequest class to provide the request information.
   You must provide the table name, its primary key, and the provisioned throughput values. For the global secondary index, you must provide the index name, its provisioned throughput settings, the attribute definitions for the index sort key, the key schema for the index, and the attribute projection.
3. Execute the CreateTable method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps. The code creates a table (WeatherData) with a global secondary index (PrecipIndex). The index partition key is Date and its sort key is Precipitation. All of the table attributes are projected into the index. Users can query this index to obtain weather data for a particular date, optionally sorting the data by precipitation amount.

Because Precipitation is not a key attribute for the table, it is not required. However, WeatherData items without Precipitation do not appear in PrecipIndex.

```csharp
client = new AmazonDynamoDBClient();
string tableName = "WeatherData";
```
// Attribute definitions
var attributeDefinitions = new List<AttributeDefinition>()
{
    {new AttributeDefinition{
        AttributeName = "Location",
        AttributeType = "S"}},
    {new AttributeDefinition{
        AttributeName = "Date",
        AttributeType = "S"}},
    {new AttributeDefinition{
        AttributeName = "Precipitation",
        AttributeType = "N"}
}
};

// Table key schema
var tableKeySchema = new List<KeySchemaElement>()
{
    {new KeySchemaElement {
        AttributeName = "Location",
        KeyType = "HASH"}}, //Partition key
    {new KeySchemaElement {
        AttributeName = "Date",
        KeyType = "RANGE"}  //Sort key
}
};

// PrecipIndex
var precipIndex = new GlobalSecondaryIndex
{
    IndexName = "PrecipIndex",
    ProvisionedThroughput = new ProvisionedThroughput
    {
        ReadCapacityUnits = (long)10,
        WriteCapacityUnits = (long)1
    },
    Projection = new Projection { ProjectionType = "ALL" }
};

var indexKeySchema = new List<KeySchemaElement> {
    {new KeySchemaElement { AttributeName = "Date", KeyType = "HASH"}}, //Partition key
    {new KeySchemaElement(AttributeName = "Precipitation",KeyType = "RANGE")}  //Sort key
};
precipIndex.KeySchema = indexKeySchema;

CreateTableRequest createTableRequest = new CreateTableRequest
{
    TableName = tableName,
    ProvisionedThroughput = new ProvisionedThroughput
    {
        ReadCapacityUnits = (long)5,
        WriteCapacityUnits = (long)1
    },
    AttributeDefinitions = attributeDefinitions,
    KeySchema = tableKeySchema,
    GlobalSecondaryIndexes = { precipIndex }
};

CreateTableResponse response = client.CreateTable(createTableRequest);
Console.WriteLine(response.CreateTableResult.TableDescription.TableName);
Console.WriteLine(response.CreateTableResult.TableDescription.TableStatus);
You must wait until DynamoDB creates the table and sets the table status to \texttt{ACTIVE}. After that, you can begin putting data items into the table.

\textbf{Describe a Table with a Global Secondary Index}

To get information about global secondary indexes on a table, use \texttt{DescribeTable}. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access global secondary index information for a table using the .NET low-level API.

1. Create an instance of the \texttt{AmazonDynamoDBClient} class.
2. Execute the \texttt{describeTable} method by providing the request object as a parameter.
   
   Create an instance of the \texttt{DescribeTableRequest} class to provide the request information. You must provide the table name.
3. 

The following C# code example demonstrates the preceding steps.

\textit{Example}

\begin{verbatim}
client = new AmazonDynamoDBClient();
string tableName = "WeatherData";
DescribeTableResponse response = client.DescribeTable(new DescribeTableRequest { TableName = tableName});
List<GlobalSecondaryIndexDescription> globalSecondaryIndexes = response.DescribeTableResult.Table.GlobalSecondaryIndexes;

// This code snippet will work for multiple indexes, even though // there is only one index in this example.
foreach (GlobalSecondaryIndexDescription gsiDescription in globalSecondaryIndexes) {
    Console.WriteLine("Info for index " + gsiDescription.IndexName + ":");
    foreach (KeySchemaElement kse in gsiDescription.KeySchema) {
        Console.WriteLine("\t" + kse.AttributeName + ": key type is " + kse.KeyType);
    }

    Projection projection = gsiDescription.Projection;
    Console.WriteLine("\tThe projection type is: " + projection.ProjectionType);
    if (projection.ProjectionType.ToString().Equals("INCLUDE")) {
        Console.WriteLine("\t\tThe non-key projected attributes are: " + projection.NonKeyAttributes);
    }
}
\end{verbatim}

\textbf{Query a Global Secondary Index}

You can use \texttt{Query} on a global secondary index, in much the same way you \texttt{Query} a table. You need to specify the index name, the query criteria for the index partition key and sort key (if present), and the attributes that you want to return. In this example, the index is \texttt{PrecipIndex}, which has a partition key of \texttt{Date} and a sort key of \texttt{Precipitation}. The index query returns all of the weather data for a particular date, where the precipitation is greater than zero.

The following are the steps to query a global secondary index using the .NET low-level API.

1. Create an instance of the \texttt{AmazonDynamoDBClient} class.
2. Create an instance of the `QueryRequest` class to provide the request information.
3. Execute the `query` method by providing the request object as a parameter.

The attribute name `Date` is a DynamoDB reserved word. Therefore, you must use an expression attribute name as a placeholder in the `KeyConditionExpression`. The following C# code example demonstrates the preceding steps.

**Example**

```csharp
client = new AmazonDynamoDBClient();
QueryRequest queryRequest = new QueryRequest
{
    TableName = "WeatherData",
    IndexName = "PrecipIndex",
    KeyConditionExpression = "#dt = :v_date and Precipitation > :v_precip",
    ExpressionAttributeNames = new Dictionary<String, String> {
        {"#dt", "Date"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":v_date", new AttributeValue { S = "2013-08-01" }},
        {":v_precip", new AttributeValue { N = "0" }}
    },
    ScanIndexForward = true
};
var result = client.Query(queryRequest);
var items = result.Items;
foreach (var currentItem in items)
{
    foreach (string attr in currentItem.Keys)
    {
        Console.Write(attr + "----> ");
        if (attr == "Precipitation")
        {
            Console.WriteLine(currentItem[attr].N);
        }
        else
        {
            Console.WriteLine(currentItem[attr].S);
        }
    }
    Console.WriteLine();
}
```

**Example: Global Secondary Indexes Using the AWS SDK for .NET Low-Level API**

The following C# code example shows how to work with global secondary indexes. The example creates a table named `Issues`, which might be used in a simple bug tracking system for software development. The partition key is `IssueId` and the sort key is `Title`. There are three global secondary indexes on this table:

- **CreateDateIndex** — The partition key is `CreateDate` and the sort key is `IssueId`. In addition to the table keys, the attributes `Description` and `Status` are projected into the index.
- **TitleIndex** — The partition key is `Title` and the sort key is `IssueId`. No attributes other than the table keys are projected into the index.
- **DueDateIndex** — The partition key is `DueDate`, and there is no sort key. All of the table attributes are projected into the index.
After the Issues table is created, the program loads the table with data representing software bug reports. It then queries the data using the global secondary indexes. Finally, the program deletes the Issues table.

Local Secondary Indexes

Some applications only need to query data using the base table's primary key. However, there might be situations where an alternative sort key would be helpful. To give your application a choice of sort keys, you can create one or more local secondary indexes on an Amazon DynamoDB table and issue Query or Scan requests against these indexes.

Scenario: Using a Local Secondary Index

As an example, consider the Thread table that is defined in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326). This table is useful for an application such as the AWS Discussion...
Forums. The following diagram shows how the items in the table would be organized. (Not all of the attributes are shown.)

<table>
<thead>
<tr>
<th>Thread</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ForumName</strong></td>
</tr>
<tr>
<td>&quot;S3&quot;</td>
</tr>
<tr>
<td>&quot;S3&quot;</td>
</tr>
<tr>
<td>&quot;S3&quot;</td>
</tr>
<tr>
<td>&quot;S3&quot;</td>
</tr>
<tr>

</tr>
<tr>
<td>&quot;EC2&quot;</td>
</tr>
<tr>
<td>&quot;RDS&quot;</td>
</tr>
<tr>
<td>&quot;RDS&quot;</td>
</tr>
<tr>
<td>&quot;RDS&quot;</td>
</tr>
</tbody>
</table>

DynamoDB stores all of the items with the same partition key value contiguously. In this example, given a particular **ForumName**, a **Query** operation could immediately locate all of the threads for that forum. Within a group of items with the same partition key value, the items are sorted by sort key value. If the sort key (**Subject**) is also provided in the query, DynamoDB can narrow down the results that are returned—for example, returning all of the threads in the "S3" forum that have a **Subject** beginning with the letter "a".

Some requests might require more complex data access patterns. For example:

- Which forum threads get the most views and replies?
- Which thread in a particular forum has the largest number of messages?
- How many threads were posted in a particular forum within a particular time period?

To answer these questions, the **Query** action would not be sufficient. Instead, you would have to **Scan** the entire table. For a table with millions of items, this would consume a large amount of provisioned read throughput and take a long time to complete.

However, you can specify one or more local secondary indexes on non-key attributes, such as **Replies** or **LastPostDateTime**.

A **local secondary index** maintains an alternate sort key for a given partition key value. A local secondary index also contains a copy of some or all of the attributes from its base table. You specify which attributes are projected into the local secondary index when you create the table. The data in a local secondary index is organized by the same partition key as the base table, but with a different sort key. This lets you access data items efficiently across this different dimension. For greater query or scan flexibility, you can create up to five local secondary indexes per table.

Suppose that an application needs to find all of the threads that have been posted within the last three months in a particular forum. Without a local secondary index, the application would have to **Scan** the entire **Thread** table and discard any posts that were not within the specified time frame. With a local secondary index, a **Query** operation could use **LastPostDateTime** as a sort key and find the data quickly.
The following diagram shows a local secondary index named LastPostIndex. Note that the partition key is the same as that of the Thread table, but the sort key is LastPostDateTime.

Every local secondary index must meet the following conditions:

- The partition key is the same as that of its base table.
- The sort key consists of exactly one scalar attribute.
- The sort key of the base table is projected into the index, where it acts as a non-key attribute.

In this example, the partition key is ForumName and the sort key of the local secondary index is LastPostDateTime. In addition, the sort key value from the base table (in this example, Subject) is projected into the index, but it is not a part of the index key. If an application needs a list that is based on ForumName and LastPostDateTime, it can issue a Query request against LastPostIndex. The query results are sorted by LastPostDateTime, and can be returned in ascending or descending order. The query can also apply key conditions, such as returning only items that have a LastPostDateTime within a particular time span.

Every local secondary index automatically contains the partition and sort keys from its base table; you can optionally project non-key attributes into the index. When you query the index, DynamoDB can retrieve these projected attributes efficiently. When you query a local secondary index, the query can also retrieve attributes that are not projected into the index. DynamoDB automatically fetches these attributes from the base table, but at a greater latency and with higher provisioned throughput costs.

For any local secondary index, you can store up to 10 GB of data per distinct partition key value. This figure includes all of the items in the base table, plus all of the items in the indexes, that have the same partition key value. For more information, see Item Collections (p. 545).
Attribute Projections

With LastPostIndex, an application could use ForumName and LastPostDateTime as query criteria. However, to retrieve any additional attributes, DynamoDB must perform additional read operations against the Thread table. These extra reads are known as fetches, and they can increase the total amount of provisioned throughput required for a query.

Suppose that you wanted to populate a webpage with a list of all the threads in "S3" and the number of replies for each thread, sorted by the last reply date/time beginning with the most recent reply. To populate this list, you would need the following attributes:

- Subject
- Replies
- LastPostDateTime

The most efficient way to query this data and to avoid fetch operations would be to project the Replies attribute from the table into the local secondary index, as shown in this diagram.

![Table of data]

A projection is the set of attributes that is copied from a table into a secondary index. The partition key and sort key of the table are always projected into the index; you can project other attributes to support your application's query requirements. When you query an index, Amazon DynamoDB can access any attribute in the projection as if those attributes were in a table of their own.

When you create a secondary index, you need to specify the attributes that will be projected into the index. DynamoDB provides three different options for this:
Local Secondary Indexes

- **KEYS_ONLY** – Each item in the index consists only of the table partition key and sort key values, plus the index key values. The **KEYS_ONLY** option results in the smallest possible secondary index.

- **INCLUDE** – In addition to the attributes described in **KEYS_ONLY**, the secondary index will include other non-key attributes that you specify.

- **ALL** – The secondary index includes all of the attributes from the source table. Because all of the table data is duplicated in the index, an **ALL** projection results in the largest possible secondary index.

In the previous diagram, the non-key attribute Replies is projected into LastPostIndex. An application can query LastPostIndex instead of the full Thread table to populate a webpage with Subject, Replies, and LastPostDateTime. If any other non-key attributes are requested, DynamoDB would need to fetch those attributes from the Thread table.

From an application's point of view, fetching additional attributes from the base table is automatic and transparent, so there is no need to rewrite any application logic. However, such fetching can greatly reduce the performance advantage of using a local secondary index.

When you choose the attributes to project into a local secondary index, you must consider the tradeoff between provisioned throughput costs and storage costs:

- If you need to access just a few attributes with the lowest possible latency, consider projecting only those attributes into a local secondary index. The smaller the index, the less that it costs to store it, and the less your write costs are. If there are attributes that you occasionally need to fetch, the cost for provisioned throughput may well outweigh the longer-term cost of storing those attributes.

- If your application frequently accesses some non-key attributes, you should consider projecting those attributes into a local secondary index. The additional storage costs for the local secondary index offset the cost of performing frequent table scans.

- If you need to access most of the non-key attributes on a frequent basis, you can project these attributes—or even the entire base table—into a local secondary index. This gives you maximum flexibility and lowest provisioned throughput consumption, because no fetching would be required. However, your storage cost would increase, or even double if you are projecting all attributes.

- If your application needs to query a table infrequently, but must perform many writes or updates against the data in the table, consider projecting **KEYS_ONLY**. The local secondary index would be of minimal size, but would still be available when needed for query activity.

**Creating a Local Secondary Index**

To create one or more local secondary indexes on a table, use the `LocalSecondaryIndexes` parameter of the `CreateTable` operation. Local secondary indexes on a table are created when the table is created. When you delete a table, any local secondary indexes on that table are also deleted.

You must specify one non-key attribute to act as the sort key of the local secondary index. The attribute that you choose must be a scalar `String`, `Number`, or `Binary`. Other scalar types, document types, and set types are not allowed. For a complete list of data types, see [Data Types](#).

**Important**

For tables with local secondary indexes, there is a 10 GB size limit per partition key value. A table with local secondary indexes can store any number of items, as long as the total size for any one partition key value does not exceed 10 GB. For more information, see [Item Collection Size Limit](#).

You can project attributes of any data type into a local secondary index. This includes scalars, documents, and sets. For a complete list of data types, see [Data Types](#).
Querying a Local Secondary Index

In a DynamoDB table, the combined partition key value and sort key value for each item must be unique. However, in a local secondary index, the sort key value does not need to be unique for a given partition key value. If there are multiple items in the local secondary index that have the same sort key value, a Query operation returns all of the items that have the same partition key value. In the response, the matching items are not returned in any particular order.

You can query a local secondary index using either eventually consistent or strongly consistent reads. To specify which type of consistency you want, use the ConsistentRead parameter of the Query operation. A strongly consistent read from a local secondary index always returns the latest updated values. If the query needs to fetch additional attributes from the base table, those attributes will be consistent with respect to the index.

Example

Consider the following data returned from a Query that requests data from the discussion threads in a particular forum.

```json
{
   "TableName": "Thread",
   "IndexName": "LastPostIndex",
   "ConsistentRead": false,
   "ProjectionExpression": "Subject, LastPostDateTime, Replies, Tags",
   "KeyConditionExpression": "ForumName = :v_forum and LastPostDateTime between :v_start and :v_end",
   "ExpressionAttributeValues": {
      ":v_start": {"S": "2015-08-31T00:00:00.000Z"},
      ":v_end": {"S": "2015-11-31T00:00:00.000Z"},
      ":v_forum": {"S": "EC2"}
   }
}
```

In this query:

- DynamoDB accesses LastPostIndex, using the ForumName partition key to locate the index items for "EC2". All of the index items with this key are stored adjacent to each other for rapid retrieval.
- Within this forum, DynamoDB uses the index to look up the keys that match the specified LastPostDateTime condition.
- Because the Replies attribute is projected into the index, DynamoDB can retrieve this attribute without consuming any additional provisioned throughput.
- The Tags attribute is not projected into the index, so DynamoDB must access the Thread table and fetch this attribute.
- The results are returned, sorted by LastPostDateTime. The index entries are sorted by partition key value and then by sort key value, and Query returns them in the order they are stored. (You can use the ScanIndexForward parameter to return the results in descending order.)

Because the Tags attribute is not projected into the local secondary index, DynamoDB must consume additional read capacity units to fetch this attribute from the base table. If you need to run this query often, you should project Tags into LastPostIndex to avoid fetching from the base table. However, if you needed to access Tags only occasionally, the additional storage cost for projecting Tags into the index might not be worthwhile.

Scanning a Local Secondary Index

You can use Scan to retrieve all of the data from a local secondary index. You must provide the base table name and the index name in the request. With a Scan, DynamoDB reads all of the data in the index...
and returns it to the application. You can also request that only some of the data be returned, and that the remaining data should be discarded. To do this, use the FilterExpression parameter of the Scan API. For more information, see Filter Expressions for Scan (p. 477).

**Item Writes and Local Secondary Indexes**

DynamoDB automatically keeps all local secondary indexes synchronized with their respective base tables. Applications never write directly to an index. However, it is important that you understand the implications of how DynamoDB maintains these indexes.

When you create a local secondary index, you specify an attribute to serve as the sort key for the index. You also specify a data type for that attribute. This means that whenever you write an item to the base table, if the item defines an index key attribute, its type must match the index key schema's data type. In the case of LastPostIndex, the LastPostDateTime sort key in the index is defined as a String data type. If you try to add an item to the Thread table and specify a different data type for LastPostDateTime (such as Number), DynamoDB returns a ValidationException because of the data type mismatch.

There is no requirement for a one-to-one relationship between the items in a base table and the items in a local secondary index. In fact, this behavior can be advantageous for many applications.

A table with many local secondary indexes incurs higher costs for write activity than tables with fewer indexes. For more information, see Provisioned Throughput Considerations for Local Secondary Indexes (p. 543).

**Important**

For tables with local secondary indexes, there is a 10 GB size limit per partition key value. A table with local secondary indexes can store any number of items, as long as the total size for any one partition key value does not exceed 10 GB. For more information, see Item Collection Size Limit (p. 547).

**Provisioned Throughput Considerations for Local Secondary Indexes**

When you create a table in DynamoDB, you provision read and write capacity units for the table's expected workload. That workload includes read and write activity on the table's local secondary indexes.

To view the current rates for provisioned throughput capacity, see Amazon DynamoDB pricing.

**Read Capacity Units**

When you query a local secondary index, the number of read capacity units consumed depends on how the data is accessed.

As with table queries, an index query can use either eventually consistent or strongly consistent reads depending on the value of ConsistentRead. One strongly consistent read consumes one read capacity unit; an eventually consistent read consumes only half of that. Thus, by choosing eventually consistent reads, you can reduce your read capacity unit charges.

For index queries that request only index keys and projected attributes, DynamoDB calculates the provisioned read activity in the same way as it does for queries against tables. The only difference is that the calculation is based on the sizes of the index entries, rather than the size of the item in the base table. The number of read capacity units is the sum of all projected attribute sizes across all of the items returned; the result is then rounded up to the next 4 KB boundary. For more information about how DynamoDB calculates provisioned throughput usage, see Managing Settings on DynamoDB Provisioned Capacity Tables (p. 342).
Local Secondary Indexes

For index queries that read attributes that are not projected into the local secondary index, DynamoDB needs to fetch those attributes from the base table, in addition to reading the projected attributes from the index. These fetches occur when you include any non-projected attributes in the `Select` or `ProjectionExpression` parameters of the `Query` operation. Fetching causes additional latency in query responses, and it also incurs a higher provisioned throughput cost: In addition to the reads from the local secondary index described previously, you are charged for read capacity units for every base table item fetched. This charge is for reading each entire item from the table, not just the requested attributes.

The maximum size of the results returned by a `Query` operation is 1 MB. This includes the sizes of all the attribute names and values across all of the items returned. However, if a `Query` against a local secondary index causes DynamoDB to fetch item attributes from the base table, the maximum size of the data in the results might be lower. In this case, the result size is the sum of:

- The size of the matching items in the index, rounded up to the next 4 KB.
- The size of each matching item in the base table, with each item individually rounded up to the next 4 KB.

Using this formula, the maximum size of the results returned by a `Query` operation is still 1 MB.

For example, consider a table where the size of each item is 300 bytes. There is a local secondary index on that table, but only 200 bytes of each item is projected into the index. Now suppose that you `Query` this index, that the query requires table fetches for each item, and that the query returns 4 items. DynamoDB sums up the following:

- The size of the matching items in the index: 200 bytes × 4 items = 800 bytes; this is then rounded up to 4 KB.
- The size of each matching item in the base table: (300 bytes, rounded up to 4 KB) × 4 items = 16 KB.

The total size of the data in the result is therefore 20 KB.

**Write Capacity Units**

When an item in a table is added, updated, or deleted, updating the local secondary indexes consumes provisioned write capacity units for the table. The total provisioned throughput cost for a write is the sum of write capacity units consumed by writing to the table and those consumed by updating the local secondary indexes.

The cost of writing an item to a local secondary index depends on several factors:

- If you write a new item to the table that defines an indexed attribute, or you update an existing item to define a previously undefined indexed attribute, one write operation is required to put the item into the index.
- If an update to the table changes the value of an indexed key attribute (from A to B), two writes are required: one to delete the previous item from the index and another write to put the new item into the index.
- If an item was present in the index, but a write to the table caused the indexed attribute to be deleted, one write is required to delete the old item projection from the index.
- If an item is not present in the index before or after the item is updated, there is no additional write cost for the index.

All of these factors assume that the size of each item in the index is less than or equal to the 1 KB item size for calculating write capacity units. Larger index entries require additional write capacity units. You can minimize your write costs by considering which attributes your queries need to return and projecting only those attributes into the index.
Storage Considerations for Local Secondary Indexes

When an application writes an item to a table, DynamoDB automatically copies the correct subset of attributes to any local secondary indexes in which those attributes should appear. Your AWS account is charged for storage of the item in the base table and also for storage of attributes in any local secondary indexes on that table.

The amount of space used by an index item is the sum of the following:

- The size in bytes of the base table primary key (partition key and sort key)
- The size in bytes of the index key attribute
- The size in bytes of the projected attributes (if any)
- 100 bytes of overhead per index item

To estimate the storage requirements for a local secondary index, you can estimate the average size of an item in the index and then multiply by the number of items in the base table.

If a table contains an item where a particular attribute is not defined, but that attribute is defined as an index sort key, then DynamoDB does not write any data for that item to the index.

Item Collections

Note
This section pertains only to tables that have local secondary indexes.

In DynamoDB, an *item collection* is any group of items that have the same partition key value in a table and all of its local secondary indexes. In the examples used throughout this section, the partition key for the *Thread* table is *ForumName*, and the partition key for *LastPostIndex* is also *ForumName*. All the table and index items with the same *ForumName* are part of the same item collection. For example, in the *Thread* table and the *LastPostIndex* local secondary index, there is an item collection for forum *EC2* and a different item collection for forum *RDS*.

The following diagram shows the item collection for forum *S3*. 
In this diagram, the item collection consists of all the items in Thread and LastPostIndex where the ForumName partition key value is "S3". If there were other local secondary indexes on the table, any items in those indexes with ForumName equal to "S3" would also be part of the item collection.

You can use any of the following operations in DynamoDB to return information about item collections:

- BatchWriteItem
Each of these operations supports the `ReturnItemCollectionMetrics` parameter. When you set this parameter to `SIZE`, you can view information about the size of each item collection in the index.

**Example**

The following is an example from the output of an `UpdateItem` operation on the `Thread` table, with `ReturnItemCollectionMetrics` set to `SIZE`. The item that was updated had a `ForumName` value of "EC2", so the output includes information about that item collection.

```json
{
  ItemCollectionMetrics: {
    ItemCollectionKey: {
      ForumName: "EC2"
    },
    SizeEstimateRangeGB: [0.0, 1.0]
  }
}
```

The `SizeEstimateRangeGB` object shows that the size of this item collection is between 0 and 1 GB. DynamoDB periodically updates this size estimate, so the numbers might be different next time the item is modified.

**Item Collection Size Limit**

The maximum size of any item collection is 10 GB. This limit does not apply to tables without local secondary indexes. Only tables that have one or more local secondary indexes are affected.

If an item collection exceeds the 10 GB limit, DynamoDB returns an `ItemCollectionSizeLimitExceededException`, and you won't be able to add more items to the item collection or increase the sizes of items that are in the item collection. (Read and write operations that shrink the size of the item collection are still allowed.) You can still add items to other item collections.

To reduce the size of an item collection, you can do one of the following:

- Delete any unnecessary items with the partition key value in question. When you delete these items from the base table, DynamoDB also removes any index entries that have the same partition key value.
- Update the items by removing attributes or by reducing the size of the attributes. If these attributes are projected into any local secondary indexes, DynamoDB also reduces the size of the corresponding index entries.
- Create a new table with the same partition key and sort key, and then move items from the old table to the new table. This might be a good approach if a table has historical data that is infrequently accessed. You might also consider archiving this historical data to Amazon Simple Storage Service (Amazon S3).

When the total size of the item collection drops below 10 GB, you can once again add items with the same partition key value.

We recommend as a best practice that you instrument your application to monitor the sizes of your item collections. One way to do so is to set the `ReturnItemCollectionMetrics` parameter to `SIZE` whenever you use `BatchWriteItem`, `DeleteItem`, `PutItem`, or `UpdateItem`. Your application
should examine the `ReturnItemCollectionMetrics` object in the output and log an error message whenever an item collection exceeds a user-defined limit (8 GB, for example). Setting a limit that is less than 10 GB would provide an early warning system so you know that an item collection is approaching the limit in time to do something about it.

**Item Collections and Partitions**

The table and index data for each item collection is stored in a single partition. Referring to the `Thread` table example, all of the base table and index items with the same `ForumName` attribute would be stored in the same partition. The "S3" item collection would be stored on one partition, "EC2" in another partition, and "RDS" in a third partition.

You should design your applications so that table data is evenly distributed across distinct partition key values. For tables with local secondary indexes, your applications should not create "hot spots" of read and write activity within a single item collection on a single partition.

**Working with Local Secondary Indexes: Java**

You can use the AWS SDK for Java Document API to create an Amazon DynamoDB table with one or more local secondary indexes, describe the indexes on the table, and perform queries using the indexes.

The following are the common steps for table operations using the AWS SDK for Java Document API.

1. Create an instance of the `DynamoDB` class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.
3. Call the appropriate method provided by the client that you created in the preceding step.

**Topics**

- Create a Table with a Local Secondary Index (p. 548)
- Describe a Table with a Local Secondary Index (p. 550)
- Query a Local Secondary Index (p. 550)
- Example: Local Secondary Indexes Using the Java Document API (p. 551)

**Create a Table with a Local Secondary Index**

Local secondary indexes must be created at the same time you create a table. To do this, use the `createTable` method and provide your specifications for one or more local secondary indexes. The following Java code example creates a table to hold information about songs in a music collection. The partition key is `Artist` and the sort key is `SongTitle`. A secondary index, `AlbumTitleIndex`, facilitates queries by album title.

The following are the steps to create a table with a local secondary index, using the DynamoDB document API.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.
   
   You must provide the table name, its primary key, and the provisioned throughput values. For the local secondary index, you must provide the index name, the name and data type for the index sort key, the key schema for the index, and the attribute projection.
3. Call the `createTable` method by providing the request object as a parameter.
The following Java code example demonstrates the preceding steps. The code creates a table (Music) with a secondary index on the AlbumTitle attribute. The table partition key and sort key, plus the index sort key, are the only attributes projected into the index.

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

String tableName = "Music";
CreateTableRequest createTableRequest = new CreateTableRequest().withTableName(tableName);

//ProvisionedThroughput
createTableRequest.setProvisionedThroughput(new
ProvisionedThroughput().withReadCapacityUnits((long)5).withWriteCapacityUnits((long)5));

//AttributeDefinitions
ArrayList<AttributeDefinition> attributeDefinitions = new ArrayList<AttributeDefinition>();
attributeDefinitions.add(new
AttributeDefinition().withAttributeName("Artist").withAttributeType("S"));
attributeDefinitions.add(new
AttributeDefinition().withAttributeName("SongTitle").withAttributeType("S"));
attributeDefinitions.add(new
AttributeDefinition().withAttributeName("AlbumTitle").withAttributeType("S"));
createTableRequest.setAttributeDefinitions(attributeDefinitions);

//KeySchema
ArrayList<KeySchemaElement> tableKeySchema = new ArrayList<KeySchemaElement>();
tableKeySchema.add(new
KeySchemaElement().withAttributeName("Artist").withKeyType(KeyType.HASH));  //Partition key
tableKeySchema.add(new
KeySchemaElement().withAttributeName("SongTitle").withKeyType(KeyType.RANGE));  //Sort key
createTableRequest.setKeySchema(tableKeySchema);

ArrayList<KeySchemaElement> indexKeySchema = new ArrayList<KeySchemaElement>();
indexKeySchema.add(new
KeySchemaElement().withAttributeName("Artist").withKeyType(KeyType.HASH));  //Partition key
indexKeySchema.add(new
KeySchemaElement().withAttributeName("AlbumTitle").withKeyType(KeyType.RANGE));  //Sort key
Projection projection = new Projection().withProjectionType(ProjectionType.INCLUDE);
ArrayList<String> nonKeyAttributes = new ArrayList<String>();
nonKeyAttributes.add("Genre");
nonKeyAttributes.add("Year");
projection.setNonKeyAttributes(nonKeyAttributes);
LocalSecondaryIndex localSecondaryIndex = new LocalSecondaryIndex()
    .withIndexName("AlbumTitleIndex").withKeySchema(indexKeySchema).withProjection(projection);
ArrayList<LocalSecondaryIndex> localSecondaryIndexes = new
    ArrayList<LocalSecondaryIndex>());
createTableRequest.setLocalSecondaryIndexes(localSecondaryIndexes);

Table table = dynamoDB.createTable(createTableRequest);
System.out.println(table.getDescription());

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table.

Describe a Table with a Local Secondary Index

To get information about local secondary indexes on a table, use the `describeTable` method. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access local secondary index information a table using the AWS SDK for Java Document API.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `Table` class. You must provide the table name.
3. Call the `describeTable` method on the `Table` object.

The following Java code example demonstrates the preceding steps.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

String tableName = "Music";
Table table = dynamoDB.getTable(tableName);
TableDescription tableDescription = table.describe();
List<LocalSecondaryIndexDescription> localSecondaryIndexes =
    tableDescription.getLocalSecondaryIndexes();

// This code snippet will work for multiple indexes, even though
// there is only one index in this example.
Iterator<LocalSecondaryIndexDescription> lsiIter = localSecondaryIndexes.iterator();
while (lsiIter.hasNext()) {
    LocalSecondaryIndexDescription lsiDescription = lsiIter.next();
    System.out.println("Info for index " + lsiDescription.getIndexName() + ":");
    Iterator<KeySchemaElement> kseIter = lsiDescription.getKeySchema().iterator();
    while (kseIter.hasNext()) {
        KeySchemaElement kse = kseIter.next();
        System.out.printf("\t%s: %s\n", kse.getAttributeName(), kse.getKeyType());
    }
    Projection projection = lsiDescription.getProjection();
    System.out.println("\tThe projection type is: " + projection.getProjectionType());
    if (projection.getProjectionType().toString().equals("INCLUDE")) {
        System.out.println("\t\tThe non-key projected attributes are: " +
                         projection.getNonKeyAttributes());
    }
}
```

Query a Local Secondary Index

You can use the `Query` operation on a local secondary index in much the same way that you `Query` a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is `AlbumTitleIndex` and the index sort key is `AlbumTitle`.

The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see `Attribute Projections` (p. 540).

The following are the steps to query a local secondary index using the AWS SDK for Java Document API.
1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class. You must provide the table name.
3. Create an instance of the Index class. You must provide the index name.
4. Call the query method of the Index class.

The following Java code example demonstrates the preceding steps.

**Example**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

String tableName = "Music";
Table table = dynamoDB.getTable(tableName);
Index index = table.getIndex("AlbumTitleIndex");

QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("Artist = :v_artist and AlbumTitle = :v_title")
    .withValueMap(new ValueMap()
        .withString(":v_artist", "Acme Band")
        .withString(":v_title", "Songs About Life");

ItemCollection<QueryOutcome> items = index.query(spec);
Iterator<Item> itemsIter = items.iterator();
while (itemsIter.hasNext()) {
    Item item = itemsIter.next();
    System.out.println(item.toJSONPretty());
}
```

**Example: Local Secondary Indexes Using the Java Document API**

The following Java code example shows how to work with local secondary indexes in Amazon DynamoDB. The example creates a table named CustomerOrders with a partition key of CustomerId and a sort key of OrderId. There are two local secondary indexes on this table:

- **OrderCreationDateIndex** — The sort key is OrderCreationDate, and the following attributes are projected into the index:
  - ProductCategory
  - ProductName
  - OrderStatus
  - ShipmentTrackingId
- **IsOpenIndex** — The sort key is IsOpen, and all of the table attributes are projected into the index.

After the CustomerOrders table is created, the program loads the table with data representing customer orders. It then queries the data using the local secondary indexes. Finally, the program deletes the CustomerOrders table.

For step-by-step instructions for testing the following sample, see Java Code Examples (p. 331).

**Working with Local Secondary Indexes: .NET**

**Topics**
- Create a Table with a Local Secondary Index (p. 558)
- Describe a Table with a Local Secondary Index (p. 560)
You can use the AWS SDK for .NET low-level API to create an Amazon DynamoDB table with one or more local secondary indexes, describe the indexes on the table, and perform queries using the indexes. These operations map to the corresponding low-level DynamoDB API actions. For more information, see .NET Code Examples (p. 333).

The following are the common steps for table operations using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.
   - For example, create a `CreateTableRequest` object to create a table and an `QueryRequest` object to query a table or an index.
3. Execute the appropriate method provided by the client that you created in the preceding step.

### Create a Table with a Local Secondary Index

Local secondary indexes must be created at the same time that you create a table. To do this, use `CreateTable` and provide your specifications for one or more local secondary indexes. The following C# code example creates a table to hold information about songs in a music collection. The partition key is `Artist` and the sort key is `SongTitle`. A secondary index, `AlbumTitleIndex`, facilitates queries by album title.

The following are the steps to create a table with a local secondary index, using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.
   - You must provide the table name, its primary key, and the provisioned throughput values. For the local secondary index, you must provide the index name, the name and data type of the index sort key, the key schema for the index, and the attribute projection.
3. Execute the `CreateTable` method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps. The code creates a table (`Music`) with a secondary index on the `AlbumTitle` attribute. The table partition key and sort key, plus the index sort key, are the only attributes projected into the index.

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "Music";
CreateTableRequest createTableRequest = new CreateTableRequest()
{
    TableName = tableName
};

//ProvisionedThroughput
createTableRequest.ProvisionedThroughput = new ProvisionedThroughput()
{
    ReadCapacityUnits = (long)5,
    WriteCapacityUnits = (long)5
};

{
    IndexName = "AlbumTitleIndex",
    KeySchema = indexKeySchema,
    Projection = projection
};

List<LocalSecondaryIndex> localSecondaryIndexes = new List<LocalSecondaryIndex>();
localSecondaryIndexes.Add(localSecondaryIndex);
createTableRequest.LocalSecondaryIndexes = localSecondaryIndexes;

CreateTableResponse result = client.CreateTable(createTableRequest);
Console.WriteLine(result.CreateTableResult.TableDescription.TableName);
Console.WriteLine(result.CreateTableResult.TableDescription.TableStatus);

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table.
Describe a Table with a Local Secondary Index

To get information about local secondary indexes on a table, use the DescribeTable API. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access local secondary index information a table using the .NET low-level API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the DescribeTableRequest class to provide the request information. You must provide the table name.
3. Execute the describeTable method by providing the request object as a parameter.
4. The following C# code example demonstrates the preceding steps.

Example

```csharp
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "Music";
DescribeTableResponse response = client.DescribeTable(new DescribeTableRequest()
  { TableName = tableName });
List<LocalSecondaryIndexDescription> localSecondaryIndexes =
  response.DescribeTableResult.Table.LocalSecondaryIndexes;

// This code snippet will work for multiple indexes, even though // there is only one index in this example.
foreach (LocalSecondaryIndexDescription lsiDescription in localSecondaryIndexes)
{
    Console.WriteLine("Info for index " + lsiDescription.IndexName + ":");
    foreach (KeySchemaElement kse in lsiDescription.KeySchema)
    {
        Console.WriteLine("\t" + kse.AttributeName + ": key type is " + kse.KeyType);
    }
    Projection projection = lsiDescription.Projection;
    Console.WriteLine("\tThe projection type is: " + projection.ProjectionType);
    if (projection.ProjectionType.ToString().Equals("INCLUDE"))
    {
        Console.WriteLine("\t\tThe non-key projected attributes are:");
        foreach (String s in projection.NonKeyAttributes)
        {
            Console.WriteLine("\t\t" + s);
        }
    }
}
```

Query a Local Secondary Index

You can use Query on a local secondary index in much the same way you Query a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is AlbumTitleIndex, and the index sort key is AlbumTitle.
The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see Attribute Projections (p. 540).

The following are the steps to query a local secondary index using the .NET low-level API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the QueryRequest class to provide the request information.
3. Execute the query method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps.

Example

```csharp
QueryRequest queryRequest = new QueryRequest {
    TableName = "Music",
    IndexName = "AlbumTitleIndex",
    Select = "ALL_ATTRIBUTES",
    ScanIndexForward = true,
    KeyConditionExpression = "Artist = :v_artist and AlbumTitle = :v_title",
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
    {
        {":v_artist", new AttributeValue {S = "Acme Band"}},
        {":v_title", new AttributeValue {S = "Songs About Life"}}
    },
};
QueryResponse response = client.Query(queryRequest);
foreach (var attribs in response.Items) {
    foreach (var attrib in attribs) {
        Console.WriteLine(attrib.Key + " ---> " + attrib.Value.S);
    }
    Console.WriteLine();
}
```

Example: Local Secondary Indexes Using the AWS SDK for .NET Low-Level API

The following C# code example shows how to work with local secondary indexes in Amazon DynamoDB. The example creates a table named CustomerOrders with a partition key of CustomerId and a sort key of OrderId. There are two local secondary indexes on this table:

- **OrderCreationDateIndex** — The sort key is OrderCreationDate, and the following attributes are projected into the index:
  - ProductCategory
  - ProductName
  - OrderStatus
  - ShipmentTrackingId
- **IsOpenIndex** — The sort key is IsOpen, and all of the table attributes are projected into the index.

After the CustomerOrders table is created, the program loads the table with data representing customer orders. It then queries the data using the local secondary indexes. Finally, the program deletes the CustomerOrders table.
For step-by-step instructions for testing the following example, see .NET Code Examples (p. 333).

Working with Local Secondary Indexes: AWS CLI

You can use the AWS CLI to create an Amazon DynamoDB table with one or more local secondary indexes, describe the indexes on the table, and perform queries using the indexes.
Create a Table with a Local Secondary Index

Local secondary indexes must be created at the same time you create a table. To do this, use the `create-table` parameter and provide your specifications for one or more local secondary indexes. The following example creates a table (Music) to hold information about songs in a music collection. The partition key is Artist and the sort key is SongTitle. A secondary index, AlbumTitleIndex on the AlbumTitle attribute facilitates queries by album title.

```bash
aws dynamodb create-table --table-name Music 
--attribute-definitions AttributeName=Artist,AttributeType=S 
AttributeName=SongTitle,AttributeType=S 
AttributeName=AlbumTitle,AttributeType=S 
--key-schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE 
--provisioned-throughput 
  ReadCapacityUnits=10,WriteCapacityUnits=5 
--local-secondary-indexes 
  
  "[{{"IndexName": "AlbumTitleIndex", "KeySchema": [{"AttributeName":"Artist","KeyType":"HASH"}, 
  {"AttributeName":"AlbumTitle","KeyType":"RANGE"}], 
  "Projection":{"ProjectionType":"INCLUDE", "NonKeyAttributes":["Genre","Year"]}}]"
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table. You can use `describe-table` to determine the status of the table creation.

Describe a Table with a Local Secondary Index

To get information about local secondary indexes on a table, use the `describe-table` parameter. For each index, you can access its name, key schema, and projected attributes.

```bash
aws dynamodb describe-table --table-name Music
```

Query a Local Secondary Index

You can use the `query` operation on a local secondary index in much the same way that you query a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is AlbumTitleIndex and the index sort key is AlbumTitle.

The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see Attribute Projections (p. 540).

```bash
aws dynamodb query --table-name Music 
--index-name AlbumTitleIndex 
--key-condition-expression "Artist = :v_artist and AlbumTitle = :v_title" 
--expression-attribute-values '{":v_artist":{"S":"Acme Band"},":v_title":{"S":"Songs About Life"}}'
```
Capturing Table Activity with DynamoDB Streams

Many applications can benefit from the ability to capture changes to items stored in a DynamoDB table, at the point in time when such changes occur. The following are some example use cases:

- An application in one AWS Region modifies the data in a DynamoDB table. A second application in another Region reads these data modifications and writes the data to another table, creating a replica that stays in sync with the original table.
- A popular mobile app modifies data in a DynamoDB table, at the rate of thousands of updates per second. Another application captures and stores data about these updates, providing near-real-time usage metrics for the mobile app.
- A global multi-player game has a multi-master topology, storing data in multiple AWS Regions. Each master stays in sync by consuming and replaying the changes that occur in the remote Regions.
- An application automatically sends notifications to the mobile devices of all friends in a group as soon as one friend uploads a new picture.
- A new customer adds data to a DynamoDB table. This event invokes another application that sends a welcome email to the new customer.

DynamoDB Streams enables solutions such as these, and many others. DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near-real time.

Encryption at rest encrypts the data in DynamoDB streams. For more information, see DynamoDB Encryption at Rest (p. 816).

A DynamoDB stream is an ordered flow of information about changes to items in a DynamoDB table. When you enable a stream on a table, DynamoDB captures information about every modification to data items in the table.

Whenever an application creates, updates, or deletes items in the table, DynamoDB Streams writes a stream record with the primary key attributes of the items that were modified. A stream record contains information about a data modification to a single item in a DynamoDB table. You can configure the stream so that the stream records capture additional information, such as the "before" and "after" images of modified items.

DynamoDB Streams helps ensure the following:

- Each stream record appears exactly once in the stream.
- For each item that is modified in a DynamoDB table, the stream records appear in the same sequence as the actual modifications to the item.

DynamoDB Streams writes stream records in near-real time so that you can build applications that consume these streams and take action based on the contents.

Endpoints for DynamoDB Streams

AWS maintains separate endpoints for DynamoDB and DynamoDB Streams. To work with database tables and indexes, your application must access a DynamoDB endpoint. To read and process DynamoDB Streams records, your application must access a DynamoDB Streams endpoint in the same Region.

The naming convention for DynamoDB Streams endpoints is `streams.dynamodb.<region>.amazonaws.com`. For example, if you use the endpoint `dynamodb.us-west-2.amazonaws.com` to access DynamoDB, you would use the endpoint `streams.dynamodb.us-west-2.amazonaws.com` to access DynamoDB Streams.

**Note**
For a complete list of DynamoDB and DynamoDB Streams Regions and endpoints, see Regions and Endpoints in the AWS General Reference.

The AWS SDKs provide separate clients for DynamoDB and DynamoDB Streams. Depending on your requirements, your application can access a DynamoDB endpoint, a DynamoDB Streams endpoint, or both at the same time. To connect to both endpoints, your application must instantiate two clients—one for DynamoDB and one for DynamoDB Streams.
Enabling a Stream

You can enable a stream on a new table when you create it. You can also enable or disable a stream on an existing table, or change the settings of a stream. DynamoDB Streams operates asynchronously, so there is no performance impact on a table if you enable a stream.

The easiest way to manage DynamoDB Streams is by using the AWS Management Console.

2. On the DynamoDB console dashboard, choose Tables.
3. On the Overview tab, choose Manage Stream.
4. In the Manage Stream window, choose the information that will be written to the stream whenever the data in the table is modified:
   - Keys only — Only the key attributes of the modified item.
   - New image — The entire item, as it appears after it was modified.
   - Old image — The entire item, as it appeared before it was modified.
   - New and old images — Both the new and the old images of the item.

   When the settings are as you want them, choose Enable.
5. (Optional) To disable an existing stream, choose Manage Stream and then choose Disable.
You can also use the `CreateTable` or `UpdateTable` API operations to enable or modify a stream. The `StreamSpecification` parameter determines how the stream is configured:

- **StreamEnabled** — Specifies whether a stream is enabled (`true`) or disabled (`false`) for the table.
- **StreamViewType** — Specifies the information that will be written to the stream whenever data in the table is modified:
  - `KEYS_ONLY` — Only the key attributes of the modified item.
  - `NEW_IMAGE` — The entire item, as it appears after it was modified.
  - `OLD_IMAGE` — The entire item, as it appeared before it was modified.
  - `NEW_AND_OLD_IMAGES` — Both the new and the old images of the item.

You can enable or disable a stream at any time. However, you receive a `ResourceInUseException` if you try to enable a stream on a table that already has a stream. You receive a `ValidationException` if you try to disable a stream on a table that doesn't have a stream.

When you set `StreamEnabled` to `true`, DynamoDB creates a new stream with a unique stream descriptor assigned to it. If you disable and then re-enable a stream on the table, a new stream is created with a different stream descriptor.

Every stream is uniquely identified by an Amazon Resource Name (ARN). The following is an example ARN for a stream on a DynamoDB table named `TestTable`.

```
```

To determine the latest stream descriptor for a table, issue a `DynamoDB DescribeTable` request and look for the `LatestStreamArn` element in the response.

## Reading and Processing a Stream

To read and process a stream, your application must connect to a DynamoDB Streams endpoint and issue API requests.

A stream consists of **stream records**. Each stream record represents a single data modification in the DynamoDB table to which the stream belongs. Each stream record is assigned a sequence number, reflecting the order in which the record was published to the stream.

Stream records are organized into groups, or **shards**. Each shard acts as a container for multiple stream records, and contains information required for accessing and iterating through these records. The stream records within a shard are removed automatically after 24 hours.

Shards are ephemeral: They are created and deleted automatically, as needed. Any shard can also split into multiple new shards; this also occurs automatically. (It's also possible for a parent shard to have just one child shard.) A shard might split in response to high levels of write activity on its parent table, so that applications can process records from multiple shards in parallel.

If you disable a stream, any shards that are open will be closed.

Because shards have a lineage (parent and children), an application must always process a parent shard before it processes a child shard. This helps ensure that the stream records are also processed in the correct order. (If you use the DynamoDB Streams Kinesis Adapter, this is handled for you. Your application processes the shards and stream records in the correct order. It automatically handles new or expired shards, in addition to shards that split while the application is running. For more information, see Using the DynamoDB Streams Kinesis Adapter to Process Stream Records (p. 579).)

The following diagram shows the relationship between a stream, shards in the stream, and stream records in the shards.
Note
If you perform a `PutItem` or `UpdateItem` operation that does not change any data in an item, DynamoDB Streams does not write a stream record for that operation.

To access a stream and process the stream records within, you must do the following:

• Determine the unique ARN of the stream that you want to access.
• Determine which shards in the stream contain the stream records that you are interested in.
• Access the shards and retrieve the stream records that you want.

Note
No more than two processes at most should be reading from the same streams shard at the same time. Having more than two readers per shard can result in throttling.

The DynamoDB Streams API provides the following actions for use by application programs:

• `ListStreams` — Returns a list of stream descriptors for the current account and endpoint. You can optionally request just the stream descriptors for a particular table name.
• `DescribeStream` — Returns detailed information about a given stream. The output includes a list of shards associated with the stream, including the shard IDs.
• `GetShardIterator` — Returns a `shard iterator`, which describes a location within a shard. You can request that the iterator provide access to the oldest point, the newest point, or a particular point in the stream.
• `GetRecords` — Returns the stream records from within a given shard. You must provide the shard iterator returned from a `GetShardIterator` request.

For complete descriptions of these API operations, including example requests and responses, see the Amazon DynamoDB Streams API Reference.

**Data Retention Limit for DynamoDB Streams**

All data in DynamoDB Streams is subject to a 24-hour lifetime. You can retrieve and analyze the last 24 hours of activity for any given table. However, data that is older than 24 hours is susceptible to trimming (removal) at any moment.

If you disable a stream on a table, the data in the stream continues to be readable for 24 hours. After this time, the data expires and the stream records are automatically deleted. There is no mechanism for
manually deleting an existing stream. You must wait until the retention limit expires (24 hours), and all the stream records will be deleted.

**DynamoDB Streams and Time to Live**

You can back up, or otherwise process, items that are deleted by Time to Live (TTL) by enabling Amazon DynamoDB Streams on the table and processing the streams records of the expired items.

The streams record contains a user identity field `Records[<index>].userIdentity`

Items that are deleted by the Time to Live process after expiration have the following fields:

- `Records[<index>].userIdentity.type`  
  "Service"
- `Records[<index>].userIdentity.principalId`  
  "dynamodb.amazonaws.com"

The following JSON shows the relevant portion of a single streams record.

```json
"Records": [
  {
    ...
    "userIdentity": {
      "type": "Service",
      "principalId": "dynamodb.amazonaws.com"
    }
    ...
  }
]
```

**Using the DynamoDB Streams Kinesis Adapter to Process Stream Records**

Using the Amazon Kinesis Adapter is the recommended way to consume streams from Amazon DynamoDB. The DynamoDB Streams API is intentionally similar to that of Kinesis Data Streams, a service for real-time processing of streaming data at massive scale. In both services, data streams are composed of shards, which are containers for stream records. Both services' APIs contain `ListStreams`, `DescribeStream`, `GetShards`, and `GetShardIterator` operations. (Although these DynamoDB Streams actions are similar to their counterparts in Kinesis Data Streams, they are not 100 percent identical.)

You can write applications for Kinesis Data Streams using the Kinesis Client Library (KCL). The KCL simplifies coding by providing useful abstractions above the low-level Kinesis Data Streams API. For more information about the KCL, see the Developing Consumers Using the Kinesis Client Library in the Amazon Kinesis Data Streams Developer Guide.

As a DynamoDB Streams user, you can use the design patterns found within the KCL to process DynamoDB Streams shards and stream records. To do this, you use the DynamoDB Streams Kinesis Adapter. The Kinesis Adapter implements the Kinesis Data Streams interface so that the KCL can be used for consuming and processing records from DynamoDB Streams.

The following diagram shows how these libraries interact with one another.
With the DynamoDB Streams Kinesis Adapter in place, you can begin developing against the KCL interface, with the API calls seamlessly directed at the DynamoDB Streams endpoint.

When your application starts, it calls the KCL to instantiate a worker. You must provide the worker with configuration information for the application, such as the stream descriptor and AWS credentials, and the name of a record processor class that you provide. As it runs the code in the record processor, the worker performs the following tasks:

- Connects to the stream.
- Enumerates the shards within the stream.
- Coordinates shard associations with other workers (if any).
- Instantiates a record processor for every shard it manages.
• Pulls records from the stream.
• Pushes the records to the corresponding record processor.
• Checkpoints processed records.
• Balances shard-worker associations when the worker instance count changes.
• Balances shard-worker associations when shards are split.

**Note**
For a description of the KCL concepts listed here, see Developing Consumers Using the Kinesis Client Library in the Amazon Kinesis Data Streams Developer Guide.

### Walkthrough: DynamoDB Streams Kinesis Adapter

This section is a walkthrough of a Java application that uses the Amazon Kinesis Client Library and the Amazon DynamoDB Streams Kinesis Adapter. The application shows an example of data replication, in which write activity from one table is applied to a second table, with both tables' contents staying in sync. For the source code, see Complete Program: DynamoDB Streams Kinesis Adapter (p. 584).

The program does the following:

1. Creates two DynamoDB tables named KCL-Demo-src and KCL-Demo-dst. Each of these tables has a stream enabled on it.
2. Generates update activity in the source table by adding, updating, and deleting items. This causes data to be written to the table's stream.
3. Reads the records from the stream, reconstructs them as DynamoDB requests, and applies the requests to the destination table.
4. Scans the source and destination tables to ensure that their contents are identical.
5. Cleans up by deleting the tables.

These steps are described in the following sections, and the complete application is shown at the end of the walkthrough.

**Topics**

- Step 1: Create DynamoDB Tables (p. 581)
- Step 2: Generate Update Activity in Source Table (p. 582)
- Step 3: Process the Stream (p. 582)
- Step 4: Ensure That Both Tables Have Identical Contents (p. 583)
- Step 5: Clean Up (p. 583)
- Complete Program: DynamoDB Streams Kinesis Adapter (p. 584)

### Step 1: Create DynamoDB Tables

The first step is to create two DynamoDB tables—a source table and a destination table. The StreamViewType on the source table's stream is NEW_IMAGE. This means that whenever an item is modified in this table, the item's "after" image is written to the stream. In this way, the stream keeps track of all write activity on the table.

The following example shows the code that is used for creating both tables.
Step 2: Generate Update Activity in Source Table

The next step is to generate some write activity on the source table. While this activity is taking place, the source table's stream is also updated in near-real time.

The application defines a helper class with methods that call the PutItem, UpdateItem, and DeleteItem API operations for writing the data. The following code example shows how these methods are used.

```java
StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName, "101", "test1");
StreamsAdapterDemoHelper.updateItem(dynamoDBClient, tableName, "101", "test2");
StreamsAdapterDemoHelper.deleteItem(dynamoDBClient, tableName, "101");
StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName, "102", "demo3");
StreamsAdapterDemoHelper.updateItem(dynamoDBClient, tableName, "102", "demo4");
StreamsAdapterDemoHelper.deleteItem(dynamoDBClient, tableName, "102");
```

Step 3: Process the Stream

Now the program begins processing the stream. The DynamoDB Streams Kinesis Adapter acts as a transparent layer between the KCL and the DynamoDB Streams endpoint, so that the code can fully use KCL rather than having to make low-level DynamoDB Streams calls. The program performs the following tasks:

- It defines a record processor class, StreamsRecordProcessor, with methods that comply with the KCL interface definition: initialize, processRecords, and shutdown. The processRecords method contains the logic required for reading from the source table's stream and writing to the destination table.
- It defines a class factory for the record processor class (StreamsRecordProcessorFactory). This is required for Java programs that use the KCL.
- It instantiates a new KCL Worker, which is associated with the class factory.
- It shuts down the Worker when record processing is complete.

To learn more about the KCL interface definition, see Developing Consumers Using the Kinesis Client Library in the Amazon Kinesis Data Streams Developer Guide.
The following code example shows the main loop in `StreamsRecordProcessor`. The `case` statement determines what action to perform, based on the `OperationType` that appears in the stream record.

```java
for (Record record : records) {
    String data = new String(record.getData().array(), Charset.forName("UTF-8"));
    System.out.println(data);
    if (record instanceof RecordAdapter) {
        com.amazonaws.services.dynamodbv2.model.Record streamRecord = ((RecordAdapter) record).getInternalObject();
        switch (streamRecord.getEventName()) {
            case "INSERT":
                StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName, streamRecord.getDynamodb().getNewImage());
                break;
            case "MODIFY":
                StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName, streamRecord.getDynamodb().getNewImage());
                break;
            case "REMOVE":
                StreamsAdapterDemoHelper.deleteItem(dynamoDBClient, tableName, streamRecord.getDynamodb().getKeys().get("Id").getN());
                break;
        }
    }
    checkpointCounter += 1;
    if (checkpointCounter % 10 == 0) {
        try {
            checkpointer.checkpoint();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

### Step 4: Ensure That Both Tables Have Identical Contents

At this point, the source and destination tables' contents are in sync. The application issues `Scan` requests against both tables to verify that their contents are, in fact, identical.

The `DemoHelper` class contains a `ScanTable` method that calls the low-level `Scan` API. The following example shows how this is used.

```java
if (StreamsAdapterDemoHelper.scanTable(dynamoDBClient, srcTable).getItems().equals(StreamsAdapterDemoHelper.scanTable(dynamoDBClient, destTable).getItems())) {
    System.out.println("Scan result is equal.");
} else {
    System.out.println("Tables are different!");
}
```

### Step 5: Clean Up

The demo is complete, so the application deletes the source and destination tables. See the following code example. Even after the tables are deleted, their streams remain available for up to 24 hours, after which they are automatically deleted.

```java
dynamoDBClient.deleteTable(new DeleteTableRequest().withTableName(srcTable));
dynamoDBClient.deleteTable(new DeleteTableRequest().withTableName(destTable));
```
Complete Program: DynamoDB Streams Kinesis Adapter

The following is the complete Java program that performs the tasks described in Walkthrough: DynamoDB Streams Kinesis Adapter (p. 581). When you run it, you should see output similar to the following.

```
Creating table KCL-Demo-src
Creating table KCL-Demo-dest
Table is active.
Starting worker...
Scan result is equal.
Done.
```

Important
To run this program, ensure that the client application has access to DynamoDB and Amazon CloudWatch using policies. For more information, see Using Identity-Based Policies (IAM Policies) for Amazon DynamoDB (p. 829).

DynamoDB Streams Low-Level API: Java Example

Note
The code on this page is not exhaustive and does not handle all scenarios for consuming Amazon DynamoDB Streams. The recommended way to consume stream records from DynamoDB is through the Amazon Kinesis Adapter using the Kinesis Client Library (KCL), as described in Using the DynamoDB Streams Kinesis Adapter to Process Stream Records (p. 579).

This section contains a Java program that shows DynamoDB Streams in action. The program does the following:
1. Creates a DynamoDB table with a stream enabled.
2. Describes the stream settings for this table.
4. Describes the shards in the stream.
5. Reads the stream records from the shards.
6. Cleans up.

When you run the program, you will see output similar to the following.

Issuing CreateTable request for TestTableForStreams
Waiting for TestTableForStreams to be created...
Current stream ARN for TestTableForStreams: arn:aws:dynamodb:us-east-2:123456789012:table/TestTableForStreams/stream/2018-03-20T16:49:55.208

Cross-Region Replication

You can create tables that are automatically replicated across two or more AWS Regions, with full
support for multimaster writes. This gives you the ability to build fast, massively scaled applications for
a global user base without having to manage the replication process. For more information, see Global
Tables: Multi-Region Replication with DynamoDB (p. 625).

DynamoDB Streams and AWS Lambda Triggers

Topics
• Tutorial: Process New Items with DynamoDB Streams and Lambda (p. 596)
• Best Practices with Lambda (p. 603)

Amazon DynamoDB is integrated with AWS Lambda so that you can create triggers—pieces of code that
automatically respond to events in DynamoDB Streams. With triggers, you can build applications that
react to data modifications in DynamoDB tables.

If you enable DynamoDB Streams on a table, you can associate the stream Amazon Resource Name (ARN)
with an AWS Lambda function that you write. Immediately after an item in the table is modified, a new
record appears in the table's stream. AWS Lambda polls the stream and invokes your Lambda function
synchronously when it detects new stream records.

The Lambda function can perform any actions you specify, such as sending a notification or initiating a
workflow. For example, you can write a Lambda function to simply copy each stream record to persistent
storage, such as Amazon Simple Storage Service (Amazon S3), to create a permanent audit trail of write
activity in your table. Or suppose that you have a mobile gaming app that writes to a GameScores table. Whenever the TopScore attribute of the GameScores table is updated, a corresponding stream record is written to the table's stream. This event could then trigger a Lambda function that posts a congratulatory message on a social media network. (The function would simply ignore any stream records that are not updates to GameScores or that do not modify the TopScore attribute.)

For more information about AWS Lambda, see the AWS Lambda Developer Guide.

**Tutorial: Process New Items with DynamoDB Streams and Lambda**

**Topics**
- Step 1: Create a DynamoDB Table with a Stream Enabled (p. 597)
- Step 2: Create a Lambda Execution Role (p. 597)
- Step 3: Create an Amazon SNS Topic (p. 599)
- Step 4: Create and Test a Lambda Function (p. 599)
- Step 5: Create and Test a Trigger (p. 602)

In this tutorial, you create an AWS Lambda trigger to process a stream from a DynamoDB table.

The scenario for this tutorial is Woofer, a simple social network. Woofer users communicate using *barks* (short text messages) that are sent to other Woofer users. The following diagram shows the components and workflow for this application.

1. A user writes an item to a DynamoDB table (*BarkTable*). Each item in the table represents a bark.
2. A new stream record is written to reflect that a new item has been added to *BarkTable*.
3. The new stream record triggers an AWS Lambda function (*publishNewBark*).
4. If the stream record indicates that a new item was added to *BarkTable*, the Lambda function reads the data from the stream record and publishes a message to a topic in Amazon Simple Notification Service (Amazon SNS).
5. The message is received by subscribers to the Amazon SNS topic. (In this tutorial, the only subscriber is an email address.)
Before You Begin

This tutorial uses the AWS Command Line Interface AWS CLI. If you have not done so already, follow the instructions in the AWS Command Line Interface User Guide to install and configure the AWS CLI.

Step 1: Create a DynamoDB Table with a Stream Enabled

In this step, you create a DynamoDB table (BarkTable) to store all of the barks from Woofer users. The primary key is composed of Username (partition key) and Timestamp (sort key). Both of these attributes are of type string.

BarkTable has a stream enabled. Later in this tutorial, you create a trigger by associating an AWS Lambda function with the stream.

1. Enter the following command to create the table.

```
aws dynamodb create-table \
  --table-name BarkTable \ 
  --attribute-definitions AttributeName=Username,AttributeType=S \ 
  AttributeName=Timestamp,AttributeType=S \ 
  --key-schema AttributeName=Username,KeyType=HASH \ 
  AttributeName=Timestamp,KeyType=RANGE \ 
  --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \ 
  --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES
```

2. In the output, look for the LatestStreamArn.

```
... 
"LatestStreamArn": "arn:aws:dynamodb:region:accountID:table/BarkTable/stream/timestamp ... 
```

Make a note of the region and the accountID, because you need them for the other steps in this tutorial.

Step 2: Create a Lambda Execution Role

In this step, you create an AWS Identity and Access Management (IAM) role (WooferLambdaRole) and assign permissions to it. This role is used by the Lambda function that you create in Step 4: Create and Test a Lambda Function (p. 599).

You also create a policy for the role. The policy contains all of the permissions that the Lambda function needs at runtime.

1. Create a file named trust-relationship.json with the following contents.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
2. Enter the following command to create **WooferLambdaRole**.

```bash
aws iam create-role --role-name WooferLambdaRole \
   --path "/service-role/" \
   --assume-role-policy-document file://trust-relationship.json
```

3. Create a file named `role-policy.json` with the following contents. (Replace `region` and `accountId` with your AWS Region and account ID.)

```json
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Effect": "Allow",
       "Action": "lambda:InvokeFunction",
       "Resource": "arn:aws:lambda:region:accountId:function:publishNewBark*"
     },
     {
       "Effect": "Allow",
       "Action": [
         "logs:CreateLogGroup",
         "logs:CreateLogStream",
         "logs:PutLogEvents"
       ],
       "Resource": "arn:aws:logs:region:accountId:*"
     },
     {
       "Effect": "Allow",
       "Action": [
         "dynamodb:DescribeStream",
         "dynamodb:GetRecords",
         "dynamodb:GetShardIterator",
         "dynamodb:ListStreams"
       ],
       "Resource": "arn:aws:dynamodb:region:accountId:table/BarkTable/stream/*"
     },
     {
       "Effect": "Allow",
       "Action": [
         "sns:Publish"
       ],
       "Resource": ["*"]
     }
   ]
}
```

The policy has four statements that allow **WooferLambdaRole** to do the following:

- Execute a Lambda function (publishNewBark). You create the function later in this tutorial.
- Access Amazon CloudWatch Logs. The Lambda function writes diagnostics to CloudWatch Logs at runtime.
- Read data from the DynamoDB stream for **BarkTable**.
- Publish messages to Amazon SNS.

4. Enter the following command to attach the policy to **WooferLambdaRole**.

```bash
aws iam put-role-policy --role-name WooferLambdaRole \
   --policyArn arn:aws:iam::region:policy/role-policy.json
```
Step 3: Create an Amazon SNS Topic

In this step, you create an Amazon SNS topic (wooferTopic) and subscribe an email address to it. Your Lambda function uses this topic to publish new barks from Woofer users.

1. Enter the following command to create a new Amazon SNS topic.

   `aws sns create-topic --name wooferTopic`

2. Enter the following command to subscribe an email address to wooferTopic. (Replace `region` and `accountID` with your AWS Region and account ID, and replace `example@example.com` with a valid email address.)

   `aws sns subscribe
   --topic-arn arn:aws:sns:region:accountID:wooferTopic
   --protocol email
   --notification-endpoint example@example.com`

3. Amazon SNS sends a confirmation message to your email address. Choose the Confirm subscription link in that message to complete the subscription process.

Step 4: Create and Test a Lambda Function

In this step, you create an AWS Lambda function (publishNewBark) to process stream records from BarkTable.

The publishNewBark function processes only the stream events that correspond to new items in BarkTable. The function reads data from such an event, and then invokes Amazon SNS to publish it.

1. Create a file named publishNewBark.js with the following contents. Replace `region` and `accountID` with your AWS Region and account ID.

   ```javascript
   'use strict';
   var AWS = require("aws-sdk");
   var sns = new AWS.SNS();
   exports.handler = (event, context, callback) => {
     event.Records.forEach((record) => {
       console.log('Stream record: ', JSON.stringify(record, null, 2));
       if (record.eventName == 'INSERT') {
         var who = JSON.stringify(record.dynamodb.NewImage.Username.S);
         var when = JSON.stringify(record.dynamodb.NewImage.Timestamp.S);
         var what = JSON.stringify(record.dynamodb.NewImage.Message.S);
         var params = {
           Subject: 'A new bark from ' + who,
           Message: 'Woofer user ' + who + ' barked the following at ' + when + ':
           
           ' + what,
         };
         sns.publish(params, function(err, data) {
           if (err) {
             console.error("Unable to send message. Error JSON:",
             JSON.stringify(err, null, 2));
           }
         });
       }
     });
   }
   ```
2. Create a zip file to contain publishNewBark.js. If you have the zip command-line utility, you can enter the following command to do this.

```bash
zip publishNewBark.zip publishNewBark.js
```

3. When you create the Lambda function, you specify the Amazon Resource Name (ARN) for WooferLambdaRole, which you created in Step 2: Create a Lambda Execution Role (p. 597). Enter the following command to retrieve this ARN.

```bash
aws iam get-role --role-name WooferLambdaRole
```

In the output, look for the ARN for WooferLambdaRole.

```
"Arn": "arn:aws:iam::region:role/service-role/WooferLambdaRole"
```

Enter the following command to create the Lambda function. Replace `roleARN` with the ARN for WooferLambdaRole.

```bash
aws lambda create-function \
  --region us-east-1 \
  --function-name publishNewBark \
  --zip-file fileb://publishNewBark.zip \
  --role roleARN \
  --handler publishNewBark.handler \
  --timeout 5 \
  --runtime nodejs10.x
```

4. Now test publishNewBark to verify that it works. To do this, you provide input that resembles a real record from DynamoDB Streams.

Create a file named `payload.json` with the following contents.

```json
{
  "Records": [
    {
      "eventID": "7de3041dd709b024af6f29e4fa13d34c",
      "eventName": "INSERT",
      "eventVersion": "1.1",
      "eventSource": "aws:dynamodb",
      "awsRegion": "us-west-2",
      "dynamodb": {
        "ApproximateCreationDateTime": 1479499740,
        "Keys": {
          "Timestamp": {
            "S": "2016-11-18:12:09:36"
          }
        }
      }
    }
  ]
}
```
Enter the following command to test the publishNewBark function.

```bash
aws lambda invoke --function-name publishNewBark --payload file://payload.json output.txt
```

If the test was successful, you will see the following output.

```
{
    "StatusCode": 200
}
```

In addition, the `output.txt` file will contain the following text.

"Successfully processed 1 records."

You will also receive a new email message within a few minutes.

**Note**

AWS Lambda writes diagnostic information to Amazon CloudWatch Logs. If you encounter errors with your Lambda function, you can use these diagnostics for troubleshooting purposes:

2. In the navigation pane, choose Logs.
3. Choose the following log group: `/aws/lambda/publishNewBark`
4. Choose the latest log stream to view the output (and errors) from the function.
Step 5: Create and Test a Trigger

In Step 4: Create and Test a Lambda Function (p. 599), you tested the Lambda function to ensure that it ran correctly. In this step, you create a trigger by associating the Lambda function (publishNewBark) with an event source (the BarkTable stream).

1. When you create the trigger, you need to specify the ARN for the BarkTable stream. Enter the following command to retrieve this ARN.

   ```bash
   aws dynamodb describe-table --table-name BarkTable
   ```

   In the output, look for the `LatestStreamArn`.

   ```json
   ...
   "LatestStreamArn": "arn:aws:dynamodb:region:accountID:table/BarkTable/stream/timestamp
   ...
   ```

2. Enter the following command to create the trigger. Replace `streamARN` with the actual stream ARN.

   ```bash
   aws lambda create-event-source-mapping
   --region us-east-1
   --function-name publishNewBark
   --event-source streamARN
   --batch-size 1
   --starting-position TRIM_HORIZON
   ```

3. Test the trigger. Enter the following command to add an item to BarkTable.

   ```bash
   aws dynamodb put-item
   --table-name BarkTable
   --item Username={S="Jane Doe"},Timestamp={S="2016-11-18:14:32:17"},Message={S="Testing...1...2...3"}
   ```

   You should receive a new email message within a few minutes.

4. Open the DynamoDB console and add a few more items to BarkTable. You must specify values for the Username and Timestamp attributes. (You should also specify a value for Message, even though it is not required.) You should receive a new email message for each item you add to BarkTable.

   The Lambda function processes only new items that you add to BarkTable. If you update or delete an item in the table, the function does nothing.

Note

AWS Lambda writes diagnostic information to Amazon CloudWatch Logs. If you encounter errors with your Lambda function, you can use these diagnostics for troubleshooting purposes.

2. In the navigation pane, choose Logs.
3. Choose the following log group: /aws/lambda/publishNewBark
4. Choose the latest log stream to view the output (and errors) from the function.
Best Practices with Lambda

An AWS Lambda function runs within a container—an execution environment that is isolated from other functions. When you run a function for the first time, AWS Lambda creates a new container and begins executing the function's code.

A Lambda function has a handler that is executed once per invocation. The handler contains the main business logic for the function. For example, the Lambda function shown in Step 4: Create and Test a Lambda Function (p. 599) has a handler that can process records in a DynamoDB stream.

You can also provide initialization code that runs one time only—after the container is created, but before AWS Lambda executes the handler for the first time. The Lambda function shown in Step 4: Create and Test a Lambda Function (p. 599) has initialization code that imports the SDK for JavaScript in Node.js, and creates a client for Amazon SNS. These objects should only be defined once, outside of the handler.

After the function executes, AWS Lambda might opt to reuse the container for subsequent invocations of the function. In this case, your function handler might be able to reuse the resources that you defined in your initialization code. (You cannot control how long AWS Lambda will retain the container, or whether the container will be reused at all.)

For DynamoDB triggers using AWS Lambda, we recommend the following:

- AWS service clients should be instantiated in the initialization code, not in the handler. This allows AWS Lambda to reuse existing connections, for the duration of the container's lifetime.
- In general, you do not need to explicitly manage connections or implement connection pooling because AWS Lambda manages this for you.

For more information, see Best Practices for Working with AWS Lambda Functions in the AWS Lambda Developer Guide.
On-Demand Backup and Restore for DynamoDB

You can create on-demand backups for your Amazon DynamoDB tables or enable continuous backups with point-in-time recovery. For information about continuous backups with point-in-time recovery, see Point-in-Time Recovery for DynamoDB (p. 619).

You can use the DynamoDB on-demand backup capability to create full backups of your tables for long-term retention and archival for regulatory compliance needs. You can back up and restore your table data anytime with a single click on the AWS Management Console or with a single API call. Backup and restore actions execute with zero impact on table performance or availability.

The on-demand backup and restore process scales without degrading the performance or availability of your applications. It uses a new and unique distributed technology that lets you complete backups in seconds regardless of table size. You can create backups that are consistent within seconds across thousands of partitions without worrying about schedules or long-running backup processes. All backups are cataloged, easily discoverable, and retained until explicitly deleted.

In addition, on-demand backup and restore operations don't affect performance or API latencies. Backups are preserved regardless of table deletion. For more information, see Back Up and Restore DynamoDB Tables: How It Works (p. 604).

You can create table backups using the console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. For more information, see Backing Up a DynamoDB Table (p. 606).

For information about restoring a table from a backup, see Restoring a DynamoDB Table from a Backup (p. 608).

DynamoDB on-demand backups are available at no additional cost beyond the normal pricing that’s associated with backup storage size. For more information about AWS Region availability and pricing, see Amazon DynamoDB pricing.

Back Up and Restore DynamoDB Tables: How It Works

You can use the on-demand backup feature to create full backups of your Amazon DynamoDB tables. This section provides an overview of what happens during the backup and restore process.

Backups

When you create an on-demand backup, a time marker of the request is cataloged. The backup is created asynchronously by applying all changes until the time of the request to the last full table snapshot. Backup requests are processed instantaneously and become available for restore within minutes.
**Note**
Each time you create an on-demand backup, the entire table data is backed up. There is no limit to the number of on-demand backups that can be taken.

All backups in DynamoDB work without consuming any provisioned throughput on the table.

DynamoDB backups do not guarantee causal consistency across items; however, the skew between updates in a backup is usually much less than a second.

While a backup is in progress, you can't do the following:
- Pause or cancel the backup operation.
- Delete the source table of the backup.
- Disable backups on a table if a backup for that table is in progress.

You can schedule periodic or future backups by using AWS Lambda functions. For more information, see the blog post [A serverless solution to schedule your Amazon DynamoDB On-Demand Backup](#).

If you don't want to create scheduling scripts and cleanup jobs, you can use AWS Backup to create backup plans with schedules and retention policies for your DynamoDB tables. AWS Backup executes the backups and deletes them when they expire. For more information, see the [AWS Backup Developer Guide](#).

If you're using the console, any backups created using AWS Backup are listed on the **Backups** tab with the **Backup type** set to **AWS**.

**Note**
You can't delete backups using the DynamoDB console. To manage these backups, use the AWS Backup console.

To learn how to perform a backup, see [Backing Up a DynamoDB Table](p. 606).

## Restores

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore from your DynamoDB backup, or you can configure the destination table settings. When you do a restore, you can change the following table settings:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity
- Encryption settings

**Important**
When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units as the source table, as recorded at the time the backup was requested. The restore process also restores the local secondary indexes and the global secondary indexes.

You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the backup resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data that you transfer out of the source Region and for restoring to a new table in the destination Region.
Note
Cross-Region restore is not supported if the source or destination Region is Asia Pacific (Hong Kong) or Middle East (Bahrain).

Restores can be faster and more cost-efficient if you choose to exclude some or all secondary indexes from being created on the new restored table.

You must manually set up the following on the restored table:

• Auto scaling policies
• AWS Identity and Access Management (IAM) policies
• Amazon CloudWatch metrics and alarms
• Tags
• Stream settings
• Time to Live (TTL) settings

You can only restore the entire table data to a new table from a backup. You can write to the restored table only after it becomes active.

Note
You can't overwrite an existing table during a restore operation.

The time it takes you to restore a table varies based on multiple factors. The restore times are not always correlated directly to the size of the table. For example, because of parallelization, restoring a 300 GB table could take the same amount of time as restoring a 3 GB table.

The following are some considerations for restore times:

• You restore backups to a new table. It can take up to 20 minutes (even if the table is empty) to perform all the actions to create the new table and initiate the restore process.
• For tables with even data distribution across your primary keys, the restore time is proportional to the largest single partition by item count and not the overall table size. For the largest partitions with billions of items, a restore could take less than 10 hours.
• If your source table contains data with significant skew, the time to restore might increase. For example, if your table's primary key is using the month of the year for partitioning, and all your data is from the month of December, you have skewed data.

To learn how to perform a restore, see Restoring a DynamoDB Table from a Backup (p. 608).

You can use IAM policies for access control. For more information, see Using IAM with DynamoDB Backup and Restore (p. 615).

All backup and restore console and API actions are captured and recorded in AWS CloudTrail for logging, continuous monitoring, and auditing.

Backing Up a DynamoDB Table

This section describes how to use the Amazon DynamoDB console or the AWS Command Line Interface to back up a table.

Topics
• Creating a Table Backup (Console) (p. 607)
Creating a Table Backup (Console)

Follow these steps to create a backup named `MusicBackup` for an existing `Music` table using the AWS Management Console.

**To create a table backup**

2. You can create a backup by doing one of the following:
   - On the **Backups** tab of the `Music` table, choose **Create backup**.
   - In the navigation pane on the left side of the console, choose **Backups**. Then choose **Create backup**.
3. Make sure that `Music` is the table name, and enter `MusicBackup` for the backup name. Then, choose **Create** to create the backup.

**Note**

If you create backups using the **Backups** section in the navigation pane, the table isn’t preselected for you. You have to manually choose the source table name for the backup.

While the backup is being created, the backup status is set to **Creating**. After the backup is complete, the backup status changes to **Available**.

Creating a Table Backup (AWS CLI)

Follow these steps to create a backup for an existing table `Music` using the AWS CLI.
To create a table backup

- Create a backup with the name MusicBackup for the Music table.

```bash
aws dynamodb create-backup --table-name Music --backup-name MusicBackup
```

While the backup is being created, the backup status is set to CREATING.

```
{
    "BackupDetails": {
        "BackupName": "MusicBackup",
        "BackupArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489602797149-73d8d5bc",
        "BackupStatus": "CREATING",
        "BackupCreationDateTime": 1489602797.149
    }
}
```

After the backup is complete, its BackupStatus should change to AVAILABLE. To confirm this, use the describe-backup command. You can get the input value of backup-arn from the output of the previous step or by using the list-backups command.

```bash
aws dynamodb describe-backup --backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-b308cd7d
```

To keep track of your backups, you can use the list-backups command. It lists all your backups that are in CREATING or AVAILABLE status.

```bash
aws dynamodb list-backups
```

The list-backups command and the describe-backup command are useful to check information about the source table of the backup.

**Restoring a DynamoDB Table from a Backup**

This section describes how to restore a table from a backup using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

**Note**

If you want to use the AWS CLI, you must configure it first. For more information, see Accessing DynamoDB (p. 55).

**Restoring a Table from a Backup (Console)**

The following procedure shows how to restore the Music table by using the MusicBackup file that is created in the Backing Up a DynamoDB Table (p. 606) tutorial.
Note
This procedure assumes that the Music table no longer exists before restoring it using the MusicBackup file.

To restore a table from a backup

2. In the navigation pane on the left side of the console, choose Backups.
3. In the list of backups, choose MusicBackup.
4. Choose Restore backup.
5. Enter Music as the new table name. Confirm the backup name and other backup details. Then choose Restore table to start the restore process.

Note
You can restore the table to the same AWS Region or to a different Region from where the backup resides. You can also exclude secondary indexes from being created on the new restored table. In addition, you can specify a different encryption mode.
Restore table from backup

New table name: Music

- Restore entire table data
  - Restored table will include all local secondary indexes and global secondary indexes.
- Restore without secondary indexes
  - Restored table will exclude the local secondary indexes and global secondary indexes. Note: Restores can be faster and more cost efficient if you choose to exclude secondary indexes from being created.

Cross region restore

- Same region
  - Restore the table to the same AWS Region.
- Cross region
  - Restore the table to a different AWS Region.

Select the encryption type

- DEFAULT
  - The key is owned by Amazon DynamoDB. You are not charged any fee for using these CMKs.
- KMS - Customer managed CMK
  - The key is stored in your account that you create, own, and manage. AWS Key Management Service (KMS) changes apply. Learn more
- KMS - AWS managed CMK
  - The key is stored in your account and is managed by AWS Key Management Service (KMS). AWS KMS changes apply.

Backup table details

- Original table name: Music
- Backup name: MusicBackup
- Primary partition key: Artist
- Sort key: SongTitle
- Read/write capacity mode: Provisioned
- Provisioned read capacity units: 5
- Provisioned write capacity units: 5
- Encryption Type: DEFAULT
- Encryption Status: -
- KMS Master Key ARN: Not Applicable
- Auto Scaling: DISABLED
- Stream enabled: No

Indexes

- There are no global secondary indexes or local secondary indexes.

Restores can take several hours to complete.

* Required
The table that is being restored is shown with the status **Creating**. After the restore process is finished, the status of the **Music** table changes to **Active**.

### Restoring a Table from a Backup (AWS CLI)

Follow these steps to use the AWS CLI to restore the **Music** table using the **MusicBackup** that is created in the [Backing Up a DynamoDB Table](p. 606) tutorial.

**To restore a table from a backup**

1. Confirm the backup that you want to restore by using the `list-backups` command. This example uses **MusicBackup**.
   
   ```bash
   aws dynamodb list-backups
   ```

   To get additional details for the backup, use the `describe-backup` command. You can get the input `backup-arn` from the previous step.
   
   ```bash
   aws dynamodb describe-backup \
   --backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-b308cd7d
   ```

2. Restore the table from the backup. In this case, the **MusicBackup** restores the **Music** table to the same AWS Region.
   
   ```bash
   aws dynamodb restore-table-from-backup \
   --target-table-name Music \
   --backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-b308cd7d
   ```

3. Restore the table from the backup with custom table settings. In this case, the **MusicBackup** restores the **Music** table and specifies an encryption mode for the restored table.

   **Note**
   The `sse-specification-override` parameter takes the same values as the `sse-specification-override` parameter used in the `CreateTable` command. To learn more, see [Managing Encrypted Tables in DynamoDB](p. 819).
   
   ```bash
   aws dynamodb restore-table-from-backup \
   --target-table-name Music \
   ```
You can restore the table to a different AWS Region from where the backup resides.

**Note**
- The `sse-specification-override` parameter is mandatory for cross-Region restores but optional for restores in the same Region as the source table.
- When performing a cross-Region restore from the command line, you must set the default AWS Region to the desired destination Region. To learn more, see Command Line Options in the *AWS Command Line Interface User Guide*.

```bash
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01581080476474-e177ebe2 \
--sse-specification-override Enabled=true,SSEType=KMS
```

You can override the billing mode and the provisioned throughput for the restored table.

```bash
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-b308cd7d \
--billing-mode-override PAY_PER_REQUEST
```

You can exclude some or all secondary indexes from being created on the restored table.

**Note**
- Restores can be faster and more cost-efficient if you exclude some or all secondary indexes from being created on the restored table.

```bash
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01581080476474-e177ebe2 \
--global-secondary-index-override '[]' \
--sse-specification-override Enabled=true,SSEType=KMS
```

**Note**
- The secondary indexes provided should match existing indexes. You cannot create new indexes at the time of restore.

You can use a combination of different overrides. For example, you can use a single global secondary index and change provisioned throughput at the same time, as follows.

```bash
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:eu-west-1:123456789012:table/Music/backup/01581082594992-303b6239 \
--billing-mode-override PROVISIONED \
--provisioned-throughput-override ReadCapacityUnits=100,WriteCapacityUnits=100 \
--global-secondary-index-override IndexName=singers-index,KeySchema=["{AttributeName=SingerName,KeyType=HASH}"]\,Projection="{ProjectionType=KEYS_ONLY}"\,ProvisionedThroughput={ReadCapacityUnits=5,WriteCapacityUnits=5}" \
--sse-specification-override Enabled=true,SSEType=KMS
```
To verify the restore, use the describe-table command to describe the Music table.

```
aws dynamodb describe-table --table-name Music
```

The table that is being restored from the backup is shown with the status **Creating**. After the restore process is finished, the status of the Music table changes to **Active**.

**Important**
While a restore is in progress, don't modify or delete your IAM role policy; otherwise, unexpected behavior can result. For example, suppose that you removed write permissions for a table while that table is being restored. In this case, the underlying RestoreTableFromBackup operation would not be able to write any of the restored data to the table. Note that IAM policies involving source IP restrictions for accessing the target restore table might similarly cause issues.
After the restore operation is complete, you can modify or delete your IAM role policy. If your backup is encrypted with an AWS managed CMK or a customer managed CMK, don't disable or delete the key while a restore is in progress, or the restore will fail. After the restore operation is complete, you can change the encryption key for the restored table and disable or delete the old key.

### Deleting a DynamoDB Table Backup

This section describes how to use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to delete an Amazon DynamoDB table backup.

**Note**
If you want to use the AWS CLI, you have to configure it first. For more information, see Using the AWS CLI (p. 57).

**Topics**
- Deleting a Table Backup (Console) (p. 613)
- Deleting a Table Backup (AWS CLI) (p. 614)

### Deleting a Table Backup (Console)

The following procedure shows how to use the console to delete the MusicBackup that is created in the **Backing Up a DynamoDB Table** (p. 606) tutorial.

**To delete a backup**

2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the list of backups, choose MusicBackup.
4. Choose Delete backup:

Choose **Delete** to delete the backup.

Are you sure you want to delete the backup "MusicBackup" of source table "Music"?

---

**Deleting a Table Backup (AWS CLI)**

The following example deletes a backup for an existing table `Music` table using the AWS CLI.

```
aws dynamodb delete-backup \
  --backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489602797149-73d8d5bc
```
Using IAM with DynamoDB Backup and Restore

You can use AWS Identity and Access Management (IAM) to restrict Amazon DynamoDB backup and restore actions for some resources. The `CreateBackup` and `RestoreTableFromBackup` APIs operate on a per-table basis.

For more information about using IAM policies in DynamoDB, see Using Identity-Based Policies (IAM Policies) for Amazon DynamoDB (p. 829).

The following are examples of IAM policies that you can use to configure specific backup and restore functionality in DynamoDB.

**Example 1: Allow the CreateBackup and RestoreTableFromBackup Actions**

The following IAM policy grants permissions to allow the `CreateBackup` and `RestoreTableFromBackup` DynamoDB actions on all tables:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "dynamodb:CreateBackup",
            "dynamodb:RestoreTableFromBackup",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:Scan",
            "dynamodb:BatchWriteItem"
         ],
         "Resource": "*"
      }
   ]
}
```

**Important**
DynamoDB write permissions are necessary for restore functionality.

**Example 2: Allow CreateBackup and Deny RestoreTableFromBackup**

The following IAM policy grants permissions for the `CreateBackup` action and denies the `RestoreTableFromBackup` action:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["dynamodb:CreateBackup"],
         "Resource": "*"
      },
      {
         "Effect": "Deny",
         "Action": ["dynamodb:RestoreTableFromBackup"],
         "Resource": "*"
      }
   ]
}
```
Example 3: Allow ListBackups and Deny CreateBackup and RestoreTableFromBackup

The following IAM policy grants permissions for the ListBackups action and denies the CreateBackup and RestoreTableFromBackup actions:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["dynamodb:ListBackups"],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": ["dynamodb:CreateBackup",
                  "dynamodb:RestoreTableFromBackup"],
      "Resource": "*"
    }
  ]
}
```

Example 4: Allow ListBackups and Deny DeleteBackup

The following IAM policy grants permissions for the ListBackups action and denies the DeleteBackup action:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["dynamodb:ListBackups"],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": ["dynamodb:DeleteBackup"],
      "Resource": "*"
    }
  ]
}
```
Example 5: Allow RestoreTableFromBackup and DescribeBackup for All Resources and Deny DeleteBackup for a Specific Backup

The following IAM policy grants permissions for the RestoreTableFromBackup and DescribeBackup actions and denies the DeleteBackup action for a specific backup resource:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeBackup",
                "dynamodb:RestoreTableFromBackup",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:GetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:BatchWriteItem"
            ],
            "Resource": "*
        },
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:DeleteBackup"
            ],
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-b308cd7d"
        }
    ]
}
```

**Important**
DynamoDB write permissions are necessary for restore functionality.

Example 6: Allow CreateBackup for a Specific Table

The following IAM policy grants permissions for the CreateBackup action on the Movies table only:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:CreateBackup"],
            "Resource": ["arn:aws:dynamodb:us-east-1:123456789012:table/Movies"
        }
    ]
}
```
Example 7: Allow ListBackups

The following IAM policy grants permissions for the ListBackups action:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:ListBackups"],
            "Resource": "*"
        }
    ]
}
```

**Important**

You cannot grant permissions for the ListBackups action on a specific table.
Point-in-Time Recovery for DynamoDB

You can create on-demand backups of your Amazon DynamoDB tables, or you can enable continuous backups using point-in-time recovery. For more information about on-demand backups, see On-Demand Backup and Restore for DynamoDB (p. 604).

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point-in-time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For example, suppose that a test script writes accidentally to a production DynamoDB table. With point-in-time recovery, you can restore that table to any point in time during the last 35 days. DynamoDB maintains incremental backups of your table.

In addition, point-in-time operations don't affect performance or API latencies. For more information, see Point-in-Time Recovery: How It Works (p. 619).

You can restore a DynamoDB table to a point in time using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. For more information, see Restoring a DynamoDB Table to a Point in Time (p. 621).

For more information about AWS Region availability and pricing, see Amazon DynamoDB pricing.

Point-in-Time Recovery: How It Works

Amazon DynamoDB point-in-time recovery (PITR) provides automatic backups of your DynamoDB table data. This section provides an overview of how the process works in DynamoDB.

You can enable point-in-time recovery using the AWS Management Console, AWS Command Line Interface (AWS CLI), or the DynamoDB API. When enabled, point-in-time recovery provides continuous backups until you explicitly turn it off. For more information, see Restoring a DynamoDB Table to a Point in Time (p. 621).

After you enable point-in-time recovery, you can restore to any point in time within EarliestRestorableDateTime and LatestRestorableDateTime. LatestRestorableDateTime is typically 5 minutes before the current time.

Note
The point-in-time recovery process always restores to a new table.

For EarliestRestorableDateTime, you can restore your table to any point in time during the last 35 days. The retention period is a fixed 35 days (5 calendar weeks) and can't be modified. Any number of users can execute up to four concurrent restores (any type of restore) in a given account.

Important
If you disable point-in-time recovery and later re-enable it on a table, you reset the start time for which you can recover that table. As a result, you can only immediately restore that table using the LatestRestorableDateTime.
When you restore using point-in-time recovery, DynamoDB restores your table data to the state based on the selected date and time (day:hour:minute:second) to a new table.

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore using point-in-time recovery, or you can configure the destination table settings. You can change the following table settings on the restored table:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity
- Encryption settings

**Important**
When you do a full table restore, all table settings for the restored table come from the current settings of the source table at the time of the restore. For example, suppose that a table's provisioned throughput was recently lowered to 50 read capacity units and 50 write capacity units. You then restore the table's state to three weeks ago, at which time its provisioned throughput was set to 100 read capacity units and 100 write capacity units. In this case, DynamoDB restores your table data to that point in time, but uses the current provisioned throughput (50 read capacity units and 50 write capacity units).

You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the source table resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you transfer out of the source Region and for restoring to a new table in the destination Region.

**Note**
Cross-Region restore is not supported if the source or destination Region is Asia Pacific (Hong Kong) or Middle East (Bahrain).

Restores can be faster and more cost-efficient if you exclude some or all indexes from being created on the restored table.

You must manually set the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management (IAM) policies
- Amazon CloudWatch metrics and alarms
- Tags
- Stream settings
- Time to Live (TTL) settings
- Point-in-time recovery settings

The time it takes you to restore a table varies based on multiple factors. The point-in-time restore times are not always correlated directly to the size of the table. For more information, see Restores (p. 605).

**Before You Begin Using Point-in-Time Recovery**

Before you enable point-in-time recovery (PITR) on an Amazon DynamoDB table, consider the following:
• If you disable point-in-time recovery and later re-enable it on a table, you reset the start time for which you can recover that table. As a result, you can only immediately restore that table using the LatestRestorableDateTime.
• If you delete a table with point-in-time recovery enabled, a system backup is automatically created and is retained for 35 days (at no additional cost). System backups allow you to restore the deleted table to the state it was in just before the point of deletion. All system backups follow a standard naming convention: $table-name$DeletedTableBackup.
• You can enable point-in-time recovery on each local replica of a global table. When you restore the table, the backup restores to an independent table that is not part of the global table. If you are using Version 2019.11.21 (Current) of global tables, you can create a new global table from the restored table. For more information, see Global Tables: How It Works.
• You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the source table resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you transfer out of the source Region and for restoring to a new table in the destination Region.
• AWS CloudTrail logs all console and API actions for point-in-time recovery to enable logging, continuous monitoring, and auditing. For more information, see Logging DynamoDB Operations by Using AWS CloudTrail.

Restoring a DynamoDB Table to a Point in Time

Amazon DynamoDB point-in-time recovery (PITR) provides continuous backups of your DynamoDB table data. You can restore a table to a point in time using the DynamoDB console or the AWS Command Line Interface (AWS CLI).

If you want to use the AWS CLI, you must configure it first. For more information, see Accessing DynamoDB.

• Restoring a Table to a Point in Time (AWS CLI)

Restoring a Table to a Point in Time (Console)

The following example demonstrates how to use the DynamoDB console to restore an existing table named Music to a point in time.

Note
This procedure assumes that you have enabled point-in-time recovery. To enable it for the Music table, on the Overview tab, in the Table details section, choose Enable for Point-in-time recovery.

To restore a table to a point in time

2. In the navigation pane on the left side of the console, choose Tables.
3. In the list of tables, choose the Music table.
5. For the new table name, enter **MusicMinutesAgo**.

   **Note**
   You can restore the table to the same AWS Region or to a different Region from where the source table resides. You can also exclude secondary indexes from being created on the restored table. In addition, you can specify a different encryption mode.

6. To confirm the restorable time, set the **Restore date and time** to the **Latest restore date**. Then choose **Restore table** to start the restore process.

   **Note**
   You can restore to any point in time within **Earliest restore date** and **Latest restore date**. DynamoDB restores your table data to the state based on the selected date and time (day:hour:minute:second).

   The table that is being restored is shown with the status **Restoring**. After the restore process is finished, the status of the **Music** table changes to **Active**.

---

**Restoring a Table to a Point in Time (AWS CLI)**

The following procedure shows how to use the AWS CLI to restore an existing table named **Music** to a point in time.

**Note**
This procedure assumes that you have enabled point-in-time recovery. To enable it for the **Music** table, run the following command.

```
aws dynamodb update-continuous-backups \
--table-name Music \
--point-in-time-recovery-specification PointInTimeRecoveryEnabled=True
```

To restore a table to a point in time

1. Confirm that point-in-time recovery is enabled for the **Music** table by using the `describe-continuous-backups` command.

   ```
   aws dynamodb describe-continuous-backups \
   --table-name Music
   ```

   Continuous backups (automatically enabled on table creation) and point-in-time recovery are enabled.

   ```
   {
   "ContinuousBackupsDescription": {
   "PointInTimeRecoveryDescription": {
   "PointInTimeRecoveryStatus": "ENABLED",
   "EarliestRestorableDateTime": 1519257118.0,
   "LatestRestorableDateTime": 1520018653.01
   },
   "ContinuousBackupsStatus": "ENABLED"
   }
   }
   ```

2. Restore the table to a point in time. In this case, the **Music** table is restored to the **LatestRestorableDateTime** (~5 minutes ago) to the same AWS Region.

   ```
   aws dynamodb restore-table-to-point-in-time \
   --source-table-name Music \
   --target-table-name MusicMinutesAgo \
   ```
Note
You can also restore to a specific point in time. To do this, run the command using the `--restore-date-time` argument, and specify a timestamp. You can specify any point in time during the last 35 days. For example, the following command restores the table to the EarliestRestorableDateTime.

```bash
aws dynamodb restore-table-to-point-in-time \\
--source-table-name Music \\
--target-table-name MusicEarliestRestorableDateTime \\
--use-latest-restorable-time \\
--restore-date-time 1519257118.0
```

Specifying the `--no-use-latest-restorable-time` argument is optional when restoring to a specific point in time.

3. Restore the table to a point in time with custom table settings. In this case, the Music table is restored to the LatestRestorableDateTime (~5 minutes ago).

You can specify a different encryption mode for the restored table, as follows.

Note
The `sse-specification-override` parameter takes the same values as the `sse-specification-override` parameter used in the CreateTable command. To learn more, see Managing Encrypted Tables in DynamoDB (p. 819).

```bash
aws dynamodb restore-table-to-point-in-time \\
--source-table-name Music \\
--target-table-name MusicMinutesAgo \\
--use-latest-restorable-time \\
--sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-a123-ab1234a1b234
```

You can restore the table to a different AWS Region from where the source table resides.

Note
• The `sse-specification-override` parameter is mandatory for cross-Region restores but optional for restores to the same Region as the source table.
• The `source-table-arn` parameter must be provided for cross-Region restores.
• When performing a cross-Region restore from the command line, you must set the default AWS Region to the desired destination Region. To learn more, see Command Line Options in the AWS Command Line Interface User Guide.

```bash
aws dynamodb restore-table-to-point-in-time \\
--source-table-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music \\
--target-table-name MusicMinutesAgo \\
--use-latest-restorable-time \\
--sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-a123-ab1234a1b234
```

You can override the billing mode and the provisioned throughput for the restored table.

```bash
aws dynamodb restore-table-to-point-in-time \\
--source-table-name Music \\
--target-table-name MusicMinutesAgo \\
--use-latest-restorable-time \\
```

API Version 2012-08-10

623
You can exclude some or all secondary indexes from being created on the restored table.

**Note**
Restores can be faster and more cost-efficient if you exclude some or all secondary indexes from being created on the new restored table.

```bash
aws dynamodb restore-table-to-point-in-time
    --source-table-name Music
    --target-table-name MusicMinutesAgo
    --use-latest-restorable-time
    --global-secondary-index-override '[]'
```

You can use a combination of different overrides. For example, you can use a single global secondary index and change provisioned throughput at the same time, as follows.

```bash
aws dynamodb restore-table-to-point-in-time
    --source-table-name Music
    --target-table-name MusicMinutesAgo
    --billing-mode-override PROVISIONED
    --provisioned-throughput-override ReadCapacityUnits=100,WriteCapacityUnits=100
    --global-secondary-index-override IndexName=singers-index,KeySchema=["{AttributeName=SingerName,KeyType=HASH}"],Projection="{ProjectionType=KEYS_ONLY}"
    --sse-specification-override Enabled=true,SSEType=KMS
    --use-latest-restorable-time
```

To verify the restore, use the `describe-table` command to describe the `MusicEarliestRestorableDateTime` table.

```bash
aws dynamodb describe-table --table-name MusicEarliestRestorableDateTime
```

The table that is being restored is shown with the status **Creating** and restore in progress as **true**. After the restore process is finished, the status of the `MusicEarliestRestorableDateTime` table changes to **Active**.

**Important**
While a restore is in progress, don't modify or delete the AWS Identity and Access Management (IAM) policies that grant the IAM entity (for example, user, group, or role) permission to perform the restore. Otherwise, unexpected behavior can result. For example, suppose that you remove write permissions for a table while that table is being restored. In this case, the underlying `RestoreTableToPointInTime` operation can't write any of the restored data to the table. IAM policies involving source IP restrictions for accessing the target restore table can similarly cause issues.

You can modify or delete permissions only after the restore operation is completed.
Global Tables: Multi-Region Replication with DynamoDB

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

Amazon DynamoDB global tables provide a fully managed solution for deploying a multiregion, multimaster database, without having to build and maintain your own replication solution. With global tables you can specify the AWS Regions where you want the table to be available. DynamoDB performs all of the necessary tasks to create identical tables in these Regions and propagate ongoing data changes to all of them.

For example, suppose that you have a large customer base spread across three geographic areas—the US East Coast, the US West Coast, and Western Europe. Customers can update their profile information using your application. To satisfy this use case, you need to create three identical DynamoDB tables named CustomerProfiles, in three different AWS Regions where the customers are located. These three tables would be entirely separate from each other. Changes to the data in one table would not be reflected in the other tables. Without a managed replication solution, you could write code to replicate data changes among these tables. However, doing this would be a time-consuming and labor-intensive effort.

Instead of writing your own code, you could create a global table consisting of your three Region-specific CustomerProfiles tables. DynamoDB would then automatically replicate data changes among those tables so that changes to CustomerProfiles data in one Region would seamlessly propagate to the other Regions. In addition, if one of the AWS Regions were to become temporarily unavailable, your customers could still access the same CustomerProfiles data in the other Regions.

DynamoDB global tables are ideal for massively scaled applications with globally dispersed users. In such an environment, users expect very fast application performance. Global tables provide automatic multimaster replication to AWS Regions worldwide. They enable you to deliver low-latency data access to your users no matter where they are located.

Note

- There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). We recommend using Version 2019.11.21 (Current) (p. 626) of global tables, which enables you to dynamically add new replica tables from a table populated with data. Version 2019.11.21 (Current) (p. 626) is more efficient and consumes less write capacity than Version 2017.11.29 (p. 639).
- Region support for global tables Version 2017.11.29 (p. 639) is limited to US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), Europe (Ireland), Europe (London), Europe (Frankfurt), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Asia Pacific (Seoul).
- If you are using Version 2019.11.21 (Current) (p. 626) of global tables and you also use the Time to Live feature, DynamoDB replicates TTL deletes to all replica tables. The initial TTL delete does not consume write capacity in the region in which the TTL expiry occurs. However, the replicated TTL delete to the replica table(s) consumes a replicated write capacity unit.
when using provisioned capacity, or replicated write when using on-demand capacity mode, in each of the replica regions and applicable charges will apply.

- Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the region where the write is made originally. Transactions are not supported across regions in global tables. For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) regions and perform a TransactWriteItems operation in the US East (N. Virginia) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated. Changes will only be replicated to other regions once they have been committed in the source region.

For information about the AWS Region availability and pricing, see Amazon DynamoDB Pricing.

Determining the Version of Global Tables You Are Using

To find out which version of global tables you are using, do the following:

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the table you want to use.
4. Choose the Global Tables tab.
5. The Global table version displays the version of global tables in use.

Version 2019.11.21 (Current)

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).
Global Tables: How It Works

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) and Version 2017.11.29. To find out which version you are using, see Determine Version.

The following sections help you understand the concepts and behavior of global tables in Amazon DynamoDB.

Global Table Concepts

A global table is a collection of one or more replica tables, all owned by a single AWS account.

A replica table (or replica, for short) is a single DynamoDB table that functions as a part of a global table. Each replica stores the same set of data items. Any given global table can only have one replica table per AWS Region. For more information about how to get started with global tables, see Tutorial: Creating a Global Table.

When you create a DynamoDB global table, it consists of multiple replica tables (one per Region) that DynamoDB treats as a single unit. Every replica has the same table name and the same primary key schema. When an application writes data to a replica table in one Region, DynamoDB propagates the write to the other replica tables in the other AWS Regions automatically.

You can add replica tables to the global table so that it can be available in additional Regions.

Consistency and Conflict Resolution

Any changes made to any item in any replica table are replicated to all the other replicas within the same global table. In a global table, a newly written item is usually propagated to all replica tables within a second.

With a global table, each replica table stores the same set of data items. DynamoDB does not support partial replication of only some of the items.

An application can read and write data to any replica table. If your application only uses eventually consistent reads and only issues reads against one AWS Region, it will work without any modification. However, if your application requires strongly consistent reads, it must perform all of its strongly consistent reads and writes in the same Region. DynamoDB does not support strongly consistent reads across Regions. Therefore, if you write to one Region and read from another Region, the read response might include stale data that doesn't reflect the results of recently completed writes in the other Region.

If applications update the same item in different Regions at about the same time, conflicts can arise. To help ensure eventual consistency, DynamoDB global tables use a last writer wins reconciliation between concurrent updates, in which DynamoDB makes a best effort to determine the last writer. With this conflict resolution mechanism, all the replicas will agree on the latest update and converge toward a state in which they all have identical data.
Availability and Durability

If a single AWS Region becomes isolated or degraded, your application can redirect to a different Region and perform reads and writes against a different replica table. You can apply custom business logic to determine when to redirect requests to other Regions.

If a Region becomes isolated or degraded, DynamoDB keeps track of any writes that have not yet been propagated to all of the replica tables. When the Region comes back online, DynamoDB resumes propagating any pending writes from that Region to the replica tables in other Regions. It also resumes propagating writes from other replica tables to the Region that is now back online.

Best Practices and Requirements for Managing Global Tables

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

Using Amazon DynamoDB global tables, you can replicate your table data across AWS Regions. It is important that the replica tables and secondary indexes in your global table have identical write capacity settings to ensure proper replication of data.

Best Practices and Requirements for Managing Capacity

Consider the following when managing capacity settings for replica tables in DynamoDB.

When using the latest version of global tables, you must either use on-demand capacity or enable autoscaling on the table. Using autoscaling or on-demand capacity ensures that you always have sufficient capacity to perform replicated writes to all regions of the global table. The number of replicated write capacity units (rWCUs) or replicated write request units will be equal in all Regions of the global table. For example, suppose that you expect 5 writes per second to your replica table in Ohio and 5 writes per second to your replica table in N. Virginia. In this case, you should expect to consume 10 rWCUs (or 10 replicated write request units, if using on-demand capacity) in both Ohio and N. Virginia. When you use the provisioned capacity mode, you manage your auto scaling policy with UpdateTableReplicaAutoScaling. Minimum and maximum throughput and target utilization are established globally for the table and passed to all replicas of the table.

For details about autoscaling and DynamoDB, see Managing Throughput Capacity Automatically with DynamoDB Auto Scaling (p. 346).

Tutorial: Creating a Global Table

This section describes how to create a global table using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Topics
Creating a Global Table (Console)

Follow these steps to create a global table using the console. The following example creates a global table with replica tables in United States and Europe.

1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/home. For this example, choose the us-east-2 (US East Ohio) Region.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**.

   For **Table name**, enter **Music**.

   For **Primary key** enter **Artist**. Choose **Add sort key**, and enter **SongTitle**. (**Artist** and **SongTitle** should both be strings.)

   To create the table, choose **Create**. This table serves as the first replica table in a new global table. It is the prototype for other replica tables that you add later.
4. Choose the **Global Tables** tab, and then choose **Enable streams**. Keep the **View type** at its default value (New and old images).
5. Choose **Add region**.
6. In **Region**, choose **US West (Oregon)**.

   The console checks to ensure that a table with the same name doesn’t exist in the selected Region. If a table with the same name does exist, you must delete the existing table before you can create a new replica table in that Region.

   Choose **Create Replica**, this starts the table creation process in US West (Oregon).
The **Global Table** tab for the selected table (and for any other replica tables) shows that the table has been replicated in multiple Regions.

7. Now add another Region so that your global table is replicated and synchronized across the United States and Europe. To do this, repeat step 5, but this time, specify **EU (Frankfurt)** instead of **US West (Oregon)**.

8. You should still be using the AWS Management Console in the **us-east-2** (US East Ohio) Region. For the **Music** table, choose the **Items** tab, and then choose **Create Item**. For **Artist**, enter **item_1**. For **SongTitle**, enter **Song Value 1**. To write the item, choose **Save**.

After a short time, the item is replicated across all three Regions of your global table. To verify this, in the console, on the Region selector in the upper-right corner, choose **Europe (Frankfurt)**. The **Music** table in Europe (Frankfurt) should contain the new item.

Repeat this for **US West (Oregon)**.

### Creating a Global Table (AWS CLI)

Follow these steps to create a global table **Music** using the AWS CLI. The following example creates a global table, with replica tables in the United States and in Europe.

1. Create a new table (**Music**) in **US East (Ohio)**, with DynamoDB Streams enabled (**NEW_AND_OLD_IMAGES**).

   ```bash
   aws dynamodb create-table --table-name Music --attribute-definitions AttributeName=Artist,AttributeType=S AttributeName=SongTitle,AttributeType=S --key-schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE --billing-mode PAY_PER_REQUEST --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES --region us-east-2
   ```

2. Create an identical **Music** table in **US East (N. Virginia)**.

   ```bash
   aws dynamodb update-table --table-name Music --cli-input-json \
   '{
   "ReplicaUpdates": [
   ```
3. Repeat step 2 to create a table in Europe (Ireland) (eu-west-1).
4. You can view the list of replicas created using `describe-table`.

   ```bash
   aws dynamodb describe-table --table-name Music --region us-east-2
   ```

5. To verify that replication is working, add a new item to the `Music` table in US East (Ohio).

   ```bash
   aws dynamodb put-item \
   --table-name Music \
   --item '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
   --region us-east-2
   ```

6. Wait for a few seconds, and then check to see whether the item has been successfully replicated to US East (N. Virginia) and Europe (Ireland).

   ```bash
   aws dynamodb get-item \
   --table-name Music \
   --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
   --region us-east-1
   aws dynamodb get-item \
   --table-name Music \
   --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
   --region eu-west-1
   ```

7. Delete the replica table in Europe (Ireland) Region.

   ```bash
   aws dynamodb update-table --table-name Music --cli-input-json \
   '{"ReplicaUpdates": [\n   {\n   "Delete": {\n   "RegionName": "eu-west-1"
   }\n   }\n   ]}'
   ```

### Creating a Global Table (Java)

The following Java code sample, create a `Music` table in Europe (Ireland) region then creates a replica in Asia Pacific (Seoul) region.

```java
package com.amazonaws.codesamples.gtv2;
import java.util.logging.Logger;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
```
public class App {
    private final static Logger LOGGER = Logger.getLogger(Logger.GLOBAL_LOGGER_NAME);

    public static void main( String[] args ) {
        String tableName = "Music";
        String indexName = "index1";

        Regions calledRegion = Regions.EU_WEST_1;
        Regions destRegion = Regions.AP_NORTHEAST_2;

        AmazonDynamoDB ddbClient = AmazonDynamoDBClientBuilder.standard()
                .withCredentials(new ProfileCredentialsProvider("default"))
                .withRegion(calledRegion)
                .build();

        LOGGER.info("Creating a regional table - TableName: " + tableName +", IndexName: " + indexName + " ..... ");
        ddbClient.createTable(new CreateTableRequest()
                .withTableName(tableName)
                .withAttributeDefinitions(new AttributeDefinition()
                        .withAttributeName("Artist").withAttributeType(ScalarAttributeType.S),
                        new AttributeDefinition()
                        .withAttributeName("SongTitle").withAttributeType(ScalarAttributeType.S))
                .withKeySchema(new KeySchemaElement().withAttributeName("Artist").withKeyType(KeyType.HASH),
                        new KeySchemaElement().withAttributeName("SongTitle").withKeyType(KeyType.RANGE))
                .withBillingMode(BillingMode.PAY_PER_REQUEST)
                .withGlobalSecondaryIndexes(new GlobalSecondaryIndex()
                        .withIndexName(indexName)
                        .withKeySchema(new KeySchemaElement()
                                .withAttributeName("SongTitle").withKeyType(KeyType.HASH)
                                .withProjection(new Projection().withProjectionType(ProjectionType.ALL)))
                        .withStreamSpecification(new StreamSpecification(new StreamViewType(StreamViewType.NEW_IMAGE))))
                .withProvisionedThroughputOverride(new ProvisionedThroughputOverride()));
    }
}
Monitoring Global Tables

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

You can use Amazon CloudWatch to monitor the behavior and performance of a global table. Amazon DynamoDB publishes ReplicationLatency metric for each replica in the global table.

- **ReplicationLatency**—The elapsed time between when an item is written to a replica table, and when that item appears in another replica in the global table. ReplicationLatency is expressed in milliseconds and is emitted for every source- and destination-Region pair.

During normal operation, ReplicationLatency should be fairly constant. An elevated value for ReplicationLatency could indicate that updates from one replica are not propagating to other replica tables in a timely manner. Over time, this could result in other replica tables falling behind because they no longer receive updates consistently. In this case, you should verify that the read capacity units (RCUs) and write capacity units (WCUs) are identical for each of the replica tables. In addition, when choosing WCU settings, follow the recommendations in Best Practices and Requirements for Managing Capacity (p. 628).

ReplicationLatency can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.
For more information, see DynamoDB Metrics and Dimensions (p. 858).

**Using IAM with Global Tables**

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

When you create a global table for the first time, Amazon DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role is named AWSServiceRoleForDynamoDBReplication, and it allows DynamoDB to manage cross-Region replication for global tables on your behalf. Don't delete this service-linked role. If you do, all of your global tables will no longer function.

For more information about service-linked roles, see Using Service-Linked Roles in the IAM User Guide.

To create replica tables in DynamoDB, you must have the following permissions in the source region.

- dynamoDb:UpdateTable

To create replica tables in DynamoDB, you must have the following permissions in destination regions.

- dynamoDb:CreateTable
- dynamoDb:CreateTableReplica
- dynamoDb:Scan
- dynamoDb:Query
- dynamoDb:UpdateItem
- dynamoDb:PutItem
- dynamoDb:GetItem
- dynamoDb:DeleteItem
- dynamoDb:BatchWriteItem

To delete replica tables in DynamoDB, you must have the following permissions in the destination regions.

- dynamoDb:DeleteTable
- dynamoDb:DeleteTableReplica

To update replica auto-scaling policy through UpdateTableReplicaAutoScaling, you must have the following permissions in all Regions where table replicas exist.

- application-autoscaling:DeleteScalingPolicy
- application-autoscaling:DeleteScheduledAction
- application-autoscaling:DeregisterScalableTarget
- application-autoscaling:DescribeScalableTargets
- application-autoscaling:DescribeScalingActivities
- application-autoscaling:DescribeScalingPolicies
• application-autoscaling:DescribeScheduledActions
• application-autoscaling:PutScalingPolicy
• application-autoscaling:PutScheduledAction
• application-autoscaling:RegisterScalableTarget

To use UpdateTimeToLive you must have permission for dynamodb:UpdateTimeToLive in all Regions where table replicas exist.

Example: Add Replica

The following IAM policy grants permissions to allow you to add replicas to a global table.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "dynamodb:CreateTable",
        "dynamodb:DescribeTable",
        "dynamodb:UpdateTable",
        "dynamodb:CreateTableReplica",
        "iam:CreateServiceLinkedRole"
      ],
      "Resource": "*
    }
  ]
}
```

Example: Update AutoScaling policy

The following IAM policy grants permissions to allow you to update replica auto-scaling policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "application-autoscaling:RegisterScalableTarget",
        "application-autoscaling:DeleteScheduledAction",
        "application-autoscaling:DescribeScalableTargets",
        "application-autoscaling:DescribeScalingActivities",
        "application-autoscaling:DescribeScalingPolicies",
        "application-autoscaling:PutScalingPolicy",
        "application-autoscaling:DescribeScheduledActions",
        "application-autoscaling:DeleteScalingPolicy",
        "application-autoscaling:PutScheduledAction",
        "application-autoscaling:DeregisterScalableTarget"
      ],
      "Resource": "*
    }
  ]
}
```
Example: Allow Replica Creations for a Specific Table Name and Regions

The following IAM policy grants permissions to allow table and replica creation for Customers table with replicas in three Regions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "dynamodb:CreateTable",
        "dynamodb:DescribeTable",
        "dynamodb:UpdateTable"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-east-1:123456789012:table/Customers",
      ]
    }
  ]
}
```

Updating Global Tables to Version 2019.11.21 (Current)

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

This section describes how to update your global tables to version 2019.11.21 (current).

Topics

- Before You Begin (p. 636)
- Updating to Version 2019.11.21 (Current) (p. 638)

Before You Begin

DynamoDB global tables version 2019.11.21 (current) introduces the following requirements:

- The global secondary indexes on the replica tables must be consistent across Regions.
- The encryption setting on the replica tables must be consistent across Regions.
- The Time To Live (TTL) settings on the replica tables must be consistent across Regions. If TTL is enabled on a replica table, TTL deletes are replicated.
- DynamoDB auto scaling or on-demand capacity must be enabled for write capacity units across all replica tables.
Global tables control plane operations (create, delete, update, and describe) APIs differ. For more information, see Global Tables: Multi-Region Replication with DynamoDB.

DynamoDB global tables version 2019.11.21 (current) introduces the following changes in behavior:

- DynamoDB Streams publishes only one record (instead of two) for each write.
- For new inserts, `aws:rep:*` attributes in the item record are not added.
- For updates to items that contain `aws:rep:*` attributes, those attributes are not updated.
- DynamoDB mapper must not require the `aws:rep:*` attributes for this table.
- When updating from version 2017.11.21 to version 2019.11.29, you might see an increase in the `ReplicationLatency` metric. This is expected because version 2019.11.29 (current) captures the full end-to-end measurement of replication delay between global tables Regions. For more information, see the `ReplicationLatency` documentation for version Version 2017.11.21 and Version 2019.11.29 (Current).

**Required Permissions**

To update to version 2019.11.21 (current), you must have `dynamodb:UpdateGlobalTableVersion` permissions across replica Regions. These permissions are in addition to the permissions needed for accessing the DynamoDB console and viewing tables.

The following IAM policy grants permissions to update any global table to version 2019.11.21 (current).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb:UpdateGlobalTableVersion",
            "Resource": "*
        }
    ]
}
```

The following IAM policy grants permissions to update only the Music global table, with replicas in two Regions, to version 2019.11.21 (current).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb:UpdateGlobalTableVersion",
            "Resource": [
                "arn:aws:dynamodb::123456789012:global-table/Music",
                "arn:aws:dynamodb:us-east-2:123456789012:table/Music"
            ]
        }
    ]
}
```

**Update Process Overview**

During the update process, the state of your global table changes from **ACTIVE** to **UPDATING**.
The process takes several minutes, but it should finish in less than an hour. During the update process, your table remains available for read and write traffic. However, auto scaling does not alter the provisioned capacity on your table during the update. As such, before you begin the update, we recommend that you switch your table to on-demand capacity.

If you choose to use provisioned capacity with auto scaling during the update, you must increase the minimum read and write throughput on your policies to accommodate expected increases in traffic for the duration of the update.

When the update process is complete, your table status returns to ACTIVE. You can check the state of your table by using DescribeTable, or verify it using the Tables view on the DynamoDB console.

Important

- Updating from version 2017.11.29 to version 2019.11.21 (current) is a one-time action and cannot be reversed. Before proceeding with the update, ensure that you have performed all necessary testing. Allow up to 60 minutes before attempting to update a newly created global table.
- In version 2017.11.29 of global tables, DynamoDB performed a write operation to insert three attributes into the item record. These attributes (aws:rep:*), used to enact replication and manage conflict resolution. In version 2019.11.21 (current) of global tables, replication activity is managed natively and is not exposed to users.
- Updating to version 2019.11.21 (current) is only available through the DynamoDB console.

Updating to Version 2019.11.21 (Current)

Follow these steps to update your version of DynamoDB global tables using the AWS Management Console.

To update global tables to version 2019.11.21

2. In the navigation pane on the left side of the console, choose Tables, and then select the global table that you want to update to 2019.11.21 (current).
3. Choose the Global Tables tab.
5. Read and agree to the new requirements, and then choose Continue.

Important

Updating from version 2017.11.29 to version 2019.11.21 (current) is a one-time action and cannot be reversed. Before starting the update, ensure that you have performed all necessary testing.
6. After the update process is complete, the global tables version that appears on the console changes to 2019.11.21.

Version 2017.11.29

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

Global Tables: How It Works

The following sections help you understand the concepts and behavior of global tables in Amazon DynamoDB.

Global Table Concepts

A global table is a collection of one or more replica tables, all owned by a single AWS account.
A replica table (or replica, for short) is a single DynamoDB table that functions as a part of a global table. Each replica stores the same set of data items. Any given global table can only have one replica table per AWS Region.

The following is a conceptual overview of how a global table is created.

1. Create an ordinary DynamoDB table, with DynamoDB Streams enabled, in an AWS Region.
2. Repeat step 1 for every other Region where you want to replicate your data.
3. Define a DynamoDB global table based on the tables that you have created.

The AWS Management Console automates these tasks, so you can create a global table more quickly and easily. For more information, see Creating a Global Table (p. 643).

The resulting DynamoDB global table consists of multiple replica tables, one per Region, that DynamoDB treats as a single unit. Every replica has the same table name and the same primary key schema. When an application writes data to a replica table in one Region, DynamoDB automatically propagates the write to the other replica tables in the other AWS Regions.

**Important**
To keep your table data in sync, global tables automatically create the following attributes for every item:

- `aws:rep:deleting`
- `aws:rep:updatetime`
- `aws:rep:updateregion`

Do not modify these attributes or create attributes with the same name.

You can add replica tables to the global table so that it can be available in additional Regions. (To do this, the global table must be empty. In other words, none of the replica tables can have any data in them.)

You can also remove a replica table from a global table. If you do this, the table is completely disassociated from the global table. This newly independent table no longer interacts with the global table, and data is no longer propagated to or from the global table.

**Consistency and Conflict Resolution**

Any changes made to any item in any replica table are replicated to all the other replicas within the same global table. In a global table, a newly written item is usually propagated to all replica tables within seconds.

With a global table, each replica table stores the same set of data items. DynamoDB does not support partial replication of only some of the items.

An application can read and write data to any replica table. If your application only uses eventually consistent reads and only issues reads against one AWS Region, it will work without any modification. However, if your application requires strongly consistent reads, it must perform all of its strongly consistent reads and writes in the same Region. DynamoDB does not support strongly consistent reads across Regions. Therefore, if you write to one Region and read from another Region, the read response might include stale data that doesn't reflect the results of recently completed writes in the other Region.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a *last writer wins* reconciliation between concurrent updates, in which DynamoDB makes a best effort to determine the last writer. With this conflict resolution mechanism, all the replicas will agree on the latest update and converge toward a state in which they all have identical data.
Availability and Durability

If a single AWS Region becomes isolated or degraded, your application can redirect to a different Region and perform reads and writes against a different replica table. You can apply custom business logic to determine when to redirect requests to other Regions.

If a Region becomes isolated or degraded, DynamoDB keeps track of any writes that have been performed but have not yet been propagated to all of the replica tables. When the Region comes back online, DynamoDB resumes propagating any pending writes from that Region to the replica tables in other Regions. It also resumes propagating writes from other replica tables to the Region that is now back online.

Best Practices and Requirements for Managing Global Tables

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) and Version 2017.11.29. To find out which version you are using, see Determine Version.

Using Amazon DynamoDB global tables, you can replicate your table data across AWS Regions. It is important that the replica tables and secondary indexes in your global table have identical write capacity settings to ensure proper replication of data.

Topics

• Requirements for Adding a New Replica Table
• Best Practices and Requirements for Managing Capacity

Requirements for Adding a New Replica Table

If you want to add a new replica table to a global table, each of the following conditions must be true:

• The table must have the same partition key as all of the other replicas.
• The table must have the same write capacity management settings specified.
• The table must have the same name as all of the other replicas.
• The table must have DynamoDB Streams enabled, with the stream containing both the new and the old images of the item.
• None of the new or existing replica tables in the global table can contain any data.

If global secondary indexes are specified, the following conditions must also be met:

• The global secondary indexes must have the same name.
• The global secondary indexes must have the same partition key and sort key (if present).

Important

Write capacity settings should be set consistently across all of your global tables' replica tables and matching secondary indexes. To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the UpdateGlobalTableSettings API operation. UpdateGlobalTableSettings applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the
UpdateTable, RegisterScalableTarget, or PutScalingPolicy operations, you should apply the change to each replica table and matching secondary index individually. For more information, see UpdateGlobalTableSettings in the Amazon DynamoDB API Reference.

We strongly recommend that you enable auto scaling to manage provisioned write capacity settings. If you prefer to manage write capacity settings manually, you should provision equal replicated write capacity units to all of your replica tables. Also provision equal replicated write capacity units to matching secondary indexes across your global table.

You must also have appropriate AWS Identity and Access Management (IAM) permissions. For more information, see Using IAM with Global Tables (p. 646).

Best Practices and Requirements for Managing Capacity

Consider the following when managing capacity settings for replica tables in DynamoDB.

Using DynamoDB Auto Scaling

Using DynamoDB auto scaling is the recommended way to manage throughput capacity settings for replica tables that use the provisioned mode. DynamoDB auto scaling automatically adjusts read capacity units (RCUs) and write capacity units (WCUs) for each replica table based upon your actual application workload. For more information, see Managing Throughput Capacity Automatically with DynamoDB Auto Scaling (p. 346).

If you create your replica tables using the AWS Management Console, auto scaling is enabled by default for each replica table, with default auto scaling settings for managing read capacity units and write capacity units.

Changes to auto scaling settings for a replica table or secondary index made through the DynamoDB console or using the UpdateGlobalTableSettings call are applied to all of the replica tables and matching secondary indexes in the global table automatically. These changes overwrite any existing auto scaling settings. This ensures that provisioned write capacity settings are consistent across the replica tables and secondary indexes in your global table. If you use the UpdateTable, RegisterScalableTarget, or PutScalingPolicy calls, you should apply the change to each replica table and matching secondary index individually.

Note
If auto scaling doesn't satisfy your application's capacity changes (unpredictable workload), or if you don't want to configure its settings (target settings for minimum, maximum, or utilization threshold), you can use on-demand mode to manage capacity for your global tables. For more information, see On-Demand Mode (p. 17).

If you enable on-demand mode on a global table, your consumption of replicated write request units (rWCUs) will be consistent with how rWCUs are provisioned. For example, if you perform 10 writes to a local table that is replicated in two additional Regions, you will consume 60 write request units (10 + 10 + 10 = 30; 30 x 2 = 60). The consumed 60 write request units include the extra write consumed by global tables Version 2017.11.29 to update the aws:rep:deleting, aws:rep:updatetime, and aws:rep:updaterregion attributes.

Managing Capacity Manually

If you decide not to use DynamoDB auto scaling, you must manually set the read capacity and write capacity settings on each replica table and secondary index.

The provisioned replicated write capacity units (rWCUs) on every replica table should be set to the total number of rWCUs needed for application writes across all Regions multiplied by two. This accommodates application writes that occur in the local Region and replicated application writes coming from other Regions. For example, suppose that you expect 5 writes per second to your replica table in Ohio and 5 writes per second to your replica table in N. Virginia. In this case, you should provision 20 WCUs to each replica table (5 + 5 = 10; 10 x 2 = 20).
To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the UpdateGlobalTableSettings API operation. UpdateGlobalTableSettings applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the UpdateTable, RegisterScalableTarget, or PutScalingPolicy operations, you should apply the change to each replica table and matching secondary index individually. For more information, see Amazon DynamoDB API Reference.

Note
To update the settings (UpdateGlobalTableSettings) for a global table in DynamoDB, you must have the dynamodb:UpdateGlobalTable, dynamodb:DescribeLimits, application-autoscaling:DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget permissions. For more information, see Using IAM with Global Tables (p. 646).

Creating a Global Table

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).

This section describes how to create a global table using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Topics
- Creating a Global Table (Console) (p. 643)
- Creating a Global Table (AWS CLI) (p. 644)

Creating a Global Table (Console)

Follow these steps to create a global table using the console. The following example creates a global table with replica tables in United States and Europe.

1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/home. For this example, choose the us-east-2 (US East Ohio) Region.
2. In the navigation pane on the left side of the console, choose Tables.
3. Choose Create Table.
4. For Table name, enter Music.
5. For Primary key enter Artist. Choose Add sort key, and enter SongTitle. (Artist and SongTitle should both be strings.)
6. To create the table, choose Create. This table serves as the first replica table in a new global table. It is the prototype for other replica tables that you add later.
7. Choose the Global Tables tab, and then choose Enable streams. Keep the View type at its default value (New and old images).
8. Choose Add region, and choose Global table 2017.11.29 mode. You can now choose another Region where you want to deploy another replica table. In this case, choose US West (Oregon), and then choose Continue. This starts the table creation process in US West (Oregon).

The console checks to ensure that there is no table with the same name in the selected Region. (If a table with the same name does exist, you must delete the existing table before you can create a new replica table in that Region.)
The **Global Table** tab for the selected table (and for any other replica tables) will show that the table is replicated in multiple Regions.

6. Now add another Region so that your global table is replicated and synchronized across the United States and Europe. To do this, repeat step 5, but this time, specify **EU (Frankfurt)** instead of **US West (Oregon)**.

7. You should still be using the AWS Management Console in the us-east-2 (US East Ohio) Region. For the **Music** table, choose the **Items** tab, and then choose **Create Item**. For **Artist**, enter **item_1**. For **SongTitle**, enter **Song Value 1**. To write the item, choose **Save**.

After a short time, the item is replicated across all three Regions of your global table. To verify this, in the console, on the Region selector in the upper-right corner, choose **Europe (Frankfurt)**. The **Music** table in Europe (Frankfurt) should contain the new item. Repeat this for US West (Oregon).

---

**Creating a Global Table (AWS CLI)**

Follow these steps to create a global table **Music** using the AWS CLI. The following example creates a global table, with replica tables in the United States and in Europe.

1. Create a new table (**Music**) in US East (Ohio), with DynamoDB Streams enabled (**NEW_AND_OLD_IMAGES**).

   ```bash
   aws dynamodb create-table \
   --table-name Music \
   --attribute-definitions \ 
   AttributeName=Artist,AttributeType=S \ 
   AttributeName=SongTitle,AttributeType=S \
   --key-schema \ 
   AttributeName=Artist,KeyType=HASH \ 
   AttributeName=SongTitle,KeyType=RANGE \ 
   --provisioned-throughput \ 
   ReadCapacityUnits=10,WriteCapacityUnits=5 \ 
   --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \ 
   --region us-east-2
   
   ```

2. Create an identical **Music** table in US East (N. Virginia).

   ```bash
   aws dynamodb create-table \
   --table-name Music \
   --attribute-definitions \ 
   AttributeName=Artist,AttributeType=S \ 
   AttributeName=SongTitle,AttributeType=S \
   --key-schema \ 
   AttributeName=Artist,KeyType=HASH \ 
   AttributeName=SongTitle,KeyType=RANGE \ 
   --provisioned-throughput \ 
   ReadCapacityUnits=10,WriteCapacityUnits=5 \ 
   --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \ 
   --region us-east-1
   
   ```

3. Create a global table (**Music**) consisting of replica tables in the **us-east-2** and **us-east-1** Regions.

   ```bash
   aws dynamodb create-global-table \
   --global-table-name Music \ 
   --replication-group RegionName=us-east-2 RegionName=us-east-1 \ 
   --region us-east-2
   ```
Note
The global table name (Music) must match the name of each of the replica tables (Music). For more information, see Best Practices and Requirements for Managing Global Tables (p. 641).

4. Create another table in Europe (Ireland), with the same settings as those you created in step 1 and step 2.

```bash
aws dynamodb create-table
--table-name Music
--attribute-definitions
  AttributeName=Artist,AttributeType=S
  AttributeName=SongTitle,AttributeType=S
--key-schema
  AttributeName=Artist,KeyType=HASH
  AttributeName=SongTitle,KeyType=RANGE
--provisioned-throughput
  ReadCapacityUnits=10,WriteCapacityUnits=5
--stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES
--region eu-west-1
```

After doing this step, add the new table to the Music global table.

```bash
aws dynamodb update-global-table
--global-table-name Music
--replica-updates 'Create={RegionName=eu-west-1}'
--region us-east-2
```

5. To verify that replication is working, add a new item to the Music table in US East (Ohio).

```bash
aws dynamodb put-item
--table-name Music
--item '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}'
--region us-east-2
```

6. Wait for a few seconds, and then check to see whether the item has been successfully replicated to US East (N. Virginia) and Europe (Ireland).

```bash
aws dynamodb get-item
--table-name Music
--key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}'
--region us-east-1

aws dynamodb get-item
--table-name Music
--key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}'
--region eu-west-1
```

Monitoring Global Tables

There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626).
You can use Amazon CloudWatch to monitor the behavior and performance of a global table. Amazon DynamoDB publishes `ReplicationLatency` and `PendingReplicationCount` metrics for each replica in the global table.

- **ReplicationLatency**—The elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. ReplicationLatency is expressed in milliseconds and is emitted for every source- and destination-Region pair.

  During normal operation, ReplicationLatency should be fairly constant. An elevated value for ReplicationLatency could indicate that updates from one replica are not propagating to other replica tables in a timely manner. Over time, this could result in other replica tables falling behind because they no longer receive updates consistently. In this case, you should verify that the read capacity units (RCUs) and write capacity units (WCUs) are identical for each of the replica tables. In addition, when choosing WCU settings, follow the recommendations in Best Practices and Requirements for Managing Capacity (p. 642).

  ReplicationLatency can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

- **PendingReplicationCount**—The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table. PendingReplicationCount is expressed in number of items and is emitted for every source- and destination-Region pair.

  During normal operation, PendingReplicationCount should be very low. If PendingReplicationCount increases for extended periods, investigate whether your replica tables' provisioned write capacity settings are sufficient for your current workload.

  PendingReplicationCount can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

For more information, see DynamoDB Metrics and Dimensions (p. 858).

**Using IAM with Global Tables**

| There are two versions of DynamoDB global tables available: Version 2019.11.21 (Current) (p. 626) and Version 2017.11.29 (p. 639). To find out which version you are using, see Determine Version (p. 626). |

When you create a global table for the first time, Amazon DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role is named AWSServiceRoleForDynamoDBReplication, and it allows DynamoDB to manage cross-Region replication for global tables on your behalf. Don't delete this service-linked role. If you do, then all of your global tables will no longer function.

For more information about service-linked roles, see Using Service-Linked Roles in the IAM User Guide.

To create and maintain global tables in DynamoDB, you must have the `dynamodb:CreateGlobalTable` permission to access each of the following:

- The replica table that you want to add.
- Each existing replica that's already part of the global table.
- The global table itself.
To update the settings (UpdateGlobalTableSettings) for a global table in DynamoDB, you must have the dynamodb:UpdateGlobalTable, dynamodb:DescribeLimits, application-autoscaling:DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget permissions.

The application-autoscaling:DeleteScalingPolicy and application-autoscaling:DeregisterScalableTarget permissions are required when updating an existing scaling policy. This is so that the global tables service can remove the old scaling policy before attaching the new policy to the table or secondary index.

If you use an IAM policy to manage access to one replica table, you should apply an identical policy to all other replicas within that global table. This practice helps you maintain a consistent permissions model across all of the replica tables.

By using identical IAM policies on all replicas in a global table, you can also avoid granting unintended read and write access to your global table data. For example, consider a user who has access to only one replica in a global table. If that user can write to this replica, DynamoDB propagates the write to all of the other replica tables. In effect, the user can (indirectly) write to all of the other replicas in the global table. This scenario can be avoided by using consistent IAM policies on all of the replica tables.

**Example: Allow the CreateGlobalTable Action**

Before you can add a replica to a global table, you must have the dynamodb:CreateGlobalTable permission for the global table and for each of its replica tables.

The following IAM policy grants permissions to allow the CreateGlobalTable action on all tables.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:CreateGlobalTable"],
            "Resource": "*"
        }
    ]
}
```

**Example: Allow the UpdateGlobalTable, DescribeLimits, application-autoscaling:DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget Actions**

To update the settings (UpdateGlobalTableSettings) for a global table in DynamoDB, you must have the dynamodb:UpdateGlobalTable, dynamodb:DescribeLimits, application-autoscaling:DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget permissions.

The following IAM policy grants permissions to allow the UpdateGlobalTableSettings action on all tables.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:UpdateGlobalTableSettings"]
        }
    ]
}
```
"dynamodb:UpdateGlobalTable",
"dynamodb:DescribeLimits",
"application-autoscaling:DeleteScalingPolicy",
"application-autoscaling:DeregisterScalableTarget"
],
"Resource": "*"
}

Example: Allow the CreateGlobalTable Action for a Specific Global Table Name with Replicas Allowed in Certain Regions Only

The following IAM policy grants permissions to allow the CreateGlobalTable action to create a global table named Customers with replicas in two Regions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "dynamodb:CreateGlobalTable",
      "Resource": [
        "arn:aws:dynamodb::123456789012:global-table/Customers",
        "arn:aws:dynamodb:us-east-1:123456789012:table/Customers",
        "arn:aws:dynamodb:us-west-1:123456789012:table/Customers"
      ]
    }
  ]
}
```
Managing Complex Workflows with DynamoDB Transactions

Amazon DynamoDB transactions simplify the developer experience of making coordinated, all-or-nothing changes to multiple items both within and across tables. Transactions provide atomicity, consistency, isolation, and durability (ACID) in DynamoDB, helping you to maintain data correctness in your applications.

You can use the DynamoDB transactional read and write APIs to manage complex business workflows that require adding, updating, or deleting multiple items as a single, all-or-nothing operation. For example, a video game developer can ensure that players' profiles are updated correctly when they exchange items in a game or make in-game purchases.

With the transaction write API, you can group multiple Put, Update, Delete, and ConditionCheck actions. You can then submit the actions as a single TransactWriteItems operation that either succeeds or fails as a unit. The same is true for multiple Get actions, which you can group and submit as a single TransactGetItems operation.

There is no additional cost to enable transactions for your DynamoDB tables. You pay only for the reads or writes that are part of your transaction. DynamoDB performs two underlying reads or writes of every item in the transaction: one to prepare the transaction and one to commit the transaction. These two underlying read/write operations are visible in your Amazon CloudWatch metrics.

To get started with DynamoDB transactions, download the latest AWS SDK or the AWS Command Line Interface (AWS CLI). Then follow the DynamoDB Transactions Example (p. 657).

The following sections provide a detailed overview of the transaction APIs and how you can use them in DynamoDB.

Amazon DynamoDB Transactions: How It Works

With Amazon DynamoDB transactions, you can group multiple actions together and submit them as a single all-or-nothing TransactWriteItems or TransactGetItems operation. The following sections describe API operations, capacity management, best practices, and other details about using transactional operations in DynamoDB.

Topics
- TransactWriteItems API (p. 650)
- TransactGetItems API (p. 651)

TransactWriteItems API

TransactWriteItems is a synchronous and idempotent write operation that groups up to 25 write actions in a single all-or-nothing operation. These actions can target up to 25 distinct items in one or more DynamoDB tables within the same AWS account and in the same Region. The aggregate size of the items in the transaction cannot exceed 4 MB. The actions are completed atomically so that either all of them succeed or none of them succeeds.

A TransactWriteItems operation differs from a BatchWriteItem operation in that all the actions it contains must be completed successfully, or no changes are made at all. With a BatchWriteItem operation, it is possible that only some of the actions in the batch succeed while the others do not.

You can't target the same item with multiple operations within the same transaction. For example, you can't perform a ConditionCheck and also an Update action on the same item in the same transaction.

You can add the following types of actions to a transaction:

- **Put** — Initiates a PutItem operation to create a new item or replace an old item with a new item, conditionally or without specifying any condition.
- **Update** — Initiates an UpdateItem operation to edit an existing item's attributes or add a new item to the table if it does not already exist. Use this action to add, delete, or update attributes on an existing item conditionally or without a condition.
- **Delete** — Initiates a DeleteItem operation to delete a single item in a table identified by its primary key.
- **ConditionCheck** — Checks that an item exists or checks the condition of specific attributes of the item.

Once a transaction completes, the changes made within that transaction are propagated to global secondary indexes (GSIs), streams, and backups. Since propagation is not immediate or instantaneous, if a table is restored from backup to a point mid-propagation, it might contain some but not all of the changes made during a recent transaction.

Idempotency

You can optionally include a client token when you make a TransactWriteItems call to ensure that the request is idempotent. Making your transactions idempotent helps prevent application errors if the same operation is submitted multiple times due to a connection time-out or other connectivity issue.

If the original TransactWriteItems call was successful, the subsequent TransactWriteItems calls with the same client token return successfully without making any changes. If the ReturnConsumedCapacity parameter is set, the initial TransactWriteItems call returns the number of write capacity units consumed in making the changes. Subsequent TransactWriteItems calls with the same client token return the number of read capacity units consumed in reading the item.

Important Points about Idempotency

- A client token is valid for 10 minutes after the request that uses it finishes. After 10 minutes, any request that uses the same client token is treated as a new request. You should not reuse the same client token for the same request after 10 minutes.
• If you repeat a request with the same client token within the 10-minute idempotency window but change some other request parameter, DynamoDB returns an **IdempotentParameterMismatch** exception.

**Error Handling for Writing**

Write transactions don't succeed under the following circumstances:

• When a condition in one of the condition expressions is not met.
• When a transaction validation error occurs because more than one action in the same **TransactWriteItems** operation targets the same item.
• When a **TransactWriteItems** request conflicts with an ongoing **TransactWriteItems** operation on one or more items in the **TransactWriteItems** request. In this case, the request fails with a **TransactionCanceledException**.
• When there is insufficient provisioned capacity for the transaction to be completed.
• When an item size becomes too large (larger than 400 KB), or a local secondary index (LSI) becomes too large, or a similar validation error occurs because of changes made by the transaction.
• When there is a user error, such as an invalid data format.

For more information about how conflicts with **TransactWriteItems** operations are handled, see Transaction Conflict Handling in DynamoDB (p. 653).

**TransactGetItems API**

**TransactGetItems** is a synchronous read operation that groups up to 25 **Get** actions together. These actions can target up to 25 distinct items in one or more DynamoDB tables within the same AWS account and Region. The aggregate size of the items in the transaction can't exceed 4 MB.

The **Get** actions are performed atomically so that either all of them succeed or all of them fail:

• **Get** — Initiates a **GetItem** operation to retrieve a set of attributes for the item with the given primary key. If no matching item is found, **Get** does not return any data.

**Error Handling for Reading**

Read transactions don't succeed under the following circumstances:

• When a **TransactGetItems** request conflicts with an ongoing **TransactWriteItems** operation on one or more items in the **TransactGetItems** request. In this case, the request fails with a **TransactionCanceledException**.
• When there is insufficient provisioned capacity for the transaction to be completed.
• When there is a user error, such as an invalid data format.

For more information about how conflicts with **TransactGetItems** operations are handled, see Transaction Conflict Handling in DynamoDB (p. 653).

**Isolation Levels for DynamoDB Transactions**

The isolation levels of transactional operations (**TransactWriteItems** or **TransactGetItems**) and other operations are as follows.
SERIALIZABLE

Serializable isolation ensures that the results of multiple concurrent operations are the same as if no operation begins until the previous one has finished.

There is serializable isolation between the following types of operation:

- Between any transactional operation and any standard write operation (PutItem, UpdateItem, or DeleteItem).
- Between any transactional operation and any standard read operation (GetItem).
- Between a TransactWriteItems operation and a TransactGetItems operation.

Although there is serializable isolation between transactional operations, and each individual standard writes in a BatchWriteItem operation, there is no serializable isolation between the transaction and the BatchWriteItem operation as a unit.

Similarly, the isolation level between a transactional operation and individual GetItems in a BatchGetItem operation is serializable. But the isolation level between the transaction and the BatchGetItem operation as a unit is read-committed.

READ-COMMITTED

Read-committed isolation ensures that read operations always return committed values for an item. Read-committed isolation does not prevent modifications of the item immediately after the read operation.

The isolation level is read-committed between any transactional operation and any read operation that involves multiple standard reads (BatchGetItem, Query, or Scan). If a transactional write updates an item in the middle of a BatchGetItem, Query, or Scan operation, the read operation returns the new committed value.

Operation Summary

To summarize, the following table shows the isolation levels between a transaction operation (TransactWriteItems or TransactGetItems) and other operations.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Isolation Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeleteItem</td>
<td>Serializable</td>
</tr>
<tr>
<td>PutItem</td>
<td>Serializable</td>
</tr>
<tr>
<td>UpdateItem</td>
<td>Serializable</td>
</tr>
<tr>
<td>GetItem</td>
<td>Serializable</td>
</tr>
<tr>
<td>BatchGetItem</td>
<td>Read-committed*</td>

<tr>
<td>BatchWriteItem</td>
<td>NOT Serializable*</td>
</tr>
<tr>
<td>Query</td>
<td>Read-committed</td>
</tr>
<tr>

</tbody>
</table>
Levels marked with an asterisk (*) apply to the operation as a unit. However, individual actions within those operations have a *serializable* isolation level.

**Transaction Conflict Handling in DynamoDB**

A transactional conflict can occur during concurrent item-level requests on an item within a transaction. Transaction conflicts can occur in the following scenarios:

- A `PutItem`, `UpdateItem`, or `DeleteItem` request for an item conflicts with an ongoing `TransactWriteItems` request that includes the same item.
- An item within a `TransactWriteItems` request is part of another ongoing `TransactWriteItems` request.
- An item within a `TransactGetItems` request is part of an ongoing `TransactWriteItems`, `BatchWriteItem`, `PutItem`, `UpdateItem`, or `DeleteItem` request.

**Note**

- When a `PutItem`, `UpdateItem`, or `DeleteItem` request is rejected, the request fails with a `TransactionConflictException`.
- If any item-level request within `TransactWriteItems` or `TransactGetItems` is rejected, the request fails with a `TransactionCanceledException`.

If you are using the AWS SDK for Java, the exception contains the list of `CancellationReasons`, ordered according to the list of items in the `TransactItems` request parameter. For other languages, a string representation of the list is included in the exception's error message.

- If an ongoing `TransactWriteItems` or `TransactGetItems` operation conflicts with a concurrent `GetItem` request, both operations can succeed.

The `TransactionConflict CloudWatch metric` is incremented for each failed item-level request.

**Using Transactional APIs in DynamoDB Accelerator (DAX)**

`TransactWriteItems` and `TransactGetItems` are both supported in DynamoDB Accelerator (DAX) with the same isolation levels as in DynamoDB.

`TransactWriteItems` writes through DAX. DAX passes a `TransactWriteItems` call to DynamoDB and returns the response. To populate the cache after the write, DAX calls `TransactGetItems` in the background for each item in the `TransactWriteItems` operation, which consumes additional read capacity units. (For more information, see Capacity Management for Transactions (p. 653).) This functionality enables you to keep your application logic simple and use DAX for both transactional operations and nontransactional ones.

`TransactGetItems` calls are passed through DAX without the items being cached locally. This is the same behavior as for strongly consistent read APIs in DAX.

**Capacity Management for Transactions**

There is no additional cost to enable transactions for your DynamoDB tables. You pay only for the reads or writes that are part of your transaction. DynamoDB performs two underlying reads or writes of every item in the transaction: one to prepare the transaction and one to commit the transaction. The two underlying read/write operations are visible in your Amazon CloudWatch metrics.
Plan for the additional reads and writes that are required by transactional APIs when you are provisioning capacity to your tables. For example, suppose that your application executes one transaction per second, and each transaction writes three 500-byte items in your table. Each item requires two write capacity units (WCUs): one to prepare the transaction and one to commit the transaction. Therefore, you would need to provision six WCUs to the table.

If you were using DynamoDB Accelerator (DAX) in the previous example, you would also use two read capacity units (RCUs) for each item in the TransactWriteItems call. So you would need to provision six additional RCUs to the table.

Similarly, if your application executes one read transaction per second, and each transaction reads three 500-byte items in your table, you would need to provision six read capacity units (RCUs) to the table. Reading each item requires two RCUs: one to prepare the transaction and one to commit the transaction. Also, default SDK behavior is to retry transactions in case of a TransactionInProgressException exception. Plan for the additional read-capacity units (RCUs) that these retries consume. The same is true if you are retrying transactions in your own code using a ClientRequestToken.

**Best Practices for Transactions**

Consider the following recommended practices when using DynamoDB transactions.

- Enable automatic scaling on your tables, or ensure that you have provisioned enough throughput capacity to perform the two read or write operations for every item in your transaction.
- If you are not using an AWS provided SDK, include a ClientRequestToken attribute when you make a TransactWriteItems call to ensure that the request is idempotent.
- Don't group operations together in a transaction if it's not necessary. For example, if a single transaction with 10 operations can be broken up into multiple transactions without compromising the application correctness, we recommend splitting up the transaction. Simpler transactions improve throughput and are more likely to succeed.
- Multiple transactions updating the same items simultaneously can cause conflicts that cancel the transactions. We recommend following DynamoDB best practices for data modeling to minimize such conflicts.
- If a set of attributes is often updated across multiple items as part of a single transaction, consider grouping the attributes into a single item to reduce the scope of the transaction.
- Avoid using transactions for ingesting data in bulk. For bulk writes, it is better to use BatchWriteItem.

**Using Transactional APIs with Global Tables**

Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the region where the write is made originally. Transactions are not supported across regions in global tables. For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) regions and perform a TransactWriteItems operation in the US East (N. Virginia) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated. Changes will only be replicated to other regions once they have been committed in the source region.

**DynamoDB Transactions vs. the AWSLabs Transactions Client Library**

DynamoDB transactions provide a more cost-effective, robust, and performant replacement for the AWSLabs transactions client library. We suggest that you update your applications to use the native, server-side transaction APIs.
Using IAM with DynamoDB Transactions

You can use AWS Identity and Access Management (IAM) to restrict the actions that transactional operations can perform in Amazon DynamoDB. For more information about using IAM policies in DynamoDB, see Using Identity-Based Policies (IAM Policies) for Amazon DynamoDB (p. 829).

Permissions for Put, Update, Delete, and Get actions are governed by the permissions used for the underlying PutItem, UpdateItem, DeleteItem, and GetItem operations. For the ConditionCheck action, you can use the dynamodb:ConditionCheck permission in IAM policies.

The following are examples of IAM policies that you can use to configure the DynamoDB transactions.

Example 1: Allow Transactional Operations

```json
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "dynamodb:ConditionCheckItem",  
        "dynamodb:PutItem",  
        "dynamodb:UpdateItem",  
        "dynamodb:DeleteItem",  
        "dynamodb:GetItem"  
      ],  
      "Resource": [  
        "arn:aws:dynamodb:*:*:table/table04"  
      ]  
    }  
  ]
}
```

Example 2: Allow Only Transactional Operations

```json
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "dynamodb:ConditionCheckItem",  
        "dynamodb:PutItem",  
        "dynamodb:UpdateItem",  
        "dynamodb:DeleteItem",  
        "dynamodb:GetItem"  
      ],  
      "Resource": [  
        "arn:aws:dynamodb:*:*:table/table04"  
      ],  
      "Condition": {  
        "ForAnyValue:StringEquals": {  
          "dynamodb:EnclosingOperation": [  
            "TransactWriteItems",  
            "TransactGetItems"  
          ]  
        }  
      }  
    }  
  ]
}
```
Example 3: Allow Nontransactional Reads and Writes, and Block Transactional Reads and Writes

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "dynamodb:ConditionCheckItem",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem",
        "dynamodb:GetItem"
      ],
      "Resource": [
        "arn:aws:dynamodb:*:*:table/table04"
      ],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "dynamodb:EnclosingOperation": [
            "TransactWriteItems",
            "TransactGetItems"
          ]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:PutItem",
        "dynamodb:DeleteItem",
        "dynamodb:GetItem",
        "dynamodb:UpdateItem"
      ],
      "Resource": [
        "arn:aws:dynamodb:*:*:table/table04"
      ]
    }
  ]
}
```

Example 4: Prevent Information from Being Returned on a ConditionCheck Failure

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:ConditionCheckItem",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem",
        "dynamodb:GetItem"
      ]
    }
  ]
}
```
DynamoDB Transactions Example

As an example of a situation in which Amazon DynamoDB transactions can be useful, consider this sample Java application for an online marketplace.

The application has three DynamoDB tables in the backend:

- Customers — This table stores details about the marketplace customers. Its primary key is a CustomerId unique identifier.
- ProductCatalog — This table stores details such as price and availability about the products for sale in the marketplace. Its primary key is a ProductId unique identifier.
- Orders — This table stores details about orders from the marketplace. Its primary key is an OrderId unique identifier.

Making an Order

The following code snippets illustrate how to use DynamoDB transactions to coordinate the multiple steps that are required to create and process an order. Using a single all-or-nothing operation ensures that if any part of the transaction fails, no actions in the transaction are executed and no changes are made.

In this example, you set up an order from a customer whose customerId is 09e8e9c8-ec48. You then execute it as a single transaction using the following simple order-processing workflow:

1. Determine that the customer ID is valid.
2. Make sure that the product is IN_STOCK, and update the product status to SOLD.
3. Make sure that the order does not already exist, and create the order.

Validate the Customer

First, define an action to verify that a customer with customerId equal to 09e8e9c8-ec48 exists in the customer table.

```
final String CUSTOMER_TABLE_NAME = "Customers";
final String CUSTOMER_PARTITION_KEY = "CustomerId";
final String customerId = "09e8e9c8-ec48";
final HashMap<String, AttributeValue> customerItemKey = new HashMap<>();
customerItemKey.put(CUSTOMER_PARTITION_KEY, new AttributeValue(customerId));
ConditionCheck checkCustomerValid = new ConditionCheck()
    .withTableName(CUSTOMER_TABLE_NAME)
    .withKey(customerItemKey)
    .withConditionExpression("attribute_exists(" + CUSTOMER_PARTITION_KEY + ")");
```
Update the Product Status

Next, define an action to update the product status to SOLD if the condition that the product status is currently set to IN_STOCK is true. Setting the ReturnValuesOnConditionCheckFailure parameter returns the item if the item's product status attribute was not equal to IN_STOCK.

```java
final String PRODUCT_TABLE_NAME = "ProductCatalog";
final String PRODUCT_PARTITION_KEY = "ProductId";
HashMap<String, AttributeValue> productItemKey = new HashMap<>();
productItemKey.put(PRODUCT_PARTITION_KEY, new AttributeValue(productKey));

Map<String, AttributeValue> expressionAttributeValues = new HashMap<>();
expressionAttributeValues.put(":new_status", new AttributeValue("SOLD"));
expressionAttributeValues.put(":expected_status", new AttributeValue("IN_STOCK"));

Update markItemSold = new Update()
    .withTableName(PRODUCT_TABLE_NAME)
    .withKey(productItemKey)
    .withUpdateExpression("SET ProductStatus = :new_status")
    .withExpressionAttributeValues(expressionAttributeValues)
    .withConditionExpression("ProductStatus = :expected_status")
    .withReturnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD);
```

Create the Order

Lastly, create the order as long as an order with that OrderId does not already exist.

```java
final String ORDER_PARTITION_KEY = "OrderId";
final String ORDER_TABLE_NAME = "Orders";

HashMap<String, AttributeValue> orderItem = new HashMap<>();
orderItem.put(ORDER_PARTITION_KEY, new AttributeValue(orderId));
orderItem.put(PRODUCT_PARTITION_KEY, new AttributeValue(productKey));
orderItem.put(CUSTOMER_PARTITION_KEY, new AttributeValue(customerId));
orderItem.put("OrderStatus", new AttributeValue("CONFIRMED"));
orderItem.put("OrderTotal", new AttributeValue("100"));

Put createOrder = new Put()
    .withTableName(ORDER_TABLE_NAME)
    .withItem(orderItem)
    .withReturnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD)
    .withConditionExpression("attribute_not_exists(" + ORDER_PARTITION_KEY + ")");
```

Execute the Transaction

The following example illustrates how to execute the actions defined previously as a single all-or-nothing operation.

```java
Collection<TransactWriteItem> actions = Arrays.asList(
    new TransactWriteItem().withConditionCheck(checkCustomerValid),
    new TransactWriteItem().withUpdate(markItemSold),
    new TransactWriteItem().withPut(createOrder));

TransactWriteItemsRequest placeOrderTransaction = new TransactWriteItemsRequest()
    .withTransactItems(actions)
    .withReturnConsumedCapacity(ReturnConsumedCapacity.TOTAL);

// Execute the transaction and process the result.
try {
```
Reading the Order Details

The following example shows how to read the completed order transactionally across the Orders and ProductCatalog tables.

```java
HashMap<String, AttributeValue> productItemKey = new HashMap<>();
productItemKey.put(PRODUCT_PARTITION_KEY, new AttributeValue(productKey));

HashMap<String, AttributeValue> orderKey = new HashMap<>();
orderKey.put(ORDER_PARTITION_KEY, new AttributeValue(orderId));

Get readProductSold = new Get()
    .withTableName(PRODUCT_TABLE_NAME)
    .withKey(productItemKey);
Get readCreatedOrder = new Get()
    .withTableName(ORDER_TABLE_NAME)
    .withKey(orderKey);

Collection<TransactGetItem> getActions = Arrays.asList(
    new TransactGetItem().withGet(readProductSold),
    new TransactGetItem().withGet(readCreatedOrder));

TransactGetItemsRequest readCompletedOrder = new TransactGetItemsRequest()
    .withTransactItems(getActions)
    .withReturnConsumedCapacity(ReturnConsumedCapacity.TOTAL);

// Execute the transaction and process the result.
try {
    TransactGetItemsResult result = client.transactGetItems(readCompletedOrder);
    System.out.println(result.getResponses());
} catch (ResourceNotFoundException rnf) {
    System.err.println("One of the table involved in the transaction is not found" + rnf.getMessage());
} catch (InternalServerErrorException ise) {
    System.err.println("Internal Server Error" + ise.getMessage());
} catch (TransactionCanceledException tce) {
    System.err.println("Transaction Canceled" + tce.getMessage());
}
```

In-Memory Acceleration with DynamoDB Accelerator (DAX)

Amazon DynamoDB is designed for scale and performance. In most cases, the DynamoDB response times can be measured in single-digit milliseconds. However, there are certain use cases that require response times in microseconds. For these use cases, DynamoDB Accelerator (DAX) delivers fast response times for accessing eventually consistent data.

DAX is a DynamoDB-compatible caching service that enables you to benefit from fast in-memory performance for demanding applications. DAX addresses three core scenarios:

1. As an in-memory cache, DAX reduces the response times of eventually consistent read workloads by an order of magnitude from single-digit milliseconds to microseconds.
2. DAX reduces operational and application complexity by providing a managed service that is API-compatible with DynamoDB. Therefore, it requires only minimal functional changes to use with an existing application.
3. For read-heavy or bursty workloads, DAX provides increased throughput and potential operational cost savings by reducing the need to overprovision read capacity units. This is especially beneficial for applications that require repeated reads for individual keys.

DAX supports server-side encryption. With encryption at rest, the data persisted by DAX on disk will be encrypted. DAX writes data to disk as part of propagating changes from the primary node to read replicas. For more information, see DAX Encryption at Rest (p. 756).

Use Cases for DAX

DAX provides access to eventually consistent data from DynamoDB tables, with microsecond latency. A Multi-AZ DAX cluster can serve millions of requests per second.

DAX is ideal for the following types of applications:
• Applications that require the fastest possible response time for reads. Some examples include real-time bidding, social gaming, and trading applications. DAX delivers fast, in-memory read performance for these use cases.

• Applications that read a small number of items more frequently than others. For example, consider an ecommerce system that has a one-day sale on a popular product. During the sale, demand for that product (and its data in DynamoDB) would sharply increase, compared to all of the other products. To mitigate the impacts of a “hot” key and a non-uniform traffic distribution, you could offload the read activity to a DAX cache until the one-day sale is over.

• Applications that are read-intensive, but are also cost-sensitive. With DynamoDB, you provision the number of reads per second that your application requires. If read activity increases, you can increase your tables’ provisioned read throughput (at an additional cost). Or, you can offload the activity from your application to a DAX cluster, and reduce the number of read capacity units that you need to purchase otherwise.

• Applications that require repeated reads against a large set of data. Such an application could potentially divert database resources from other applications. For example, a long-running analysis of regional weather data could temporarily consume all the read capacity in a DynamoDB table. This situation would negatively impact other applications that need to access the same data. With DAX, the weather analysis could be performed against cached data instead.

DAX is not ideal for the following types of applications:

• Applications that require strongly consistent reads (or that cannot tolerate eventually consistent reads).

• Applications that do not require microsecond response times for reads, or that do not need to offload repeated read activity from underlying tables.

• Applications that are write-intensive, or that do not perform much read activity.

• Applications that are already using a different caching solution with DynamoDB, and are using their own client-side logic for working with that caching solution.

## DAX Usage Notes

• For a list of AWS Regions where DAX is available, see Amazon DynamoDB pricing.

• DAX supports applications written in Go, Java, Node.js, Python, and .NET, using AWS-provided clients for those programming languages.

• DAX does not support Transport Layer Security (TLS).

• DAX is only available for the EC2-VPC platform. (There is no support for the EC2-Classic platform.)

• The DAX cluster service role policy must allow the `dynamodb:DescribeTable` action in order to maintain metadata about the DynamoDB table.

• DAX clusters maintain metadata about the attribute names of items they store. That metadata is maintained indefinitely (even after the item has expired or been evicted from the cache). Applications that use an unbounded number of attribute names can, over time, cause memory exhaustion in the DAX cluster. This limitation applies only to top-level attribute names, not nested attribute names. Examples of problematic top-level attribute names include timestamps, UUIDs, and session IDs.

This limitation applies only to attribute names, not their values. Items like the following are not a problem.

```json
{
  "Id": 123,
  "Title": "Bicycle 123",
  "CreationDate": "2017-10-24T01:02:03+00:00"
}
```
But items like the following are a problem if there are enough of them and they each have a different timestamp.

```json
{
  "Id": 123,
  "Title": "Bicycle 123",
  "2017-10-24T01:02:03+00:00": "created"
}
```

DAX: How It Works

Amazon DynamoDB Accelerator (DAX) is designed to run within an Amazon Virtual Private Cloud (Amazon VPC) environment. The Amazon VPC service defines a virtual network that closely resembles a traditional data center. With a VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings. You can launch a DAX cluster in your virtual network and control access to the cluster by using Amazon VPC security groups.

**Note**

If you created your AWS account after December 4, 2013, you already have a default VPC in each AWS Region. The VPC is ready for you to use immediately—without having to perform any additional configuration steps.

For more information, see Default VPC and Default Subnets in the *Amazon VPC User Guide*.

The following diagram shows a high-level overview of DAX.

![DAX Diagram](image)

To create a DAX cluster, you use the AWS Management Console. Unless you specify otherwise, your DAX cluster runs within your default VPC. To run your application, you launch an Amazon EC2 instance into your Amazon VPC. You then deploy your application (with the DAX client) on the EC2 instance.

At runtime, the DAX client directs all of your application's DynamoDB API requests to the DAX cluster. If DAX can process one of these API requests directly, it does so. Otherwise, it passes the request through to DynamoDB.

Finally, the DAX cluster returns the results to your application.
How DAX Processes Requests

A DAX cluster consists of one or more nodes. Each node runs its own instance of the DAX caching software. One of the nodes serves as the primary node for the cluster. Additional nodes (if present) serve as read replicas. For more information, see Nodes (p. 665).

Your application can access DAX by specifying the endpoint for the DAX cluster. The DAX client software works with the cluster endpoint to perform intelligent load balancing and routing. Incoming requests are evenly distributed across all of the nodes in the cluster.

Read Operations

DAX can respond to the following API calls:

- GetItem
- BatchGetItem
- Query
- Scan

If the request specifies eventually consistent reads (the default behavior), it tries to read the item from DAX:

- If DAX has the item available (a cache hit), DAX returns the item to the application without accessing DynamoDB.
- If DAX does not have the item available (a cache miss), DAX passes the request through to DynamoDB. When it receives the response from DynamoDB, DAX returns the results to the application. But it also writes the results to the cache on the primary node.

**Note**
If there are any read replicas in the cluster, DAX automatically keeps the replicas in sync with the primary node. For more information, see Clusters (p. 665).

If the request specifies strongly consistent reads, DAX passes the request through to DynamoDB. The results from DynamoDB are not cached in DAX. Instead, they are simply returned to the application.

Write Operations

The following DAX API operations are considered "write-through":

- BatchWriteItem
- UpdateItem
- DeleteItem
- PutItem

With these operations, data is first written to the DynamoDB table, and then to the DAX cluster. The operation is successful only if the data is successfully written to both the table and to DAX.
Other Operations

DAX does not recognize any DynamoDB operations for managing tables (such as CreateTable, UpdateTable, and so on). If your application needs to perform these operations, it must access DynamoDB directly rather than using DAX.

For detailed information about DAX and DynamoDB consistency, see DAX and DynamoDB Consistency Models (p. 677).

For information about how transactions work in DAX, see Using Transactional APIs in DynamoDB Accelerator (DAX) (p. 653).

Request Rate Limiting

If the number of requests sent to DAX exceeds the capacity of a node, DAX limits the rate at which it accepts additional requests by returning a ThrottlingException. DAX continuously evaluates your CPU utilization to determine the volume of requests it can process while maintaining a healthy cluster state.

You can monitor the ThrottledRequestCount metric (p. 735) that DAX publishes to Amazon CloudWatch. If you see these exceptions regularly, you should consider scaling up your cluster (p. 729).

Item Cache

DAX maintains an item cache to store the results from GetItem and BatchGetItem operations. The items in the cache represent eventually consistent data from DynamoDB, and are stored by their primary key values.

When an application sends a GetItem or BatchGetItem request, DAX tries to read the items directly from the item cache using the specified key values. If the items are found (cache hit), DAX returns them to the application immediately. If the items are not found (cache miss), DAX sends the request to DynamoDB. DynamoDB processes the requests using eventually consistent reads and returns the items to DAX. DAX stores them in the item cache and then returns them to the application.

The item cache has a Time to Live (TTL) setting, which is 5 minutes by default. DAX assigns a timestamp to every item that it writes to the item cache. An item expires if it has remained in the cache for longer than the TTL setting. If you issue a GetItem request on an expired item, this is considered a cache miss, and DAX sends the GetItem request to DynamoDB.

Note
You can specify the TTL setting for the item cache when you create a new DAX cluster. For more information, see Managing DAX Clusters (p. 727).

DAX also maintains a least recently used (LRU) list for the item cache. The LRU list tracks when an item was first written to the cache, and when the item was last read from the cache. If the item cache becomes full, DAX evicts older items (even if they haven't expired yet) to make room for new items. The LRU algorithm is always enabled for the item cache and is not user-configurable.

For detailed information about the consistency of the item cache in DAX, see DAX Item Cache Behavior (p. 677).

Query Cache

DAX also maintains a query cache to store the results from Query and Scan operations. The items in this cache represent result sets from queries and scans on DynamoDB tables. These result sets are stored by their parameter values.

When an application sends a Query or Scan request, DAX tries to read a matching result set from the query cache using the specified parameter values. If the result set is found (cache hit), DAX returns it
to the application immediately. If the result set is not found (cache miss), DAX sends the request to DynamoDB. DynamoDB processes the requests using eventually consistent reads and returns the result set to DAX. DAX stores it in the query cache and then returns it to the application.

**Note**

You can specify the TTL setting for the query cache when you create a new DAX cluster. For more information, see [Managing DAX Clusters](#). DAX also maintains an LRU list for the query cache. The list tracks when a result set was first written to the cache, and when the result was last read from the cache. If the query cache becomes full, DAX evicts older result sets (even if they have not expired yet) to make room for new result sets. The LRU algorithm is always enabled for the query cache, and is not user-configurable.

For detailed information about the consistency of the query cache in DAX, see [DAX Query Cache Behavior](#).

## DAX Cluster Components

An Amazon DynamoDB Accelerator (DAX) cluster consists of AWS infrastructure components. This section describes these components and how they work together.

### Topics

- Maintenance Window (p. 668)

### Nodes

A *node* is the smallest building block of a DAX cluster. Each node runs an instance of the DAX software, and maintains a single replica of the cached data.

You can scale your DAX cluster in one of two ways:

- By adding more nodes to the cluster. This increases the overall read throughput of the cluster.
- By using a larger node type. Larger node types provide more capacity and can increase throughput. (You must create a new cluster with the new node type.)

Every node within a cluster is of the same node type and runs the same DAX caching software. For a list of available node types, see [Amazon DynamoDB pricing](#).

### Clusters

A *cluster* is a logical grouping of one or more nodes that DAX manages as a unit. One of the nodes in the cluster is designated as the *primary* node, and the other nodes (if any) are *read replicas*. 
The primary node is responsible for the following:

- Fulfilling application requests for cached data.
- Handling write operations to DynamoDB.
- Evicting data from the cache according to the cluster's eviction policy.

When changes are made to cached data on the primary node, DAX propagates the changes to all of the read replica nodes.

Read replicas are responsible for the following:

- Fulfilling application requests for cached data.
- Evicting data from the cache according to the cluster's eviction policy.

However, unlike the primary node, read replicas don't write to DynamoDB.

Read replicas serve two additional purposes:

- **Scalability.** If you have a large number of application clients that need to access DAX concurrently, you can add more replicas for read-scaling. DAX spreads the load evenly across all the nodes in the cluster. (Another way to increase throughput is to use larger cache node types.)
- **High availability.** In the event of a primary node failure, DAX automatically fails over to a read replica and designates it as the new primary. If a replica node fails, other nodes in the DAX cluster can still serve requests until the failed node can be recovered. For maximum fault tolerance, you should deploy read replicas in separate Availability Zones. This configuration ensures that your DAX cluster can continue to function, even if an entire Availability Zone becomes unavailable.

A DAX cluster can support up to 10 nodes per cluster (the primary node, plus a maximum of nine read replicas).

**Important**
For production usage, we strongly recommend using DAX with at least three nodes, where each node is placed in different Availability Zones. Three nodes are required for a DAX cluster to be fault-tolerant.
A DAX cluster can be deployed with one or two nodes for development or test workloads. One- and two-node clusters are not fault-tolerant, and we don't recommend using fewer than three nodes for production use. If a one- or two-node cluster encounters software or hardware errors, the cluster can become unavailable or lose cached data.

### Regions and Availability Zones

A DAX cluster in an AWS Region can only interact with DynamoDB tables that are in the same Region. For this reason, ensure that you launch your DAX cluster in the correct Region. If you have DynamoDB tables in other Regions, you must launch DAX clusters in those Regions too.

Each Region is designed to be completely isolated from the other Regions. Within each Region are multiple Availability Zones. By launching your nodes in different Availability Zones, you can achieve the greatest possible fault tolerance.

**Important**
Don't place all of your cluster's nodes in a single Availability Zone. In this configuration, your DAX cluster becomes unavailable if there is an Availability Zone failure.
For production usage, we strongly recommend using DAX with at least three nodes, where each node is placed in different Availability Zones. Three nodes are required for a DAX cluster to be fault-tolerant.
A DAX cluster can be deployed with one or two nodes for development or test workloads. One- and two-node clusters are not fault-tolerant, and we don't recommend using fewer than three nodes for production use. If a one- or two-node cluster encounters software or hardware errors, the cluster can become unavailable or lose cached data.

**Parameter Groups**

*Parameter groups* are used to manage runtime settings for DAX clusters. DAX has several parameters that you can use to optimize performance (such as defining a TTL policy for cached data). A parameter group is a named set of parameters that you can apply to a cluster. You can thereby ensure that all the nodes in that cluster are configured in exactly the same way.

**Security Groups**

A DAX cluster runs in an Amazon Virtual Private Cloud (Amazon VPC) environment. This environment is a virtual network that is dedicated to your AWS account and is isolated from other VPCs. A *security group* acts as a virtual firewall for your VPC, allowing you to control inbound and outbound network traffic.

When you launch a cluster in your VPC, you add an *ingress* rule to your security group to allow incoming network traffic. The ingress rule specifies the protocol (TCP) and port number (8111) for your cluster. After you add this rule to your security group, the applications that are running within your VPC can access the DAX cluster.

**Cluster ARN**

Every DAX cluster is assigned an *Amazon Resource Name* (ARN). The ARN format is as follows.

```
arn:aws:dax:region:accountID:cache/clusterName
```

You use the cluster ARN in an IAM policy to define permissions for DAX API operations. For more information, see DAX Access Control (p. 746).

**Cluster Endpoint**

Every DAX cluster provides a *cluster endpoint* for use by your application. By accessing the cluster using its endpoint, your application does not need to know the hostnames and port numbers of individual nodes in the cluster. Your application automatically "knows" all the nodes in the cluster, even if you add or remove read replicas.

The following is an example of a cluster endpoint.

```
myDAXcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com:8111
```

**Node Endpoints**

Each of the individual nodes in a DAX cluster has its own hostname and point number. The following is an example of a *node endpoint*.

```
myDAXcluster-a.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com:8111
```

Your application can access a node directly by using its endpoint. However, we recommend that you treat the DAX cluster as a single unit and access it using the cluster endpoint instead. The cluster endpoint insulates your application from having to maintain a list of nodes and keep that list up to date when you add or remove nodes from the cluster.
Subnet Groups

Access to DAX cluster nodes is restricted to applications running on Amazon EC2 instances within an Amazon VPC environment. You can use subnet groups to grant cluster access from Amazon EC2 instances running on specific subnets. A subnet group is a collection of subnets (typically private) that you can designate for your clusters running in an Amazon VPC environment.

When you create a DAX cluster, you must specify a subnet group. DAX uses that subnet group to select a subnet and IP addresses within that subnet to associate with your nodes.

Events

DAX records significant events within your clusters, such as a failure to add a node, success in adding a node, or changes to security groups. By monitoring key events, you can know the current state of your clusters and, depending upon the event, be able to take corrective action. You can access these events using the AWS Management Console or the DescribeEvents action in the DAX management API.

You can also request that notifications be sent to a specific Amazon Simple Notification Service (Amazon SNS) topic. Then you will know immediately when an event occurs in your DAX cluster.

Maintenance Window

Every cluster has a weekly maintenance window during which any system changes are applied. If you don't specify a preferred maintenance window when you create or modify a cache cluster, DAX assigns a 60-minute maintenance window on a randomly selected day of the week.

The 60-minute maintenance window is selected at random from an 8-hour block of time per AWS Region. The following table lists the time blocks for each Region from which the default maintenance windows are assigned.

Creating a DAX Cluster

This section walks you through the first-time setup and usage of Amazon DynamoDB Accelerator (DAX) in your default Amazon Virtual Private Cloud (Amazon VPC) environment. You can create your first DAX cluster using either the AWS Command Line Interface (AWS CLI) or the AWS Management Console.

After you create your DAX cluster, you can access it from an Amazon EC2 instance running in the same VPC. You can then use your DAX cluster with an application program. For more information, see Developing with the DynamoDB Accelerator (DAX) Client (p. 683).

Topics
- Creating an IAM Service Role for DAX to Access DynamoDB (p. 669)
- Creating a DAX Cluster Using the AWS CLI (p. 670)
- Creating a DAX Cluster Using the AWS Management Console (p. 674)

Creating an IAM Service Role for DAX to Access DynamoDB

For your DAX cluster to access DynamoDB tables on your behalf, you must create a service role. A service role is an AWS Identity and Access Management (IAM) role that authorizes an AWS service to act on your behalf. The service role allows DAX to access your DynamoDB tables, as if you were accessing those tables yourself. You must create the service role before you can create the DAX cluster.

If you are using the console, the workflow for creating a cluster checks for the presence of a pre-existing DAX service role. If none is found, the console creates a new service role for you. For more information, see the section called “Step 2: Create a DAX Cluster” (p. 675).

If you are using the AWS CLI, you must specify a DAX service role that you have created previously. Otherwise, you need to create a new service role beforehand. For more information, see Step 1: Create an IAM Service Role for DAX to Access DynamoDB Using the AWS CLI (p. 671).

Permissions Required to Create a Service Role

The AWS managed AdministratorAccess policy provides all the permissions needed for creating a DAX cluster and a service role. If your IAM user has AdministratorAccess attached, no further action is needed.

Otherwise, you must add the following permissions to your IAM policy so that your IAM user can create the service role:

- iam:CreateRole
- iam:CreatePolicy
- iam:AttachRolePolicy
• `iam:PassRole`

Attach these permissions to the user who is trying to perform the action.

**Note**
The `iam:CreateRole`, `iam:CreatePolicy`, `iam:AttachPolicy`, and `iam:PassRole` permissions are not included in the AWS managed policies for DynamoDB. This is by design because these permissions provide the possibility of privilege escalation: That is, a user could use these permissions to create a new administrator policy and then attach that policy to an existing role. For this reason, you (the administrator of your DAX cluster) must explicitly add these permissions to your policy.

**Troubleshooting**

If your user policy is missing the `iam:CreateRole`, `iam:CreatePolicy`, and `iam:AttachPolicy` permissions, you will get error messages. The following table lists these messages and describes how to correct the problems.

<table>
<thead>
<tr>
<th>If you see this error message...</th>

</tr>

<tr>
<td>User: <code>arn:aws:iam::accountID:user/.userName</code> is not authorized to perform: <code>iam:CreateRole</code> on resource: <code>arn:aws:iam::accountID:role/service-role/roleName</code></td>
<td>Add <code>iam:CreateRole</code> to your user policy.</td>
</tr>

</tr>
</tbody>
</table>

**Creating a DAX Cluster Using the AWS CLI**

This section describes how to create an Amazon DynamoDB Accelerator (DAX) cluster using the AWS Command Line Interface (AWS CLI). If you haven't already done so, you must install and configure the AWS CLI. To do this, see the following instructions in the [AWS Command Line Interface User Guide]:

- Installing the AWS CLI
- Configuring the AWS CLI

**Important**
To manage DAX clusters using the AWS CLI, install or upgrade to version 1.11.110 or higher.

All of the AWS CLI examples use the `us-west-2` Region and fictitious account IDs.
Step 1: Create an IAM Service Role for DAX to Access DynamoDB Using the AWS CLI

Before you can create an Amazon DynamoDB Accelerator (DAX) cluster, you must create a service role for it. A service role is an AWS Identity and Access Management (IAM) role that authorizes an AWS service to act on your behalf. The service role allows DAX to access your DynamoDB tables as if you were accessing those tables yourself.

In this step, you create an IAM policy and then attach that policy to an IAM role. This enables you to assign the role to a DAX cluster so that it can perform DynamoDB operations on your behalf.

To create an IAM service role for DAX

1. Create a file named `service-trust-relationship.json` with the following contents.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "dax.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

2. Create the service role.

   ```bash
   aws iam create-role \
   --role-name DAXServiceRoleForDynamoDBAccess \
   --assume-role-policy-document file://service-trust-relationship.json
   ```

3. Create a file named `service-role-policy.json` with the following contents.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Action": [
           "dynamodb:DescribeTable",
           "dynamodb:PutItem",
           "dynamodb:GetItem",
           "dynamodb:UpdateItem",
           "dynamodb:DeleteItem",
           "dynamodb:Query",
           "dynamodb:Scan",
           "dynamodb:BatchGetItem",
           "dynamodb:BatchWriteItem",
           "dynamodb:ConditionCheckItem"
         ]
       }
     ]
   }
   ```
Replace `accountID` with your AWS account ID. To find your AWS account ID, in the upper-right corner of the console, choose your login ID. Your AWS account ID appears in the drop-down menu.

In the Amazon Resource Name (ARN) in the example, `accountID` must be a 12-digit number. Don’t use hyphens or any other punctuation.

4. Create an IAM policy for the service role.

   ```bash
   aws iam create-policy \
   --policy-name DAXServicePolicyForDynamoDBAccess \
   --policy-document file://service-role-policy.json
   ```

   In the output, note the ARN for the policy that you created, as in the following example.

   ```
   arn:aws:iam::123456789012:policy/DAXServicePolicyForDynamoDBAccess
   ```

5. Attach the policy to the service role. Replace `arn` in the following code with the actual role ARN from the previous step.

   ```bash
   aws iam attach-role-policy \
   --role-name DAXServiceRoleForDynamoDBAccess \
   --policy-arn arn
   ```

Next, you specify a subnet group for your default VPC. A subnet group is a collection of one or more subnets within your VPC. See Step 2: Create a Subnet Group (p. 672).

**Step 2: Create a Subnet Group**

Follow this procedure to create a subnet group for your Amazon DynamoDB Accelerator (DAX) cluster using the AWS Command Line Interface (AWS CLI).

**Note**

If you already created a subnet group for your default VPC, you can skip this step.

DAX is designed to run within an Amazon Virtual Private Cloud environment (Amazon VPC). If you created your AWS account after December 4, 2013, you already have a default VPC in each AWS Region. For more information, see Default VPC and Default Subnets in the *Amazon VPC User Guide*.

**To create a subnet group**

1. To determine the identifier for your default VPC, enter the following command.

   ```bash
   aws ec2 describe-vpcs
   ```

   In the output, note the identifier for your default VPC, as in the following example.

   ```
   vpc-12345678
   ```

2. Determine the subnet IDs associated with your default VPC. Replace `vpcID` with your actual VPC ID — for example, `vpc-12345678`.
3. Create the subnet group. Ensure that you specify at least one subnet ID in the `--subnet-ids` parameter.

```bash
aws dax create-subnet-group \
  --subnet-group-name my-subnet-group \
  --subnet-ids subnet-11111111 subnet-22222222 subnet-33333333 subnet-44444444
```

To create the cluster, see Step 3: Create a DAX Cluster Using the AWS CLI (p. 673).

## Step 3: Create a DAX Cluster Using the AWS CLI

Follow this procedure to use the AWS Command Line Interface (AWS CLI) to create an Amazon DynamoDB Accelerator (DAX) cluster in your default Amazon VPC.

### To create a DAX cluster

1. Get the Amazon Resource Name (ARN) for your service role.

   ```bash
   aws iam get-role \
     --role-name DAXServiceRoleForDynamoDBAccess \
     --query "Role.Arn" --output text
   ```

   In the output, note the service role ARN, as in the following example.

   ```
   arn:aws:iam::123456789012:role/DAXServiceRoleForDynamoDBAccess
   ```

2. Create the DAX cluster. Replace `roleARN` with the ARN from the previous step.

   ```bash
   aws dax create-cluster \
     --cluster-name mydaxcluster \
     --node-type dax.r4.large \
     --replication-factor 3 \
     --iam-role-arn roleARN \
     --subnet-group my-subnet-group \
     --sse-specification Enabled=true \
     --region us-west-2
   ```

   All of the nodes in the cluster are of type `dax.r4.large`(`--node-type`). There are three nodes (`--replication-factor`)—one primary node and two replicas.

   To view the cluster status, enter the following command.

   ```bash
   aws dax describe-clusters
   ```

   The status is shown in the output—for example, "Status": "creating".

   **Note**
   Creating the cluster takes several minutes. When the cluster is ready, its status changes to `available`. In the meantime, proceed to Step 4: Configure Security Group Inbound Rules Using the AWS CLI (p. 674) and follow the instructions there.
Step 4: Configure Security Group Inbound Rules Using the AWS CLI

The nodes in your Amazon DynamoDB Accelerator (DAX) cluster use the default security group for your Amazon VPC. For the default security group, you must authorize inbound traffic on TCP port 8111. This allows Amazon EC2 instances in your Amazon VPC to access your DAX cluster.

Note
If you launched your DAX cluster with a different security group (other than default), you must perform this procedure for that group instead.

To configure security group inbound rules

1. To determine the default security group identifier, enter the following command. Replace vpcID with your actual VPC ID (from Step 2: Create a Subnet Group (p. 672)).

   ```bash
   aws ec2 describe-security-groups --filters Name=vpc-id,Values=vpcID,Name=group-name,Values=default --query "SecurityGroups[*].{GroupName:GroupName,GroupId:GroupId}"
   ```

   In the output, note the security group identifier—for example, sg-01234567.

2. Then enter the following. Replace sgID with your actual security group identifier.

   ```bash
   aws ec2 authorize-security-group-ingress --group-id sgID --protocol tcp --port 8111
   ```

Creating a DAX Cluster Using the AWS Management Console

This section describes how to create an Amazon DynamoDB Accelerator (DAX) cluster using the AWS Management Console.

Topics
- Step 1: Create a Subnet Group Using the AWS Management Console (p. 674)
- Step 2: Create a DAX Cluster Using the AWS Management Console (p. 675)
- Step 3: Configure Security Group Inbound Rules Using the AWS Management Console (p. 676)

Step 1: Create a Subnet Group Using the AWS Management Console

Follow this procedure to create a subnet group for your Amazon DynamoDB Accelerator (DAX) cluster using the AWS Management Console.

Note
If you already created a subnet group for your default VPC, you can skip this step.

DAX is designed to run within an Amazon Virtual Private Cloud (Amazon VPC) environment. If you created your AWS account after December 4, 2013, you already have a default VPC in each AWS Region. For more information, see Default VPC and Default Subnets in the Amazon VPC User Guide.

As part of the creation process for a DAX cluster, you must specify a subnet group. A subnet group is a collection of one or more subnets within your VPC. When you create your DAX cluster, the nodes are deployed to the subnets within the subnet group.
To create a subnet group

2. In the navigation pane, choose DAX.
3. Choose Create subnet group.
4. In the Create subnet group window, do the following:
   a. Name—Enter a short name for the subnet group.
   b. Description—Enter a description for the subnet group.
   c. VPC ID—Choose the identifier for your Amazon VPC environment.
   d. Subnets—Choose one or more subnets from the list.

Note
The subnets are distributed among multiple Availability Zones. If you plan to create a multi-node DAX cluster (a primary node and one or more read replicas), we recommend that you choose multiple subnet IDs. Then DAX can deploy the cluster nodes into multiple Availability Zones. If an Availability Zone becomes unavailable, DAX automatically fails over to a surviving Availability Zone. Your DAX cluster will continue to function without interruption.

When the settings are as you want them, choose Create subnet group.

To create the cluster, see Step 2: Create a DAX Cluster Using the AWS Management Console (p. 675).

Step 2: Create a DAX Cluster Using the AWS Management Console

Follow this procedure to create an Amazon DynamoDB Accelerator (DAX) cluster in your default Amazon VPC.

To create a DAX cluster

2. In the navigation pane, under DAX, choose Clusters.
3. Choose Create cluster.
4. In the Create cluster window, do the following:
   a. Cluster name—Enter a short name for your DAX cluster.
   b. Cluster description—Enter a description for the cluster.
   c. Node type—Choose the node type for all of the nodes in the cluster.
   d. Cluster size—Choose the number of nodes in the cluster. A cluster consists of one primary node and up to nine read replicas.

Note
If you want to create a single-node cluster, choose 1. Your cluster will consist of one primary node.
If you want to create a multi-node cluster, choose a number between 3 (one primary and two read replicas) and 10 (one primary and nine read replicas).

Important
For production usage, we strongly recommend using DAX with at least three nodes, where each node is placed in a different Availability Zone. Three nodes are required for a DAX cluster to be fault-tolerant.
A DAX cluster can be deployed with one or two nodes for development or test workloads. One- and two-node clusters are not fault-tolerant, and we don’t recommend using fewer than three nodes for production use. If a one- or two-node cluster encounters software or hardware errors, the cluster can become unavailable or lose cached data.

e. **Encryption**—Choose enable encryption for your DAX cluster to help protect data at rest. For more information, see DAX Encryption at Rest (p. 756).

f. **IAM service role for DynamoDB access**—Choose Create new, and enter the following information:

   - **IAM role name**—Enter a name for an IAM role, for example, DAXServiceRole. The console creates a new IAM role, and your DAX cluster assumes this role at runtime.
   - **IAM policy name**—Enter a name for an IAM policy, for example, DAXServicePolicy. The console creates a new IAM policy and attaches the policy to the IAM role.
   - **IAM role policy**—Choose Read/Write. This allows the DAX cluster to perform read and write operations in DynamoDB.
   - **Target DynamoDB table**—Choose All tables.

g. **Subnet group**—Choose the subnet group that you created in Step 1: Create a Subnet Group Using the AWS Management Console (p. 674).

h. **Security Groups**—Choose default.

A separate service role for DAX to access Amazon EC2 is also required. DAX automatically creates this service role for you. For more information, see Using Service-Linked Roles for DAX.

5. When the settings are as you want them, choose **Launch cluster**.

On the **Clusters** screen, your DAX cluster will be listed with a status of **Creating**.

**Note**
Creating the cluster takes several minutes. When the cluster is ready, its status changes to **Available**.
In the meantime, proceed to Step 3: Configure Security Group Inbound Rules Using the AWS Management Console (p. 676) and follow the instructions there.

### Step 3: Configure Security Group Inbound Rules Using the AWS Management Console

Your Amazon DynamoDB Accelerator (DAX) cluster uses TCP port 8111 for communication, so you must authorize inbound traffic on that port. This allows Amazon EC2 instances in your Amazon VPC to access your DAX cluster.

**Note**
If you launched your DAX cluster with a different security group (other than default), you must perform this procedure for that group instead.

**To configure security group inbound rules**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Choose the default security group. On the **Actions** menu, choose **Edit inbound rules**.
4. Choose **Add Rule**, and enter the following information:
   - **Port Range**—Enter 8111.
   - **Source**—Enter default, and then choose the identifier for your default security group.
When the settings are as you want them, choose **Save**.

# DAX and DynamoDB Consistency Models

Amazon DynamoDB Accelerator (DAX) is a write-through caching service that is designed to simplify the process of adding a cache to DynamoDB tables. Because DAX operates separately from DynamoDB, it is important that you understand the consistency models of both DAX and DynamoDB to ensure that your applications behave as you expect.

In many use cases, the way that your application uses DAX affects the consistency of data within the DAX cluster, and the consistency of data between DAX and DynamoDB.

## Topics
- Consistency Among DAX Cluster Nodes (p. 677)
- DAX Item Cache Behavior (p. 677)
- DAX Query Cache Behavior (p. 679)
- Strongly Consistent and Transactional Reads (p. 680)
- Negative Caching (p. 680)
- Strategies for Writes (p. 681)

## Consistency Among DAX Cluster Nodes

To achieve high availability for your application, we recommend that you provision your DAX cluster with at least three nodes. Then place those nodes in multiple Availability Zones within a Region.

When your DAX cluster is running, it replicates the data among all of the nodes in the cluster (assuming that you provisioned more than one node). Consider an application that performs a successful `UpdateItem` using DAX. This action causes the item cache in the primary node to be modified with the new value. That value is then replicated to all the other nodes in the cluster. This replication is eventually consistent and usually takes less than one second to complete.

In this scenario, it's possible for two clients to read the same key from the same DAX cluster but receive different values, depending on the node that each client accessed. The nodes are all consistent when the update has been fully replicated throughout all the nodes in the cluster. (This behavior is similar to the eventually consistent nature of DynamoDB.)

If you are building an application that uses DAX, that application should be designed so that it can tolerate eventually consistent data.

## DAX Item Cache Behavior

Every DAX cluster has two distinct caches—an item cache and a query cache. For more information, see DAX: How It Works (p. 662).

This section addresses the consistency implications of reading from and writing to the DAX item cache.

## Consistency of Reads

With DynamoDB, the `GetItem` operation performs an eventually consistent read by default. Suppose that you use `UpdateItem` with the DynamoDB client. If you then try to read the same item immediately afterward, you might see the data as it appeared before the update. This is due to propagation delay...
across all the DynamoDB storage locations. Consistency is usually reached within seconds. So if you retry the read, you will likely see the updated item.

When you use `GetItem` with the DAX client, the operation (in this case, an eventually consistent read) proceeds as shown following.

1. The DAX client issues a `GetItem` request. DAX tries to read the requested item from the item cache. If the item is in the cache (cache hit), DAX returns it to the application.
2. If the item is not available (cache miss), DAX performs an eventually consistent `GetItem` operation against DynamoDB.
3. DynamoDB returns the requested item, and DAX stores it in the item cache.
4. DAX returns the item to the application.
5. (Not shown) If the DAX cluster contains more than one node, the item is replicated to all the other nodes in the cluster.

The item remains in the DAX item cache, subject to the Time to Live (TTL) setting and the least recently used (LRU) algorithm for the cache. For more information, see DAX: How It Works (p. 662).

However, during this period, DAX doesn't re-read the item from DynamoDB. If someone else updates the item using a DynamoDB client, bypassing DAX entirely, a `GetItem` request using the DAX client yields different results from the same `GetItem` request using the DynamoDB client. In this scenario, DAX and DynamoDB hold inconsistent values for the same key until the TTL for the DAX item expires.

If an application modifies data in an underlying DynamoDB table, bypassing DAX, the application needs to anticipate and tolerate data inconsistencies that might arise.

**Note**
In addition to `GetItem`, the DAX client also supports `BatchGetItem` requests. `BatchGetItem` is essentially a wrapper around one or more `GetItem` requests, so DAX treats each of these as an individual `GetItem` operation.

**Consistency of Writes**

DAX is a write-through cache, which simplifies the process of keeping the DAX item cache consistent with the underlying DynamoDB tables.
The DAX client supports the same write API operations as DynamoDB (PutItem, UpdateItem, DeleteItem, BatchWriteItem, and TransactWriteItems). When you use these operations with the DAX client, the items are modified in both DAX and DynamoDB. DAX updates the items in its item cache, regardless of the TTL value for these items.

For example, suppose that you issue a GetItem request from the DAX client to read an item from the ProductCatalog table. (The partition key is Id, and there is no sort key.) You retrieve the item whose Id is 101. The QuantityOnHand value for that item is 42. DAX stores the item in its item cache with a specific TTL. For this example, assume that the TTL is 10 minutes. Then, 3 minutes later, another application uses the DAX client to update the same item so that its QuantityOnHand value is now 41. Assuming that the item is not updated again, any subsequent reads of the same item during the next 10 minutes return the cached value for QuantityOnHand (41).

How DAX Processes Writes

DAX is intended for applications that require high-performance reads. As a write-through cache, DAX allows you to issue writes directly so that your writes are immediately reflected in the item cache. You don't need to manage cache invalidation logic because DAX handles it for you.

DAX supports the following write operations: PutItem, UpdateItem, DeleteItem, BatchWriteItem, and TransactWriteItems.

When you send a PutItem, UpdateItem, DeleteItem, or BatchWriteItem request to DAX, the following occurs:

- DAX sends the request to DynamoDB.
- DynamoDB replies to DAX, confirming that the write succeeded.
- DAX writes the item to its item cache.
- DAX returns success to the requester.

When you send a TransactWriteItems request to DAX, the following occurs:

- DAX sends the request to DynamoDB.
- DynamoDB replies to DAX, confirming that the transaction completed.
- DAX returns success to the requester.
- In the background, DAX makes a TransactGetItems request for each item in the TransactWriteItems request to store the item in the item cache. TransactGetItems is used to ensure serializable isolation (p. 652).

If a write to DynamoDB fails for any reason, including throttling, the item is not cached in DAX. The exception for the failure is returned to the requester. This ensures that data is not written to the DAX cache unless it is first written successfully to DynamoDB.

**Note**

Every write to DAX alters the state of the item cache. However, writes to the item cache don't affect the query cache. (The DAX item cache and query cache serve different purposes, and operate independently from one another.)

DAX Query Cache Behavior

DAX caches the results from Query and Scan requests in its query cache. However, these results don't affect the item cache at all. When your application issues a Query or Scan request with DAX, the result set is saved in the query cache—not in the item cache. You can't "warm up" the item cache by performing a Scan operation because the item cache and query cache are separate entities.
Consistency of Query-Update-Query

Updates to the item cache, or to the underlying DynamoDB table, do not invalidate or modify the results stored in the query cache.

To illustrate, consider the following scenario. An application is working with the DocumentRevisions table, which has DocId as its partition key and RevisionNumber as its sort key.

1. A client issues a Query for DocId 101, for all items with RevisionNumber greater than or equal to 5. DAX stores the result set in the query cache and returns the result set to the user.
2. The client issues a PutItem request for DocId 101 with a RevisionNumber value of 20.
3. The client issues the same Query as described in step 1 (DocId 101 and RevisionNumber >= 5).

In this scenario, the cached result set for the Query issued in step 3 is identical to the result set that was cached in step 1. The reason is that DAX does not invalidate Query or Scan result sets based on updates to individual items. The PutItem operation from step 2 is only reflected in the DAX query cache when the TTL for the Query expires.

Your application should consider the TTL value for the query cache and how long your application can tolerate inconsistent results between the query cache and the item cache.

Strongly Consistent and Transactional Reads

To perform a strongly consistent GetItem, BatchGetItem, Query, or Scan request, you set the ConsistentRead parameter to true. DAX passes strongly consistent read requests to DynamoDB. When it receives a response from DynamoDB, DAX returns the results to the client, but it does not cache the results. DAX can’t serve strongly consistent reads by itself because it’s not tightly coupled to DynamoDB. For this reason, any subsequent reads from DAX would have to be eventually consistent reads. And any subsequent strongly consistent reads would have to be passed through to DynamoDB.

DAX handles TransactGetItems requests the same way it handles strongly consistent reads. DAX passes all TransactGetItems requests to DynamoDB. When it receives a response from DynamoDB, DAX returns the results to the client, but it doesn’t cache the results.

Negative Caching

DAX supports negative cache entries in both the item cache and the query cache. A negative cache entry occurs when DAX can’t find requested items in an underlying DynamoDB table. Instead of generating an error, DAX caches an empty result and returns that result to the user.

For example, suppose that an application sends a GetItem request to a DAX cluster, and that there is no matching item in the DAX item cache. This causes DAX to read the corresponding item from the underlying DynamoDB table. If the item doesn’t exist in DynamoDB, DAX stores an empty item in its item cache and returns the empty item to the application. Now suppose that the application sends another GetItem request for the same item. DAX finds the empty item in the item cache and returns it to the application immediately. It does not consult DynamoDB at all.

A negative cache entry remains in the DAX item cache until its item TTL has expired, its LRU is invoked, or the item is modified using PutItem, UpdateItem, or DeleteItem.

The DAX query cache handles negative cache results in a similar way. If an application performs a Query or Scan, and the DAX query cache doesn’t contain a cached result, DAX sends the request to DynamoDB. If there are no matching items in the result set, DAX stores an empty result set in the query cache and returns the empty result set to the application. Subsequent Query or Scan requests yield the same (empty) result set, until the TTL for that result set has expired.
Strategies for Writes

The write-through behavior of DAX is appropriate for many application patterns. However, there are some application patterns where a write-through model might not be appropriate.

For applications that are sensitive to latency, writing through DAX incurs an extra network hop. So a write to DAX is a little slower than a write directly to DynamoDB. If your application is sensitive to write latency, you can reduce the latency by writing directly to DynamoDB instead. For more information, see Write-Around (p. 682).

For write-intensive applications (such as those that perform bulk data loading), you might not want to write all of the data through DAX because only a small percentage of that data is ever read by the application. When you write large amounts of data through DAX, it must invoke its LRU algorithm to make room in the cache for the new items to be read. This diminishes the effectiveness of DAX as a read cache.

When you write an item to DAX, the item cache state is altered to accommodate the new item. (For example, DAX might need to evict older data from the item cache to make room for the new item.) The new item remains in the item cache, subject to the cache's LRU algorithm and the TTL setting for the cache. As long as the item persists in the item cache, DAX doesn't re-read the item from DynamoDB.

Write-Through

The DAX item cache implements a write-through policy. For more information, see How DAX Processes Writes (p. 679).

When you write an item, DAX ensures that the cached item is synchronized with the item as it exists in DynamoDB. This is helpful for applications that need to re-read an item immediately after writing it. However, if other applications write directly to a DynamoDB table, the item in the DAX item cache is no longer in sync with DynamoDB.

To illustrate, consider two users (Alice and Bob), who are working with the ProductCatalog table. Alice accesses the table using DAX, but Bob bypasses DAX and accesses the table directly in DynamoDB.
1. Alice updates an item in the ProductCatalog table. DAX forwards the request to DynamoDB, and the update succeeds. DAX then writes the item to its item cache and returns a successful response to Alice. From that point on, until the item is ultimately evicted from the cache, any user who reads the item from DAX sees the item with Alice’s update.

2. A short time later, Bob updates the same ProductCatalog item that Alice wrote. However, Bob updates the item directly in DynamoDB. DAX does not automatically refresh its item cache in response to updates via DynamoDB. Therefore, DAX users don’t see Bob’s update.

3. Alice reads the item from DAX again. The item is in the item cache, so DAX returns it to Alice without accessing the DynamoDB table.

In this scenario, Alice and Bob see different representations of the same ProductCatalog item. This is the case until DAX evicts the item from the item cache, or until another user updates the same item again using DAX.

**Write-Around**

If your application needs to write large quantities of data (such as a bulk data load), it might make sense to bypass DAX and write the data directly to DynamoDB. Such a write-around strategy reduces write latency. However, the item cache doesn’t remain in sync with the data in DynamoDB.

If you decide to use a write-around strategy, remember that DAX populates its item cache whenever applications use the DAX client to read data. This can be advantageous in some cases because it ensures that only the most frequently read data is cached (as opposed to the most frequently written data).

For example, consider a user (Charlie) who wants to work with a different table, the GameScores table, using DAX. The partition key for GameScores is UserId, so all of Charlie’s scores would have the same UserId.

1. Charlie wants to retrieve all of his scores, so he sends a query to DAX. Assuming that this query has not been issued before, DAX forwards the query to DynamoDB for processing. It stores the results in the DAX query cache, and then returns the results to Charlie. The result set remains available in the query cache until it is evicted.

2. Now suppose that Charlie plays the Meteor Blasters game and achieves a high score. Charlie sends an UpdateItem request to DynamoDB, modifying an item in the GameScores table.
3. Finally, Charlie decides to rerun his earlier query to retrieve all of his data from GameScores. Charlie does not see his high score for Meteor Blasters in the results. This is because the query results come from the query cache, not the item cache. The two caches are independent from one another, so a change in one cache does not affect the other cache.

DAX does not refresh result sets in the query cache with the most current data from DynamoDB. Each result set in the query cache is current as of the time that the Query or Scan operation was performed. Thus, Charlie's Query results don't reflect his PutItem operation. This is the case until DAX evicts the result set from the query cache.

Developing with the DynamoDB Accelerator (DAX) Client

To use DAX from an application, you use the DAX client for your programming language. The DAX client is designed for minimal disruption to your existing Amazon DynamoDB applications—with only a few simple code modifications needed.

**Note**

DAX clients for various programming languages are available on the following site:

**Tutorial: Running a Sample Application Using DynamoDB Accelerator (DAX)**

This tutorial demonstrates how to launch an Amazon EC2 instance in your default virtual private cloud (VPC), connect to the instance, and run a sample application that uses Amazon DynamoDB Accelerator (DAX).

**Note**

To complete this tutorial, you must have a DAX cluster running in your default VPC. If you haven't created a DAX cluster, see Creating a DAX Cluster (p. 669) for instructions.

**Topics**

- Step 1: Launch an Amazon EC2 Instance (p. 684)
- Step 2: Create an IAM User and Policy (p. 685)
- Step 3: Configure an Amazon EC2 Instance (p. 686)
- Step 4: Run a Sample Application (p. 686)
Step 1: Launch an Amazon EC2 Instance

When your Amazon DynamoDB Accelerator (DAX) cluster is available, you can launch an Amazon EC2 instance in your default Amazon VPC. You can then install and run DAX client software on that instance.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance, and do the following:

   Step 1: Choose an Amazon Machine Image (AMI)
   1. In the list of AMIs, find the Amazon Linux AMI, and choose Select.

   Step 2: Choose an Instance Type
   1. In the list of instance types, choose t2.micro.
   2. Choose Next: Configure Instance Details.

   Step 3: Configure Instance Details
   1. For Network, choose your default VPC.
   2. Choose Next: Add Storage.

   Step 4: Add Storage
   1. Skip this step by choosing Next: Add Tags.

   Step 5: Add Tags

   Step 6: Configure Security Group
   1. Choose Select an existing security group.
   2. In the list of security groups, choose default. This is the default security group for your VPC.

   Step 7: Review Instance Launch
   1. Choose Launch.
   2. In the Select an existing key pair or create a new key pair window, do one of the following:
      - If you don't have an Amazon EC2 key pair, choose Create a new key pair and follow the instructions. You are asked to download a private key file (.pem file). You need this file later when you log in to your Amazon EC2 instance.
      - If you already have an existing Amazon EC2 key pair, go to Select a key pair and choose your key pair from the list. You must already have the private key file (.pem file) available in order to log in to your Amazon EC2 instance.
   4. After configuring your key pair, choose Launch Instances.
5. In the console navigation pane, choose **EC2 Dashboard**, and then choose the instance that you launched. In the lower pane, on the **Description** tab, find the **Public DNS** for your instance, for example: `ec2-11-22-33-44.us-west-2.compute.amazonaws.com`. Make a note of this public DNS name because you need it for Step 3: Configure an Amazon EC2 Instance (p. 686).

**Note**
It takes a few minutes for your Amazon EC2 instance to become available. In the meantime, proceed to Step 2: Create an IAM User and Policy (p. 685) and follow the instructions there.

**Step 2: Create an IAM User and Policy**

In this step, you create an AWS Identity and Access Management (IAM) user with a policy that grants access to your Amazon DynamoDB Accelerator (DAX) cluster and to DynamoDB. You can then run applications that interact with your DAX cluster.

**To create an IAM user and policy**

2. In the navigation pane, choose **Users**.
3. Choose **Add user**.
4. On the **Details** page, enter the following information:
   - **User name**—Enter a unique name, for example: `MyDAXUser`.
   - **Access type**—Choose **Programmatic access**.

Choose **Next: Permissions**.

5. On the **Set permissions** page, choose **Attach existing policies directly**, and then choose **Create policy**.

6. On the **Create policy** page, choose **Create Your Own Policy**.

7. On the **Review policy** page, provide the following information:
   - **Policy Name**—Enter a unique name, for example, `MyDAXUserPolicy`.
   - **Description**—Enter a short description for the policy.
   - **Policy Document**—Copy and paste the following document.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "dax:*"
      ],
      "Effect": "Allow",
      "Resource": [
        "*"
      ]
    },
    {
      "Action": [
        "dynamodb:*"
      ],
      "Effect": "Allow",
      "Resource": [
        "*"
      ]
    }
  ]
}
```
Choose **Create policy**.

8. Return to the **Permissions** page. In the list of policies, choose **Refresh**.

9. To narrow the list of policies, choose **Filter**, **Customer managed**. Choose the IAM policy that you created in the previous step (for example: MyDAXUserPolicy), and then choose **Next: Review**.

10. On the **Review** page, choose **Create user**.

11. On the **Complete** page, go to the **Secret access key** and choose **Show**. After you do this, copy both the **Access key ID** and **Secret access key**. You need both of these identifiers for **Step 3: Configure an Amazon EC2 Instance** (p. 686).

### Step 3: Configure an Amazon EC2 Instance

When your Amazon EC2 instance is available, you can log in to the instance and prepare it for use.

**Note**
The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see **Connect to Your Linux Instance** in the **Amazon EC2 User Guide for Linux Instances**.

To configure the EC2 instance

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Use the `ssh` command to log in to your Amazon EC2 instance, as shown in the following example.

   ```
   ssh -i my-keypair.pem ec2-user@public-dns-name
   ```

   You need to specify your private key file (.pem file) and the public DNS name of your instance. (See **Step 1: Launch an Amazon EC2 Instance** (p. 684).)

   The login ID is **ec2-user**. No password is required.

3. After you log in to your EC2 instance, configure your AWS credentials as shown following. Enter your AWS access key ID and secret key (from **Step 2: Create an IAM User and Policy** (p. 685)), and set the default Region name to your current Region. (In the following example, the default Region name is us-west-2.)

   ```
   aws configure
   AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
   AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
   Default region name [None]: us-west-2
   Default output format [None]:
   ```

After launching and configuring your Amazon EC2 instance, you can test the functionality of DAX using one of the available sample applications. For more information, see **Step 4: Run a Sample Application** (p. 686).

### Step 4: Run a Sample Application

To help you test Amazon DynamoDB Accelerator (DAX) functionality, you can run one of the available sample applications on your Amazon EC2 instance.
Topics

- DAX SDK for Go (p. 687)
- Java and DAX (p. 689)
- .NET and DAX (p. 698)
- Node.js and DAX (p. 707)
- Python and DAX (p. 714)

DAX SDK for Go

Follow this procedure to run the Amazon DynamoDB Accelerator (DAX) SDK for Go sample application on your Amazon EC2 instance.

To run the SDK for Go sample for DAX

1. Set up the SDK for Go on your Amazon EC2 instance:
   a. Install the Go programming language (Golang).
      
      ```bash
      sudo yum install -y golang
      ```
   b. Set the GOPATH environment variable.
      
      ```bash
      # GOROOT is the location where Go package is installed on your system
      export GOROOT=/usr/lib/golang

      # GOPATH is the location of your work directory
      export GOPATH=$HOME/projects

      # PATH in order to access go binary system wide
      export PATH=$PATH:$GOROOT/bin
      ```

      **Note**
      The preceding commands set the environment variables for your current session only. To make these settings permanent, add the commands in the `~/.bash_profile` file.
   c. Test that Golang is installed and running correctly.
      
      ```bash
      go version
      ```
      The following message should appear.

      ```
      go version go1.9.6 linux/amd64/
      ```

2. Install the DAX Golang client.
   
   ```bash
   go get github.com/aws/aws-dax-go
   ```

3. Install the sample Golang application.
   
   ```bash
   go get github.com/aws-samples/aws-dax-go-sample
   ```

4. Run the following Golang programs. The first program creates a DynamoDB table named TryDaxGoTable. The second program writes data to the table.
5. Run the following Golang programs.

```go
go run $GOPATH/src/github.com/aws-samples/aws-dax-go-sample/try_dax.go -service dynamodb -command create-table
```

```go
go run $GOPATH/src/github.com/aws-samples/aws-dax-go-sample/try_dax.go -service dynamodb -command put-item
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

6. In the previous step, you ran the programs against the DynamoDB endpoint. Now, run the programs again, but this time, the GetItem, Query, and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

  ```
  mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
  ```

- **Using the AWS CLI** — Enter the following command.

  ```
  aws dax describe-clusters --query "Clusters[*.ClusterDiscoveryEndpoint"
  ```

  The cluster endpoint port and address are shown in the output, as in the following example.

  ```
  {
    "Port": 8111,
    "Address":"mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com"
  }
  ```

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```go
go run $GOPATH/src/github.com/aws-samples/aws-dax-go-sample/try_dax.go -service dax -command get-item -endpoint mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
```

```go
go run $GOPATH/src/github.com/aws-samples/aws-dax-go-sample/try_dax.go -service dax -command query -endpoint mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
```
go run $GOPATH/src/github.com/aws-samples/aws-dax-go-sample/try_dax.go -service dax -command scan -endpoint mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

7. Run the following Golang program to delete TryDaxGoTable.

```go
go run $GOPATH/src/github.com/aws-samples/aws-dax-go-sample/try_dax.go -service dynamodb -command delete-table
```

Java and DAX

Follow this procedure to run the Java sample for Amazon DynamoDB Accelerator (DAX) on your Amazon EC2 instance.

**To run the Java sample for DAX**

1. Install the Java Development Kit (JDK).
   ```bash
   sudo yum install -y java-devel
   ```

2. Download the AWS SDK for Java (.zip file), and then extract it.
   ```bash
   wget http://sdk-for-java.amazonwebservices.com/latest/aws-java-sdk.zip
   unzip aws-java-sdk.zip
   ```

3. Download the latest version of the DAX Java client (.jar file).
   ```bash
   wget http://dax-sdk.s3-website-us-west-2.amazonaws.com/java/DaxJavaClient-latest.jar
   ```

   **Note**
   The client for the DAX SDK for Java is available on Apache Maven. For more information, see Using the Client as an Apache Maven Dependency (p. 691).

4. Set your CLASSPATH variable. In this example, replace `sdkVersion` with the actual version number of the AWS SDK for Java (for example, 1.11.112).
   ```bash
   export SDKVERSION=sdkVersion
   ```

5. Download the sample program source code (.zip file).
   ```bash
   wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
   ```

   When the download is complete, extract the source files.
6. Compile the code as follows.

   *unzip TryDax.zip*

   *javac TryDax*.java*

7. Run the program.

   *java TryDax*

You should see output similar to the following.

```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.
8. In the previous step, you ran the program against the DynamoDB endpoint. Now run the program again, but this time, the GetItem, Query, and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

  mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111

- **Using the AWS CLI** — Enter the following command.

  `aws dax describe-clusters --query "Clusters[0].ClusterDiscoveryEndpoint"`

The cluster endpoint port and address are shown in the output, as in the following example.

```
{
  "Port": 8111,
  "Address":"mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com"
}
```

Now run the program again, but this time, specify the cluster endpoint as a command line parameter.

`java TryDax mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111`

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

For more information about this program, see the following sections:

- TryDax.java (p. 692)
- TryDaxHelper.java (p. 693)
- TryDaxTests.java (p. 696)

**Using the Client as an Apache Maven Dependency**

Follow these steps to use the client for the DAX SDK for Java in your application as a dependency.

**To use the client as a Maven dependency**

1. Download and install Apache Maven. For more information, see Downloading Apache Maven and Installing Apache Maven.
2. Add the client Maven dependency to your application's Project Object Model (POM) file. In this example, replace `x.x.x.x` with the actual version number of the client (for example, `1.0.200704.0`).

```xml
<dependency>
  <groupId>com.amazonaws.dax</groupId>
  <artifactId>dax-java-library</artifactId>
  <version>1.0.200704.0</version>
</dependency>
```
TryDax.java

The TryDax.java file contains the main method. If you run the program with no command line parameters, it creates an Amazon DynamoDB client and uses that client for all API operations. If you specify a DynamoDB Accelerator (DAX) cluster endpoint on the command line, the program also creates a DAX client and uses it for GetItem, Query, and Scan operations.

You can modify the program in several ways:

- Use the DAX client instead of the DynamoDB client. For more information, see Java and DAX (p. 689).
- Choose a different name for the test table.
- Modify the number of items written by changing the helper.writeData parameters. The second parameter is the number of partition keys, and the third parameter is the number of sort keys. By default, the program uses 1–10 for partition key values and 1–10 for sort key values, for a total of 100 items written to the table. For more information, see TryDaxHelper.java (p. 693).
- Modify the number of GetItem, Query, and Scan tests, and modify their parameters.
- Comment out the lines containing helper.createTable and helper.deleteTable (if you don't want to create and delete the table each time you run the program).

Note

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the Client as an Apache Maven Dependency (p. 691).
Alternatively, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX (p. 689) for an example of setting your CLASSPATH variable.

```java
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
public class TryDax {
    public static void main(String[] args) throws Exception {
        TryDaxHelper helper = new TryDaxHelper();
        TryDaxTests tests = new TryDaxTests();
        DynamoDB ddbClient = helper.getDynamoDBClient();
        DynamoDB daxClient = null;
    }
```

if (args.length >= 1) {
    daxClient = helper.getDaxClient(args[0]);
}

String tableName = "TryDaxTable";
System.out.println("Creating table...");
helper.createTable(tableName, ddbClient);
System.out.println("Populating table...");
helper.writeData(tableName, ddbClient, 10, 10);

DynamoDB testClient = null;
if (daxClient != null) {
    testClient = daxClient;
} else {
    testClient = ddbClient;
}

System.out.println("Running GetItem, Scan, and Query tests...");
System.out.println("First iteration of each test will result in cache misses");
System.out.println("Next iterations are cache hits\n");

// GetItem
tests.GetItemTest(tableName, testClient, 1, 10, 5);

// Query
tests.QueryTest(tableName, testClient, 5, 2, 9, 5);

// Scan
tests.ScanTest(tableName, testClient, 5);

helper.deleteTable(tableName, ddbClient);
}

TryDaxHelper.java

The TryDaxHelper.java file contains utility methods.

The getDynamoDBClient and getDaxClient methods provide Amazon DynamoDB and DynamoDB Accelerator (DAX) clients. For control plane operations (CreateTable, DeleteTable) and write operations, the program uses the DynamoDB client. If you specify a DAX cluster endpoint, the main program creates a DAX client for performing read operations (GetItem, Query, Scan).

The other TryDaxHelper methods (createTable, writeData, deleteTable) are for setting up and tearing down the DynamoDB table and its data.

You can modify the program in several ways:

- Use different provisioned throughput settings for the table.
- Modify the size of each item written (see the stringSize variable in the writeData method).
- Modify the number of GetItem, Query, and Scan tests and their parameters.
- Comment out the lines containing helper.CreateTable and helper.DeleteTable (if you don't want to create and delete the table each time you run the program).
**Note**

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the Client as an Apache Maven Dependency (p. 691).

Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX (p. 689) for an example of setting your CLASSPATH variable.

TryDaxTests.java

The TryDaxTests.java file contains methods that perform read operations against a test table in Amazon DynamoDB. These methods are not concerned with how they access the data (using either the DynamoDB client or the DAX client), so there is no need to modify the application logic.

You can modify the program in several ways:

- Modify the queryTest method so that it uses a different KeyConditionExpression.
- Add a ScanFilter to the scanTest method so that only some of the items are returned to you.

Note

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the Client as an Apache Maven Dependency (p. 691).

Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX (p. 689) for an example of setting your CLASSPATH variable.

Follow these steps to run the .NET sample on your Amazon EC2 instance.

Note
This tutorial uses the .NET Core SDK. It shows how you can run a program in your default Amazon VPC to access your Amazon DynamoDB Accelerator (DAX) cluster. If you prefer, you can use the AWS Toolkit for Visual Studio to write a .NET application and deploy it into your VPC. For more information, see Creating and Deploying Elastic Beanstalk Applications in .NET Using AWS Toolkit for Visual Studio in the AWS Elastic Beanstalk Developer Guide.

To run the .NET sample for DAX

1. Go to the Microsoft Downloads page and download the latest .NET Core SDK for Linux. The downloaded file is `dotnet-sdk-N.N.N-linux-x64.tar.gz`.

2. Extract the .NET Core files.

   ```bash
   mkdir dotnet
   tar zxvf dotnet-sdk-N.N.N-linux-x64.tar.gz -C dotnet
   ```

   Replace `N.N.N` with the actual version number of the .NET Core SDK (for example: `2.1.4`).

3. Verify the installation.

   ```bash
   alias dotnet=$HOME/dotnet/dotnet
   dotnet --version
   ```

   This should print the version number of the .NET Core SDK.

   Note
   Instead of the version number, you might receive the following error:
   
   ```bash
   error: libunwind.so.8: cannot open shared object file: No such file or directory
   ```
   
   To resolve the error, install the `libunwind` package.

   ```bash
   sudo yum install -y libunwind
   ```

   After you do this, you should be able to run the `dotnet --version` command without any errors.

4. Create a new .NET project.

   ```bash
   dotnet new console -o myApp
   ```

   This requires a few minutes to perform a one-time-only setup. When it is complete, run the sample project.

   ```bash
   dotnet run --project myApp
   ```

   You should receive the following message: Hello World!
5. The `myApp/myApp.csproj` file contains metadata about your project. To use the DAX client in your application, modify the file so that it looks like the following.

```xml
<Project Sdk="Microsoft.NET.Sdk">
    <PropertyGroup>
        <OutputType>Exe</OutputType>
        <TargetFramework>netcoreapp2.0</TargetFramework>
    </PropertyGroup>
    <ItemGroup>
        <PackageReference Include="AWSSDK.DAX.Client" Version="*" />
    </ItemGroup>
</Project>
```

6. Download the sample program source code (.zip file).

```bash
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
```

When the download is complete, extract the source files.

```bash
unzip TryDax.zip
```

7. Now run the sample programs, one at a time. For each program, copy its contents into the `myApp/Program.cs`, and then run the `MyApp` project.

Run the following .NET programs. The first program creates a DynamoDB table named `TryDaxTable`. The second program writes data to the table.

```bash
cp 01-CreateTable.cs myApp/Program.cs
dotnet run --project myApp
cp 02-Write-Data.cs myApp/Program.cs
dotnet run --project myApp
```

8. Next, run some programs to perform `GetItem`, `Query`, and `Scan` operations on your DAX cluster. To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

  ```text
  mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
  ```

- **Using the AWS CLI** — Enter the following command.

  ```bash
  aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
  ```

  The cluster endpoint port and address are shown in the output, as in the following example.

  ```json
  {
    "Port": 8111,
    "Address": "mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com"
  }
  ```

Now run the following programs, specifying your cluster endpoint as a command line parameter. (Replace the sample endpoint with your actual DAX cluster endpoint.)
Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

9. Run the following .NET program to delete TryDaxTable.

```csharp
cp 06-DeleteTable.cs myApp/Program.cs
dotnet run --project myApp
```

For more information about these programs, see the following sections:

- 01-CreateTable.cs (p. 700)
- 02-Write-Data.cs (p. 701)
- 03-GetItem-Test.cs (p. 702)
- 04-Query-Test.cs (p. 703)
- 05-Scan-Test.cs (p. 705)
- 06-DeleteTable.cs (p. 706)

**01-CreateTable.cs**

The 01-CreateTable.cs program creates a table (TryDaxTable). The remaining .NET programs in this section depend on this table.

06-DeleteTable.cs

The 06-DeleteTable.cs program deletes TryDaxTable. Run this program after you have finished testing.

namespace ClientTest
{
    class Program
    {
        static void Main(string[] args)

            var request = new DeleteTableRequest()
            {
                TableName = tableName
            };
            var response = client.DeleteTableAsync(request).Result;
        }
    }
}
Node.js and DAX

Follow these steps to run the Node.js sample application on your Amazon EC2 instance.

To run the Node.js sample for DAX

1. Set up Node.js on your Amazon EC2 instance, as follows:
   a. Install node version manager (nvm).
      ```
      curl -o- https://raw.githubusercontent.com/nvm-sh/nvm/v0.35.3/install.sh | bash
      ```
   b. Use nvm to install Node.js.
      ```
      nvm install 12.16.3
      ```
   c. Test that Node.js is installed and running correctly.
      ```
      node -e "console.log('Running Node.js ' + process.version)"
      ```
      This should display the following message.
      ```
      Running Node.js v12.16.3
      ```

2. Install the DAX Node.js client using the node package manager (npm).
   ```
   npm install amazon-dax-client
   ```

3. Download the sample program source code (.zip file).
   ```
   wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
   ```
   When the download is complete, extract the source files.
   ```
   unzip TryDax.zip
   ```

4. Run the following Node.js programs. The first program creates an Amazon DynamoDB table named TryDaxTable. The second program writes data to the table.
   ```
   node 01-create-table.js
   node 02-write-data.js
   ```

5. Run the following Node.js programs.
   ```
   node 03-getitem-test.js
   ```
Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

6. In the previous step, you ran the programs against the DynamoDB endpoint. Run the programs again, but this time, the GetItem, Query and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following.

- **Using the DynamoDB console**—Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```plain
mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
```

- **Using the AWS CLI**—Enter the following command.

```bash
aws dax describe-clusters --query "Clusters[\*].ClusterDiscoveryEndpoint"
```

The cluster endpoint port and address are shown in the output, as in the following example.

```json
{
  "Port": 8111,
  "Address":"mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com"
}
```

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```bash
node 03-getitem-test.js mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
node 04-query-test.js mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
node 05-scan-test.js mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
```

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

7. Run the following Node.js program to delete TryDaxTable.

```bash
node 06-delete-table
```

For more information about these programs, see the following sections:

- 01-create-table.js (p. 709)

01-create-table.js

The 01-create-table.js program creates a table (TryDaxTable). The remaining Node.js programs in this section depend on this table.

```javascript
const AmazonDaxClient = require('amazon-dax-client');
var AWS = require("aws-sdk");
var region = "us-west-2";
AWS.config.update({
  region: region
});
var dynamodb = new AWS.DynamoDB() //low-level client
var tableName = "TryDaxTable";
var params = {
  TableName : tableName,
  KeySchema: [
    { AttributeName: "pk", KeyType: "HASH"},  //Partition key
    { AttributeName: "sk", KeyType: "RANGE" }  //Sort key
  ],
  AttributeDefinitions: [
    { AttributeName: "pk", AttributeType: "N" },
    { AttributeName: "sk", AttributeType: "N" }
  ],
  ProvisionedThroughput: {
    ReadCapacityUnits: 10,
    WriteCapacityUnits: 10
  }
};
dynamodb.createTable(params, function(err, data) {
  if (err) {
    console.error("Unable to create table. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("Created table. Table description JSON:", JSON.stringify(data, null, 2));
  }
});
```

02-write-data.js

The 02-write-data.js program writes test data to TryDaxTable.

```javascript
```

API Version 2012-08-10
709
```
const AmazonDaxClient = require('amazon-dax-client');
var AWS = require("aws-sdk");
var region = "us-west-2";
AWS.config.update({
  region: region
});
var ddbClient = new AWS.DynamoDB.DocumentClient()
var tableName = "TryDaxTable";

var someData = "X".repeat(1000);
var pkmax = 10;
var skmax = 10;

for (var ipk = 1; ipk <= pkmax; ipk++) {
  for (var isk = 1; isk <= skmax; isk++) {
    var params = {
      TableName: tableName,
      Item: {
        "pk": ipk,
        "sk": isk,
        "someData": someData
      }
    };
    //put item
    ddbClient.put(params, function(err, data) {
      if (err) {
        console.error("Unable to write data: ", JSON.stringify(err, null, 2));
      } else {
        console.log("PutItem succeeded");
      }
    });
  }
}

03-getitem-test.js
The 03-getitem-test.js program performs GetItem operations on TryDaxTable.
```

/**

var daxClient = null;
if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({endpoints: [process.argv[2]], region: region})
  daxClient = new AWS.DynamoDB.DocumentClient({service: dax });
}
var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";
var pk = 1;
var sk = 10;
var iterations = 5;
for (var i = 0; i < iterations; i++) {

        }
      });
    }
  }
  var endTime = new Date().getTime();
  console.log("\tTotal time: ",(endTime - startTime) , "ms - Avg time: ",(endTime - startTime) / iterations, "ms");
04-query-test.js

The 04-query-test.js program performs Query operations on TryDaxTable.

```javascript

    }
  });
}
```
The 05-scan-test.js program performs Scan operations on TryDaxTable.
```javascript
var endTime = new Date().getTime();
console.log("Total time: ", (endTime - startTime), "ms - Avg time: ", (endTime -
startTime) / iterations, "ms");

06-delete-table.js

The 06-delete-table.js program deletes TryDaxTable. Run this program after you have finished
testing.

/**

const AmazonDaxClient = require('amazon-dax-client');
var AWS = require("aws-sdk");

var region = "us-west-2";
AWS.config.update({
  region: region
});

var dynamodb = new AWS.DynamoDB(); //low-level client
var tableName = "TryDaxTable";

var params = {
  TableName : tableName
};

dynamodb.deleteTable(params, function(err, data) {
  if (err) {
    console.error("Unable to delete table. Error JSON:", JSON.stringify(err, null, 2));
  } else {
    console.log("Deleted table. Table description JSON:", JSON.stringify(data, null, 2));
  }
});

Python and DAX

Follow this procedure to run the Python sample application on your Amazon EC2 instance.

To run the Python sample for DAX

1. Install the DAX Python client using the pip utility.
2. Download the sample program source code (.zip file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

3. Run the following Python programs. The first program creates an Amazon DynamoDB table named TryDaxTable. The second program writes data to the table.

```
python 01-create-table.py
python 02-write-data.py
```

4. Run the following Python programs.

```
python 03-getitem-test.py
python 04-query-test.py
python 05-scan-test.py
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now run the programs again, but this time, the GetItem, Query, and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
```

- **Using the AWS CLI** — Enter the following command.

```
aws dax describe-clusters --query "Clusters[0].ClusterDiscoveryEndpoint"
```

The cluster endpoint port and address are shown in the output, as in this example.

```
{
    "Port": 8111,
    "Address":"mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com"
}
```

Run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
python 03-getitem-test.py mycluster.frfx8h.clustercfg.dax.usw2.amazonaws.com:8111
```
Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

6. Run the following Python program to delete TryDaxTable.

```python
python 06-delete-table.py
```

For more information about these programs, see the following sections:

- **01-create-table.py** (p. 716)

- **06-delete-table.py** (p. 720)

**01-create-table.py**

The **01-create-table.py** program creates a table (TryDaxTable). The remaining Python programs in this section depend on this table.

```python
import boto3

def create_dax_table(dyn_resource=None):
    """
    Creates a DynamoDB table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The newly created table.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource('dynamodb')
    table_name = 'TryDaxTable'
    params = {
        'TableName': table_name,
        'KeySchema': [
            {'AttributeName': 'partition_key', 'KeyType': 'HASH'},
            {'AttributeName': 'sort_key', 'KeyType': 'RANGE'}
        ],
        'AttributeDefinitions': [
            {'AttributeName': 'partition_key', 'AttributeType': 'N'},
            {'AttributeName': 'sort_key', 'AttributeType': 'N'}
        ],
        'ProvisionedThroughput': {
            'ReadCapacityUnits': 10,
            'WriteCapacityUnits': 10
        }
    }
    table = dyn_resource.create_table(**params)
    print(f"Creating {table_name}"),
    table.wait_until_exists()
    return table
```
if __name__ == '__main__':
    dax_table = create_dax_table()
    print(f"Created table.")

02-write-data.py

The 02-write-data.py program writes test data to TryDaxTable.

```python
import boto3

def write_data_to_dax_table(key_count, item_size, dyn_resource=None):
    """

    :param key_count: The number of partition and sort keys to use to populate the
                      table. The total number of items is key_count * key_count.
    :param item_size: The size of non-key data for each test item.
    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource('dynamodb')
    table = dyn_resource.Table('TryDaxTable')
    some_data = 'X' * item_size
    for partition_key in range(1, key_count + 1):

                'some_data': some_data
            })
            print(f"Put item ((partition_key), (sort_key)) succeeded.")

if __name__ == '__main__':
    write_key_count = 10
    write_item_size = 1000
    print(f"Writing {write_key_count*write_key_count} items to the table. "
          f"Each item is {write_item_size} characters."")
    write_data_to_dax_table(write_key_count, write_item_size)
```

03-getitem-test.py

The 03-getitem-test.py program performs GetItem operations on TryDaxTable.

```python
import argparse
import sys
import time
import amazondax
import boto3

def get_item_test(key_count, iterations, dyn_resource=None):
    """

05-scan-test.py

The 05-scan-test.py program performs Scan operations on TryDaxTable.

```
Scans the table a specified number of times. The time before the first iteration and the time after the last iteration are both captured and reported.

:param iterations: The number of iterations to run.

              f"{(test_end - test_start)/test_iterations}" )
```

06-delete-table.py

The 06-delete-table.py program deletes TryDaxTable. Run this program after you have finished testing Amazon DynamoDB Accelerator (DAX) functionality.

```python
import boto3

def delete_dax_table(dyn_resource=None):
    ""
    Deletes the demonstration table.
    ""
    if dyn_resource is None:
        dyn_resource = boto3.resource('dynamodb')

table = dyn_resource.Table('TryDaxTable')
table.delete()
print(f"Deleting {table.name}...")
table.wait_until_not_exists()
```
Modifying an Existing Application to Use DAX

If you already have a Java application that uses Amazon DynamoDB, you have to modify it so that it can access your DynamoDB Accelerator (DAX) cluster. You don't have to rewrite the entire application because the DAX Java client is similar to the DynamoDB low-level client included in the AWS SDK for Java.

Suppose that you have a DynamoDB table named Music. The partition key for the table is Artist, and its sort key is SongTitle. The following program reads an item directly from the Music table.

```java
import java.util.HashMap;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {
    public static void main(String[] args) throws Exception {
        // Create a DynamoDB client
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

        GetItemRequest request = new GetItemRequest()
            .withTableName("Music")
            .withKey(key);

        try {
            System.out.println("Attempting to read the item...");
            GetItemResult result = client.getItem(request);
            System.out.println("GetItem succeeded: "+ result);
        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }
    }
}
```

To modify the program, replace the DynamoDB client with a DAX client.

```java
import java.util.HashMap;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {
    public static void main(String[] args) throws Exception {
        // Create a DAX client
        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
        AmazonDaxClient daxClient = daxClientBuilder.build();

        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

        GetItemRequest request = new GetItemRequest()
            .withTableName("Music")
            .withKey(key);

        try {
            System.out.println("Attempting to read the item...");
            GetItemResult result = daxClient.getItem(request);
            System.out.println("GetItem succeeded: "+ result);
        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }
    }
}
```
public static void main(String[] args) throws Exception {
    // Create a DAX client
    AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
    daxClientBuilder.withRegion("us-east-1").withEndpointConfiguration("mydaxcluster.2cmrwl.cluster.cfg.dax.use1.cache.amazonaws.com:8111");
    AmazonDynamoDB client = daxClientBuilder.build();

    /*
    ** ....
    ** Remaining code omitted (it is identical)
    ** ....
    */
}

Using the DynamoDB Document API

The AWS SDK for Java provides a document interface for DynamoDB. The document API acts as a wrapper around the low-level DynamoDB client. For more information, see Document Interfaces.

The document interface can also be used with the low-level DAX client, as shown in the following example.

```java
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.GetItemOutcome;
import com.amazonaws.services.dynamodbv2.document.Table;

public class GetMusicItemWithDocumentApi {
    public static void main(String[] args) throws Exception {
        // Create a DAX client
        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
        daxClientBuilder.withRegion("us-east-1").withEndpointConfiguration("mydaxcluster.2cmrwl.cluster.cfg.dax.use1.cache.amazonaws.com:8111");
        AmazonDynamoDB client = daxClientBuilder.build();

        // Document client wrapper
        DynamoDB docClient = new DynamoDB(client);
        Table table = docClient.getTable("Music");

        try {
            System.out.println("Attempting to read the item...");
            GetItemOutcome outcome = table.getItemOutcome(
                "Artist", "No One You Know",
                "SongTitle", "Scared of My Shadow");
            System.out.println(outcome.getItem());
            System.out.println("GetItem succeeded: " + outcome);
        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }
    }
}
```
DAX Async Client

The AmazonDaxClient is synchronous. For a long-running DAX API operation, such as a Scan of a large table, this can block program execution until the operation is complete. If your program needs to perform other work while a DAX API operation is in progress, you can use ClusterDaxAsyncClient instead.

The following program shows how to use ClusterDaxAsyncClient, along with Java Future, to implement a non-blocking solution.

```java
public class DaxAsyncClientDemo {
  public static void main(String[] args) throws Exception {
    ClientConfig daxConfig = new ClientConfig().withCredentialsProvider(new ProfileCredentialsProvider()).withEndpoints("mydaxcluster.2cmrw1.clustercfg.dax.use1.cache.amazonaws.com:8111");
    AmazonDynamoDBAsync client = new ClusterDaxAsyncClient(daxConfig);

    HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
    key.put("Artist", new AttributeValue().withS("No One You Know"));
    key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

    GetItemRequest request = new GetItemRequest().withTableName("Music").withKey(key);

    Future<GetItemResult> call = client.getItemAsync(request);
    while (!call.isDone()) {
      // Do other processing while you're waiting for the response
      System.out.println("Doing something else for a few seconds...");
      Thread.sleep(3000);
    }
    // The results should be ready by now
    try {
      call.get();
    } catch (ExecutionException e) {
      e.printStackTrace();
    } catch (InterruptedException e) {
      e.printStackTrace();
    }
  }
}
```
Querying Global Secondary Indexes

You can use Amazon DynamoDB Accelerator (DAX) to query global secondary indexes using DynamoDB programmatic interfaces.

The following example demonstrates how to use DAX to query the `CreateDateIndex` global secondary index that is created in Example: Global Secondary Indexes Using the AWS SDK for Java Document API.

The `DaxClient` class instantiates the client objects that are needed to interact with the DynamoDB programming interfaces.

```java
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.util.EC2MetadataUtils;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
public class DaxClient {
    private static final String region = EC2MetadataUtils.getEC2InstanceRegion();
    DynamoDB getDaxDocClient(String daxEndpoint) {
        System.out.println("Creating a DAX client with cluster endpoint "+ daxEndpoint);
        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
        daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
        AmazonDynamoDB client = daxClientBuilder.build();
        return new DynamoDB(client);
    }
```
DynamoDBMapper getDaxMapperClient(String daxEndpoint) {
    System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
    AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
    daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
    AmazonDynamoDB client = daxClientBuilder.build();
    return new DynamoDBMapper(client);
}
}

You can query a global secondary index in the following ways:

- Use the queryIndex method on the QueryIndexDax class defined in the following example. The QueryIndexDax takes as a parameter the client object that is returned by the getDaxDocClient method on the DaxClient class.

- If you are using the object persistence interface, use the queryIndexMapper method on the QueryIndexDax class defined in the following example. The queryIndexMapper takes as a parameter the client object that is returned by the getDaxMapperClient method defined on the DaxClient class.

```
import java.util.Iterator;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import java.util.List;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBQueryExpression;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import java.util.HashMap;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.utils.ValueMap;
import com.amazonaws.services.dynamodbv2.document.spec.QuerySpec;
import com.amazonaws.services.dynamodbv2.document.QueryOutcome;
import com.amazonaws.services.dynamodbv2.document.ItemCollection;
import com.amazonaws.services.dynamodbv2.document.Index;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
public class QueryIndexDax {
    // This is used to query Index using the low-level interface.
    public static void queryIndex(DynamoDB client, String tableName, String indexName) {
        Table table = client.getTable(tableName);
        System.out.println("***********************************************************");
        System.out.print("Querying index " + indexName + "...");
        Index index = table.getIndex(indexName);
        ItemCollection<QueryOutcome> items = null;
        QuerySpec querySpec = new QuerySpec();
        if (indexName == "CreateDateIndex") {
            System.out.println("Issues filed on 2013-11-01");
            querySpec.withKeyConditionExpression("CreateDate = :v_date and begins_with(IssueId, :v_issue)"
                .withValueMap(new ValueMap().withString(":v_date", "2013-11-01").withString(":v_issue", "A-"));
            items = index.query(querySpec);
        } else {
            System.out.println("\nNo valid index name provided");
            return;
        }
    }
```
Iterator<Item> iterator = items.iterator();
System.out.println("Query: printing results...");
while (iterator.hasNext()) {
    System.out.println(iterator.next().toJSONPretty());
}

//This is used to query Index using the high-level mapper interface.
public static void queryIndexMapper(DynamoDBMapper mapper, String tableName, String indexName) {
    HashMap<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
eav.put(":v_date", new AttributeValue().withS("2013-11-01"));
eav.put(":v_issue", new AttributeValue().withS("A-"));
DynamoDBQueryExpression<CreateDate> queryExpression = new DynamoDBQueryExpression<CreateDate>()
    .withIndexName("CreateDateIndex").withConsistentRead(false)
    .withKeyConditionExpression("CreateDate = :v_date and begins_with(IssueId, :v_issue)"
    .withExpressionAttributeValues(eav);
List<CreateDate> items = mapper.query(CreateDate.class, queryExpression);
Iterator<CreateDate> iterator = items.iterator();
System.out.println("Query: printing results...");
while (iterator.hasNext()) {
    CreateDate iterObj = iterator.next();
    System.out.println(iterObj.getCreateDate());
    System.out.println(iterObj.getIssueId());
}
}

The class definition below represents the Issues table and is used in the queryIndexMapper method.

import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIndexHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIndexRangeKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;

@DynamoDBTable(tableName = "Issues")
public class CreateDate {
    private String createDate;
    @DynamoDBHashKey(attributeName = "IssueId")
    private String issueId;

    @DynamoDBIndexHashKey(globalSecondaryIndexName = "CreateDateIndex", attributeName = "CreateDate")
    public String getCreateDate() {
        return createDate;
    }

    public void setCreateDate(String createDate) {
        this.createDate = createDate;
    }

    @DynamoDBIndexRangeKey(globalSecondaryIndexName = "CreateDateIndex", attributeName = "IssueId")
    public String getIssueId() {
        return issueId;
    }
}
Managing DAX Clusters

This section addresses some of the common management tasks for Amazon DynamoDB Accelerator (DAX) clusters.

• Scaling a DAX Cluster (p. 729)
• Customizing DAX Cluster Settings (p. 730)

IAM Permissions for Managing a DAX Cluster

When you administer a DAX cluster using the AWS Management Console or the AWS Command Line Interface (AWS CLI), we strongly recommend that you narrow the scope of actions that users can perform. By doing so, you help mitigate risk while following the principle of least privilege.

The following discussion focuses on access control for the DAX management APIs. For more information, see Amazon DynamoDB Accelerator in the Amazon DynamoDB API Reference.

Note

For more detailed information about managing AWS Identity and Access Management (IAM) permissions, see the following:

• IAM and creating DAX clusters: Creating a DAX Cluster (p. 669).
• IAM and DAX data plane operations: DAX Access Control (p. 746).

For the DAX management APIs, you can't scope API actions to a specific resource. The Resource element must be set to "*". This is different from DAX data plane API operations, such as GetItem, Query, and Scan. Data plane operations are exposed through the DAX client, and those operations can be scoped to specific resources.

To illustrate, consider the following IAM policy document.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "dax:*"
            ],
            "Effect": "Allow",
            "Resource": 
```
Suppose that the intent of this policy is to allow DAX management API calls for the cluster DAXCluster01— and only that cluster.

Now suppose that a user issues the following AWS CLI command.

```bash
aws dax describe-clusters
```

This command fails with a Not Authorized exception because the underlying DescribeClusters API call can’t be scoped to a specific cluster. Even though the policy is syntactically valid, the command fails because the Resource element must be set to "*". However, if the user runs a program that sends DAX data plane calls (such as GetItem or Query) to DAXCluster01, those calls do succeed. This is because DAX data plane APIs can be scoped to specific resources (in this case, DAXCluster01).

If you want to write a single comprehensive IAM policy to encompass both DAX management APIs and DAX data plane APIs, we suggest that you include two distinct statements in the policy document. One of these statements should address the DAX data plane APIs, while the other statement addresses the DAX management APIs.

The following example policy shows this approach. Note how the DAXDataAPIs statement is scoped to the DAXCluster01 resource, but the resource for DAXManagementAPIs must be "*". The actions shown in each statement are for illustration only. You can customize them as needed for your application.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DAXDataAPIs",
         "Action": [
            "dax:GetItem",
            "dax:BatchGetItem",
            "dax:Query",
            "dax:Scan",
            "dax:PutItem",
            "dax:UpdateItem",
            "dax:DeleteItem",
            "dax:BatchWriteItem",
            "dax:DefineAttributeList",
            "dax:DefineAttributeListId",
            "dax:DefineKeySchema",
            "dax:Endpoints"
         ],
         "Effect": "Allow",
         ]
      },
      {
         "Sid": "DAXManagementAPIs",
         "Action": [
            "dax:CreateParameterGroup",
            "dax:CreateSubnetGroup",
            "dax:DecreaseReplicationFactor",
            "dax:DeleteCluster",
            "dax:DeleteParameterGroup"
         ]
      }
   ]
}
```
Scaling a DAX Cluster

There are two options available for scaling a DAX cluster. The first option is horizontal scaling, where you add read replicas to the cluster. The second option is vertical scaling, where you select different node types. For advice on how to approach choosing an appropriate cluster size and node type for your application, see DAX Cluster Sizing Guide (p. 767).

Horizontal Scaling

With horizontal scaling, you can improve throughput for read operations by adding more read replicas to the cluster. A single DAX cluster supports up to 10 read replicas, and you can add or remove replicas while the cluster is running.

The following AWS CLI examples show how to increase or decrease the number of nodes. The `--new-replication-factor` argument specifies the total number of nodes in the cluster. One of the nodes is the primary node, and the other nodes are read replicas.

```
aws dax increase-replication-factor \
  --cluster-name MyNewCluster \
  --new-replication-factor 5
```

```
aws dax decrease-replication-factor \
  --cluster-name MyNewCluster \
  --new-replication-factor 3
```

Note

The cluster status changes to modifying when you modify the replication factor. The status changes to available when the modification is complete.

Vertical Scaling

If you have a large working set of data, your application might benefit from using larger node types. Larger nodes can enable the cluster to store more data in memory, reducing cache misses and improving
overall application performance of the application. (All of the nodes in a DAX cluster must be of the same type.)

If your DAX cluster has a high rate of write operations or cache misses, your application might also benefit from using larger node types. Write operations and cache misses consume resources on the cluster's primary node. Therefore, using larger node types might increase the performance of the primary node and thereby allow a higher throughput for these types of operations.

You can't modify the node types on a running DAX cluster. Instead, you must create a new cluster with the desired node type. For a list of supported node types, see Nodes (p. 665).

You can create a new DAX cluster using the AWS Management Console, AWS CloudFormation, the AWS CLI, or the AWS SDK. (For the AWS CLI, use the `--node-type` parameter to specify the node type.)

## Customizing DAX Cluster Settings

When you create a DAX cluster, the following default settings are used:

- Automatic cache eviction enabled with Time to Live (TTL) of 5 minutes
- No preference for Availability Zones
- No preference for maintenance windows
- Notifications disabled

For new clusters, you can customize the settings at creation time. To do this in the AWS Management Console, clear **Use default settings** to modify the following settings:

- **Network and Security**—Allows you to run individual DAX cluster nodes in different Availability Zones within the current AWS Region. If you choose **No Preference**, the nodes are distributed among Availability Zones automatically.
- **Parameter Group**—A named set of parameters that are applied to every node in the cluster. You can use a parameter group to specify cache TTL behavior. You can change the value of any given parameter within a parameter group (except default parameter group `default.dax.1.0`) at any time.
- **Maintenance Window**—A weekly time period during which software upgrades and patches are applied to the nodes in the cluster. You can choose the start day, start time, and duration of the maintenance window. If you choose **No Preference**, the maintenance window is selected at random from an 8-hour block of time per Region. For more information, see **Maintenance Window (p. 668)**.

  **Note**
  
  Parameter Group and Maintenance Window can also be changed at any time on a running cluster.

When a maintenance event occurs, DAX can notify you using Amazon Simple Notification Service (Amazon SNS). To configure notifications, choose an option from the **Topic for SNS notification** selector. You can create a new Amazon SNS topic, or use an existing topic.

For more information about setting up and subscribing to an Amazon SNS topic, see **Getting Started with Amazon SNS** in the Amazon Simple Notification Service Developer Guide.

## Configuring TTL Settings

DAX maintains two caches for data that it reads from DynamoDB:

- **Item cache**—For items retrieved using `GetItem` or `BatchGetItem`.
- **Query cache**—For result sets retrieved using `Query` or `Scan`.
Tagging Support for DAX

Many AWS services, including DynamoDB, support *tagging*—the ability to label resources with user-defined names. You can assign tags to DAX clusters, allowing you to quickly identify all of your AWS resources that have the same tag, or to categorize your AWS bills by the tags you assign.

For more information, see Adding Tags and Labels to Resources (p. 360).

**Using the AWS Management Console**

**To manage DAX cluster tags**

2. In the navigation pane, under DAX, choose Clusters.
3. Choose the cluster that you want to work with.
4. Choose the Tags tab. You can add, list, edit, or delete your tags here.
   When the settings are as you want them, choose Apply Changes.

Using the AWS CLI

When you use the AWS CLI to manage DAX cluster tags, you must first determine the Amazon Resource Name (ARN) for the cluster. The following example shows how to determine the ARN for a cluster named MyDAXCluster.

```bash
aws dax describe-clusters
   --cluster-name MyDAXCluster
   --query "Clusters[*].ClusterArn"
```

In the output, the ARN will look similar to this: arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster

The following example shows how to tag the cluster.

```bash
aws dax tag-resource
   --tags="Key=ClusterUsage,Value=prod"
```

List all the tags for a cluster.

```bash
aws dax list-tags
```

To remove a tag, specify its key.

```bash
aws dax untag-resource
   --tag-keys ClusterUsage
```

AWS CloudTrail Integration

DAX is integrated with AWS CloudTrail, allowing you to audit DAX cluster activities. You can use CloudTrail logs to view all the changes that have been made at the cluster level. You can also see changes to cluster components such as nodes, subnet groups, and parameter groups. For more information, see Logging DynamoDB Operations by Using AWS CloudTrail (p. 878).

Deleting a DAX Cluster

If you are no longer using a DAX cluster, you should delete it to avoid being charged for unused resources.

You can delete a DAX cluster using the console or the AWS CLI. The following is an example.

```bash
aws dax delete-cluster --cluster-name mydaxcluster
```
Monitoring DAX

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon DynamoDB Accelerator (DAX) and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure, if one occurs.

Before you start monitoring DAX, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

The next step is to establish a baseline for normal DAX performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DAX, you should consider storing historical monitoring data. This stored data gives you a baseline from which to compare current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline, you should, at a minimum, monitor the following items both during load testing and in production:

- CPU utilization and throttled requests, so that you can determine whether you might need to use a larger node type in your cluster. The CPU utilization of your cluster is available through the CPUUtilization CloudWatch metric (p. 735).
- Operation latency (as measured on the client side) should remain consistently within your application's latency requirements.
- Error rates should remain low, as seen from the ErrorRequestCount, FaultRequestCount, and FailedRequestCount CloudWatch metrics (p. 735).

Apart from the preceding items, you should, at a minimum, monitor the following additional items in production:

- Estimated database size and evicted size, so that you can determine whether the cluster's node type has sufficient memory to hold your working set.
- Client connections, so that you can monitor for any unexplained spikes in connections to the cluster.

Monitoring Tools

AWS provides tools that you can use to monitor Amazon DynamoDB Accelerator (DAX). You can configure some of these tools to do the monitoring for you, and some require manual intervention. We recommend that you automate monitoring tasks as much as possible.
Topics

- Automated Monitoring Tools (p. 734)
- Manual Monitoring Tools (p. 734)

Automated Monitoring Tools

You can use the following automated monitoring tools to watch DAX and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring with Amazon CloudWatch (p. 858).

- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see Monitoring Log Files in the Amazon CloudWatch User Guide.

- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see What Is Amazon CloudWatch Events in the Amazon CloudWatch User Guide.

- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Working with CloudTrail Log Files in the AWS CloudTrail User Guide.

Manual Monitoring Tools

Another important part of monitoring DAX involves manually monitoring those items that the CloudWatch alarms don't cover. The DAX, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on DAX.

- The DAX dashboard shows the following:
  - Service health
- The CloudWatch home page shows the following:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:

- Create customized dashboards to monitor the services that you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all of your AWS resource metrics.
- Create and edit alarms to be notified of problems.

Monitoring with Amazon CloudWatch

You can monitor Amazon DynamoDB Accelerator (DAX) using Amazon CloudWatch, which collects and processes raw data from DAX into readable, near real-time metrics. These statistics are recorded for a period of two weeks. You can then access historical information for a better perspective on how
your web application or service is performing. By default, DAX metric data is sent to CloudWatch automatically. For more information, see What Is Amazon CloudWatch? in the Amazon CloudWatch User Guide.

How Do I Use DAX Metrics?

The metrics reported by DAX provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, and not a comprehensive list.

<table>
<thead>
<tr>
<th>How Can I?</th>
<th>Relevant Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine if any system errors occurred</td>
<td>Monitor FaultRequestCount to determine if any requests resulted in an HTTP 500 (server error) code. This can indicate a DAX internal service error or an HTTP 500 in the underlying table's SystemErrors metric.</td>
</tr>
<tr>
<td>Determine if any user errors occurred</td>
<td>Monitor ErrorRequestCount to determine if any requests resulted in an HTTP 400 (client error) code. If you see the error count growing, you might want to investigate and make sure you are sending correct client requests.</td>
</tr>
<tr>
<td>Determine if any cache misses occurred</td>
<td>Monitor ItemCacheMisses to determine the number of times an item was not found in the cache, and QueryCacheMisses and ScanCacheMisses to determine the number of times a query or scan result was not found in the cache.</td>
</tr>
<tr>
<td>Monitor cache hit rates</td>
<td>Use CloudWatch Metric Math to define a cache hit rate metric using math expressions. For example, for the item cache, you can use the expression m1/ SUM([m1, m2]) * 100, where m1 is the ItemCacheHits metric and m2 is the ItemCacheMisses metric for your cluster. For the query and scan caches, you can follow the same pattern using the corresponding query and scan cache metric.</td>
</tr>
</tbody>
</table>

Viewing DAX Metrics and Dimensions

When you interact with Amazon DynamoDB, it sends metrics and dimensions to Amazon CloudWatch. You can use the following procedures to view the metrics for DynamoDB Accelerator (DAX).

To view metrics (console)

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

2. In the navigation pane, choose Metrics.
3. Select the **DAX** namespace.

**To view metrics (AWS CLI)**

- At a command prompt, use the following command.

  
  ```bash
  aws cloudwatch list-metrics --namespace "AWS/DAX"
  ```

**DAX Metrics and Dimensions**

The following sections contain the metrics and dimensions that DAX sends to CloudWatch.

**DAX Metrics**

The following metrics are available from DAX. DAX sends metrics to CloudWatch only when they have a non-zero value.

**Note**

CloudWatch aggregates the following DAX metrics at one-minute intervals:

- CPUUtilization
- NetworkBytesIn
- NetworkBytesOut
- NetworkPacketsIn
- NetworkPacketsOut
- GetItemRequestCount
- BatchGetItemRequestCount
- BatchWriteItemRequestCount
- DeleteItemRequestCount
- PutItemRequestCount
- UpdateItemRequestCount
- TransactWriteItemsCount
- TransactGetItemsCount
- ItemCacheHits
- ItemCacheMisses
- QueryCacheHits
- QueryCacheMisses
- ScanCacheHits
- ScanCacheMisses
- TotalRequestCount
- ErrorRequestCount
- FaultRequestCount
- FailedRequestCount
- QueryRequestCount
- ScanRequestCount
- ClientConnections
- EstimatedDbSize
• **EvictedSize**

Not all statistics, such as Average or Sum, are applicable for every metric. However, all of these values are available through the DAX console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics. In the following table, each metric has a list of valid statistics that are applicable to that metric.

<table>

### Dimensions for DAX Metrics

The metrics for DAX are qualified by the values for the account, cluster ID, or cluster ID and node ID combination. You can use the CloudWatch console to retrieve DAX data along any of the dimensions in the following table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account</td>
<td>Provides aggregated statistics across all nodes in an account.</td>
</tr>
<tr>
<td>ClusterId</td>
<td>Limits the data to a cluster.</td>
</tr>
<tr>
<td>ClusterId, NodeId</td>
<td>Limits the data to a node within a cluster.</td>
</tr>
</tbody>
</table>

### Creating CloudWatch Alarms to Monitor DAX

You can create an Amazon CloudWatch alarm that sends an Amazon Simple Notification Service (Amazon SNS) message when the alarm changes state. An alarm watches a single metric over a time period that you specify. It performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification that is sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

### How Can I Be Notified of Query Cache Misses?

   For more information, see Set Up Amazon Simple Notification Service in the Amazon CloudWatch User Guide.

2. Create the alarm.
Monitoring with CloudWatch

### How Can I Be Notified If Requests Cause Any Internal Error in the Cluster?

   For more information, see Set Up Amazon Simple Notification Service in the Amazon CloudWatch User Guide.

2. Create the alarm.

   ```bash
   Prompt>aws cloudwatch put-metric-alarm \
   --alarm-name FaultRequestCountAlarm \n   --alarm-description "Alarm when a request causes an internal error" \n   --namespace AWS/DAX \n   --metric-name FaultRequestCount \n   --dimensions Name=ClusterID,Value=myCluster \n   --statistic Sum \n   --threshold 0 \n   --comparison-operator GreaterThanThreshold \n   --period 60 \n   --unit Count \n   --evaluation-periods 1 \n   --alarm-actions arn:aws:sns:us-east-1:123456789012:notify-on-system-errors
   ```

3. Test the alarm.

   ```bash
   Prompt>aws cloudwatch set-alarm-state --alarm-name FaultRequestCountAlarm --state-reason "initializing" --state-value OK
   ```

   ```bash
   Prompt>aws cloudwatch set-alarm-state --alarm-name FaultRequestCountAlarm --state-reason "initializing" --state-value ALARM
   ```

**Note**

You can increase or decrease the threshold to one that makes sense for your application. You can also use CloudWatch Metric Math to define a cache miss rate metric and set an alarm over that metric.
Logging DAX Operations Using AWS CloudTrail

Amazon DynamoDB Accelerator (DAX) is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DAX.

To learn more about DAX and CloudTrail, see the DynamoDB Accelerator (DAX) section in Logging DynamoDB Operations by Using AWS CloudTrail (p. 878).

DAX Access Control

DynamoDB Accelerator (DAX) is designed to work together with DynamoDB, to seamlessly add a caching layer to your applications. However, DAX and DynamoDB have separate access control mechanisms. Both services use AWS Identity and Access Management (IAM) to implement their respective security policies, but the security models for DAX and DynamoDB are different.

We highly recommend that you understand both security models, so that you can implement proper security measures for your applications that use DAX.

This section describes the access control mechanisms provided by DAX and provides sample IAM policies that you can tailor to your needs.

With DynamoDB, you can create IAM policies that limit the actions a user can perform on individual DynamoDB resources. For example, you can create a user role that only allows the user to perform read-only actions on a particular DynamoDB table. (For more information, see the section called “Identity and Access Management” (p. 825).) By comparison, the DAX security model focuses on cluster security, and the ability of the cluster to perform DynamoDB API actions on your behalf.

Warning
If you are currently using IAM roles and policies to restrict access to DynamoDB tables data, then the use of DAX can subvert those policies. For example, a user could have access to a DynamoDB table via DAX but not have explicit access to the same table accessing DynamoDB directly. For more information, see the section called “Identity and Access Management” (p. 825).

DAX does not enforce user-level separation on data in DynamoDB. Instead, users inherit the permissions of the DAX cluster’s IAM policy when they access that cluster. Thus, when accessing DynamoDB tables via DAX, the only access controls that are in effect are the permissions in the DAX cluster’s IAM policy. No other permissions are recognized.

If you require isolation, we recommend that you create additional DAX clusters and scope the IAM policy for each cluster accordingly. For example, you could create multiple DAX clusters and allow each cluster to access only a single table.

IAM Service Role for DAX

When you create a DAX cluster, you must associate the cluster with an IAM role. This is known as the service role for the cluster.

Suppose that you wanted to create a new DAX cluster named DAXCluster01. You could create a service role named DAXServiceRole, and associate the role with DAXCluster01. The policy for DAXServiceRole would define the DynamoDB actions that DAXCluster01 could perform, on behalf of the users who interact with DAXCluster01.

When you create a service role, you must specify a trust relationship between DAXServiceRole and the DAX service itself. A trust relationship determines which entities can assume a role and make use of its permissions. The following is an example trust relationship document for DAXServiceRole:

```json
{
    "Version": "2012-10-17",
    "Statement":
        [ 
}
```
This trust relationship allows a DAX cluster to assume `DAXServiceRole` and perform DynamoDB API calls on your behalf.

The DynamoDB API actions that are allowed are described in an IAM policy document, which you attach to `DAXServiceRole`. The following is an example policy document.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DaxAccessPolicy",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:PutItem",
                "dynamodb:GetItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:BatchGetItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": [
            ]
        }
    ]
}
```

This policy allows DAX to perform necessary DynamoDB API actions on a DynamoDB table. The `dynamodb:DescribeTable` action is required for DAX to maintain metadata about the table, and the others are read and write actions performed on items in the table. The table, named `Books`, is in the us-west-2 Region and is owned by AWS account ID 123456789012.

## IAM Policy to Allow DAX Cluster Access

After you create a DAX cluster, you need to grant permissions to an IAM user so that the user can access the DAX cluster.

For example, suppose that you want to grant access to `DAXCluster01` to an IAM user named Alice. You would first create an IAM policy (`AliceAccessPolicy`) that defines the DAX clusters and DAX API actions that the recipient can access. You would then confer access by attaching this policy to user Alice.

The following policy document gives the recipient full access on `DAXCluster01`.

```json
{
    "Version": "2012-10-17",
    "Statement": [
```
The policy document allows access to the DAX cluster, but it does not grant any DynamoDB permissions. (The DynamoDB permissions are conferred by the DAX service role.)

For user Alice, you would first create `AliceAccessPolicy` with the policy document shown previously. You would then attach the policy to Alice.

**Note**
Instead of attaching the policy to an IAM user, you could attach it to an IAM role. That way, all of the users who assume that role would have the permissions that you defined in the policy.

The user policy, together with the DAX service role, determine the DynamoDB resources and API actions that the recipient can access via DAX.

**Case Study: Accessing DynamoDB and DAX**

The following scenario can help further your understanding of IAM policies for use with DAX. (This scenario is referred to throughout the rest of this section.) The following diagram shows a high-level overview of the scenario.

In this scenario, there are the following entities:

- An IAM user (Bob).
- An IAM role (BobUserRole). Bob assumes this role at runtime.
- An IAM policy (BobAccessPolicy). This policy is attached to BobUserRole. BobAccessPolicy defines the DynamoDB and DAX resources that BobUserRole is allowed to access.
- A DAX cluster (DAXCluster01).  

```json
{
  "Action": [
    "dax:*"
  ],
  "Effect": "Allow",
  "Resource": [
    "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
  ]
}
```
• An IAM service role (DAXServiceRole). This role allows DAXCluster01 to access DynamoDB.
• An IAM policy (DAXAccessPolicy). This policy is attached to DAXServiceRole. DAXAccessPolicy defines the DynamoDB APIs and resources that DAXCluster01 is allowed to access.
• A DynamoDB table (Books).

The combination of policy statements in BobAccessPolicy and DAXAccessPolicy determine what Bob can do with the Books table. For example, Bob might be able to access Books directly (using the DynamoDB endpoint), indirectly (using the DAX cluster), or both. Bob might also be able to read data from Books, write data to Books, or both.

Access to DynamoDB, But No Access with DAX

It is possible to allow direct access to a DynamoDB table, while preventing indirect access using a DAX cluster. For direct access to DynamoDB, the permissions for BobUserRole are determined by BobAccessPolicy (which is attached to the role).

Read-Only Access to DynamoDB (Only)

Bob can access DynamoDB with BobUserRole. The IAM policy attached to this role (BobAccessPolicy) determines the DynamoDB tables that BobUserRole can access, and what APIs that BobUserRole can invoke.

Consider the following policy document for BobAccessPolicy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
        }
    ]
}
```
When this document is attached to `BobAccessPolicy`, it allows `BobUserRole` to access the DynamoDB endpoint and perform read-only operations on the `Books` table.

DAX does not appear in this policy, so access via DAX is denied.

### Read/Write Access to DynamoDB (Only)

If `BobUserRole` requires read/write access to DynamoDB, the following policy would work:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DynamoDBAccessStmt",
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:Scan",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem",
        "dynamodb:BatchWriteItem",
        "dynamodb:ConditionCheckItem"
      ],
    }
  ]
}
```

Again, DAX does not appear in this policy, so access via DAX is denied.

### Access to DynamoDB and to DAX

![Diagram showing access to DynamoDB and DAX]

API Version 2012-08-10

750
To allow access to a DAX cluster, you must include DAX-specific actions in an IAM policy.

The following DAX-specific actions correspond to their similarly named counterparts in the DynamoDB API:

- dax:GetItem
- dax:BatchGetItem
- dax:Query
- dax:Scan
- dax:PutItem
- dax:UpdateItem
- dax:DeleteItem
- dax:BatchWriteItem
- dax:ConditionCheckItem

The same is true for the dax:EnclosingOperation condition key.

In addition, there are four other DAX-specific actions that do not correspond to any DynamoDB APIs:

- dax:DefineAttributeList
- dax:DefineAttributeListId
- dax:DefineKeySchema
- dax:Endpoints

You must specify all four of these actions in any IAM policy that allows access to a DAX cluster. These actions are specific to the low-level DAX data transport protocol. Your application does not need to concern itself with these actions—they are only used in IAM policies.

**Read-Only Access to DynamoDB and Read-Only Access to DAX**

Suppose that Bob requires read-only access to the Books table, from DynamoDB and from DAX. The following policy (attached to BobUserRole) confers this access.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DAXAccessStmt",
         "Effect": "Allow",
         "Action": [
            "dax:GetItem",
            "dax:BatchGetItem",
            "dax:Query",
            "dax:Scan",
            "dax:DefineAttributeList",
            "dax:DefineAttributeListId",
            "dax:DefineKeySchema",
            "dax:Endpoints"
         ],
      },
      {
         "Sid": "DynamoDBAccessStmt",
         "Effect": "Allow",
         "Action": ["dynamodb:GetItem",
```
"dynamodb:BatchGetItem",
"dynamodb:Query",
"dynamodb:Scan"
],
} }
]
}

The policy has a statement for DAX access (DAXAccessStmt) and another statement for DynamoDB access (DynamoDBAccessStmt). These statements allow Bob to send GetItem, BatchGetItem, Query, and Scan requests to DAXCluster01.

However, the service role for DAXCluster01 would also require read-only access to the Books table in DynamoDB. The following IAM policy, attached to DAXServiceRole, would fulfill this requirement.

```json
{
  "Version": "2012-10-17",
  "Statement": [
  {
    "Sid": "DynamoDBAccessStmt",
    "Effect": "Allow",
    "Action": [
      "dynamodb:GetItem",
      "dynamodb:BatchGetItem",
      "dynamodb:Query",
      "dynamodb:Scan"
    ],
  }
  }
}
```

Read/Write Access to DynamoDB and Read-Only with DAX

For a given user role, you can provide read/write access to a DynamoDB table, while also allowing read-only access via DAX.

For Bob, the IAM policy for BobUserRole would need to allow DynamoDB read and write actions on the Books table, while also supporting read-only actions via DAXCluster01.

The following example policy document for BobUserRole confers this access.

```json
{
  "Version": "2012-10-17",
  "Statement": [
  {
    "Sid": "DAXAccessStmt",
    "Effect": "Allow",
    "Action": [
      "dax:GetItem",
      "dax:BatchGetItem",
      "dax:Query",
      "dax:Scan",
      "dax:DefineKeySchema",
      "dax:DefineAttributeList",
      "dax:DefineAttributeListId",
      "dax:Endpoints"
    ],
  },
  {
    "Sid": "DynamoDBAccessStmt",
    "Effect": "Allow",
    "Action": [
      "dynamodb:GetItem",
      "dynamodb:BatchGetItem",
      "dynamodb:Query",
      "dynamodb:Scan"
    ],
  }
  }
}
```
"Sid": "DynamoDBAccessStmt",
"Effect": "Allow",
"Action": [
  "dynamodb:GetItem",
  "dynamodb:BatchGetItem",
  "dynamodb:Query",
  "dynamodb:Scan",
  "dynamodb:PutItem",
  "dynamodb:UpdateItem",
  "dynamodb:DeleteItem",
  "dynamodb:BatchWriteItem",
  "dynamodb:DescribeTable",
  "dynamodb:ConditionCheckItem"
],
}

In addition, DAXServiceRole would require an IAM policy that allows DAXCluster01 to perform read-only actions on the Books table.

{
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "DynamoDBAccessStmt",
    "Effect": "Allow",
    "Action": [
      "dynamodb:GetItem",
      "dynamodb:BatchGetItem",
      "dynamodb:Query",
      "dynamodb:Scan",
      "dynamodb:DescribeTable"
    ],
  }
]

Read/Write Access to DynamoDB and Read/Write Access to DAX

Now suppose that Bob required read/write access to the Books table, directly from DynamoDB or indirectly from DAXCluster01. The following policy document, attached to BobAccessPolicy, confers this access.

{
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "DAXAccessStmt",
    "Effect": "Allow",
    "Action": [
      "dax:GetItem",
      "dax:BatchGetItem",
      "dax:Query",
      "dax:Scan",
      "dax:PutItem",
      "dax:UpdateItem",
      "dax:DeleteItem",
      "dax:BatchWriteItem",
      "dax:DefineKeySchema",
      "dax:CreateTable",
      "dax:DropTable",
      "dax:CreateIndices",
      "dax:UpdateIndices",
      "dax:RestoreTableFromSnapshot",
      "dax:RestoreTableFromBackup",
      "dax:ScheduleMaintenanceWindow",
      "dax:MaintenanceWindowStatus",
      "dax:DescribeTable",
      "dax:ListTables",
      "dax:GetTable",
      "dax:ListTagsForResource",
      "dax:TagResource",
      "dax:UntagResource",
      "dax:GetTableContext",
      "dax:UpdateTableContext",
      "dax:CreateMigrationTask",
      "dax:StartMigrationTask",
      "dax:DescribeMigrationTask",
      "dax:CancelMigrationTask",
      "dax:CancelMigrationTaskItems",
      "dax:GetMigrationTask",
      "dax:ListMigrationTasks",
      "dax:ListTagsForResource",
      "dax:TagResource",
      "dax:UntagResource",
      "dax:GetTableContext",
      "dax:UpdateTableContext"
    ],
  }
]
Access to DynamoDB Via DAX, But No Direct Access to DynamoDB

In this scenario, Bob can access the Books table via DAX, but he does not have direct access to the Books table in DynamoDB. Thus, when Bob gains access to DAX, he also gains access to a DynamoDB table that he otherwise might not be able to access. When you configure an IAM policy for the DAX service role, remember that any user that is given access to the DAX cluster via the user access policy gains access to the tables specified in that policy. In this case, BobAccessPolicy gains access to the tables specified in DAXAccessPolicy.

API Version 2012-08-10
754
If you are currently using IAM roles and policies to restrict access to DynamoDB tables and data, using DAX can subvert those policies. In the following policy, Bob has access to a DynamoDB table via DAX but does not have explicit direct access to the same table in DynamoDB.

The following policy document (`BobAccessPolicy`), attached to `BobUserRole`, would confer this access.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DAXAccessStmt",
      "Effect": "Allow",
      "Action": [
        "dax:GetItem",
        "dax:BatchGetItem",
        "dax:Query",
        "dax:Scan",
        "dax:PutItem",
        "dax:UpdateItem",
        "dax:DeleteItem",
        "dax:BatchWriteItem",
        "dax:DefineKeySchema",
        "dax:DefineAttributeList",
        "dax:DefineAttributeListId",
        "dax:Endpoints",
        "dax:ConditionCheckItem"
      ],
    }
  ]
}
```

In this access policy, there are no permissions to access DynamoDB directly.

Together with `BobAccessPolicy`, the following `DAXAccessPolicy` gives `BobUserRole` access to the DynamoDB table `Books` even though `BobUserRole` cannot directly access the `Books` table.

```json
{
  "Version": "2012-10-17",

  "Statement": [
    {
      "Sid": "DAXPermissionsStmt",
      "Effect": "Allow",
      "Action": [
        "dynamodb:BatchGetItem",
        "dynamodb:GetItem",
        "dynamodb:Query",
        "dynamodb:Scan",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem"
      ],
    }
  ]
}
```
As this example shows, when you configure access control for the user access policy and the DAX cluster access policy, you must fully understand the end-to-end access to ensure that the principle of least privilege is observed. Also ensure that giving a user access to a DAX cluster does not subvert previously established access control policies.

## DAX Encryption at Rest

Amazon DynamoDB Accelerator (DAX) encryption at rest provides an additional layer of data protection by helping secure your data from unauthorized access to the underlying storage. Organizational policies, industry or government regulations, and compliance requirements might require the use of encryption at rest to protect your data. You can use encryption to increase the data security of your applications that are deployed in the cloud.

With encryption at rest, the data persisted by DAX on disk is encrypted using 256-bit Advanced Encryption Standard, also known as AES-256 encryption. DAX writes data to disk as part of propagating changes from the primary node to read replicas.

DAX encryption at rest automatically integrates with AWS Key Management Service (AWS KMS) for managing the single service default key that is used to encrypt your clusters. If a service default key doesn't exist when you create your encrypted DAX cluster, AWS KMS automatically creates a new key for you. This key is used with encrypted clusters that are created in the future. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud.

After your data is encrypted, DAX handles the decryption of your data transparently with minimal impact on performance. You don’t need to modify your applications to use encryption.

**Note**

DAX does not call AWS KMS for every single DAX operation. DAX only uses the key at the cluster launch. Even if access is revoked, DAX can still access the data until the cluster is shut down.

Customer-specified AWS KMS keys are not supported.

DAX encryption at rest is available for the following cluster node types.

**Important**

DAX encryption at rest is not supported for dax.r3.* node types.

You cannot enable or disable encryption at rest after a cluster has been created. You must re-create the cluster to enable encryption at rest if it was not enabled at creation.

DAX encryption at rest is offered at no additional cost (AWS KMS encryption key usage charges apply). For information about pricing, see [Amazon DynamoDB Pricing](https://aws.amazon.com/dynamodb/pricing/).

### Enabling Encryption at Rest Using the AWS Management Console

Follow these steps to enable DAX encryption at rest on a table using the console.

**To enable DAX encryption at rest**

2. In the navigation pane on the left side of the console, under DAX, choose Clusters.
3. Choose Create cluster.
4. For Cluster name, enter a short name for your cluster. Choose the node type for all of the nodes in the cluster, and for the cluster size, use 3 nodes.
5. In Encryption, make sure that Enable encryption is selected.

![Encryption](enable_encryption.png)

You may enable encryption for your DAX cluster to help protect data at rest. [Learn more](https://aws.amazon.com/dynamodb/pricing/)

6. After choosing the IAM role, subnet group, security groups, and cluster settings, choose Launch cluster.

To confirm that the cluster is encrypted, check the cluster details under the Clusters pane. Encryption should be ENABLED.

### Using Service-Linked IAM Roles for DAX

Amazon DynamoDB Accelerator (DAX) uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to DAX. Service-linked roles...
are predefined by DAX and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up DAX easier because you don't have to manually add the necessary permissions. DAX defines the permissions of its service-linked roles, and unless defined otherwise, only DAX can assume its roles. The defined permissions include the trust policy and the permissions policy. That permissions policy can't be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your DAX resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM in the IAM User Guide. Look for the services that have Yes in the Service-linked roles column. Choose a Yes link to view the service-linked role documentation for that service.

• Service-Linked Role Permissions for DAX (p. 758)
• Creating a Service-Linked Role for DAX (p. 759)
• Editing a Service-Linked Role for DAX (p. 759)
• Deleting a Service-Linked Role for DAX (p. 759)

Service-Linked Role Permissions for DAX

DAX uses the service-linked role named AWSServiceRoleForDAX. This role allows DAX to call AWS services on behalf of your DAX cluster.

Important

The AWSServiceRoleForDAX service-linked role makes it easier for you to set up and maintain a DAX cluster. However, you must still grant each cluster access to DynamoDB before you can use it. For more information, see DAX Access Control (p. 746).

The AWSServiceRoleForDAX service-linked role trusts the following services to assume the role:

• dax.amazonaws.com

The role permissions policy allows DAX to complete the following actions on the specified resources:

• Actions on ec2:
  • AuthorizeSecurityGroupIngress
  • CreateNetworkInterface
  • CreateSecurityGroup
  • DeleteNetworkInterface
  • DeleteSecurityGroup
  • DescribeAvailabilityZones
  • DescribeNetworkInterfaces
  • DescribeSecurityGroups
  • DescribeSubnets
  • DescribeVpcs
  • ModifyNetworkInterfaceAttribute
  • RevokeSecurityGroupIngress
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

To allow an IAM entity to create AWSServiceRoleForDAX service-linked roles

Add the following policy statement to the permissions for that IAM entity.

```json
{
  "Effect": "Allow",
  "Action": [
    "iam:CreateServiceLinkedRole"
  ],
  "Resource": "*",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "dax.amazonaws.com"
    }
  }
}
```

Creating a Service-Linked Role for DAX

You don't need to manually create a service-linked role. When you create a cluster, DAX creates the service-linked role for you.

Important

If you were using the DAX service before February 28, 2018, when it began supporting service-linked roles, DAX created the AWSServiceRoleForDAX role in your account. For more information, see A New Role Appeared in My AWS Account in the IAM User Guide.

If you delete this service-linked role and then need to create it again, you can use the same process to re-create the role in your account. When you create an instance or a cluster, DAX creates the service-linked role for you again.

Editing a Service-Linked Role for DAX

DAX does not allow you to edit the AWSServiceRoleForDAX service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a Service-Linked Role for DAX

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DAX clusters before you can delete the service-linked role.

Cleaning Up a Service-Linked Role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForDAX role.
3. On the Summary page for the selected role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

Note
If you are unsure whether DAX is using the AWSServiceRoleForDAX role, you can try to delete the role. If the service is using the role, the deletion fails, and you can view the Regions where the role is being used. If the role is being used, you must delete your DAX clusters before you can delete the role. You can't revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForDAX role, you must first delete all of your DAX clusters.

Deleting All of Your DAX Clusters

Use one of these procedures to delete each of your DAX clusters.

To delete a DAX cluster (console)
2. In the navigation pane, under DAX, choose Clusters.
3. Choose Actions, and then choose Delete.
4. In the Delete cluster confirmation box, choose Delete.

To delete a DAX cluster (AWS CLI)

See delete-cluster in the AWS CLI Command Reference.

To delete a DAX cluster (API)

See DeleteCluster in the Amazon DynamoDB API Reference.

Deleting the Service-Linked Role

To manually delete the service-linked role using IAM

Use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForDAX service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Accessing DAX Across AWS Accounts

Imagine that you have a DynamoDB Accelerator (DAX) cluster running in one AWS account (account A), and the DAX cluster needs to be accessible from an Amazon Elastic Compute Cloud (Amazon EC2) instance in another AWS account (account B). In this tutorial, you accomplish this by launching an EC2 instance in account B with an IAM role from account A. You then use temporary security credentials from the EC2 instance to assume an IAM role from account A. Finally, you use the temporary security credentials from assuming the IAM role in account A to make application calls over an Amazon VPC peering connection to the DAX cluster in account A. In order to perform these tasks you will need administrative access in both AWS accounts.

Topics
- Set Up IAM (p. 761)
- Set Up a VPC (p. 762)
- Modify the DAX Client to Allow Cross-account Access (p. 764)
Set Up IAM

1. Create a text file named `AssumeDaxRoleTrust.json` with the following content, which allows Amazon EC2 to work on your behalf.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "ec2.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

2. In account B, create a role that Amazon EC2 can use when launching instances.

   ```
   aws iam create-role \
   --role-name AssumeDaxRole \
   --assume-role-policy-document file://AssumeDaxRoleTrust.json
   ```

3. Create a text file named `AssumeDaxRolePolicy.json` with the following content, which allows code running on the EC2 instance in account B to assume an IAM role in account A. Replace `accountA` with the actual ID of account A.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "sts:AssumeRole",
         "Resource": "arn:aws:iam::accountA:role/DaxCrossAccountRole"
      }
   ]
}
```

4. Add that policy to the role you just created.

   ```
   aws iam put-role-policy \
   --role-name AssumeDaxRole \
   --policy-name AssumeDaxRolePolicy \
   --policy-document file://AssumeDaxRolePolicy.json
   ```

5. Create an instance profile to allow instances to use the role.

   ```
   aws iam create-instance-profile \
   --instance-profile-name AssumeDaxInstanceProfile
   ```

6. Associate the role with the instance profile.

   ```
   aws iam add-role-to-instance-profile \
   --instance-profile-name AssumeDaxInstanceProfile \
   --role-name AssumeDaxRole
   ```

7. Create a text file named `DaxCrossAccountRoleTrust.json` with the following content, which allows account B to assume an account A role. Replace `accountB` with the actual ID of account B.

```
```
8. In account A, create the role that account B can assume.

```bash
aws iam create-role \
  --role-name DaxCrossAccountRole \
  --assume-role-policy-document file://DaxCrossAccountRoleTrust.json
```

9. Create a text file named `DaxCrossAccountPolicy.json` that allows access to the DAX cluster. Replace `dax-cluster-arn` with the correct Amazon Resource Name (ARN) of your DAX cluster.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dax:GetItem",
        "dax:BatchGetItem",
        "dax:Query",
        "dax:Scan",
        "dax:PutItem",
        "dax:UpdateItem",
        "dax:DeleteItem",
        "dax:BatchWriteItem",
        "dax:ConditionCheckItem",
        "dax:DefineAttributeList",
        "dax:DefineAttributeListId",
        "dax:DefineKeySchema",
        "dax:Endpoints"
      ],
      "Resource": "dax-cluster-arn"
    }
  ]
}
```

10. In account A, add the policy to the role.

```bash
aws iam put-role-policy \
  --role-name DaxCrossAccountRole \
  --policy-name DaxCrossAccountPolicy \
  --policy-document file://DaxCrossAccountPolicy.json
```

**Set Up a VPC**

1. Find the subnet group of account A's DAX cluster. Replace `cluster-name` with the name of the DAX cluster that account B must access.
Set Up a VPC

aws dax describe-clusters \ 
   --cluster-name cluster-name \ 
   --query 'Clusters[0].SubnetGroup'

2. Using that `subnet-group`, find the cluster's VPC.

aws dax describe-subnet-groups \ 
   --subnet-group-name subnet-group \ 
   --query 'SubnetGroups[0].VpcId'

3. Using that `vpc-id`, find the VPC's CIDR.

aws ec2 describe-vpcs \ 
   --vpc vpc-id \ 
   --query 'Vpcs[0].CidrBlock'

4. From account B, create a VPC using a different, non-overlapping CIDR than the one found in the previous step. Then, create at least one subnet. You can use either the VPC creation wizard in the AWS Management Console or the AWS CLI.

5. From account B, request a peering connection to the account A VPC as described in Creating and Accepting a VPC Peering Connection. From account A, accept the connection.

6. From account B, find the new VPC's routing table. Replace `vpc-id` with the ID of the VPC you created in account B.

aws ec2 describe-route-tables \ 
   --filters 'Name=vpc-id,Values=vpc-id' \ 
   --query 'RouteTables[0].RouteTableId'

7. Add a route to send traffic destined for account A's CIDR to the VPC peering connection. Remember to replace each `user input placeholder` with the correct values for your accounts.

aws ec2 create-route \ 
   --route-table-id accountB-route-table-id \ 
   --destination-cidr accountA-vpc-cidr \ 
   --vpc-peering-connection-id peering-connection-id

8. From account A, find the DAX cluster's route table using the `vpc-id` you found previously.

aws ec2 describe-route-tables \ 
   --filters 'Name=vpc-id, Values=accountA-vpc-id' \ 
   --query 'RouteTables[0].RouteTableId'

9. From account A, add a route to send traffic destined for account B's CIDR to the VPC peering connection. Replace each `user input placeholder` with the correct values for your accounts.

aws ec2 create-route \ 
   --route-table-id accountA-route-table-id \ 
   --destination-cidr accountB-vpc-cidr \ 
   --vpc-peering-connection-id peering-connection-id

10. From account B, launch an EC2 instance in the VPC that you created earlier. Give it the AssumeDaxInstanceProfile. You can use either the launch wizard in the AWS Management Console or the AWS CLI. Take note of the instance's security group.

11. From account A, find the security group used by the DAX cluster. Remember to replace `cluster-name` with the name of your DAX cluster.

aws dax describe-clusters \ 
   --cluster-name cluster-name \ 
   --query 'Clusters[0].SubnetGroup'
Modify the DAX Client to Allow Cross-account Access

**Note**
AWS Security Token Service (AWS STS) credentials are temporary credentials. Some clients handle refreshing automatically, while others require additional logic to refresh the credentials. We recommend that you follow the guidance of the appropriate documentation.

**Java**

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don’t have DAX client code already, you can find working code examples in the Java and DAX (p. 689) tutorial.

1. Add the following imports.

```java
import com.amazonaws.auth.STSAssumeRoleSessionCredentialsProvider;
import com.amazonaws.services.securitytoken.AWSSecurityTokenService;
import com.amazonaws.services.securitytoken.AWSSecurityTokenServiceClientBuilder;
```

2. Get a credentials provider from AWS STS and create a DAX client object. Remember to replace each *user input placeholder* with the correct values for your accounts.

```java
AWSSecurityTokenService awsSecurityTokenService =
    AWSSecurityTokenServiceClientBuilder
        .standard()
        .withRegion(region)
        .build();

STSAssumeRoleSessionCredentialsProvider credentials =
    new STSAssumeRoleSessionCredentialsProvider.Builder("arn:aws:iam::accountA:role/RoleName", "TryDax")
        .withStsClient(awsSecurityTokenService)
        .build();

DynamoDB client = AmazonDaxClientBuilder.standard()
    .withRegion(region)
    .withEndpointConfiguration(dax_endpoint)
    .withCredentials(credentials)
    .build();
```
This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the .NET and DAX (p. 698) tutorial.

1. Add the AWSSDK.SecurityToken NuGet package to the solution.

   ```xml
   <PackageReference Include="AWSSDK.SecurityToken" Version="latest version" />
   ```

   ```csharp
   using Amazon.SecurityToken;
   using Amazon.SecurityToken.Model;
   ```

3. Get temporary credentials from AmazonSimpleTokenService and create a ClusterDaxClient object. Remember to replace each user input placeholder with the correct values for your accounts.

   ```csharp
   IAmazonSecurityTokenService sts = new AmazonSecurityTokenServiceClient();
   var assumeRoleResponse = sts.AssumeRole(new AssumeRoleRequest
   {
       RoleArn = "arn:aws:iam::accountA:role/RoleName",
       RoleSessionName = "TryDax"
   });
   Credentials credentials = assumeRoleResponse.Credentials;
   var clientConfig = new DaxClientConfig(dax_endpoint, port)
   {
       AwsCredentials = assumeRoleResponse.Credentials
   };
   var client = new ClusterDaxClient(clientConfig);
   ```

Go

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples on GitHub.

1. Import the AWS STS and session packages.

   ```go
   import {
       "github.com/aws/aws-sdk-go/aws/session"
       "github.com/aws/aws-sdk-go/service/sts"
       "github.com/aws/aws-sdk-go/aws/credentials/stscreds"
   }
   ```

2. Get temporary credentials from AmazonSimpleTokenService and create a DAX client object. Remember to replace each user input placeholder with the correct values for your accounts.

   ```go
   sess, err := session.NewSession(&aws.Config{
       Region: aws.String(region),
   })
   if err != nil {
       return nil, err
   }
Modify the DAX Client to Allow Cross-account Access

```python
stsClient := sts.New(sess)
arp := &stscreds.AssumeRoleProvider{
    Duration:     900 * time.Second,
    ExpiryWindow: 10 * time.Second,
    RoleARN:      "arn:aws:iam::accountA:role/role_name",
    Client:       stsClient,
    RoleSessionName: "session_name",
}
cfg := dax.DefaultConfig()
cfg.HostPorts = []string(dax_endpoint)
cfg.Region = region
cfg.Credentials = credentials.NewCredentials(arp)
daxClient := dax.New(cfg)
```

**Python**

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don’t have DAX client code already, you can find working code examples in the Python and DAX (p. 714) tutorial.

1. Import `boto3`.

   ```python
   import boto3
   ```

2. Get temporary credentials from `sts` and create an `AmazonDaxClient` object. Remember to replace each `user input placeholder` with the correct values for your accounts.

   ```python
   sts = boto3.client('sts')
   stsresponse =
       sts.assume_role(RoleArn='arn:aws:iam::accountA:role/RoleName',
                       RoleSessionName='tryDax')
   credentials = botocore.session.get_session()['Credentials']
   
   dax = amazondax.AmazonDaxClient(session, region_name=region,
                                   endpoints=[dax_endpoint],
                                   aws_access_key_id=credentials['AccessKeyId'],
                                   aws_secret_access_key=credentials['SecretAccessKey'],
                                   aws_session_token=credentials['SessionToken'])
   client = dax
   ```

**Node.js**

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don’t have DAX client code already, you can find working code examples in the Node.js and DAX (p. 707) tutorial. Remember to replace each `user input placeholder` with the correct values for your accounts.

```javascript
const AmazonDaxClient = require('amazon-dax-client');
const AWS = require('aws-sdk');
const region = 'region';
const endpoints = [daxEndpoint1, ...];

const getCredentials = async() => {
    return new Promise((resolve, reject) => {
        const sts = new AWSSTS();
        const roleParams = {
            RoleArn: 'arn:aws:iam::accountA:role/RoleName',
            RoleSessionName: 'tryDax',
        };
        sts.assumeRole(roleParams, (err, session) => {
```
DAX Cluster Sizing Guide

This guide provides advice for choosing an appropriate Amazon DynamoDB Accelerator (DAX) cluster size and node type for your application. These instructions guide you through the steps of estimating your application's DAX traffic, selecting a cluster configuration, and testing it.

If you have an existing DAX cluster and want to evaluate whether it has the appropriate number and size of nodes, please refer to Scaling a DAX Cluster (p. 729).

Topics

- Overview (p. 767)
- Estimating Traffic (p. 768)
- Load Testing (p. 768)

Overview

It's important to scale your DAX cluster appropriately for your workload, whether you're creating a new cluster or maintaining an existing cluster. As time goes on and your application's workload changes, you should periodically revisit your scaling decisions to make sure that they are still appropriate.

The process typically follows these steps:

1. **Estimating traffic.** In this step, you make predictions about the volume of traffic that your application will send to DAX, the nature of the traffic (read vs. write operations), and the expected cache hit rate.
2. **Load testing.** In this step, you create a cluster and send traffic to it mirroring your estimates from the previous step. Repeat this step until you find a suitable cluster configuration.
3. **Production monitoring.** While your application is using DAX in production, you should monitor the cluster (p. 733) to continuously validate that it is still scaled correctly as your workload changes over time.
Estimating Traffic

There are three main factors that characterize a typical DAX workload:

- Cache hit rate
- Read capacity units (p. 342) (RCUs) per second
- Write capacity units (p. 343) (WCUs) per second

Estimating Cache Hit Rate

If you already have a DAX cluster, you can use the ItemCacheHits and ItemCacheMisses Amazon CloudWatch metrics (p. 735) to determine the cache hit rate. The cache hit rate is equal to ItemCacheHits / (ItemCacheHits + ItemCacheMisses). If your workload includes Query or Scan operations, you should also look at the QueryCacheHits, QueryCacheMisses, ScanCacheHits, and ScanCacheMisses metrics. Cache hit rates vary from one application to another and are heavily influenced by the cluster's Time to Live (TTL) setting. Typical hit rates for applications using DAX are 85–95 percent.

Estimating Read and Write Capacity Units

If you already have DynamoDB tables for your application, look at the ConsumedReadCapacityUnits and ConsumedWriteCapacityUnits CloudWatch metrics (p. 735). Use the Sum statistic and divide by the number of seconds in the period.

If you also already have a DAX cluster, remember that the DynamoDB ConsumedReadCapacityUnits metric only accounts for cache misses. So, to get an idea of the read capacity units per second handled by your DAX cluster, divide the number by your cache miss rate (that is, 1 - cache hit rate).

If you don’t already have a DynamoDB table, see the documentation about read capacity units (p. 342) and write capacity units (p. 343) to estimate your traffic based on your application's estimated request rate, items accessed per request, and item size.

When making traffic estimates, plan for future growth and for expected and unexpected peaks to ensure that your cluster has enough headroom for traffic increases.

Load Testing

The next step after estimating traffic is to test the cluster configuration under load.

1. For your initial load test, we recommend that you start with the dax.r4.large node type, the lowest-cost fixed performance, memory-optimized node type.
2. A fault-tolerant cluster requires at least three nodes, spread across three Availability Zones. In this case, if an Availability Zone becomes unavailable, the effective number of Availability Zones is reduced by one-third. For your initial load test, we recommend that you start with a two-node cluster, which simulates the failure of one Availability Zone in a three-node cluster.
3. Drive sustained traffic (as estimated in the previous step) to your test cluster for the duration of the load test.
4. Monitor the performance of the cluster during the load test.

Ideally, the traffic profile that you drive during the load test should be as similar as possible to your application's real traffic. This includes the distribution of operations (for example, 70 percent GetItem, 25 percent Query, and 5 percent PutItem), the request rate for each operation, the number of items accessed per request, and the distribution of item sizes. To achieve a cache hit rate similar to your application's expected cache hit rate, pay close attention to the distribution of keys in your test traffic.
Note
Be careful when load testing T2 node types (dax.t2.small and dax.t2.medium). T2 node
types provide burstable CPU performance that varies over time depending on the node's CPU
credit balance. A DAX cluster running on T2 nodes might appear to be operating normally, but
if any node is bursting above the baseline performance of its instance, the node is spending its
accumulated CPU credit balance. When the credit balance runs low, performance is gradually lowered
to the baseline performance level.

Monitor your DAX cluster (p. 733) during the load test to determine whether the node type that you're
using for the load test is the right node type for you. In addition, during a load test, you should monitor
your request rate and cache hit rate to ensure that your test infrastructure is actually driving the amount
of traffic you intend.

If load testing indicates that the selected cluster configuration can't sustain your application's workload,
we recommend switching to a larger node type (p. 729), especially if you see high CPU utilization on
the primary node in the cluster or high eviction rates. If hit rates are consistently high, and the ratio of
read to write traffic is high, you may want to consider adding more nodes to your cluster (p. 729). Refer
to Scaling a DAX Cluster (p. 729) for additional guidance on when to use a larger node type (vertical
scaling) or add more nodes (horizontal scaling).

You should repeat your load test after making changes to your cluster configuration.

NoSQL Workbench for Amazon DynamoDB

NoSQL Workbench for Amazon DynamoDB is a cross-platform client-side application for modern database development and operations and is available for Windows and macOS. NoSQL Workbench is a unified visual tool that provides data modeling, data visualization, and query development features to help you design, create, query, and manage DynamoDB tables.

**Data Modeling**

With NoSQL Workbench for DynamoDB, you can build new data models from, or design models based on, existing data models that satisfy your application's data access patterns. You can also import and export the designed data model at the end of the process. For more information, see Building Data Models with NoSQL Workbench (p. 771).

**Data Visualization**

The data model visualizer provides a canvas where you can map queries and visualize the access patterns (facets) of the application without having to write code. Every facet corresponds to a different access pattern in DynamoDB. You can manually add data to your data model or import data from MySQL. For more information, see Visualizing Data Access Patterns (p. 780).

**Operation Building**

NoSQL Workbench provides a rich graphical user interface for you to develop and test queries. You can use the operation builder to view, explore, and query datasets. You can also use the structured operation builder to build and perform data plane operations. It supports projection and condition expression, and lets you generate sample code in multiple languages. For more information, see Exploring Datasets and Building Operations with NoSQL Workbench (p. 786).

Building Data Models with NoSQL Workbench

You can use the data modeler tool in NoSQL Workbench for Amazon DynamoDB to build new data models, or to design models based on existing data models that satisfy your applications’ data access patterns. The data modeler includes a few sample data models to help you get started.

Topics

• Creating a New Data Model (p. 771)
• Importing an Existing Data Model (p. 775)
• Exporting a Data Model (p. 776)
• Editing an Existing Data Model (p. 777)

Creating a New Data Model

Follow these steps to create a new data model in Amazon DynamoDB using NoSQL Workbench.

To create a new data model

1. Open NoSQL Workbench, and in the navigation pane on the left side, choose the Data modeler icon.

2. Choose Create data model.

3. Enter a name for the data model, and then choose Create.
4. On the newly created model, choose Open.

5. Choose Add table.

For more information about tables, see Working with Tables in DynamoDB.

6. Specify the following:
   - **Table name** — Enter a unique name for the table.
   - **Partition key** — Enter a partition key name and specify its type.
   - If you want to add a sort key:
     1. Select Add sort key.
     2. Specify the sort key name and its type.
     3.
To add other attributes, do the following for each attribute:

1. Choose **Add other attribute**.
2. Specify the attribute name and type.

**Note**

Facets represent an application's different data access patterns for DynamoDB.

- Select **Add facets**.
- Choose **Add facet**.

Add a facet:
• Specify the following:
  • The Facet name.
  • A Partition key alias.
  • A Sort key alias.
  • Choose the Other attributes that are part of this facet.

Choose Add facet.

Repeat step 8 if you want to add more facets.

9. If you want to add a global secondary index, choose Add global secondary index.

Specify the Global secondary index name, Partition key attribute, and Projection type.
Importing an Existing Data Model

You can use NoSQL Workbench for Amazon DynamoDB to build a data model by importing and modifying an existing model.

**To import a data model**

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Data modeler** icon.

For more information about the **CreateTable** API operation, see **CreateTable** in the *Amazon DynamoDB API Reference*.

For more information about working with global secondary indexes in DynamoDB, see **Global Secondary Indexes**.

10. Choose **Add table definition**.

For more information about working with global secondary indexes in DynamoDB, see **Global Secondary Indexes**.
2. Choose Import data model.

3. Choose a model to import.

Exporting a Data Model

After you create a data model using NoSQL Workbench for Amazon DynamoDB, you can save and export the model.

To export a data model

1. In NoSQL Workbench, in the navigation pane on the left side, choose the Data modeler icon.
2. Choose **Export data model**.

3. Choose a location to save your model.

---

**Editing an Existing Data Model**

**To edit an existing model**

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Data modeler** button.
2. Choose the table you wish to edit.

Choose **Edit**.

3. Make the needed edits, and then choose **Save edits**.

**To manually edit an existing model and add a facet**

1. Export your model. For more information, see [Exporting a Data Model](p. 776).
2. Open the exported file in an editor.
3. Locate the `DataModel` Object for the table you want to create a facet for.

Add a `TableFacets` array representing all the facets for the table.

For each facet add an object to the `TableFacets` array. Each array element has the following properties:

- **FacetName**: A name for your facet. This value must be unique across the model.
- **PartitionKeyAlias** — A friendly name for the table's partition key. This alias is displayed when you view the facet in NoSQL Workbench.
- **SortKeyAlias** — A friendly name for the table's sort key. This alias is displayed when you view the facet in NoSQL Workbench. This property is not needed if the table has no sort key defined.
- **NonKeyAttributes** — An array of attribute names that are needed for the access pattern. These names must map to the attribute names that are defined for the table.

```json
{
    "ModelName": "Music Library Data Model",
    "DataModel": [
        {
            "TableName": "Songs",
```
"KeyAttributes": { 
  "PartitionKey": { 
    "AttributeName": "Id",
    "AttributeType": "S"
  },
  "SortKey": { 
    "AttributeName": "Metadata",
    "AttributeType": "S"
  }
}, 
"NonKeyAttributes": [ 
  { 
    "AttributeName": "DownloadMonth",
    "AttributeType": "S"
  }, 
  { 
    "AttributeName": "TotalDownloadsInMonth",
    "AttributeType": "S"
  }, 
  { 
    "AttributeName": "Title",
    "AttributeType": "S"
  }, 
  { 
    "AttributeName": "Artist",
    "AttributeType": "S"
  }, 
  { 
    "AttributeName": "TotalDownloads",
    "AttributeType": "S"
  }, 
  { 
    "AttributeName": "DownloadTimestamp",
    "AttributeType": "S"
  }
], 
"TableFacets": [ 
  { 
    "FacetName": "SongDetails",
    "KeyAttributeAlias": { 
      "PartitionKeyAlias": "SongId",
      "SortKeyAlias": "Metadata"
    }, 
    "NonKeyAttributes": [ 
      "Title",
      "Artist",
      "TotalDownloads"
    ]
  }, 
  { 
    "FacetName": "Downloads",
    "KeyAttributeAlias": { 
      "PartitionKeyAlias": "SongId",
      "SortKeyAlias": "Metadata"
    }, 
    "NonKeyAttributes": [ 
      "DownloadTimestamp"
    ]
  }
]
4. You can now import the modified model into NoSQL Workbench. For more information, see Importing an Existing Data Model (p. 775).

Visualizing Data Access Patterns

You can use the visualizer tool in NoSQL Workbench for Amazon DynamoDB to map queries and visualize different access patterns (known as facets) of an application. Every facet corresponds to a different access pattern in DynamoDB. You can also manually add data to your data model or import data from MySQL.

Topics
- Adding Sample Data to a Data Model (p. 780)
- Viewing Data Access Patterns (p. 781)
- Viewing All Tables in a Data Model Using Aggregate View (p. 782)
- Committing a Data Model to DynamoDB (p. 783)

Adding Sample Data to a Data Model

By adding sample data to your model, you can display data when visualizing the model and its various data access patterns, or facets.

Follow these steps to add sample data to a data model using NoSQL Workbench for Amazon DynamoDB.

To add sample data

1. In the navigation pane on the left side, choose the visualizer icon.

2. In the visualizer, choose Update next to the table name.

3. Choose Add Data.
4. Enter the sample data into the empty textboxes, and then choose **Save**.

Viewing Data Access Patterns

In NoSQL Workbench, **facets** represent an application's different data access patterns for Amazon DynamoDB.

**To view information about facets in NoSQL Workbench**

1. In the navigation pane on the left side, choose the **visualizer** icon.

2. In the data model on the left side, choose a table to view.
3. Choose the **Facets** drop-down arrow for the selected table.
4. In the list, choose a facet to view.
You can also edit the facet definitions using the Data Modeler. For more information, see Editing an Existing Data Model (p. 777).

Viewing All Tables in a Data Model Using Aggregate View

The aggregate view in NoSQL Workbench for Amazon DynamoDB represents all the tables in a data model. For each table, the following information appears:

- Table column names.
- Sample data.
- All global secondary indexes that are associated with the table. The following information is displayed for each index:
  - Index column names
  - Sample data

To view all table information

1. In the navigation pane on the left side, choose the visualizer icon.

2. In the visualizer, choose Aggregate view.
Committing a Data Model to DynamoDB

When you are satisfied with your data model, you can commit the model to Amazon DynamoDB.

**Note**

- This action results in the creation of server-side resources in AWS for the tables and global secondary indexes represented in the data model.
- Tables are created with the following characteristics:
  - Auto scaling is set to 70 percent target utilization.
  - Provisioned capacity is set to 5 read capacity units and 5 write capacity units.
- Global secondary indexes are created with provisioned capacity of 10 read capacity units and 5 write capacity units.

**To commit the data model to DynamoDB**

1. In the navigation pane on the left side, choose the **visualizer** icon.

2. Choose **Commit to DynamoDB**.
3. Choose an already existing connection, or create a new connection by choosing the **Add new remote connection** tab.

   - To add a new connection, specify the following information:
     - **Account Alias**
     - **AWS Region**
     - **Access key ID**
     - **Secret access key**

   For more information about how to obtain the access keys, see [Getting an AWS Access Key](#).

   - You can optionally specify the following:
     - **Session token**
     - **IAM role ARN**

   - If you don't want to sign up for a free tier account, and prefer to use [DynamoDB Local (Downloadable Version)](#):
     1. Choose the **Add a new DynamoDB local connection** tab
     2. Specify the **Connection name** and **Port**.

4. Choose **Commit**.
Commit to DynamoDB

On this page, you create server-side resources such as tables and global secondary indexes for the selected data model. By default, all tables and indexes are created with a read capacity of five read capacity units and a write capacity of five write capacity units.

Exploring Datasets and Building Operations with NoSQL Workbench

NoSQL Workbench for Amazon DynamoDB provides a rich graphical user interface for developing and testing queries. You can use the operation builder in NoSQL Workbench to view, explore, and query datasets. You can also use the structured operation builder to build and perform data plane operations, with support for projection and condition expression, and generate sample code in multiple languages.

Topics

- Exploring Datasets (p. 786)
- Building Complex Operations (p. 790)

Exploring Datasets

To explore your Amazon DynamoDB tables, you first need to connect to your AWS account.

To add a connection to your database

1. In NoSQL Workbench, in the navigation pane on the left side, choose the Operation builder icon.
2. Choose Add connection.
3. Specify the following information:
   - Account alias
   - AWS Region
   - Access key ID
   - Secret access key
   - For more information about how to obtain the access keys, see Getting an AWS Access Key.
   - You can optionally, specify the following:
     - Session token
     - IAM role ARN
4. Choose Connect.
If you don't want to sign up for a free tier account, and prefer to use DynamoDB Local (Downloadable Version):

a. Choose the Local tab on the connection screen
b. Specify the following information:
   • **Connection name**
   • **Port**
  c. Choose the connect button.
5. On the created connection, choose Open.

Note

- When adding a connection to DynamoDB Local (Downloadable Version), NoSQL Workbench generates a random AWS access key ID and secret access key. To retrieve the values of these keys, choose View credentials from the connection context menu.
• When adding a connection to DynamoDB Local (Downloadable Version), the NoSQL Workbench uses localhost as the Region for the DynamoDB Local connection.

• If DynamoDB Local (Downloadable Version) is launched without the -sharedDb command line option, a new database file is created in DynamoDB Local for each connection from NoSQL Workbench.

• You can't use an existing DynamoDB Local (Downloadable Version) database (created via AWS CLI/SDK) via NoSQL Workbench, unless the DynamoDB Local instance was started with the -sharedDb command line option.

After connecting to your DynamoDB database, the list of available tables appears in the left pane. Choose one of the tables to return a sample of the data stored in the table.

You can now execute queries against the selected table.

To execute queries on a table

1. In the Attribute name list, choose the attribute that you want to query on.
2. Specify the comparison operator.
3. Specify the data type of the value.
4. Specify the value to query for.
5. Choose Scan.

For more information about this operation, see Scan in the Amazon DynamoDB API Reference.

You can update and delete any row that is returned. To update, choose the Edit (pencil) icon on the right side of the row. To delete, choose the Delete (trash can) icon.
Choosing the **Delete** icon starts a **Delete Item (p. 794)** operation.

* Partition key: 1933
* Sort key: King Kong

Choosing the **Edit** icon starts an **Update Item (p. 793)** operation.

* Partition key: 1933
* Sort key: King Kong

Choosing the **+** (plus sign) in the bottom left of the row list starts a **Put Item (p. 791)** operation.

**Building Complex Operations**

The operation builder in NoSQL Workbench for Amazon DynamoDB provides a visual interface where you can perform complex data plane operations. It includes support for projection expressions and condition expressions. You can also choose to generate sample code for these operations, in multiple languages.
To build DynamoDB operations

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Operation builder** icon.

2. Choose **Build operations**, and then choose the operation that you want.

You can perform the following operations in the operation builder.

**Topics**

- **Put Item** (p. 791)
- **Update Item** (p. 793)
- **Delete Item** (p. 794)
- **Query** (p. 795)
- **Scan** (p. 796)
- **TransactWriteItems** (p. 797)

**Put Item**

To execute or generate code for a **Put Item** operation, do the following.

1. Specify the partition key value.
2. Specify the sort key value, if one exists.
3. If you want to add non-key attributes, do the following:
   a. Choose the + (plus sign) next to **Other attributes**.
   b. Specify the **Attribute name**, **Type**, and **Value**.
4. If a condition expression must be satisfied for the **Put Item** operation to succeed, do the following:
   a. Choose **Condition**.
   b. Specify the attribute name, comparison operator, attribute type, and attribute value.
   c. If other conditions are needed, choose **Condition** again.
5. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

6. If you want the operation to be executed immediately, choose **Execute**.

For more information about this operation, see **PutItem** in the *Amazon DynamoDB API Reference*. 
Update Item

To execute or generate code for an Update Item operation, do the following:

1. Enter the partition key value.
2. Enter the sort key value, if one exists.
3. In **Update expression**, choose the expression in the list.
4. Choose the + (plus sign) for the expression.
5. Enter the attribute name and attribute value for the selected expression.
6. If you want to add more expressions, choose another expression in the **Update Expression** dropdown list, and then select the +.
7. If a condition expression must be satisfied for the Update Item operation to succeed, do the following:
   a. Choose **Condition**.
   b. Specify the attribute name, comparison operator, attribute type, and attribute value.
   c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition Expressions (p. 393)](https://docs.aws.amazon.com/dynamodb/latest/developerguide/).

8. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.
9. If you want the operation to be executed immediately, choose **Execute**.

For more information about this operation, see **UpdateItem** in the *Amazon DynamoDB API Reference*.

**Delete Item**

To execute or generate code for a Delete Item operation, do the following.

1. Enter the partition key value.
2. Enter the sort key value, if one exists.
3. If a condition expression must be satisfied for the Delete Item operation to succeed, do the following:
   a. Choose **Condition**.
   b. Specify the attribute name, comparison operator, attribute type, and attribute value.
   c. If other conditions are needed, choose **Condition** again.

For more information, see **Condition Expressions (p. 393)**.
4. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

5. If you want the operation to be executed immediately, choose **Execute**.

For more information about this operation, see **DeleteItem** in the *Amazon DynamoDB API Reference*.

**Query**

To execute or generate code for a **Query** operation, do the following.

1. Specify the partition key value.
2. If a sort key is needed for the **Query** operation:
   a. Select **Sort key**.
   b. Specify the comparison operator, attribute type, and attribute value.
3. If not all the attributes should be returned with the operation result, select **Projection expression**.
4. Choose the + (plus sign).
5. Enter the attribute to return with the query result.
6. If more attributes are needed, choose the + .
7. If a condition expression must be satisfied for the **Query** operation to succeed, do the following:
   a. Choose **Condition**.
   b. Specify the attribute name, comparison operator, attribute type, and attribute value.
   c. If other conditions are needed, choose **Condition** again.

For more information, see **Condition Expressions (p. 393)**.
8. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

For more information about this operation, see **Query** in the Amazon DynamoDB API Reference.

**Scan**

To execute or generate code for a **Scan** operation, do the following.

1. If not all the attributes should be returned with the operation result, select **Projection expression**.
Choose the + (plus sign).

3. Specify the attribute to return with the query result.

4. If more attributes are needed, choose the + again.

5. If a condition expression must be satisfied for the scan operation to succeed, do the following:
   
a. Choose **Condition**.
   
b. Specify the attribute name, comparison operator, attribute type, and attribute value.
   
c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition Expressions (p. 393)](#).

6. If you want to generate code, choose **Generate code**.

   Choose the tab for the language that you want. You can now copy this code and use it in your application.

7. If you want the operation to be executed immediately, choose **Execute**.

**TransactWriteItems**

To execute or generate code for a **TransactWriteItems** operation, do the following.

1. In the **Actions** drop-down list, choose the operation that you want.

   - For **DeleteItem**, follow the instructions for the [Delete Item (p. 794)](#) operation.
   - For **PutItem**, follow the instructions for the [Put Item (p. 791)](#) operation.
   - For **UpdateItem**, follow the instructions for the [Update Item (p. 793)](#) operation.

   When you are done specifying the details of the operation, choose the + button.
To change the order of actions, choose an action in the list on the left side, and then choose the up or down arrows to move it up or down in the list.

To delete an action, choose the action in the list, and then choose the **Delete** (trash can) icon.

2. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.
3. If you want the operation to be executed immediately, choose Execute.

For more information about transactions, see Amazon DynamoDB Transactions.

Sample Data Models for NoSQL Workbench

The home page for the modeler and visualizer display a number of sample models that ship with the NoSQL Workbench. This section describes these models and their potential uses.

Topics
- Employee Data Model (p. 799)
- Discussion Forum Data Model (p. 800)
- Music Library Data Model (p. 800)
- Ski Resort Data Model (p. 800)
- Credit Card Offers Data Model (p. 800)
- Bookmarks Data Model (p. 801)

Employee Data Model

This data model is an introductory model. It represents an employee's basic details such as a unique alias, first name, last name, designation, manager, and skills.

This data model depicts a few techniques such as handling complex attribute such as having more than one skill. This model is also an example of one-to-many relationship through the manager and their reporting employees that has been achieved by the secondary index DirectReports.

The access patterns facilitated by this data model are:
- Retrieval of an employee record using the employee's login alias, facilitated by a table called Employee.
- Search for employees by name, facilitated by the Employee table's global secondary index called Name.
- Retrieval of all direct reports of a manager using the manager's login alias, facilitated by the Employee table's global secondary index called DirectReports.
Discussion Forum Data Model

This data model represents a discussion forums. Using this model customers can engage with the developer community, ask questions, and respond to other customers' posts. Each AWS service has a dedicated forum. Anyone can start a new discussion thread by posting a message in a forum, and each thread receives any number of replies.

The access patterns facilitated by this data model are:

- Retrieval of a forum record using the forum's name, facilitated by a table called Forum.
- Retrieval of a specific thread or all threads for a forum, facilitated by a table called Thread.
- Search for replies using the posting user's email address, facilitated by the Reply table's global secondary index called PostedBy-Message-Index.

Music Library Data Model

This data model represents a music library that has a large collection of songs and showcases its most downloaded songs in near-real time.

The access patterns facilitated by this data model are:

- Retrieval of a song record, facilitated by a table called Songs.
- Retrieval of a specific download record or all download records for a song, facilitated by a table called Songs.
- Retrieval of a specific monthly download count record or all monthly download count records for a song, facilitated by a table called Songs.
- Retrieval of all records (including song record, download records, and monthly download count records) for a song, facilitated by a table called Songs.
- Search for most downloaded songs, facilitated by the Songs table's global secondary index called DownloadsByMonth.

Ski Resort Data Model

This data model represents a ski resort that has a large collection of data for each ski lift collected daily.

The access patterns facilitated by this data model are:

- Retrieval of all data for a given ski lift or overall resort, dynamic and static, facilitated by a table called SkiLifts.
- Retrieval of all dynamic data (including unique lift riders, snow coverage, avalanche danger, and lift status) for a ski lift or the overall resort on a specific date, facilitated by a table called SkiLifts.
- Retrieval of all static data (including if the lift is for experienced riders only, vertical feet the lift rises, and lift riding time) for a specific ski lift, facilitated by a table called SkiLifts.
- Retrieval of date of data recorded for a specific ski lift or the overall resort sorted by total unique riders, facilitated by the SkiLifts table's global secondary index called SkiLiftsByRiderss.

Credit Card Offers Data Model

This data model is used by a Credit Card Offers Application.
A credit card provider produces offers over time. These offers include balance transfers without fees, increased credit limits, lower interest rates, cash back, and airline miles. After a customer accepts or declines these offers, the respective offer status is updated accordingly.

The access patterns facilitated by this data model are:

- Retrieval of account records using AccountId, as facilitated by the main table.
- Retrieval of all the accounts with few projected items, as facilitated by the secondary index AccountIndex.
- Retrieval of accounts and all the offer records associated with those accounts by using AccountId, as facilitated by the main table.
- Retrieval of accounts and specific offer records associated with those accounts by using AccountId and OfferId, as facilitated by the main table.
- Retrieval of all ACCEPTED/DECLINED offer records of specific OfferType associated with accounts using AccountId, OfferType, and Status, as facilitated by the secondary index GSI1.
- Retrieval of offers and associated offer item records using OfferId, as facilitated by the main table.

**Bookmarks Data Model**

This data model is used to store bookmarks for customers.

A customer can have many bookmarks and a bookmark can belong to many customers. This data model represents a many-to-many relationship.

The access patterns facilitated by this data model are:

- A single query by customerId can now return customer data as well as bookmarks.
- A query ByEmail index returns customer data by email address. Note that bookmarks are not retrieved by this index.
- A queryByUrl index gets bookmarks data by URL. Note that we have customerId as the sort key for the index because the same URL can be bookmarked by multiple customers.
- A query ByCustomerFolder index gets bookmarks by folder for each customer.

Analyzing Data Access Using CloudWatch Contributor Insights for DynamoDB

Amazon CloudWatch Contributor Insights for Amazon DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your table or index at a glance. This tool uses CloudWatch Contributor Insights.

By enabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, you can view the most accessed and throttled items in those resources.

**Note**
CloudWatch charges apply for Contributor Insights for DynamoDB. For more information about pricing, see Amazon CloudWatch pricing.

**Topics**

CloudWatch Contributor Insights for DynamoDB: How It Works

Amazon DynamoDB integrates with Amazon CloudWatch Contributor Insights to provide information about the most accessed and throttled items in a table or global secondary index. DynamoDB delivers this information to you via CloudWatch Contributor Insights rules, reports, and graphs of report data.

For more information about CloudWatch Contributor Insights, see Using Contributor Insights to Analyze High-Cardinality Data in the Amazon CloudWatch User Guide.

The following sections describe the core concepts and behavior of CloudWatch Contributor Insights for DynamoDB.

**Topics**
- CloudWatch Contributor Insights for DynamoDB Rules (p. 803)
- Understanding CloudWatch Contributor Insights for DynamoDB Graphs (p. 804)
- Interactions with Other DynamoDB Features (p. 806)
- CloudWatch Contributor Insights for DynamoDB Billing (p. 807)

CloudWatch Contributor Insights for DynamoDB Rules

When you enable CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, DynamoDB creates the following rules on your behalf:
• **Most accessed items (partition key)** — Identifies the partition keys of the most accessed items in your table or global secondary index.

CloudWatch rule name format: `DynamoDBContributorInsights-PKC-[resource_name]-[creationtimestamp]`

• **Most throttled keys (partition key)** — Identifies the partition keys of the most throttled items in your table or global secondary index.

CloudWatch rule name format: `DynamoDBContributorInsights-PKT-[resource_name]-[creationtimestamp]`

If your table or global secondary index has a sort key, DynamoDB also creates the following rules specific to sort keys:

• **Most accessed keys (partition and sort keys)** — Identifies the partition and sort keys of the most accessed items in your table or global secondary index.

CloudWatch rule name format: `DynamoDBContributorInsights-SKC-[resource_name]-[creationtimestamp]`

• **Most throttled keys (partition and sort keys)** — Identifies the partition and sort keys of the most throttled items in your table or global secondary index.

CloudWatch rule name format: `DynamoDBContributorInsights-SKT-[resource_name]-[creationtimestamp]`

**Note**

- You can't use the CloudWatch console or APIs to directly modify or delete the rules created by CloudWatch Contributor Insights for DynamoDB. Disabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index automatically deletes the rules created for that table or global secondary index.
- When you use the `GetInsightRuleReport` operation with CloudWatch Contributor Insights rules that are created by DynamoDB, only `MaxContributorValue` and `Maximum` return useful statistics. The other statistics in this list don't return meaningful values.

You can create CloudWatch Alarms using the CloudWatch Contributor Insights for DynamoDB rules. This allows you to be notified when any item exceed or meets a specific threshold for `ConsumedThroughputUnits` or `ThrottleCount`. For more information, see Setting an Alarm on Contributor Insights Metric Data.

**Understanding CloudWatch Contributor Insights for DynamoDB Graphs**

CloudWatch Contributor Insights for DynamoDB displays two types of graphs on both the DynamoDB and CloudWatch consoles: **Most Accessed Items** and **Most Throttled Items**.

**Most Accessed Items**

Use this graph to identify the most accessed items in the table or global secondary index. The graph displays `ConsumedThroughputUnits` on the y-axis and time on the x-axis. Each of the top N keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures key access frequency by using `ConsumedThroughputUnits`, which measures combined read and write traffic. `ConsumedThroughputUnits` is defined as the following:
• Provisioned — \((3 \times \text{consumed write capacity units}) + \text{consumed read capacity units}\)
• On-demand — \((3 \times \text{write request units}) + \text{read request units}\)

On the DynamoDB console, each data point in the graph represents the maximum of \(\text{ConsumedThroughputUnits}\) over a 1-minute period. For example, a graph value of 180,000 \(\text{ConsumedThroughputUnits}\) indicates that the item was accessed continuously at the per-item maximum throughput of 1,000 write request units or 3,000 read request units for a 60-second span within that 1-minute period (3,000 x 60 seconds). In other words, the graphed values represent the highest-traffic minute within each 1-minute period. You can change the time granularity of the \(\text{ConsumedThroughputUnits}\) metric (for example, to view 5-minute metrics instead of 1-minute) on the CloudWatch console.

If you see several closely clustered lines without any obvious outliers, it indicates that your workload is relatively balanced across items over the given time window. If you see isolated points in the graph instead of connected lines, it indicates an item that was frequently accessed only for a brief period.

If your table or global secondary index has a sort key, DynamoDB creates two graphs: one for the most accessed partition keys and one for the most accessed partition + sort key pairs. You can see traffic at the partition key level in the partition key-only graph. You can see traffic at the item level in the partition + sort key graphs.

**Most Throttled Items**

Use this graph to identify the most throttled items in the table or global secondary index. The graph displays \(\text{ThrottleCount}\) on the y-axis and time on the x-axis. Each of the top N keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures throttle frequency using \(\text{ThrottleCount}\), which is the count of \(\text{ProvisionedThroughputExceededException}, \text{ThrottlingException}, \text{and RequestLimitExceeded}\) errors.

On the DynamoDB console, each data point in the graph represents the count of throttle events over a 1-minute period.

If you see no data in this graph, it indicates that your requests are not being throttled. If you see isolated points in the graph instead of connected lines, it indicates that an item was frequently throttled for a brief period.

If your table or global secondary index has a sort key, DynamoDB creates two graphs: one for most throttled partition keys and one for most throttled partition + sort key pairs. You can see throttle count at the partition key level in the partition key-only graph, and throttle count at the item level in the partition + sort key graphs.

**Report Examples**

The following are examples of the reports generated for a table with both a partition key and sort key.
Interactions with Other DynamoDB Features

The following sections describe how CloudWatch Contributor Insights for DynamoDB behaves and interacts with several other features in DynamoDB.

Global Tables

CloudWatch Contributor Insights for DynamoDB monitors global table replicas as distinct tables. The Contributor Insights graphs for a replica in one AWS Region might not show the same patterns as another Region. This is because write data is replicated across all replicas in a global table, but each replica can serve Region-bound read traffic.

DynamoDB Accelerator (DAX)

CloudWatch Contributor Insights for DynamoDB doesn't show DAX cache responses. It only shows responses to accessing a table or a global secondary index.

Encryption at Rest

CloudWatch Contributor Insights for DynamoDB doesn't affect how encryption works in DynamoDB. The primary key data that is published in CloudWatch is encrypted with the AWS owned customer master key (CMK). However, DynamoDB also supports the AWS managed CMK and a customer managed CMK.

If you require your primary key data to be encrypted with the AWS managed CMK or a customer managed CMK, you should not enable CloudWatch Contributor Insights for DynamoDB for that table.

Fine-Grained Access Control

CloudWatch Contributor Insights for DynamoDB doesn't function differently for tables with fine-grained access control (FGAC). In other words, any user who has the appropriate CloudWatch permissions can view FGAC-protected primary keys in CloudWatch Contributor Insights graphs.

If the table's primary key contains FGAC-protected data that you don't want published to CloudWatch, you should not enable CloudWatch Contributor Insights for DynamoDB for that table.
Access Control

You control access to CloudWatch Contributor Insights for DynamoDB using AWS Identity and Access Management (IAM) by limiting DynamoDB control plane permissions and CloudWatch data plane permissions. For more information see, Using IAM with CloudWatch Contributor Insights for DynamoDB.

CloudWatch Contributor Insights for DynamoDB Billing

Charges for CloudWatch Contributor Insights for DynamoDB appear in the CloudWatch section of your monthly bill. These charges are calculated based on the number of DynamoDB events that are processed. For tables and global secondary indexes with CloudWatch Contributor Insights for DynamoDB enabled, each item that is written or read via a data plane operation represents one event.

If a table or global secondary index includes a sort key, each item that is read or written represents two events. This is because DynamoDB is identifying top contributors from separate time series: one for partitions keys only, and one for partition and sort key pairs.

For example, assume that your application performs the following DynamoDB operations: a GetItem, a PutItem, and a BatchWriteItem that puts five items

- If your table or global secondary index has only a partition key, it results in 7 events (1 for the GetItem, 1 for the PutItem, and 5 for the BatchWriteItem).
- If your table or global secondary index has a partition key and sort key, it results in 14 events (2 for the GetItem, 2 for the PutItem, and 10 for the BatchWriteItem).
- A Query operation always results in 1 event, regardless of the number of items returned.

Unlike other DynamoDB features, CloudWatch Contributor Insights for DynamoDB billing does not vary based on the following:

- The capacity mode (provisioned vs. on-demand)
- Whether you perform read or write requests
- The size (KB) of the items read or written

Getting Started with CloudWatch Contributor Insights for DynamoDB

This section describes how to use Amazon CloudWatch Contributor Insights with the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

In the following examples, you use the DynamoDB table that is defined in the Getting Started with DynamoDB tutorial.

Topics

- Using Contributor Insights (Console) (p. 808)
- Using Contributor Insights (AWS CLI) (p. 811)
Using Contributor Insights (Console)

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the Music table.
4. Choose the Contributor Insights tab.
5. Choose Manage Contributor Insights.

6. In the Manage Contributor Insights dialog box, under Contributor Insights Status, choose Enabled for both the Music base table and the AlbumTitle-index global secondary index. Then choose Confirm.

If the operation fails, see DescribeContributorInsights FailureException in the Amazon DynamoDB API Reference for possible reasons.

7. Choose View in DynamoDB.
8. The Contributor Insights graphs are now visible on the **Contributor Insights** tab for the **Music** table.

---

**Creating CloudWatch Alarms**

Follow these steps to create a CloudWatch alarm and be notified when any partition key consumes more than 50,000 **ConsumedThroughputUnits**.

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
2. In the navigation pane on the left side of the console, choose **Contributor Insights**.
3. Choose the **DynamoDBContributorInsights-PKC-Music** rule.
4. Choose the **Actions** drop down.
5. Choose **View in metrics**.
6. Choose **Max Contributor Value**.

**Note**

Only **Max Contributor Value** and **Maximum** return useful statistics. The other statistics in this list don't return meaningful values.
7. On the Actions column, Choose Create Alarm.

8. Enter a value of 50000 for threshold and choose Next.

9. See Using Amazon CloudWatch Alarms for details on how to configure the notification for the alarm.
Using Contributor Insights (AWS CLI)

1. Enable CloudWatch Contributor Insights for DynamoDB on the `Music` base table.

   ```
   aws dynamodb update-contributor-insights --table-name Music --contributor-insights-action=ENABLE
   ```

2. Enable Contributor Insights for DynamoDB on the `AlbumTitle-index` global secondary index.

   ```
   aws dynamodb update-contributor-insights --table-name Music --index-name AlbumTitle-index --contributor-insights-action=ENABLE
   ```

3. Get the status and rules for the `Music` table and all its indexes.

   ```
   aws dynamodb describe-contributor-insights --table-name Music
   ```

4. Disable CloudWatch Contributor Insights for DynamoDB on the `AlbumTitle-index` global secondary index.

   ```
   aws dynamodb update-contributor-insights --table-name Music --index-name AlbumTitle-index --contributor-insights-action=DISABLE
   ```

5. Get the status of the `Music` table and all its indexes.

   ```
   aws dynamodb list-contributor-insights --table-name Music
   ```

Using IAM with CloudWatch Contributor Insights for DynamoDB

The first time that you enable Amazon CloudWatch Contributor Insights for Amazon DynamoDB, DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role, `AWSServiceRoleForDynamoDBCloudWatchContributorInsights`, allows DynamoDB to manage CloudWatch Contributor Insights rules on your behalf. Don't delete this service-linked role. If you delete it, all your managed rules will no longer be cleaned up when you delete your table or global secondary index.

For more information about service-linked roles, see Using Service-Linked Roles in the IAM User Guide.

The following permissions are required:

- To enable or disable CloudWatch Contributor Insights for DynamoDB, you must have `dynamodb:UpdateContributorInsights` permission on the table or index.
- To view CloudWatch Contributor Insights for DynamoDB graphs, you must have `cloudwatch:GetInsightRuleReport` permission.
- To describe CloudWatch Contributor Insights for DynamoDB for a given DynamoDB table or index, you must have `dynamodb:DescribeContributorInsights` permission.
- To list CloudWatch Contributor Insights for DynamoDB statuses for each table and global secondary index, you must have `dynamodb:ListContributorInsights` permission.
Example: Enable or Disable CloudWatch Contributor Insights for DynamoDB

The following IAM policy grants permissions to enable or disable CloudWatch Contributor Insights for DynamoDB.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:CreateServiceLinkedRole",
        "dynamodb:UpdateContributorInsights"
      ],
      "Resource": "*"
    }
  ]
}
```

Example: Retrieve CloudWatch Contributor Insights Rule Report

The following IAM policy grants permissions to retrieve CloudWatch Contributor Insights rule report.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:GetInsightRuleReport"
      ],
      "Resource": "arn:aws:cloudwatch:*:*:insight-rule/DynamoDBContributorInsights*"
    }
  ]
}
```

Example: Selectively Apply CloudWatch Contributor Insights for DynamoDB Permissions Based on Resource

The following IAM policy grants permissions to allow the ListContributorInsights and DescribeContributorInsights actions and denies the UpdateContributorInsights action for a specific global secondary index.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",

Using Service-Linked Roles for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Contributor Insights for DynamoDB. Service-linked roles are predefined by CloudWatch Contributor Insights for DynamoDB and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Contributor Insights for DynamoDB easier because you don't have to manually add the necessary permissions. CloudWatch Contributor Insights for DynamoDB defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Contributor Insights for DynamoDB can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-Linked Role Permissions for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses the service-linked role named AWSServiceRoleForDynamoDBCloudWatchContributorInsights. The purpose of the service-linked role is to allow Amazon DynamoDB to manage Amazon CloudWatch Contributor Insights rules created for DynamoDB tables and global secondary indexes, on your behalf.

The AWSServiceRoleForDynamoDBCloudWatchContributorInsights service-linked role trusts the following services to assume the role:

* contributorinsights.dynamodb.amazonaws.com

The role permissions policy allows CloudWatch Contributor Insights for DynamoDB to complete the following actions on the specified resources:

* Action: Create and manage Insight Rules on DynamoDBContributorInsights

API Version 2012-08-10

813
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

Creating a Service-Linked Role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually create a service-linked role. When you enable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Contributor Insights, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you again.

Editing a Service-Linked Role for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB does not allow you to edit the AWSServiceRoleForDynamoDBCloudWatchContributorInsights service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a Service-Linked Role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually delete the AWSServiceRoleForDynamoDBCloudWatchContributorInsights role. When you disable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB cleans up the resources.

You can also use the IAM console, the AWS CLI or the AWS API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role and then you can manually delete it.

Note

If the CloudWatch Contributor Insights for DynamoDB service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForDynamoDBCloudWatchContributorInsights service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.
Security and Compliance in Amazon DynamoDB

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to DynamoDB, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation will help you understand how to apply the shared responsibility model when using DynamoDB. The following topics show you how to configure DynamoDB to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you to monitor and secure your DynamoDB resources.

**Topics**
- Data Protection in DynamoDB (p. 815)

Data Protection in DynamoDB

Amazon DynamoDB provides a highly durable storage infrastructure designed for mission-critical and primary data storage. Data is redundantly stored on multiple devices across multiple facilities in an Amazon DynamoDB Region.

DynamoDB protects user data stored at rest and also data in transit between on-premises clients and DynamoDB, and between DynamoDB and other AWS resources within the same AWS Region.

**Topics**
- DynamoDB Encryption at Rest (p. 816)
- Data Protection in DynamoDB Accelerator (p. 824)
All user data stored in Amazon DynamoDB is fully encrypted at rest. DynamoDB encryption at rest provides enhanced security by encrypting all your data at rest using encryption keys stored in AWS Key Management Service (AWS KMS). This functionality helps reduce the operational burden and complexity involved in protecting sensitive data. With encryption at rest, you can build security-sensitive applications that meet strict encryption compliance and regulatory requirements.

DynamoDB encryption at rest provides an additional layer of data protection by securing your data in an encrypted table—including its primary key, local and global secondary indexes, streams, global tables, backups, and DynamoDB Accelerator (DAX) clusters whenever the data is stored in durable media. Organizational policies, industry or government regulations, and compliance requirements often require the use of encryption at rest to increase the data security of your applications.

Encryption at rest integrates with AWS KMS for managing the encryption key that is used to encrypt your tables. For more information, see AWS Key Management Service Concepts in the AWS Key Management Service Developer Guide.

When creating a new table, you can choose one of the following customer master keys (CMK) to encrypt your table:

- AWS owned CMK – Default encryption type. The key is owned by DynamoDB (no additional charge).
- AWS managed CMK – The key is stored in your account and is managed by AWS KMS (AWS KMS charges apply).
- Customer managed CMK – The key is stored in your account and is created, owned, and managed by you. You have full control over the CMK (AWS KMS charges apply).

When you access an encrypted table, DynamoDB decrypts the table data transparently. You can switch between the AWS owned CMK, AWS managed CMK, and customer managed CMK at any given time. You don’t have to change any code or applications to use or manage encrypted tables. DynamoDB continues to deliver the same single-digit millisecond latency that you have come to expect, and all DynamoDB queries work seamlessly on your encrypted data.

You can specify an encryption key when you create a new table or switch the encryption keys on an existing table by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or the Amazon DynamoDB API. To learn how, see Managing Encrypted Tables in DynamoDB (p. 819).

Encryption at rest using the AWS owned CMK is offered at no additional charge. However, AWS KMS charges apply for an AWS managed CMK and for a customer managed CMK. For more information about pricing, see AWS KMS pricing.

DynamoDB encryption at rest is available in all AWS Regions, including the AWS China (Beijing) and AWS China (Ningxia) Regions and the AWS GovCloud (US) Regions. Encryption at rest support for customer managed CMKs is available in all AWS Regions except the Asia Pacific (Osaka-Local) Region. For more information, see Encryption at Rest: How It Works (p. 816) and DynamoDB Encryption at Rest Usage Notes (p. 818).

Encryption at Rest: How It Works

Amazon DynamoDB encryption at rest encrypts your data using 256-bit Advanced Encryption Standard (AES-256), which helps secure your data from unauthorized access to the underlying storage.

Encryption at rest integrates with AWS Key Management Service (AWS KMS) for managing the encryption key that is used to encrypt your tables.
When creating a new table or switching the encryption keys on an existing table, you can choose one of the following customer master keys (CMK):

- AWS owned CMK – Default encryption type. The key is owned by DynamoDB (no additional charge).
- AWS managed CMK – The key is stored in your account and is managed by AWS KMS (AWS KMS charges apply).
- Customer managed CMK – The key is stored in your account and is created, owned, and managed by you. You have full control over the CMK (AWS KMS charges apply).

**AWS Owned CMK**

AWS owned CMKs are not stored in your AWS account. They are part of a collection of CMKs that AWS owns and manages for use in multiple AWS accounts. AWS services can use AWS owned CMKs to protect your data.

You cannot view, manage, or use AWS owned CMKs, or audit their use. However, you do not need to do any work or change any programs to protect the keys that encrypt your data.

You are not charged a monthly fee or a usage fee for use of AWS owned CMKs, and they do not count against AWS KMS limits for your account.

**AWS Managed CMK**

AWS managed CMKs are CMKs in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can view the AWS managed CMKs in your account, view their key policies, and audit their use in AWS CloudTrail logs. However, you cannot manage these CMKs or change their permissions.

Encryption at rest automatically integrates with AWS KMS for managing the AWS managed CMK for DynamoDB that is used to encrypt your tables. If an AWS managed CMK doesn’t exist when you create your encrypted DynamoDB table, AWS KMS automatically creates a new key for you. This key is used with encrypted tables that are created in the future. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud.

For more information about managing permissions of the AWS managed CMK, see Authorizing Use of the AWS Managed CMK in the AWS Key Management Service Developer Guide.

**Customer Managed CMK**

Customer managed CMKs are CMKs in your AWS account that you create, own, and manage. You have full control over these CMKs, including establishing and maintaining their key policies, IAM policies, and grants; enabling and disabling them; rotating their cryptographic material; adding tags; creating aliases that refer to them; and scheduling them for deletion. For more information about managing permissions of a customer managed CMK, see Customer Managed CMK Key Policy.

When you specify a customer managed CMK as the table-level encryption key, the DynamoDB table, local and global secondary indexes, and streams are encrypted with the same customer managed CMK. On-demand backups are encrypted with the table-level encryption key that is specified at the time the backup is created. Updating the table-level encryption key does not change the encryption key that is associated with existing on-demand backups.

Setting the state of the customer managed CMK to disabled or scheduling it for deletion prevents all users and the DynamoDB service from being able to encrypt or decrypt data and to perform read and write operations on the table. DynamoDB must have access to your encryption key to ensure that you can continue to access your table and to prevent data loss.

If you disable your customer managed CMK or schedule it for deletion, your table status becomes Inaccessible. To ensure that you can continue working with the table, you must provide DynamoDB
access to the specified encryption key within seven days. As soon as the service detects that your encryption key is inaccessible, DynamoDB sends you an email notification to alert you.

**Note**

If your customer managed CMK remains inaccessible to the DynamoDB service for longer than seven days, the table is archived and can no longer be accessed. DynamoDB creates an on-demand backup of your table, and you are billed for it. You can use this on-demand backup to restore your data to a new table. To initiate the restore, the last customer managed CMK on the table must be enabled, and DynamoDB must have access to it.

**Notes on Using Managed CMKs**

Amazon DynamoDB can't read your table data unless it has access to the CMK stored in your AWS KMS account. DynamoDB uses envelope encryption and key hierarchy to encrypt data. Your AWS KMS encryption key is used to encrypt the root key of this key hierarchy. For more information, see Envelope Encryption in the *AWS Key Management Service Developer Guide*.

You can use AWS CloudTrail and Amazon CloudWatch Logs to track the requests that DynamoDB sends to AWS KMS on your behalf. For more information, see Monitoring DynamoDB Interaction with AWS KMS in the *AWS Key Management Service Developer Guide*.

DynamoDB doesn't call AWS KMS for every DynamoDB operation. The key is refreshed once every 5 minutes per client connection with active traffic.

Ensure that you have configured the SDK to reuse connections. Otherwise, you will experience latencies from DynamoDB having to reestablish new AWS KMS cache entries for each DynamoDB operation. In addition, you might potentially have to face higher AWS KMS and CloudTrail costs. For example, to do this using the Node.js SDK, you can create a new HTTPS agent with `keepAlive` turned on. For more information, see Configuring maxSockets in Node.js in the *AWS SDK for JavaScript Developer Guide*.

**DynamoDB Encryption at Rest Usage Notes**

Consider the following when you are using encryption at rest in Amazon DynamoDB.

**All Table Data Is Encrypted**

Server-side encryption at rest is enabled on all DynamoDB table data and cannot be disabled. You cannot encrypt only a subset of items in a table. DynamoDB has encrypted all existing tables that were previously unencrypted by using the AWS owned customer master key (CMK).

Encryption at rest only encrypts data while it is static (at rest) on a persistent storage media. If data security is a concern for data in transit or data in use, you might need to take additional measures:

- **Data in transit**: All your data in DynamoDB is encrypted in transit (except the data in DAX). By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using Secure Sockets Layer (SSL)/Transport Layer Security (TLS) encryption.
- **Data in use**: Protect your data before sending it to DynamoDB using client-side encryption. For more information, see Client-Side and Server-Side Encryption in the *Amazon DynamoDB Encryption Client Developer Guide*.

You can use streams with encrypted tables. DynamoDB streams are always encrypted with a table-level encryption key. For more information, see Capturing Table Activity with DynamoDB Streams (p. 574).

DynamoDB backups are encrypted, and the table that is restored from a backup also has encryption enabled. You can use the AWS owned CMK, AWS managed CMK, or customer managed CMK to encrypt your backup data. For more information, see On-Demand Backup and Restore for DynamoDB (p. 604).

Local secondary indexes and global secondary indexes are encrypted using the same key as the base table.
Global tables can be encrypted using an AWS owned CMK or AWS managed CMK.

**Encryption Types**

On the AWS Management Console, the encryption type is **KMS** when you use the AWS managed CMK or customer managed CMK to encrypt your data. The encryption type is **DEFAULT** when you use the AWS owned CMK. In the Amazon DynamoDB API, the encryption type is **KMS** when you use the AWS managed CMK or customer managed CMK. In the absence of encryption type, your data is encrypted using the AWS owned CMK. You can switch between the AWS owned CMK, AWS managed CMK, and customer managed CMK at any given time. You can use the console, the AWS Command Line Interface (AWS CLI), or the Amazon DynamoDB API to switch the encryption keys.

Note the following limitations when using customer managed CMKs:

- You cannot use a customer managed CMK to encrypt global tables. For more information, see Global Tables: Multi-Region Replication with DynamoDB (p. 625).
- You cannot use a customer managed CMK with DynamoDB Accelerator (DAX) clusters. For more information, see DAX Encryption at Rest (p. 756).
- You can use a customer managed CMK to encrypt tables that use transactions. However, during transaction propagation, data is encrypted using an AWS owned CMK. Data at rest is still encrypted using your customer managed CMK.
- You can use a customer managed CMK to encrypt tables that use Contributor Insights. However, data that is transmitted to Amazon CloudWatch is encrypted with an AWS owned CMK.
- If you disable your customer managed CMK or schedule it for deletion, any data in DynamoDB Streams is still subject to a 24-hour lifetime. Any unretrieved activity data is eligible for trimming when it is older than 24 hours.
- If you disable your customer managed CMK or schedule it for deletion, Time to Live (TTL) deletes continue for 30 minutes. These TTL deletes continue to be emitted to DynamoDB Streams and are subject to the standard trimming/retention interval.

**Managing Encrypted Tables in DynamoDB**

You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to specify the encryption key on new tables and update the encryption keys on existing tables in Amazon DynamoDB.

**Topics**

- Specifying the Encryption Key for a New Table (p. 819)
- Updating an Encryption Key (p. 822)

**Specifying the Encryption Key for a New Table**

Follow these steps to specify the encryption key on a new table using the Amazon DynamoDB console or the AWS CLI.

**Creating an Encrypted Table (Console)**

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose Create Table. For the Table name, enter Music. For the primary key, enter Artist, and for the sort key, enter SongTitle, both as strings.
4. In Table settings, make sure that Use default settings is not selected.
Table settings

Default settings provide the fastest way to get started with your table. You can modify these default settings now or after your table has been created.

- Use default settings

Note

If Use default settings is selected, tables are encrypted at rest with the AWS owned customer master key (CMK) at no additional cost.

5. Under Encryption at rest, choose an encryption type:

- **Default** – AWS owned CMK. The key is owned by DynamoDB (no additional charge).
- **KMS** – Customer managed CMK. The key is stored in your account and is created, owned, and managed by you (AWS KMS charges apply).
- **KMS** – AWS managed CMK. The key is stored in your account and is managed by AWS Key Management Service (AWS KMS charges apply).

Encryption At Rest

Select Server-side encryption settings for your DynamoDB table to help protect data at rest. Learn more

- **DEFAULT**
  The key is owned by Amazon DynamoDB. You are not charged any fee for using these CMKs.

- **KMS - Customer managed CMK**
  The key is stored in your account that you create, own, and manage. AWS Key Management Service (KMS) charges apply. Learn more

- **KMS - AWS managed CMK**
  The key is stored in your account and is managed by AWS Key Management Service (KMS). AWS KMS charges apply.

6. Choose Create to create the encrypted table. To confirm the encryption type, check the table details on the Overview tab.

Creating an Encrypted Table (AWS CLI)

Use the AWS CLI to create a table with the default AWS owned CMK, the AWS managed CMK, or a customer managed CMK for Amazon DynamoDB.

To create an encrypted table with the default AWS owned CMK

- Create the encrypted Music table as follows.

  ```bash
  aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
  AttributeName=Artist,AttributeType=S \
  AttributeName=SongTitle,AttributeType=S \
  --key-schema \
  ```

  API Version 2012-08-10

  820
To create an encrypted table with the AWS managed CMK for DynamoDB

- Create the encrypted Music table as follows.

```bash
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
   AttributeName=Artist,AttributeType=S \n   AttributeName=SongTitle,AttributeType=S \
--key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
   ReadCapacityUnits=10,WriteCapacityUnits=5 \
--sse-specification Enabled=true,SSEType=KMS
```

The SSEDescription status of the table description is set to ENABLED and the SSEType is KMS.

```
"SSEDescription": {
    "SSEType": "KMS",
    "Status": "ENABLED",
    "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-a123-ab1234a1b234",
}
```

To create an encrypted table with a customer managed CMK for DynamoDB

- Create the encrypted Music table as follows.

```bash
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
   AttributeName=Artist,AttributeType=S \n   AttributeName=SongTitle,AttributeType=S \
--key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
   ReadCapacityUnits=10,WriteCapacityUnits=5 \
--sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-a123-ab1234a1b234
```

The SSEDescription status of the table description is set to ENABLED and the SSEType is KMS.

```
"SSEDescription": {
    "SSEType": "KMS",
    "Status": "ENABLED",
    "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-a123-ab1234a1b234",
}
```
Updating an Encryption Key

You can also use the DynamoDB console or the AWS CLI to update the encryption keys of an existing table between an AWS owned CMK, AWS managed CMK, and customer managed CMK at any time.

Updating an Encryption Key (Console)

2. In the navigation pane on the left side of the console, choose Tables.
3. Choose the table that you want to update, and then choose the Overview tab.

5. Choose an encryption type.

- **Default** – AWS owned CMK. The key is owned by DynamoDB (no additional charge).
• **KMS** – Customer managed CMK. The key is stored in your account and is created, owned, and managed by you (AWS KMS charges apply).

• **KMS** – AWS managed CMK. The key is stored in your account and is managed by AWS Key Management Service (AWS KMS charges apply).

Then choose **Save** to update the encrypted table. To confirm the encryption type, check the table details under the **Overview** tab.

### Updating an Encryption Key (AWS CLI)

The following examples show how to update an encrypted table using the AWS CLI.

**To update an encrypted table with the default AWS owned CMK**

- Update the encrypted **Music** table, as in the following example.

```bash
aws dynamodb update-table \
--table-name Music \
--sse-specification Enabled=false
```

**Note**

This table is now encrypted using the default AWS owned CMK in the DynamoDB service account.

**To update an encrypted table with the AWS managed CMK for DynamoDB**

- Update the encrypted **Music** table, as in the following example.

```bash
aws dynamodb update-table \
--table-name Music \
--sse-specification Enabled=true
```

The **SSEDescription** status of the table description is set to **ENABLED** and the **SSEType** is **KMS**.

```json
"SSEDescription": {
  "SSEType": "KMS",
  "Status": "ENABLED",
  "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-a123-ab1234a1b234",
}
```

**To update an encrypted table with a customer managed CMK for DynamoDB**

- Update the encrypted **Music** table, as in the following example.

```bash
aws dynamodb update-table \
--table-name Music \
--sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-a123-ab1234a1b234
```

The **SSEDescription** status of the table description is set to **ENABLED** and the **SSEType** is **KMS**.

```json
"SSEDescription": {
}
```
Data Protection in DynamoDB Accelerator

Amazon DynamoDB Accelerator (DAX) encryption at rest provides an additional layer of data protection by helping secure your data from unauthorized access to the underlying storage. Organizational policies, industry or government regulations, and compliance requirements might require the use of encryption at rest to protect your data. You can use encryption to increase the data security of your applications that are deployed in the cloud.

For more information about data protection in DAX, see DAX Encryption at Rest (p. 756).

Internetwork Traffic Privacy

Connections are protected both between Amazon DynamoDB and on-premises applications and between DynamoDB and other AWS resources within the same AWS Region.

Traffic Between Service and On-Premises Clients and Applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN? in the AWS Site-to-Site VPN User Guide.
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect? in the AWS Direct Connect User Guide.

Access to DynamoDB via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2 or above. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the AWS Security Token Service (STS) to generate temporary security credentials to sign requests.

Traffic Between AWS Resources in the Same Region

An Amazon Virtual Private Cloud (Amazon VPC) endpoint for DynamoDB is a logical entity within a VPC that allows connectivity only to DynamoDB. The Amazon VPC routes requests to DynamoDB and routes responses back to the VPC. For more information, see VPC Endpoints in the Amazon VPC User Guide. For example policies that you can use to control access from VPC endpoints, see Using IAM Policies to Control Access to DynamoDB.

Identity and Access Management

IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon DynamoDB resources. You can use AWS Identity and Access Management (IAM) to
manage access permissions and implement security policies for both Amazon DynamoDB and DynamoDB Accelerator (DAX).

Identity and Access Management in Amazon DynamoDB

Access to Amazon DynamoDB requires credentials. Those credentials must have permissions to access AWS resources, such as an Amazon DynamoDB table or an Amazon Elastic Compute Cloud (Amazon EC2) instance. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and DynamoDB to help secure access to your resources.

- Authentication (p. 825)
- Access Control (p. 826)

Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

- **IAM user** – An IAM user is an identity within your AWS account that has specific custom permissions (for example, permissions to create a table in DynamoDB). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

In addition to a user name and password, you can also generate **access keys** for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys to cryptographically sign your request. If you don’t use AWS tools, you must sign the request yourself. DynamoDB supports **Signature Version 4**, a protocol for authenticating inbound API requests. For more information about authenticating requests, see **Signature Version 4 Signing Process** in the AWS General Reference.

- **IAM role** – An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. IAM roles with temporary credentials are useful in the following situations:
• **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated Users and Roles in the IAM User Guide.

• **AWS service access** – A service role is an IAM role that a service assumes to perform actions in your account on your behalf. When you set up some AWS service environments, you must define a role for the service to assume. This service role must include all the permissions that are required for the service to access the AWS resources that it needs. Service roles vary from service to service, but many allow you to choose your permissions as long as you meet the documented requirements for that service. Service roles provide access only within your account and cannot be used to grant access to services in other accounts. You can create, modify, and delete a service role from within IAM. For example, you can create a role that allows Amazon Redshift to access an Amazon S3 bucket on your behalf and then load data from that bucket into an Amazon Redshift cluster. For more information, see Creating a Role to Delegate Permissions to an AWS Service in the IAM User Guide.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances in the IAM User Guide.

**Access Control**

You can have valid credentials to authenticate your requests, but unless you have permissions you cannot create or access Amazon DynamoDB resources. For example, you must have permissions to create an Amazon DynamoDB table.

The following sections describe how to manage permissions for Amazon DynamoDB. We recommend that you read the overview first.

• Overview of Managing Access (p. 826)
• Using Identity-Based Policies (IAM Policies) (p. 829)
• DynamoDB API Permissions Reference (p. 836)
• Using Conditions (p. 841)

**Overview of Managing Access Permissions to Your Amazon DynamoDB Resources**

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles), and some services (such as AWS Lambda) also support attaching permissions policies to resources.

**Note**

An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific actions that you want to allow on those resources.

DynamoDB Resources and Operations

In DynamoDB, the primary resources are tables. DynamoDB also supports additional resource types, indexes, and streams. However, you can create indexes and streams only in the context of an existing DynamoDB table. These are referred to as subresources.

These resources and subresources have unique Amazon Resource Names (ARNs) associated with them, as shown in the following table.

<table>
<thead>
<tr>
<th>Resource Type</th>
<th>ARN Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>arn:aws:dynamodb:region:account-id:table/table-name</td>
</tr>
<tr>
<td>Index</td>
<td>arn:aws:dynamodb:region:account-id:table/table-name/index/index-name</td>
</tr>
</tbody>
</table>

DynamoDB provides a set of operations to work with DynamoDB resources. For a list of available operations, see Amazon DynamoDB Actions.

Understanding Resource Ownership

The AWS account owns the resources that are created in the account, regardless of who created the resources. Specifically, the resource owner is the AWS account of the principal entity (that is, the AWS account root user, an IAM user, or an IAM role) that authenticates the resource creation request. The following examples illustrate how this works:

- If you use your AWS account root user credentials to create a table, your AWS account is the owner of the resource (in DynamoDB, the resource is a table).
- If you create an IAM user in your AWS account and grant permissions to create a table to that user, the user can create a table. However, your AWS account, to which the user belongs, owns the table resource.
- If you create an IAM role in your AWS account with permissions to create a table, anyone who can assume the role can create a table. Your AWS account, to which the role belongs, owns the table resource.

Managing Access to Resources

A permissions policy describes who has access to what. The following section explains the available options for creating permissions policies.

Note

This section discusses using IAM in the context of DynamoDB. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the
Policies attached to an IAM identity are referred to as *identity-based* policies (IAM policies). Policies attached to a resource are referred to as *resource-based* policies. DynamoDB supports only identity-based policies (IAM policies).

**Topics**

- Identity-Based Policies (IAM Policies) (p. 828)
- Resource-Based Policies (p. 829)

**Identity-Based Policies (IAM Policies)**

You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – To grant a user permissions to create an Amazon DynamoDB resource, such as a table, you can attach a permissions policy to a user or group that the user belongs to.

- **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in account A can create a role to grant cross-account permissions to another AWS account (for example, account B) or an AWS service as follows:

  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in account A.

  2. Account A administrator attaches a trust policy to the role identifying account B as the principal who can assume the role.

  3. Account B administrator can then delegate permissions to assume the role to any users in account B. Doing this allows users in account B to create or access resources in account A. The principal in the trust policy can also be an AWS service principal if you want to grant an AWS service permissions to assume the role.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

The following is an example policy that grants permissions for one DynamoDB action (dynamodb:ListTables). The wildcard character (*) in the Resource value means that you can use this action to obtain the names of all the tables owned by the AWS account in the current AWS Region.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ListTables",
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListTables"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about using identity-based policies with DynamoDB, see Using Identity-Based Policies (IAM Policies) for Amazon DynamoDB (p. 829). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.
**Resource-Based Policies**

Other services, such as Amazon S3, also support resource-based permissions policies. For example, you can attach a policy to an S3 bucket to manage access permissions to that bucket. DynamoDB doesn't support resource-based policies.

**Specifying Policy Elements: Actions, Effects, and Principals**

For each DynamoDB resource, the service defines a set of API operations. To grant permissions for these API operations, DynamoDB defines a set of actions that you can specify in a policy. Some API operations can require permissions for more than one action in order to perform the API operation. For more information about resources and API operations, see DynamoDB Resources and Operations (p. 827) and DynamoDB Actions.

The following are the most basic policy elements:

- **Resource** – You use an Amazon Resource Name (ARN) to identify the resource that the policy applies to. For more information, see DynamoDB Resources and Operations (p. 827).
- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, `dynamodb:Query` allows the user permissions to perform the DynamoDB Query operation.
- **Effect** – You specify the effect, either allow or deny, when the user requests the specific action. If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.
- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. For resource-based policies, you specify the user, account, service, or other entity that you want to receive permissions (applies to resource-based policies only). DynamoDB doesn't support resource-based policies.

To learn more about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

For a list showing all of the Amazon DynamoDB API operations and the resources that they apply to, see DynamoDB API Permissions: Actions, Resources, and Conditions Reference (p. 836).

**Specifying Conditions in a Policy**

When you grant permissions, you can use the access policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

To express conditions, you use predefined condition keys. There are AWS-wide condition keys and DynamoDB–specific keys that you can use as appropriate. For a complete list of AWS-wide keys, see Available Keys for Conditions in the IAM User Guide. For a complete list of DynamoDB–specific keys, see Using IAM Policy Conditions for Fine-Grained Access Control (p. 841).

**Using Identity-Based Policies (IAM Policies) for Amazon DynamoDB**

This topic provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on Amazon DynamoDB resources.

**Important**

We recommend that you first review the introductory topics that explain the basic concepts and options available to manage access to your Amazon DynamoDB resources. For more
The sections in this topic cover the following:

- Permissions Required to Use the Amazon DynamoDB Console (p. 830)
- AWS Managed (Predefined) Policies for Amazon DynamoDB (p. 830)
- Customer Managed Policy Examples (p. 831)

The following shows an example of a permissions policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DescribeQueryScanBooksTable",
         "Effect": "Allow",
         "Action": [
            "dynamodb:DescribeTable",
            "dynamodb:Query",
            "dynamodb:Scan"
         ],
      }
   ]
}
```

The policy has one statement that grants permissions for three DynamoDB actions (dynamodb:DescribeTable, dynamodb:Query, and dynamodb:Scan) on a table in the us-west-2 Region, which is owned by the AWS account specified by `account-id`. The Amazon Resource Name (ARN) in the Resource value specifies the table to which the permissions apply.

**Permissions Required to Use the Amazon DynamoDB Console**

For a user to work with the DynamoDB console, that user must have a minimum set of permissions that allow the user to work with the DynamoDB resources for their AWS account. In addition to these DynamoDB permissions, the console requires permissions from the following services:

- Amazon CloudWatch permissions to display metrics and graphs.
- AWS Data Pipeline permissions to export and import DynamoDB data.
- AWS Identity and Access Management permissions to access roles necessary for exports and imports.
- Amazon Simple Notification Service permissions to notify you whenever a CloudWatch alarm is triggered.
- AWS Lambda permissions to process DynamoDB Streams records.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console won't function as intended for users with that IAM policy. To ensure that those users can still use the DynamoDB console, also attach the AmazonDynamoDBReadOnlyAccess managed policy to the user, as described in *AWS Managed (Predefined) Policies for Amazon DynamoDB* (p. 830).

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon DynamoDB API.

**AWS Managed (Predefined) Policies for Amazon DynamoDB**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases
so that you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to DynamoDB and are grouped by use case scenario:

- **AmazonDynamoDBReadOnlyAccess** – Grants read-only access to DynamoDB resources by using the AWS Management Console.
- **AmazonDynamoDBFullAccess** – Grants full access to DynamoDB resources by using the AWS Management Console.
- **AmazonDynamoDBFullAccesswithDataPipeline** – Grants full access to DynamoDB resources, including export and import using AWS Data Pipeline, by using AWS Management Console.

**Note**
You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

We do not recommend using these AWS managed policies for production databases. Instead, you should create your own custom IAM policies to allow permissions for DynamoDB actions and resources following the least privilege model. You can attach these custom policies to the IAM users or groups that require those permissions.

**Customer Managed Policy Examples**

In this section, you can find example user policies that grant permissions for various DynamoDB actions. These policies work when you are using AWS SDKs or the AWS CLI. When you are using the console, you need to grant additional permissions specific to the console, which is discussed in Permissions Required to Use the Amazon DynamoDB Console (p. 830).

**Note**
All examples use the us-west-2 Region and contain fictitious account IDs.

**Examples**

- **Example 1: Allow a User to Perform Any DynamoDB Actions on a Table (p. 831)**
- **Example 2: Allow Read-Only Access on Items in a Table (p. 832)**
- **Example 3: Allow Put, Update, and Delete Operations on a Specific Table (p. 832)**
- **Example 4: Allow Access to a Specific Table and All of Its Indexes (p. 832)**
- **Example 5: Set Up Permissions Policies for Separate Test and Production Environments (p. 833)**
- **Example 6: Prevent a User from Purchasing Reserved Capacity Offerings (p. 834)**
- **Example 7: Allow Read Access for a DynamoDB Stream Only (Not for the Table) (p. 835)**
- **Example 8: Allow an AWS Lambda Function to Process DynamoDB Stream Records (p. 836)**

**Example 1: Allow a User to Perform Any DynamoDB Actions on a Table**

The following permissions policy grants permissions for all DynamoDB actions on a table. The ARN value specified in the Resource identifies a table in a specific Region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllAPIActionsOnBooks",
            "Effect": "Allow",
            "Action": "dynamodb:*",
        }
    ]
}
```
Note

If you replace the table name in the resource ARN (Books) with a wildcard character (*), you allow any DynamoDB actions on all tables in the account. Carefully consider the security implications if you decide to do this.

Example 2: Allow Read-Only Access on Items in a Table

The following permissions policy grants permissions for the GetItem and BatchGetItem DynamoDB actions only and thereby sets read-only access to a table.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ReadOnlyAPIActionsOnBooks",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem"
            ],
        }
    ]
}
```

Example 3: Allow Put, Update, and Delete Operations on a Specific Table

The following permissions policy grants permissions for the PutItem, UpdateItem, and DeleteItem actions on a specific DynamoDB table.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PutUpdateDeleteOnBooks",
            "Effect": "Allow",
            "Action": [
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem"
            ],
        }
    ]
}
```

Example 4: Allow Access to a Specific Table and All of Its Indexes

The following permissions policy grants permissions for all of the DynamoDB actions on a table (Book) and all of the table's indexes. For more information about how indexes work, see Improving Data Access with Secondary Indexes (p. 497).

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessAllIndexesOnBooks",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem"
            ],
        }
    ]
}
```
Example 5: Set Up Permissions Policies for Separate Test and Production Environments

Suppose that you have separate test and production environments where each environment maintains its own version of a table named ProductCatalog. If you create these ProductCatalog tables from the same AWS account, testing work might affect the production environment because of the way that permissions are set up. (For example, the limits on concurrent create and delete actions are set at the AWS account level.) As a result, each action in the test environment reduces the number of actions that are available in your production environment. There is also a risk that the code in your test environment might accidentally access tables in the production environment. To prevent these issues, consider creating separate AWS accounts for your production and test environments.

Suppose further that you have two developers, Bob and Alice, who are testing the ProductCatalog table. Instead of creating a separate AWS account for every developer, your developers can share the same test account. In this test account, you can create a copy of the same table for each developer to work on, such as Alice_ProductCatalog and Bob_ProductCatalog. In this case, you can create IAM users Alice and Bob in the AWS account that you created for the test environment. You can then grant permissions to these users to perform DynamoDB actions on the tables that they own.

To grant these user permissions, you can do either of the following:

- Create a separate policy for each user and then attach each policy to its user separately. For example, you can attach the following policy to user Alice to allow her access to all DynamoDB actions on the Alice_ProductCatalog table:

  ```json
  {
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "AllAPIActionsOnAliceTable",
        "Effect": "Allow",
        "Action": ["dynamodb:*"],
      }
    ]
  }
  ```

  Then, you can create a similar policy with a different resource (Bob_ProductCatalog table) for user Bob.

- Instead of attaching policies to individual users, you can use IAM policy variables to write a single policy and attach it to a group. You need to create a group and, for this example, add both users Alice and user Bob to the group. The following example grants permissions to perform all DynamoDB actions on the `${aws:username}_ProductCatalog` table. The policy variable `${aws:username}` is replaced by the requester's user name when the policy is evaluated. For example, if Alice sends a request to add an item, the action is allowed only if Alice is adding items to the Alice_ProductCatalog table.
Identity and Access Management

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllAPIActionsOnUserSpecificTable",
      "Effect": "Allow",
      "Action": [
        "dynamodb:*"
      ],
    },
    {
      "Sid": "AdditionalPrivileges",
      "Effect": "Allow",
      "Action": [
        "dynamodb:ListTables",
        "dynamodb:DescribeTable",
        "cloudwatch:*",
        "sns:*"
      ],
      "Resource": "*"
    }
  ]
}
```

**Note**
When using IAM policy variables, you must explicitly specify the 2012-10-17 version of the access policy language in the policy. The default version of the access policy language (2008-10-17) does not support policy variables.

Instead of identifying a specific table as a resource, you can use a wildcard character (*) to grant permissions on all tables where the name is prefixed with the name of the IAM user that is making the request, as shown following.

```
```

**Example 6: Prevent a User from Purchasing Reserved Capacity Offerings**

DynamoDB customers can purchase reserved capacity, as described at [Amazon DynamoDB Pricing](https://aws.amazon.com/dynamodb/pricing/). With reserved capacity, you pay a one-time upfront fee and commit to paying for a minimum usage level, at significant savings, over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all of the users in your organization to have the same levels of access.

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- **dynamodb:DescribeReservedCapacity** – returns the reserved capacity purchases that are currently in effect.
- **dynamodb:DescribeReservedCapacityOfferings** – returns details about the reserved capacity plans that are currently offered by AWS.
- **dynamodb:PurchaseReservedCapacityOfferings** – performs an actual purchase of reserved capacity.

The AWS Management Console uses these API operations to display reserved capacity information and to make purchases. You cannot call these operations from an application program, because they can be
accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity offerings and current purchases using the AWS Management Console—but new purchases are denied.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowReservedCapacityDescriptions",
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeReservedCapacity",
        "dynamodb:DescribeReservedCapacityOfferings"
      ],
    },
    {
      "Sid": "DenyReservedCapacityPurchases",
      "Effect": "Deny",
      "Action": "dynamodb:PurchaseReservedCapacityOfferings",
    }
  ]
}
```

**Example 7: Allow Read Access for a DynamoDB Stream Only (Not for the Table)**

When you enable DynamoDB Streams on a table, it captures information about every modification to data items in the table. For more information, see Capturing Table Activity with DynamoDB Streams (p. 574).

In some cases, you might want to prevent an application from reading data from a DynamoDB table, while still allowing access to that table's stream. For example, you can configure AWS Lambda to poll the stream and invoke a Lambda function when item updates are detected, and then perform additional processing.

The following actions are available for controlling access to DynamoDB Streams:

- `dynamodb:DescribeStream`
- `dynamodb:GetRecords`
- `dynamodb:GetShardIterator`
- `dynamodb:ListStreams`

The following example creates a policy that grants users permissions to access the streams on a table named `GameScores`. The final wildcard character (*) in the ARN matches any stream ID associated with that table.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessGameScoresStreamOnly",
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeStream",
        "dynamodb:GetRecords",
        "dynamodb:GetShardIterator"
      ]
    }
  ]
}
```
Note that this policy permits access to the streams on the `GameScores` table, but not to the table itself.

**Example 8: Allow an AWS Lambda Function to Process DynamoDB Stream Records**

If you want certain actions to be performed based on new events in a DynamoDB stream, you can write an AWS Lambda function that is triggered by these new events. For more information about using Lambda with stream events, see [DynamoDB Streams and AWS Lambda Triggers](p. 595). A Lambda function such as this needs permissions to read data from the DynamoDB stream.

To grant permissions to Lambda, you use the permissions policy that is associated with the Lambda function's IAM role (execution role), which you specify when you create the Lambda function.

For example, you can associate the following permissions policy with the execution role to grant Lambda permissions to perform the DynamoDB Streams actions listed.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowLambdaFunctionInvocation",
            "Effect": "Allow",
            "Action": [
                "lambda:InvokeFunction"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "AllAPIAccessForDynamoDBStreams",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:ListStreams"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information, see [AWS Lambda Permission Model](in the [AWS Lambda Developer Guide](p. 836)).

**DynamoDB API Permissions: Actions, Resources, and Conditions Reference**

When you are setting up [Access Control](p. 826) and writing a permissions policy that you can attach to an IAM identity (identity-based policies), you can use the following list as a reference. The list includes each DynamoDB API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's `Action` field, and you specify the resource value in the policy's `Resource` field.
You can use AWS-wide condition keys in your DynamoDB policies to express conditions. For a complete list of AWS-wide keys, see Available Keys in the IAM User Guide.

In addition to the AWS-wide condition keys, DynamoDB has its own specific keys that you can use in conditions. For more information, see Using IAM Policy Conditions for Fine-Grained Access Control (p. 841).

**Note**
To specify an action, use the `dynamodb:` prefix followed by the API operation name (for example, `dynamodb:CreateTable`).

Using IAM Policy Conditions for Fine-Grained Access Control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect.

**Overview**

In DynamoDB, you have the option to specify conditions when granting permissions using an IAM policy (see [Access Control (p. 826)]). For example, you can:

- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

In DynamoDB, you can specify conditions in an IAM policy using condition keys, as illustrated in the use case in the following section.

**Note**

Some AWS services also support tag-based conditions; however, DynamoDB does not.

**Permissions Use Case**

In addition to controlling access to DynamoDB API actions, you can also control access to individual data items and attributes. For example, you can do the following:

- Grant permissions on a table, but restrict access to specific items in that table based on certain primary key values. An example might be a social networking app for games, where all users' saved game data
is stored in a single table, but no users can access data items that they do not own, as shown in the following illustration:

- Hide information so that only a subset of attributes is visible to the user. An example might be an app that displays flight data for nearby airports, based on the user's location. Airline names, arrival and departure times, and flight numbers are all displayed. However, attributes such as pilot names or the number of passengers are hidden, as shown in the following illustration:

To implement this kind of fine-grained access control, you write an IAM permissions policy that specifies conditions for accessing security credentials and the associated permissions. You then apply the policy to IAM users, groups, or roles that you create using the IAM console. Your IAM policy can restrict access to individual items in a table, access to the attributes in those items, or both at the same time.

You can optionally use web identity federation to control access by users who are authenticated by Login with Amazon, Facebook, or Google. For more information, see Using Web Identity Federation (p. 851).

You use the IAM Condition element to implement a fine-grained access control policy. By adding a Condition element to a permissions policy, you can allow or deny access to items and attributes in DynamoDB tables and indexes, based upon your particular business requirements.

As an example, consider a mobile gaming app that lets players select from and play a variety of different games. The app uses a DynamoDB table named GameScores to keep track of high scores and other user data. Each item in the table is uniquely identified by a user ID and the name of the game that the user played. The GameScores table has a primary key consisting of a partition key (UserId) and sort key
(GameTitle). Users only have access to game data associated with their user ID. A user who wants to play a game must belong to an IAM role named GameRole, which has a security policy attached to it.

To manage user permissions in this app, you could write a permissions policy such as the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToOnlyItemsMatchingUserID",
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem",
        "dynamodb:BatchWriteItem"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
      ],
      "Condition": {
        "ForAllValues:StringEquals": {
          "dynamodb:LeadingKeys": [
            "${www.amazon.com:user_id}"
          ],
          "dynamodb:Attributes": [
            "UserId",
            "GameTitle",
            "Wins",
            "Losses",
            "TopScore",
            "TopScoreDateTime"
          ]
        },
        "StringEqualsIfExists": {
          "dynamodb:Select": "SPECIFIC_ATTRIBUTES"
        }
      }
    }
  ]
}
```

In addition to granting permissions for specific DynamoDB actions (Action element) on the GameScores table (Resource element), the Condition element uses the following condition keys specific to DynamoDB that limit the permissions as follows:

- **dynamodb:LeadingKeys** – This condition key allows users to access only the items where the partition key value matches their user ID. This ID, `${www.amazon.com:user_id}`, is a substitution variable. For more information about substitution variables, see Using Web Identity Federation (p. 851).

- **dynamodb:Attributes** – This condition key limits access to the specified attributes so that only the actions listed in the permissions policy can return values for these attributes. In addition, the StringEqualsIfExists clause ensures that the app must always provide a list of specific attributes to act upon and that the app can't request all attributes.

When an IAM policy is evaluated, the result is always either true (access is allowed) or false (access is denied). If any part of the Condition element is false, the entire policy evaluates to false and access is denied.
Important
If you use `dynamodb:Attributes`, you must specify the names of all of the primary key and index key attributes for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can’t use these key attributes to perform the requested action.

IAM policy documents can contain only the following Unicode characters: horizontal tab (U+0009), linefeed (U+000A), carriage return (U+000D), and characters in the range U+0020 to U+00FF.

Specifying Conditions: Using Condition Keys
AWS provides a set of predefined condition keys (AWS-wide condition keys) for all AWS services that support IAM for access control. For example, you can use the `aws:SourceIp` condition key to check the requester's IP address before allowing an action to be performed. For more information and a list of the AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.

The following table shows the DynamoDB service-specific condition keys that apply to DynamoDB.

</tr>
</tbody>
</table>

**dynamodb:ReturnConsumedCapacity**

ReturnConsumedCapacity represents the parameter of a request. ReturnConsumedCapacity can be one of the following values:

- TOTAL
- NONE

**Limiting User Access**

Many IAM permissions policies allow users to access only those items in a table where the partition key value matches the user identifier. For example, the game app preceding limits access in this way so that users can only access game data that is associated with their user ID. The IAM substitution variables `${www.amazon.com:user_id}`, `${graph.facebook.com:id}`, and `${accounts.google.com:sub}` contain user identifiers for Login with Amazon, Facebook, and Google. To learn how an application logs in to one of these identity providers and obtains these identifiers, see Using Web Identity Federation (p. 851).

**Note**

Each of the examples in the following section sets the **Effect** clause to **Allow** and specifies only the actions, resources, and parameters that are allowed. Access is permitted only to what is explicitly listed in the IAM policy.

In some cases, it is possible to rewrite these policies so that they are deny-based (that is, setting the **Effect** clause to **Deny** and inverting all of the logic in the policy). However, we recommend that you avoid using deny-based policies with DynamoDB because they are difficult to write correctly, compared to allow-based policies. In addition, future changes to the DynamoDB API (or changes to existing API inputs) can render a deny-based policy ineffective.

**Example Policies: Using Conditions for Fine-Grained Access Control**

This section shows several policies for implementing fine-grained access control on DynamoDB tables and indexes.

**Note**

All examples use the us-west-2 Region and contain fictitious account IDs.

1: **Grant Permissions That Limit Access to Items with a Specific Partition Key Value**

The following permissions policy grants permissions that allow a set of DynamoDB actions on the GamesScore table. It uses the `dynamodb:LeadingKeys` condition key to limit user actions only on the items whose `UserID` partition key value matches the Login with Amazon unique user ID for this app.

**Important**

The list of actions does not include permissions for `Scan` because `Scan` returns all items regardless of the leading keys.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "FullAccessToUserItems",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
```

Note
When using policy variables, you must explicitly specify version 2012-10-17 in the policy. The default version of the access policy language, 2008-10-17, does not support policy variables.

To implement read-only access, you can remove any actions that can modify the data. In the following policy, only those actions that provide read-only access are included in the condition.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ReadOnlyAccessToUserItems",
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
      ],
      "Condition": {
        "ForAllValues:StringEquals": {
          "dynamodb:LeadingKeys": [
            "#{www.amazon.com:user_id}"  
          ]
        }
      }
    }
  ]
}
```

Important
If you use dynamodb:Attributes, you must specify the names of all of the primary key and index key attributes, for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can’t use these key attributes to perform the requested action.

2: Grant Permissions That Limit Access to Specific Attributes in a Table

The following permissions policy allows access to only two specific attributes in a table by adding the dynamodb:Attributes condition key. These attributes can be read, written, or evaluated in a conditional write or scan filter.
The policy takes an allow list (sometimes known as whitelist) approach, which allows access to a named set of attributes. You can write an equivalent policy that denies access to other attributes instead. We don't recommend this deny list (or blacklist) approach. Users can determine the names of these denied attributes by repeatedly issuing requests for all possible attribute names, eventually finding an attribute that they aren't allowed to access. To avoid this, follow the principle of least privilege, as explained in Wikipedia at http://en.wikipedia.org/wiki/Principle_of_least_privilege, and use an allow list approach to enumerate all of the allowed values, rather than specifying the denied attributes.

This policy doesn't permit PutItem, DeleteItem, or BatchWriteItem. These actions always replace the entire previous item, which would allow users to delete the previous values for attributes that they are not allowed to access.

The StringEqualsIfExists clause in the permissions policy ensures the following:

- If the user specifies the Select parameter, then its value must be SPECIFIC_ATTRIBUTES. This requirement prevents the API action from returning any attributes that aren't allowed, such as from an index projection.
- If the user specifies the ReturnValues parameter, then its value must be NONE, UPDATED_OLD, or UPDATED_NEW. This is required because the UpdateItem action also performs implicit read operations to check whether an item exists before replacing it, and so that previous attribute values can be returned if requested. Restricting ReturnValues in this way ensures that users can only read or write the allowed attributes.
• The StringEqualsIfExists clause assures that only one of these parameters — Select or ReturnValues — can be used per request, in the context of the allowed actions.

The following are some variations on this policy:

• To allow only read actions, you can remove UpdateItem from the list of allowed actions. Because none of the remaining actions accept ReturnValues, you can remove ReturnValues from the condition. You can also change StringEqualsIfExists to StringEquals because the Select parameter always has a value (ALL_ATTRIBUTES, unless otherwise specified).

• To allow only write actions, you can remove everything except UpdateItem from the list of allowed actions. Because UpdateItem does not use the Select parameter, you can remove Select from the condition. You must also change StringEqualsIfExists to StringEquals because the ReturnValues parameter always has a value (NONE unless otherwise specified).

• To allow all attributes whose name matches a pattern, use StringLike instead of StringEquals, and use a multi-character pattern match wildcard character (*).

3: Grant Permissions to Prevent Updates on Certain Attributes

The following permissions policy limits user access to updating only the specific attributes identified by the dynamodb:Attributes condition key. The StringNotLike condition prevents an application from updating the attributes specified using the dynamodb:Attributes condition key.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PreventUpdatesOnCertainAttributes",
      "Effect": "Allow",
      "Action": [ "dynamodb:UpdateItem" ],
      "Condition": {
        "ForAllValues:StringNotLike": {
          "dynamodb:Attributes": [
            "FreeGamesAvailable",
            "BossLevelUnlocked"
          ],
        },
        "StringEquals": {
          "dynamodb:ReturnValues": [ "NONE", "UPDATED_OLD", "UPDATED_NEW" ]
        }
      }
    }
  ]
}
```

Note the following:

• The UpdateItem action, like other write actions, requires read access to the items so that it can return values before and after the update. In the policy, you limit the action to accessing only the attributes that are allowed to be updated by specifying the dynamodb:ReturnValues condition key. The condition key restricts ReturnValues in the request to specify only NONE, UPDATED_OLD, or UPDATED_NEW and doesn't include ALL_OLD or ALL_NEW.
• The PutItem and DeleteItem actions replace an entire item, and thus allows applications to modify any attributes. So when limiting an application to updating only specific attributes, you should not grant permission for these APIs.

4: Grant Permissions to Query Only Projected Attributes in an Index

The following permissions policy allows queries on a secondary index (TopScoreDateTimeIndex) by using the dynamodb:Attributes condition key. The policy also limits queries to requesting only specific attributes that have been projected into the index.

To require the application to specify a list of attributes in the query, the policy also specifies the dynamodb:Select condition key to require that the Select parameter of the DynamoDB query action is SPECIFIC_ATTRIBUTES. The list of attributes is limited to a specific list that is provided using the dynamodb:Attributes condition key.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "QueryOnlyProjectedIndexAttributes",
            "Effect": "Allow",
            "Action": [
                "dynamodb:Query"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/TopScoreDateTimeIndex"
            ],
            "Condition": {
                "ForAllValues:StringEquals": {
                    "dynamodb:Attributes": [
                        "TopScoreDateTime",
                        "GameTitle",
                        "Wins",
                        "Losses",
                        "Attempts"
                    ]
                },
                "StringEquals": {
                    "dynamodb:Select": "SPECIFIC_ATTRIBUTES"
                }
            }
        }
    ]
}
```

The following permissions policy is similar, but the query must request all of the attributes that have been projected into the index.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "QueryAllIndexAttributes",
            "Effect": "Allow",
            "Action": [
                "dynamodb:Query"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/TopScoreDateTimeIndex"
            ],
            "Condition": {
                "ForAllValues:StringEquals": {
                    "dynamodb:Attributes": [
                        "TopScoreDateTime",
                        "GameTitle",
                        "Wins",
                        "Losses",
                        "Attempts"
                    ]
                }
            }
        }
    ]
}
```
"Condition": {  
  "StringEquals": {  
    "dynamodb:Select": "ALL_PROJECTED_ATTRIBUTES"  
  }  
}  
}  
]  
}  
}

5: Grant Permissions to Limit Access to Certain Attributes and Partition Key Values

The following permissions policy allows specific DynamoDB actions (specified in the Action element) on a table and a table index (specified in the Resource element). The policy uses the dynamodb:LeadingKeys condition key to restrict permissions to only the items whose partition key value matches the user’s Facebook ID.

```json
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "LimitAccessToCertainAttributesAndKeyValues",  
      "Effect": "Allow",  
      "Action": [  
        "dynamodb:UpdateItem",  
        "dynamodb:GetItem",  
        "dynamodb:Query",  
        "dynamodb:BatchGetItem"  
      ],  
      "Resource": [  
        "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/TopScoreDateTimeIndex"  
      ],  
      "Condition": {  
        "ForAllValues:StringEquals": {  
          "dynamodb:LeadingKeys": [  
            "{graph.facebook.com:id}"  
          ],  
          "dynamodb:Attributes": [  
            "attribute-A",  
            "attribute-B"  
          ]  
        },  
        "StringEqualsIfExists": {  
          "dynamodb:Select": "SPECIFIC_ATTRIBUTES",  
          "dynamodb:ReturnValues": [  
            "NONE",  
            "UPDATED_OLD",  
            "UPDATED_NEW"  
          ]  
        }  
      }  
    }  
  ]  
}
```

Note the following:

- Write actions allowed by the policy (UpdateItem) can only modify attribute-A or attribute-B.
- Because the policy allows UpdateItem, an application can insert new items, and the hidden attributes will be null in the new items. If these attributes are projected into TopScoreDateTimeIndex, the policy has the added benefit of preventing queries that cause fetches from the table.
• Applications cannot read any attributes other than those listed in `dynamodb:Attributes`. With this policy in place, an application must set the `Select` parameter to `SPECIFIC_ATTRIBUTES` in read requests, and only whitelisted attributes can be requested. For write requests, the application cannot set `ReturnValues` to `ALL_OLD` or `ALL_NEW` and it cannot perform conditional write operations based on any other attributes.

Using Web Identity Federation

If you are writing an application targeted at large numbers of users, you can optionally use web identity federation for authentication and authorization. Web identity federation removes the need for creating individual IAM users. Instead, users can sign in to an identity provider and then obtain temporary security credentials from AWS Security Token Service (AWS STS). The app can then use these credentials to access AWS services.

Web identity federation supports the following identity providers:

• Login with Amazon
• Facebook
• Google

Additional Resources for Web Identity Federation

The following resources can help you learn more about web identity federation:

• The post Web Identity Federation using the AWS SDK for .NET on the AWS Developer blog walks through how to use web identity federation with Facebook. It includes code snippets in C# that show how to assume an IAM role with web identity and how to use temporary security credentials to access an AWS resource.
• The AWS SDK for iOS and the AWS SDK for Android contain sample apps. They include code that shows how to invoke the identity providers, and then how to use the information from these providers to get and use temporary security credentials.
• The article Web Identity Federation with Mobile Applications discusses web identity federation and shows an example of how to use web identity federation to access an AWS resource.

Example Policy for Web Identity Federation

To show how you can use web identity federation with DynamoDB, revisit the `GameScores` table that was introduced in Using IAM Policy Conditions for Fine-Grained Access Control (p. 841). Here is the primary key for `GameScores`.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Primary Key Type</th>
<th>Partition Key Name and Type</th>
<th>Sort Key Name and Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>GameScores (UserId, GameTitle, ...)</td>
<td>Composite</td>
<td>Attribute Name: Userld Type: String</td>
<td>Attribute Name: GameTitle Type: String</td>
</tr>
</tbody>
</table>
Now suppose that a mobile gaming app uses this table, and that app needs to support thousands, or even millions, of users. At this scale, it becomes very difficult to manage individual app users, and to guarantee that each user can only access their own data in the GameScores table. Fortunately, many users already have accounts with a third-party identity provider, such as Facebook, Google, or Login with Amazon. So it makes sense to use one of these providers for authentication tasks.

To do this using web identity federation, the app developer must register the app with an identity provider (such as Login with Amazon) and obtain a unique app ID. Next, the developer needs to create an IAM role. (For this example, this role is named GameRole.) The role must have an IAM policy document attached to it, specifying the conditions under which the app can access GameScores table.

When a user wants to play a game, they sign in to their Login with Amazon account from within the gaming app. The app then calls AWS Security Token Service (AWS STS), providing the Login with Amazon app ID and requesting membership in GameRole. AWS STS returns temporary AWS credentials to the app and allows it to access the GameScores table, subject to the GameRole policy document.

The following diagram shows how these pieces fit together.

**Web Identity Federation Overview**

1. The app calls a third-party identity provider to authenticate the user and the app. The identity provider returns a web identity token to the app.
2. The app calls AWS STS and passes the web identity token as input. AWS STS authorizes the app and gives it temporary AWS access credentials. The app is allowed to assume an IAM role (GameRole) and access AWS resources in accordance with the role's security policy.
3. The app calls DynamoDB to access the GameScores table. Because it has assumed the GameRole, the app is subject to the security policy associated with that role. The policy document prevents the app from accessing data that does not belong to the user.

Once again, here is the security policy for GameRole that was shown in Using IAM Policy Conditions for Fine-Grained Access Control (p. 841):

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToOnlyItemsMatchingUserID",
      "Effect": "Allow",
      "Action": ["dynamodb:GetItem",
                 "dynamodb:BatchGetItem",
                 "dynamodb:Query",
                 "dynamodb:PutItem",
                 "dynamodb:UpdateItem",
                 "dynamodb:DeleteItem",
                 "dynamodb:BatchWriteItem"
               ],
                ],
      "Condition": {
        "ForAllValues:StringEquals": {
          "dynamodb:LeadingKeys": ["#{www.amazon.com:user_id}"],
          "dynamodb:Attributes": {
            "UserId",
            "GameTitle",
            "Wins",
            "Losses",
            "TopScore",
            "TopScoreDateTime"
          }
        },
        "StringEqualsIfExists": {
          "dynamodb:Select": "SPECIFIC_ATTRIBUTES"
        }
      }
    }
  ]
}
```

The Condition clause determines which items in GameScores are visible to the app. It does this by comparing the Login with Amazon ID to the UserId partition key values in GameScores. Only the items belonging to the current user can be processed using one of DynamoDB actions that are listed in this policy. Other items in the table cannot be accessed. Furthermore, only the specific attributes listed in the policy can be accessed.

Preparing to Use Web Identity Federation

If you are an application developer and want to use web identity federation for your app, follow these steps:

1. **Sign up as a developer with a third-party identity provider.** The following external links provide information about signing up with supported identity providers:
   - Login with Amazon Developer Center
• Registration on the Facebook site
• Using OAuth 2.0 to Access Google APIs on the Google site

2. **Register your app with the identity provider.** When you do this, the provider gives you an ID that’s unique to your app. If you want your app to work with multiple identity providers, you need to obtain an app ID from each provider.

3. **Create one or more IAM roles.** You need one role for each identity provider for each app. For example, you might create a role that can be assumed by an app where the user signed in using Login with Amazon, a second role for the same app where the user has signed in using Facebook, and a third role for the app where users sign in using Google.

As part of the role creation process, you need to attach an IAM policy to the role. Your policy document should define the DynamoDB resources required by your app, and the permissions for accessing those resources.

For more information, see About Web Identity Federation in IAM User Guide.

**Note**
As an alternative to AWS Security Token Service, you can use Amazon Cognito. Amazon Cognito is the preferred service for managing temporary credentials for mobile apps. For more information, see the following pages:

• How to Authenticate Users (AWS Mobile SDK for iOS)
• How to Authenticate Users (AWS Mobile SDK for Android)

**Generating an IAM Policy Using the DynamoDB Console**

The DynamoDB console can help you create an IAM policy for use with web identity federation. To do this, you choose a DynamoDB table and specify the identity provider, actions, and attributes to be included in the policy. The DynamoDB console then generates a policy that you can attach to an IAM role.

2. In the navigation pane, choose Tables.
3. In the list of tables, choose the table for which you want to create the IAM policy.
4. Choose the Access control tab.
5. Choose the identity provider, actions, and attributes for the policy.

When the settings are as you want them, click Create policy. The generated policy appears.

6. Click Attach policy instructions, and follow the steps required to attach the generated policy to an IAM role.

**Writing Your App to Use Web Identity Federation**

To use web identity federation, your app must assume the IAM role that you created. From that point on, the app honors the access policy that you attached to the role.

At runtime, if your app uses web identity federation, it must follow these steps:

1. **Authenticate with a third-party identity provider.** Your app must call the identity provider using an interface that they provide. The exact way in which you authenticate the user depends on the provider and on what platform your app is running. Typically, if the user is not already signed in, the identity provider takes care of displaying a sign-in page for that provider.
After the identity provider authenticates the user, the provider returns a web identity token to your app. The format of this token depends on the provider, but is typically a very long string of characters.

2. **Obtain temporary AWS security credentials.** To do this, your app sends a `AssumeRoleWithWebIdentity` request to AWS Security Token Service (AWS STS). This request contains the following:

- The web identity token from the previous step
- The app ID from the identity provider
- The Amazon Resource Name (ARN) of the IAM role that you created for this identity provider for this app

AWS STS returns a set of AWS security credentials that expire after a certain amount of time (3,600 seconds, by default).

The following is a sample request and response from a `AssumeRoleWithWebIdentity` action in AWS STS. The web identity token was obtained from the Login with Amazon identity provider.

```
GET / HTTP/1.1
Host: sts.amazonaws.com
Content-Type: application/json; charset=utf-8
URL: https://sts.amazonaws.com/?ProviderId=www.amazon.com
&DurationSeconds=900&Action=AssumeRoleWithWebIdentity
&Version=2011-06-15&RoleSessionName=web-identity-federation
&RoleArn=arn:aws:iam::123456789012:role/GameRole
&WebIdentityToken=Atza|IQEBLjAsAhQluyKqyBiYZ8-kclvGTYMB...}
```
• The `SubjectFromWebIdentityToken` field contains the unique ID that appears in an IAM policy variable for this particular identity provider. The following are the IAM policy variables for supported providers, and some example values for them:

<table>
<thead>
<tr>
<th>Policy Variable</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${www.amazon.com:user_id}</code></td>
<td><code>amzn1.account.AGJZDKHJKAUUSW6C44CHPEXAMPLE</code></td>
</tr>
<tr>
<td><code>${graph.facebook.com:id}</code></td>
<td><code>123456789</code></td>
</tr>
<tr>
<td><code>${accounts.google.com:sub}</code></td>
<td><code>123456789012345678901</code></td>
</tr>
</tbody>
</table>

For example IAM policies where these policy variables are used, see Example Policies: Using Conditions for Fine-Grained Access Control (p. 845).

For more information about how AWS STS generates temporary access credentials, see Requesting Temporary Security Credentials in IAM User Guide.

Identity and Access Management in DynamoDB Accelerator

DynamoDB Accelerator (DAX) is designed to work together with DynamoDB, to seamlessly add a caching layer to your applications. However, DAX and DynamoDB have separate access control mechanisms. Both services use AWS Identity and Access Management (IAM) to implement their respective security policies, but the security models for DAX and DynamoDB are different.

For more information about Identity and Access Management in DAX, see DAX Access Control (p. 746).

Logging and Monitoring

Monitoring is an important part of maintaining the reliability, availability, and performance of DynamoDB and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your DynamoDB resources and responding to potential incidents:

Topics

• Logging and Monitoring in DynamoDB (p. 856)
• Logging and Monitoring in DynamoDB Accelerator (p. 886)
• Who will perform the monitoring tasks?
• Who should be notified when something goes wrong?

The next step is to establish a baseline for normal DynamoDB performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DynamoDB, you should consider storing historical monitoring data. This stored data will give you a baseline from which to compare current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline you should, at a minimum, monitor the following items:

• The number of read or write capacity units consumed over the specified time period, so you can track how much of your provisioned throughput is used.
• Requests that exceeded a table's provisioned write or read capacity during the specified time period, so you can determine which requests exceed the provisioned throughput limits of a table.
• System errors, so you can determine if any requests resulted in an error.

**Topics**
- Monitoring Tools (p. 857)
- Monitoring with Amazon CloudWatch (p. 858)
- Logging DynamoDB Operations by Using AWS CloudTrail (p. 878)

**Monitoring Tools**

AWS provides tools that you can use to monitor DynamoDB. You can configure some of these tools to do the monitoring for you; some require manual intervention. We recommend that you automate monitoring tasks as much as possible.

**Automated Monitoring Tools**

You can use the following automated monitoring tools to watch DynamoDB and report when something is wrong:

• **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring with Amazon CloudWatch (p. 858).

• **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see Monitoring Log Files in the Amazon CloudWatch User Guide.

• **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see What is Amazon CloudWatch Events in the Amazon CloudWatch User Guide.

• **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Working with CloudTrail Log Files in the AWS CloudTrail User Guide.

**Manual Monitoring Tools**

Another important part of monitoring DynamoDB involves manually monitoring those items that the CloudWatch alarms don't cover. The DynamoDB, CloudWatch, Trusted Advisor, and other AWS console
dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on Amazon DynamoDB.

- DynamoDB dashboard shows:
  - Recent alerts
  - Total capacity
  - Service health
- CloudWatch home page shows:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:
- Create customized dashboards to monitor the services you care about
- Graph metric data to troubleshoot issues and discover trends
- Search and browse all of your AWS resource metrics
- Create and edit alarms to be notified of problems

Monitoring with Amazon CloudWatch

You can monitor Amazon DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so that you can access historical information for a better perspective on how your web application or service is performing. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see What Is Amazon CloudWatch? and Metrics Retention in the Amazon CloudWatch User Guide.

DynamoDB Metrics and Dimensions

When you interact with DynamoDB, it sends the following metrics and dimensions to CloudWatch. You can use the following procedures to view the metrics for DynamoDB.

To view metrics (console)

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

2. In the navigation pane, choose Metrics.
3. Select the DynamoDB namespace.

To view metrics (CLI)

- At a command prompt, use the following command:

  ```bash
  aws cloudwatch list-metrics --namespace "AWS/DynamoDB"
  ```
CloudWatch displays the following metrics for DynamoDB:

**DynamoDB Dimensions and Metrics**

The metrics and dimensions that DynamoDB sends to Amazon CloudWatch are listed here.

**DynamoDB Metrics**

**Note**

Amazon CloudWatch aggregates the following DynamoDB metrics at one-minute intervals:

- ConditionalCheckFailedRequests
- ConsumedReadCapacityUnits
- ConsumedWriteCapacityUnits
- ReadThrottleEvents
- ReturnedBytes
- ReturnedItemCount
- ReturnedRecordsCount
- SuccessfulRequestLatency
- SystemErrors
- TimeToLiveDeletedItemCount
- ThrottledRequests
- TransactionConflict
- UserErrors
- WriteThrottleEvents

For all other DynamoDB metrics, the aggregation granularity is five minutes.

Not all statistics, such as *Average* or *Sum*, are applicable for every metric. However, all of these values are available through the Amazon DynamoDB console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics. In the following table, each metric has a list of valid statistics that are applicable to that metric.

| ConsumedReadCapacityUnits   | The number of read capacity units consumed over the specified time period, so you can track how much of your provisioned throughput is used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see Read/Write Capacity Mode. **Note** Use the \textit{Sum} statistic to calculate the consumed throughput. For example, get the \textit{Sum} value over a span of one minute, and divide it by the number of seconds in a minute (60) to calculate the average \textit{ConsumedReadCapacityUnits} per second (recognizing that this average does not highlight any large but brief spikes in read activity that occurred during that minute). | ProvisionedReadCapacityUnits   | The number of provisioned read capacity units for a table or a global secondary index. The TableName dimension returns the ProvisionedReadCapacityUnits for the table, but not for any global secondary indexes. To view ProvisionedReadCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndex. Units: Count Dimensions: TableName, GlobalSecondaryIndexName Valid Statistics:
  • Minimum – The lowest setting for provisioned read capacity. If you use UpdateTable to increase read capacity, this metric shows the lowest value of provisioned ReadCapacityUnits during this time period.
  • Maximum – The highest setting for provisioned read capacity. If you use UpdateTable to decrease read capacity, this metric shows the highest value of provisioned ReadCapacityUnits during this time period.
  • Average – The average provisioned read capacity. The ProvisionedReadCapacityUnits metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average. |

<tr>
<td>ThrottledRequests</td>
<td>Requests to DynamoDB that exceed the provisioned throughput limits on a resource (such as a table or an index).</td>
</tr>
</tbody>
</table>

ThrottledRequests is incremented by one if any event within a request exceeds a provisioned throughput limit. For example, if you update an item in a table with global secondary indexes, there are multiple events—a write to the table, and a write to each index. If one or more of these events are throttled, then ThrottledRequests is incremented by one.

**Note**
In a batch request (BatchGetItem or BatchWriteItem), ThrottledRequests is incremented only if every request in the batch is throttled. If any individual request within the batch is throttled, one of the following metrics is incremented:

- ReadThrottleEvents – For a throttled GetItem event within BatchGetItem.
- WriteThrottleEvents – For a throttled PutItem or DeleteItem event within BatchWriteItem.

To gain insight into which event is throttling a request, compare ThrottledRequests with the ReadThrottleEvents and WriteThrottleEvents for the table and its indexes.

**Note**
A throttled request will result in an HTTP 400 status code. All such events are reflected in the ThrottledRequests metric, but not in the UserErrors metric.

| UserErrors | Requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 400 status code during the specified time period. An HTTP 400 usually indicates a client-side error, such as an invalid combination of parameters, an attempt to update a nonexistent table, or an incorrect request signature. All such events are reflected in the UserErrors metric, except for the following:  

• `ProvisionedThroughputExceededException` – See the ThrottledRequests metric in this section.  
• `ConditionalCheckFailedException` – See the ConditionalCheckFailedRequests metric in this section.  

UserErrors represents the aggregate of HTTP 400 errors for DynamoDB or Amazon DynamoDB Streams requests for the current AWS Region and the current AWS account.

For each event, the WriteThrottleEvents metric is incremented by one if that event is throttled. For single PutItem requests, if any of the events are throttled, ThrottledRequests is also incremented by one. For BatchWriteItem, the ThrottledRequests metric for the entire BatchWriteItem is not incremented unless all of the individual PutItem or DeleteItem events are throttled. ### How Do I Use DynamoDB Metrics?

The metrics reported by DynamoDB provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, not a comprehensive list.

<table>
<thead>
<tr>
<th>How can I?</th>
<th>Relevant Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>How can I monitor the rate of TTL deletions on my table?</td>
<td>You can monitor TimeToLiveDeletedItemCount over the specified time period, to track the rate of TTL deletions on your table. For an example of a server-less application using the TimeToLiveDeletedItemCount metric, see <a href="#">Automatically archive items to S3 using DynamoDB Time to Live (TTL) with AWS Lambda and Amazon Kinesis Firehose</a>.</td>
</tr>
<tr>
<td>How can I determine how much of my provisioned throughput is being used?</td>
<td>You can monitor ConsumedReadCapacityUnits or ConsumedWriteCapacityUnits over the specified time period, to track how much of your provisioned throughput is being used.</td>
</tr>
<tr>
<td>How can I determine which requests exceed the provisioned throughput limits of a table?</td>
<td>ThrottledRequests is incremented by one if any event within a request exceeds a provisioned throughput limit. Then, to gain insight into which event is throttling a request, compare ThrottledRequests with the ReadThrottleEvents and WriteThrottleEvents metrics for the table and its indexes.</td>
</tr>
<tr>
<td>How can I determine if any system errors occurred?</td>
<td>You can monitor SystemErrors to determine if any requests resulted in an HTTP 500 (server error) code. Typically, this metric should be equal to zero. If it isn't, then you might want to investigate.</td>
</tr>
</tbody>
</table>

**Note**

You might encounter internal server errors while working with items. These are expected during the lifetime of a table. Any failed requests can be retried immediately.
Creating CloudWatch Alarms to Monitor DynamoDB

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period you specify, and performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods.

How can I be notified before I consume my entire read capacity?

2. Create the alarm. In this example, we assume a provisioned capacity of five read capacity units.

```
Prompt>aws cloudwatch put-metric-alarm \
  --alarm-name ReadCapacityUnitsLimitAlarm \n  --alarm-description "Alarm when read capacity reaches 80% of my provisioned read capacity" \n  --namespace AWS/DynamoDB \n  --metric-name ConsumedReadCapacityUnits \n  --dimensions Name=TableName,Value=myTable \n  --statistic Sum \n  --threshold 240 \n  --comparison-operator GreaterThanOrEqualToThreshold \n  --period 60 \n  --evaluation-periods 1 \n  --alarm-actions arn:aws:sns:us-east-1:123456789012:capacity-alarm
```

3. Test the alarm.

```
Prompt>aws cloudwatch set-alarm-state --alarm-name ReadCapacityUnitsLimitAlarm --state-reason "initializing" --state-value OK
```

```
Prompt>aws cloudwatch set-alarm-state --alarm-name ReadCapacityUnitsLimitAlarm --state-reason "initializing" --state-value ALARM
```

Note

The alarm is activated whenever the consumed read capacity is at least 4 units per second (80% of provisioned read capacity of 5) for 1 minute (60 seconds). So the threshold is 240 read capacity units (4 units/sec * 60 seconds). Any time the read capacity is updated you should update the alarm calculations appropriately. You can avoid this process by creating alarms through the DynamoDB Console. In this way, the alarms are automatically updated for you.

How can I be notified if any requests exceed the provisioned throughput limits of a table?

2. Create the alarm.

```
Prompt>aws cloudwatch put-metric-alarm \
  --alarm-name RequestsExceedingThroughputAlarm\n  --alarm-description "Alarm when my requests are exceeding provisioned throughput limits of a table"
```

Logging DynamoDB Operations by Using AWS CloudTrail

DynamoDB is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DynamoDB. CloudTrail captures all API calls for DynamoDB as events. The calls captured include calls from the DynamoDB console and code calls to the DynamoDB API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for DynamoDB. If you don't configure a trail, you can still view the most recent
events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can
determine the request that was made to DynamoDB, the IP address from which the request was made,
who made the request, when it was made, and additional details.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User
Guide.

DynamoDB Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity
occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events
in Event history. You can view, search, and download recent events in your AWS account. For more
information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail.
A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a
trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the
AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can
configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs.
For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple
  Accounts

The following API actions are logged as events in CloudTrail files:

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.
Understanding DynamoDB Log File Entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log that demonstrates the `CreateTable`, `DescribeTable`, `UpdateTable`, `ListTables`, `DeleteTable`, and `CreateCluster` actions.

Logging and Monitoring in DynamoDB Accelerator

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon DynamoDB Accelerator (DAX) and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure, if one occurs.

For more information about logging and monitoring in DAX, see Monitoring DAX (p. 733).

Compliance Validation by Industry for DynamoDB

The security and compliance of DynamoDB is assessed by third-party auditors as part of multiple AWS compliance programs, including the following:

- System and Organization Controls (SOC)
- Payment Card Industry (PCI)
- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)

AWS provides a frequently updated list of AWS services in scope of specific compliance programs at AWS Services in Scope by Compliance Program.

Third-party audit reports are available for you to download using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.
For more information about AWS compliance programs, see AWS Compliance Programs.

Your compliance responsibility when using DynamoDB is determined by the sensitivity of your data, your organization’s compliance objectives, and applicable laws and regulations. If your use of DynamoDB is subject to compliance with standards like HIPAA, PCI, or FedRAMP, AWS provides resources to help:

- **Security and Compliance Quick Start Guides** – Deployment guides that discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance Whitepaper** – A whitepaper that describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS Compliance Resources** – A collection of workbooks and guides that might apply to your industry and location.
- **AWS Config** – A service that assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – A comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

## Resilience and Disaster Recovery in Amazon DynamoDB

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

If you need to replicate your data or applications over greater geographic distances, use AWS Local Regions. An AWS Local Region is a single data center designed to complement an existing AWS Region. Like all AWS Regions, AWS Local Regions are completely isolated from other AWS Regions.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon DynamoDB offers several features to help support your data resiliency and backup needs.

**On-demand backup and restore**

DynamoDB provides on-demand backup capability. It allows you to create full backups of your tables for long-term retention and archival. For more information, see On-Demand Backup and Restore for DynamoDB.

**Point-in-time recovery**

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point in time recovery, you don’t have to worry about creating, maintaining, or scheduling on-demand backups. For more information, see Point-in-Time Recovery for DynamoDB.

## Infrastructure Security in Amazon DynamoDB

As a managed service, Amazon DynamoDB is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.
You use AWS published API calls to access DynamoDB through the network. Clients must support TLS (Transport Layer Security) 1.0. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

You can also use a virtual private cloud (VPC) endpoint for DynamoDB to enable Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. For more information, see Using Amazon VPC Endpoints to Access DynamoDB (p. 888).

Using Amazon VPC Endpoints to Access DynamoDB

For security reasons, many AWS customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a virtual private cloud, which is logically isolated from other networks—including the public internet. With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

**Note**

If you created your AWS account after December 4, 2013, then you already have a default VPC in each AWS Region. A default VPC is ready for you to use—you can immediately start using it without having to perform any additional configuration steps.

For more information, see Default VPC and Default Subnets in the Amazon VPC User Guide.

To access the public internet, your VPC must have an internet gateway—a virtual router that connects your VPC to the internet. This allows applications running on Amazon EC2 in your VPC to access internet resources, such as Amazon DynamoDB.

By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using SSL/TLS encryption. The following diagram shows how an EC2 instance in a VPC accesses DynamoDB:

Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. You can address these concerns by using a virtual private network (VPN) to route all
DynamoDB network traffic through your own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for DynamoDB can alleviate these challenges. A VPC endpoint for DynamoDB enables Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. Your EC2 instances do not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to DynamoDB. Traffic between your VPC and the AWS service does not leave the Amazon network.

When you create a VPC endpoint for DynamoDB, any requests to a DynamoDB endpoint within the Region (for example, dynamodb.us-west-2.amazonaws.com) are routed to a private DynamoDB endpoint within the Amazon network. You don't need to modify your applications running on EC2 instances in your VPC. The endpoint name remains the same, but the route to DynamoDB stays entirely within the Amazon network, and does not access the public internet.

The following diagram shows how an EC2 instance in a VPC can use a VPC endpoint to access DynamoDB.

For more information, see the section called “Tutorial: Using a VPC Endpoint for DynamoDB” (p. 889).

Tutorial: Using a VPC Endpoint for DynamoDB

This section walks you through setting up and using a VPC endpoint for DynamoDB.

Topics
- Step 1: Launch an Amazon EC2 Instance (p. 889)
- Step 2: Configure Your Amazon EC2 Instance (p. 891)
- Step 3: Create a VPC Endpoint for DynamoDB (p. 892)
- Step 4: (Optional) Clean Up (p. 893)

Step 1: Launch an Amazon EC2 Instance

In this step, you launch an Amazon EC2 instance in your default Amazon VPC. You can then create and use a VPC endpoint for DynamoDB.
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance and do the following:
   
   Step 1: Choose an Amazon Machine Image (AMI)
   • At the top of the list of AMIs, go to Amazon Linux AMI and choose Select.

   Step 2: Choose an Instance Type
   • At the top of the list of instance types, choose t2.micro.
   • Choose Next: Configure Instance Details.

   Step 3: Configure Instance Details
   • Go to Network and choose your default VPC.
     Choose Next: Add Storage.

   Step 4: Add Storage
   • Skip this step by choosing Next: Tag Instance.

   Step 5: Tag Instance
   • Skip this step by choosing Next: Configure Security Group.

   Step 6: Configure Security Group
   • Choose Select an existing security group.
   • In the list of security groups, choose default. This is the default security group for your VPC.
   • Choose Next: Review and Launch.

   Step 7: Review Instance Launch
   • Choose Launch.

3. In the Select an existing key pair or create a new key pair window, do one of the following:
   • If you do not have an Amazon EC2 key pair, choose Create a new key pair and follow the instructions. You will be asked to download a private key file (.pem file); you will need this file later when you log in to your Amazon EC2 instance.
   • If you already have an existing Amazon EC2 key pair, go to Select a key pair and choose your key pair from the list. You must already have the private key file (.pem file) available in order to log in to your Amazon EC2 instance.

4. When you have configured your key pair, choose Launch Instances.

5. Return to the Amazon EC2 console home page and choose the instance that you launched. In the lower pane, on the Description tab, find the Public DNS for your instance. For example: ec2-00-00-00-00.us-east-1.compute.amazonaws.com.

   Make a note of this public DNS name, because you will need it in the next step in this tutorial (Step 2: Configure Your Amazon EC2 Instance (p. 891)).
Note
It will take a few minutes for your Amazon EC2 instance to become available. Before you go on to the next step, ensure that the Instance State is running and that all of its Status Checks have passed.

Step 2: Configure Your Amazon EC2 Instance

When your Amazon EC2 instance is available, you will be able to log into it and prepare it for first use.

Note
The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see Connect to Your Linux Instance in the Amazon EC2 User Guide for Linux Instances.

1. You will need to authorize inbound SSH traffic to your Amazon EC2 instance. To do this, you will create a new EC2 security group, and then assign the security group to your EC2 instance.
   a. In the navigation pane, choose Security Groups.
   b. Choose Create Security Group. In the Create Security Group window, do the following:
      • Security group name—type a name for your security group. For example: my-ssh-access
      • Description—type a short description for the security group.
      • VPC—choose your default VPC.
      • In the Security group rules section, choose Add Rule and do the following:
         • Type—choose SSH.
         • Source—choose My IP.
   c. In the navigation pane, choose Instances.
   d. Choose the Amazon EC2 instance that you launched in Step 1: Launch an Amazon EC2 Instance (p. 889).
   f. In the Change Security Groups, select the security group that you created earlier in this procedure (for example: my-ssh-access). The existing default security group should also be selected. When the settings are as you want them, choose Assign Security Groups.

2. Use the ssh command to log in to your Amazon EC2 instance, as in the following example.

   \texttt{ssh -i my-keypair.pem ec2-user@public-dns-name}

   You will need to specify your private key file (.pem file) and the public DNS name of your instance. (See Step 1: Launch an Amazon EC2 Instance (p. 889)).

   The login ID is ec2-user. No password is required.

3. Configure your AWS credentials, as shown following. Enter your AWS access key ID, secret key, and default Region name when prompted.

   \texttt{aws configure}

   AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
   AWS Secret Access Key [None]: wJalrXUtznFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
   Default region name [None]: us-east-1
   Default output format [None]:
You are now ready to create a VPC endpoint for DynamoDB.

**Step 3: Create a VPC Endpoint for DynamoDB**

In this step, you will create a VPC endpoint for DynamoDB and test it to make sure that it works.

1. **Before you begin, verify that you can communicate with DynamoDB using its public endpoint.**

   ```
   aws dynamodb list-tables
   ```

   The output will show a list of DynamoDB tables that you currently own. (If you don't have any tables, the list will be empty.)

2. **Verify that DynamoDB is an available service for creating VPC endpoints in the current AWS Region.** (The command is shown in bold text, followed by example output.)

   ```
   aws ec2 describe-vpc-endpoint-services
   {
   "ServiceNames": [
   "com.amazonaws.us-east-1.s3",
   "com.amazonaws.us-east-1.dynamodb"
   ]
   }
   ```

   In the example output, DynamoDB is one of the services available, so you can proceed with creating a VPC endpoint for it.

3. **Determine your VPC identifier.**

   ```
   aws ec2 describe-vpcs
   {
   "Vpcs": [
   {
   "VpcId": "vpc-0bbc736e",
   "InstanceTenancy": "default",
   "State": "available",
   "DhcpOptionsId": "dopt-8454b7e1",
   "CidrBlock": "172.31.0.0/16",
   "IsDefault": true
   }
   ]
   }
   ```

   In the example output, the VPC ID is `vpc-0bbc736e`.

4. **Create the VPC endpoint.** For the `--vpc-id` parameter, specify the VPC ID from the previous step. Use the `--route-table-ids` parameter to associate the endpoint with your route tables.

   ```
   aws ec2 create-vpc-endpoint --vpc-id vpc-0bbc736e --service-name com.amazonaws.us-east-1.dynamodb --route-table-ids rtb-11aa22bb
   ```

   ```
   VpcEndpoint: {
   "PolicyDocument": "{
   "Version": "2008-10-17",
   "Statement": [{
   "Effect": "Allow",
   "Principal": "*",
   "Action": "*",
   "Resource": "*"
   }],
   "VpcId": "vpc-0bbc736e",
   "State": "available",
   "ServiceName": "com.amazonaws.us-east-1.dynamodb",
   "RouteTableIds": [
   "rtb-11aa22bb"
   ]
   }
   ```
5. Verify that you can access DynamoDB through the VPC endpoint.

```bash
aws dynamodb list-tables
```

If you want, you can try some other AWS CLI commands for DynamoDB. For more information, see the AWS CLI Command Reference.

### Step 4: (Optional) Clean Up

If you want to delete the resources you have created in this tutorial, follow these procedures:

**To remove your VPC endpoint for DynamoDB**

1. Log in to your Amazon EC2 instance.
2. Determine the VPC endpoint ID.

```bash
aws ec2 describe-vpc-endpoints
```

In the example output, the VPC endpoint ID is `vpce-9b15e2f2`.

3. Delete the VPC endpoint.

```bash
aws ec2 delete-vpc-endpoints --vpc-endpoint-ids vpce-9b15e2f2
```

The empty array `[]` indicates success (there were no unsuccessful requests).

**To terminate your Amazon EC2 instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Choose your Amazon EC2 instance.
4. Choose **Actions**, **Instance State**, **Terminate**.
5. In the confirmation window, choose **Yes, Terminate**.
Configuration and Vulnerability Analysis in Amazon DynamoDB

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- Compliance Validation for Amazon DynamoDB
- Shared Responsibility Model
- Amazon Web Services: Overview of Security Processes (whitepaper)

The following security best practices also address configuration and vulnerability analysis in Amazon DynamoDB:

- Monitor DynamoDB compliance with AWS Config Rules
- Monitor DynamoDB configuration with AWS Config

Security Best Practices for Amazon DynamoDB

Amazon DynamoDB provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don’t represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

- DynamoDB Detective Security Best Practices (p. 896)

DynamoDB Preventative Security Best Practices

The following best practices can help you anticipate and prevent security incidents in Amazon DynamoDB.

Encryption at rest

DynamoDB encrypts at rest all user data stored in tables, indexes, streams, and backups using encryption keys stored in AWS Key Management Service (AWS KMS). This provides an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can specify whether DynamoDB should use an AWS owned CMK (default encryption type) or an AWS managed CMK to encrypt the user data. For more information, see Amazon DynamoDB Encryption at Rest.

Use IAM roles to authenticate access to DynamoDB

For users, applications, and other AWS services to access DynamoDB, they must include valid AWS credentials in their AWS API requests. You should not store AWS credentials directly in the application or EC2 instance. These are long-term credentials that are not automatically rotated, and therefore could have significant business impact if they are compromised. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources.
Use IAM policies for DynamoDB base authorization

When granting permissions, you decide who is getting them, which DynamoDB APIs they are getting permissions for, and the specific actions you want to allow on those resources. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

Attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on DynamoDB resources.

You can do this by using the following:
- AWS Managed (predefined) policies
- Customer managed policies

Use IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

You can specify conditions when granting permissions using an IAM policy. For example, you can do the following:
- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

For more information, see Using IAM Policy Conditions for Fine-Grained Access Control.

Use a VPC endpoint and policies to access DynamoDB

If you only require access to DynamoDB from within a virtual private cloud (VPC), you should use a VPC endpoint to limit access from only the required VPC. Doing this prevents that traffic from traversing the open internet and being subject to that environment.

Using a VPC endpoint for DynamoDB allows you to control and limit access using the following:
- VPC endpoint policies – These policies are applied on the DynamoDB VPC endpoint. They allow you to control and limit API access to the DynamoDB table.
- IAM policies – By using the aws:sourceVpce condition on policies attached to IAM users, groups, or roles, you can enforce that all access to the DynamoDB table is via the specified VPC endpoint.

For more information, see Endpoints for Amazon DynamoDB.

Consider client-side encryption

If you store sensitive or confidential data in DynamoDB, you might want to encrypt that data as close as possible to its origin so that your data is protected throughout its lifecycle. Encrypting your sensitive data in transit and at rest helps ensure that your plaintext data isn’t available to any third party.

The Amazon DynamoDB Encryption Client is a software library that helps you protect your table data before you send it to DynamoDB.

At the core of the DynamoDB Encryption Client is an item encryptor that encrypts, signs, verifies, and decrypts table items. It takes in information about your table items and instructions about which items to encrypt and sign. It gets the encryption materials and instructions on how to use them from a cryptographic material provider that you select and configure.
DynamoDB Detective Security Best Practices

The following best practices for Amazon DynamoDB can help you detect potential security weaknesses and incidents.

Use AWS CloudTrail to monitor AWS managed KMS key usage

If you are using an AWS managed customer master key (CMK) for encryption at rest, usage of this key is logged into AWS CloudTrail. CloudTrail provides visibility into user activity by recording actions taken on your account. CloudTrail records important information about each action, including who made the request, the services used, the actions performed, parameters for the actions, and the response elements returned by the AWS service. This information helps you track changes made to your AWS resources and troubleshoot operational issues. CloudTrail makes it easier to ensure compliance with internal policies and regulatory standards.

You can use CloudTrail to audit key usage. CloudTrail creates log files that contain a history of AWS API calls and related events for your account. These log files include all AWS KMS API requests made using the AWS Management Console, AWS SDKs, and command line tools, in addition to those made through integrated AWS services. You can use these log files to get information about when the CMK was used, the operation that was requested, the identity of the requester, the IP address that the request came from, and so on. For more information, see Logging AWS KMS API Calls with AWS CloudTrail and the AWS CloudTrail User Guide.

Use CloudTrail to monitor DynamoDB control-plane operations

CloudTrail provides visibility into user activity by recording actions taken on your account. CloudTrail records important information about each action, including who made the request, the services used, the actions performed, parameters for the actions, and the response elements returned by the AWS service. This information helps you track changes made to your AWS resources and to troubleshoot operational issues. CloudTrail makes it easier to ensure compliance with internal policies and regulatory standards.

Control-plane operations let you create and manage DynamoDB tables. They also let you work with indexes, streams, and other objects that are dependent on tables.

When activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in the event history. For more information, see Logging DynamoDB Operations by Using AWS CloudTrail. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in the AWS CloudTrail User Guide.

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail. A trail enables CloudTrail to deliver log files to an Amazon Simple Storage Service (Amazon S3) bucket. By default, when you create a trail on the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs.

Consider using DynamoDB Streams to monitor modify/update data-plane operations

AWS CloudTrail does not support logging of DynamoDB data-plane operations, such as GetItem and PutItem. So you might want to consider using Amazon DynamoDB Streams as a source for these events occurring in your environment.

DynamoDB is integrated with AWS Lambda so that you can create triggers—pieces of code that automatically respond to events in DynamoDB Streams. With triggers, you can build applications that react to data modifications in DynamoDB tables.

If you enable DynamoDB Streams on a table, you can associate the stream Amazon Resource Name (ARN) with a Lambda function that you write. Immediately after an item in the table is modified, a
new record appears in the table's stream. AWS Lambda polls the stream and invokes your Lambda function synchronously when it detects new stream records. The Lambda function can perform any actions that you specify, such as sending a notification or initiating a workflow.

For an example, see Tutorial: Using AWS Lambda with Amazon DynamoDB Streams. This example receives a DynamoDB event input, processes the messages that it contains, and writes some of the incoming event data to Amazon CloudWatch Logs.

Monitor DynamoDB configuration with AWS Config

Using AWS Config, you can continuously monitor and record configuration changes of your AWS resources. AWS Config also enables you to inventory your AWS resources. When a change from a previous state is detected, an Amazon Simple Notification Service (Amazon SNS) notification can be delivered for you to review and take action. Follow the guidance in Setting Up AWS Config with the Console, ensuring that DynamoDB resource types are included.

You can configure AWS Config to stream configuration changes and notifications to an Amazon SNS topic. For example, when a resource is updated, you can get a notification sent to your email, so that you can view the changes. You can also be notified when AWS Config evaluates your custom or managed rules against your resources.

For an example, see Notifications that AWS Config Sends to an Amazon SNS topic in the AWS Config Developer Guide.

Monitor DynamoDB compliance with AWS Config rules

AWS Config continuously tracks the configuration changes that occur among your resources. It checks whether these changes violate any of the conditions in your rules. If a resource violates a rule, AWS Config flags the resource and the rule as noncompliant.

By using AWS Config to evaluate your resource configurations, you can assess how well your resource configurations comply with internal practices, industry guidelines, and regulations. AWS Config provides AWS managed rules, which are predefined, customizable rules that AWS Config uses to evaluate whether your AWS resources comply with common best practices.

Tag your DynamoDB resources for identification and automation

You can assign metadata to your AWS resources in the form of tags. Each tag is a simple label consisting of a customer-defined key and an optional value that can make it easier to manage, search for, and filter resources.

Tagging allows for grouped controls to be implemented. Although there are no inherent types of tags, they enable you to categorize resources by purpose, owner, environment, or other criteria. The following are some examples:

- Security – Used to determine requirements such as encryption.
- Confidentiality – An identifier for the specific data-confidentiality level a resource supports.
- Environment – Used to distinguish between development, test, and production infrastructure.

For more information, see AWS Tagging Strategies and Tagging for DynamoDB.

NoSQL Design for DynamoDB

NoSQL database systems like Amazon DynamoDB use alternative models for data management, such as key-value pairs or document storage. When you switch from a relational database management system to a NoSQL database system like DynamoDB, it's important to understand the key differences and specific design approaches.

Differences Between Relational Data Design and NoSQL

Relational database systems (RDBMS) and NoSQL databases have different strengths and weaknesses:

- In RDBMS, data can be queried flexibly, but queries are relatively expensive and don’t scale well in high-traffic situations (see First Steps for Modeling Relational Data in DynamoDB (p. 923)).
- In a NoSQL database such as DynamoDB, data can be queried efficiently in a limited number of ways, outside of which queries can be expensive and slow.

These differences make database design different between the two systems:

- In RDBMS, you design for flexibility without worrying about implementation details or performance. Query optimization generally doesn't affect schema design, but normalization is important.
- In DynamoDB, you design your schema specifically to make the most common and important queries as fast and as inexpensive as possible. Your data structures are tailored to the specific requirements of your business use cases.
Two Key Concepts for NoSQL Design

NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can go ahead and create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. You can organize each type of data into its own table.

How NoSQL design is different

- By contrast, you shouldn’t start designing your schema for DynamoDB until you know the questions it will need to answer. Understanding the business problems and the application use cases up front is essential.
- You should maintain as few tables as possible in a DynamoDB application.

Approaching NoSQL Design

The first step in designing your DynamoDB application is to identify the specific query patterns that the system must satisfy.

In particular, it is important to understand three fundamental properties of your application’s access patterns before you begin:

- **Data size**: Knowing how much data will be stored and requested at one time will help determine the most effective way to partition the data.
- **Data shape**: Instead of reshaping data when a query is processed (as an RDBMS system does), a NoSQL database organizes data so that its shape in the database corresponds with what will be queried. This is a key factor in increasing speed and scalability.
- **Data velocity**: DynamoDB scales by increasing the number of physical partitions that are available to process queries, and by efficiently distributing data across those partitions. Knowing in advance what the peak query loads might help determine how to partition data to best use I/O capacity.

After you identify specific query requirements, you can organize data according to general principles that govern performance:

- **Keep related data together**. Research on routing-table optimization 20 years ago found that "locality of reference" was the single most important factor in speeding up response time: keeping related data together in one place. This is equally true in NoSQL systems today, where keeping related data in close proximity has a major impact on cost and performance. Instead of distributing related data items across multiple tables, you should keep related items in your NoSQL system as close together as possible.

As a general rule, you should maintain as few tables as possible in a DynamoDB application.

Exceptions are cases where high-volume time series data are involved, or datasets that have very different access patterns. A single table with inverted indexes can usually enable simple queries to create and retrieve the complex hierarchical data structures required by your application.

- **Use sort order**. Related items can be grouped together and queried efficiently if their key design causes them to sort together. This is an important NoSQL design strategy.
- **Distribute queries**. It is also important that a high volume of queries not be focused on one part of the database, where they can exceed I/O capacity. Instead, you should design data keys to distribute traffic evenly across partitions as much as possible, avoiding "hot spots."
- **Use global secondary indexes**. By creating specific global secondary indexes, you can enable different queries than your main table can support, and that are still fast and relatively inexpensive.
These general principles translate into some common design patterns that you can use to model data efficiently in DynamoDB.

Best Practices for Designing and Using Partition Keys Effectively

The primary key that uniquely identifies each item in an Amazon DynamoDB table can be simple (a partition key only) or composite (a partition key combined with a sort key).

Generally speaking, you should design your application for uniform activity across all logical partition keys in the table and its secondary indexes. You can determine the access patterns that your application requires, and estimate the total read capacity units (RCU) and write capacity units (WCU) that each table and secondary index requires.

DynamoDB supports your access patterns using the throughput that you provisioned as long as the traffic against a given partition does not exceed 3,000 RCU's or 1,000 WCU's.

Using Burst Capacity Effectively

DynamoDB provides some flexibility in your per-partition throughput provisioning by providing burst capacity. Whenever you're not fully using a partition's throughput, DynamoDB reserves a portion of that unused capacity for later bursts of throughput to handle usage spikes.

DynamoDB currently retains up to 5 minutes (300 seconds) of unused read and write capacity. During an occasional burst of read or write activity, these extra capacity units can be consumed quickly—even faster than the per-second provisioned throughput capacity that you've defined for your table.

DynamoDB can also consume burst capacity for background maintenance and other tasks without prior notice.

Note that these burst capacity details might change in the future.

Understanding DynamoDB Adaptive Capacity

Adaptive capacity is a feature that enables DynamoDB to run imbalanced workloads indefinitely. It minimizes throttling due to throughput exceptions. It also helps you reduce costs by enabling you to provision only the throughput capacity that you need.

Adaptive capacity is enabled automatically for every DynamoDB table, at no additional cost. You don't need to explicitly enable or disable it.

- Isolate Frequently Accessed Items (p. 902)
Boost Throughput Capacity to High-Traffic Partitions

It's not always possible to distribute read and write activity evenly. When data access is imbalanced, a "hot" partition can receive a higher volume of read and write traffic compared to other partitions. In extreme cases, throttling can occur if a single partition receives more than 3,000 RCU's or 1,000 WCU's.

To better accommodate uneven access patterns, DynamoDB adaptive capacity enables your application to continue reading and writing to hot partitions without being throttled, provided that traffic does not exceed your table's total provisioned capacity or the partition maximum capacity. Adaptive capacity works by automatically and instantly increasing throughput capacity for partitions that receive more traffic.

The following diagram illustrates how adaptive capacity works. The example table is provisioned with 400 WCU's evenly shared across four partitions, allowing each partition to sustain up to 100 WCU's per second. Partitions 1, 2, and 3 each receive write traffic of 50 WCU/second. Partition 4 receives 150 WCU/sec. This hot partition can accept write traffic while it still has unused burst capacity, but eventually it throttles traffic that exceeds 100 WCU/sec.

DynamoDB adaptive capacity responds by increasing partition 4's capacity so that it can sustain the higher workload of 150 WCU/sec without being throttled.

Isolate Frequently Accessed Items

If your application drives disproportionately high traffic to one or more items, adaptive capacity rebalances your partitions such that frequently accessed items don't reside on the same partition. This isolation of frequently accessed items reduces the likelihood of request throttling due to your workload exceeding the throughput limit on a single partition.

If your application drives consistently high traffic to a single item, adaptive capacity might rebalance your data such that a partition contains only that single, frequently accessed item. In this case, DynamoDB can deliver throughput up to the partition maximum of 3,000 RCU's or 1,000 WCU's to that single item's primary key.

Note
This isolation functionality is not available for:

- Tables that have a local secondary index.
- Tables using Provisioned Read/Write Capacity Mode that have enabled DynamoDB Streams.
Designing Partition Keys to Distribute Your Workload Evenly

The partition key portion of a table's primary key determines the logical partitions in which a table's data is stored. This in turn affects the underlying physical partitions. Provisioned I/O capacity for the table is divided evenly among these physical partitions. Therefore, a partition key design that doesn't distribute I/O requests evenly can create "hot" partitions that result in throttling and use your provisioned I/O capacity inefficiently.

The optimal usage of a table's provisioned throughput depends not only on the workload patterns of individual items, but also on the partition key design. This doesn't mean that you must access all partition key values to achieve an efficient throughput level, or even that the percentage of accessed partition key values must be high. It does mean that the more distinct partition key values that your workload accesses, the more those requests will be spread across the partitioned space. In general, you will use your provisioned throughput more efficiently as the ratio of partition key values accessed to the total number of partition key values increases.

The following is a comparison of the provisioned throughput efficiency of some common partition key schemas.

<table>
<thead>
<tr>
<th>Partition key value</th>
<th>Uniformity</th>
</tr>
</thead>
<tbody>
<tr>
<td>User ID, where the application has many users.</td>
<td>Good</td>
</tr>
<tr>
<td>Status code, where there are only a few possible status codes.</td>
<td>Bad</td>
</tr>
<tr>
<td>Item creation date, rounded to the nearest time period (for example, day, hour, or minute).</td>
<td>Bad</td>
</tr>
<tr>
<td>Device ID, where each device accesses data at relatively similar intervals.</td>
<td>Good</td>
</tr>
<tr>
<td>Device ID, where even if there are many devices being tracked, one is by far more popular than all the others.</td>
<td>Bad</td>
</tr>
</tbody>
</table>

If a single table has only a small number of partition key values, consider distributing your write operations across more distinct partition key values. In other words, structure the primary key elements to avoid one "hot" (heavily requested) partition key value that slows overall performance.

For example, consider a table with a composite primary key. The partition key represents the item's creation date, rounded to the nearest day. The sort key is an item identifier. On a given day, say 2014-07-09, all of the new items are written to that single partition key value (and corresponding physical partition).

If the table fits entirely into a single partition (considering growth of your data over time), and if your application's read and write throughput requirements don't exceed the read and write capabilities of a single partition, your application won't encounter any unexpected throttling as a result of partitioning.

However, if you anticipate your table scaling beyond a single partition, you should architect your application so that it can use more of the table's full provisioned throughput.
Using Write Sharding to Distribute Workloads Evenly

One way to better distribute writes across a partition key space in Amazon DynamoDB is to expand the space. You can do this in several different ways. You can add a random number to the partition key values to distribute the items among partitions. Or you can use a number that is calculated based on something that you’re querying on.

Sharding Using Random Suffixes

One strategy for distributing loads more evenly across a partition key space is to add a random number to the end of the partition key values. Then you randomize the writes across the larger space.

For example, for a partition key that represents today's date, you might choose a random number between 1 and 200 and concatenate it as a suffix to the date. This yields partition key values like 2014-07-09.1, 2014-07-09.2, and so on, through 2014-07-09.200. Because you are randomizing the partition key, the writes to the table on each day are spread evenly across multiple partitions. This results in better parallelism and higher overall throughput.

However, to read all the items for a given day, you would have to query the items for all the suffixes and then merge the results. For example, you would first issue a Query request for the partition key value 2014-07-09.1. Then issue another Query for 2014-07-09.2, and so on, through 2014-07-09.200. Finally, your application would have to merge the results from all those Query requests.

Sharding Using Calculated Suffixes

A randomizing strategy can greatly improve write throughput. But it's difficult to read a specific item because you don't know which suffix value was used when writing the item. To make it easier to read individual items, you can use a different strategy. Instead of using a random number to distribute the items among partitions, use a number that you can calculate based upon something that you want to query on.

Consider the previous example, in which a table uses today's date in the partition key. Now suppose that each item has an accessible OrderId attribute, and that you most often need to find items by order ID in addition to date. Before your application writes the item to the table, it could calculate a hash suffix based on the order ID and append it to the partition key date. The calculation might generate a number between 1 and 200 that is fairly evenly distributed, similar to what the random strategy produces.

A simple calculation would likely suffice, such as the product of the UTF-8 code point values for the characters in the order ID, modulo 200, + 1. The partition key value would then be the date concatenated with the calculation result.

With this strategy, the writes are spread evenly across the partition key values, and thus across the physical partitions. You can easily perform a GetItem operation for a particular item and date because you can calculate the partition key value for a specific OrderId value.

To read all the items for a given day, you still must Query each of the 2014-07-09.N keys (where N is 1–200), and your application then has to merge all the results. The benefit is that you avoid having a single "hot" partition key value taking all of the workload.

Note

For a more efficient strategy specifically designed to handle high-volume time series data, see Time Series Data (p. 915).
Distributing Write Activity Efficiently During Data Upload

Typically, when you load data from other data sources, Amazon DynamoDB partitions your table data on multiple servers. You get better performance if you upload data to all the allocated servers simultaneously.

For example, suppose that you want to upload user messages to a DynamoDB table that uses a composite primary key with UserID as the partition key and MessageID as the sort key.

When you upload the data, one approach you can take is to upload all message items for each user, one user after another:

<table>
<thead>
<tr>
<th>UserID</th>
<th>MessageID</th>
</tr>
</thead>
<tbody>
<tr>
<td>U1</td>
<td>1</td>
</tr>
<tr>
<td>U1</td>
<td>2</td>
</tr>
<tr>
<td>U1</td>
<td>...</td>
</tr>
<tr>
<td>U1</td>
<td>... up to 100</td>
</tr>
<tr>
<td>U2</td>
<td>1</td>
</tr>
<tr>
<td>U2</td>
<td>2</td>
</tr>
<tr>
<td>U2</td>
<td>...</td>
</tr>
<tr>
<td>U2</td>
<td>... up to 200</td>
</tr>
</tbody>
</table>

The problem in this case is that you are not distributing your write requests to DynamoDB across your partition key values. You are taking one partition key value at a time and uploading all of its items before going to the next partition key value and doing the same.

Behind the scenes, DynamoDB is partitioning the data in your table across multiple servers. To fully use all the throughput capacity that is provisioned for the table, you must distribute your workload across your partition key values. By directing an uneven amount of upload work toward items that all have the same partition key value, you are not fully using all the resources that DynamoDB has provisioned for your table.

You can distribute your upload work by using the sort key to load one item from each partition key value, then another item from each partition key value, and so on:

<table>
<thead>
<tr>
<th>UserID</th>
<th>MessageID</th>
</tr>
</thead>
<tbody>
<tr>
<td>U1</td>
<td>1</td>
</tr>
<tr>
<td>U2</td>
<td>1</td>
</tr>
<tr>
<td>U3</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>U1</td>
<td>2</td>
</tr>
</tbody>
</table>
Every upload in this sequence uses a different partition key value, keeping more DynamoDB servers busy simultaneously and improving your throughput performance.

<table>
<thead>
<tr>
<th>UserID</th>
<th>MessageID</th>
</tr>
</thead>
<tbody>
<tr>
<td>U2</td>
<td>2</td>
</tr>
<tr>
<td>U3</td>
<td>2</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

**Best Practices for Using Sort Keys to Organize Data**

In an Amazon DynamoDB table, the primary key that uniquely identifies each item in the table can be composed not only of a partition key, but also of a sort key.

Well-designed sort keys have two key benefits:

- They gather related information together in one place where it can be queried efficiently. Careful design of the sort key lets you retrieve commonly needed groups of related items using range queries with operators such as `begins_with`, `between`, `>`, `<`, and so on.
- Composite sort keys let you define hierarchical (one-to-many) relationships in your data that you can query at any level of the hierarchy.

For example, in a table listing geographical locations, you might structure the sort key as follows.

```
[country][region][state][county][city][neighborhood]
```

This would let you make efficient range queries for a list of locations at any one of these levels of aggregation, from `country`, to a `neighborhood`, and everything in between.

**Using Sort Keys for Version Control**

Many applications need to maintain a history of item-level revisions for audit or compliance purposes and to be able to retrieve the most recent version easily. There is an effective design pattern that accomplishes this using sort key prefixes:

- For each new item, create two copies of the item: One copy should have a version-number prefix of zero (such as `v0_`) at the beginning of the sort key, and one should have a version-number prefix of one (such as `v1_`).
- Every time the item is updated, use the next higher version-prefix in the sort key of the updated version, and copy the updated contents into the item with version-prefix zero. This means that the latest version of any item can be located easily using the zero prefix.

For example, a parts manufacturer might use a schema like the one illustrated below.
The Equipment_1 item goes through a sequence of audits by various auditors. The results of each new audit are captured in a new item in the table, starting with version number one, and then incrementing the number for each successive revision.

When each new revision is added, the application layer replaces the contents of the zero-version item (having sort key equal to v0_Audit) with the contents of the new revision.

Whenever the application needs to retrieve the most recent audit status, it can query for the sort key prefix of v0_.

If the application needs to retrieve the entire revision history, it can query all the items under the item's partition key and filter out the v0_ item.

This design also works for audits across multiple parts of a piece of equipment, if you include the individual part-IDs in the sort key after the sort key prefix.

### Best Practices for Using Secondary Indexes in DynamoDB

Secondary indexes are often essential to support the query patterns that your application requires. At the same time, overusing secondary indexes or using them inefficiently can add cost and reduce performance unnecessarily.

General Guidelines for Secondary Indexes in DynamoDB

Amazon DynamoDB supports two types of secondary indexes:

- **Global secondary index**—An index with a partition key and a sort key that can be different from those on the base table. A global secondary index is considered "global" because queries on the index can span all of the data in the base table, across all partitions. A global secondary index has no size limitations and has its own provisioned throughput settings for read and write activity that are separate from those of the table.

- **Local secondary index**—An index that has the same partition key as the base table, but a different sort key. A local secondary index is "local" in the sense that every partition of a local secondary index is scoped to a base table partition that has the same partition key value. As a result, the total size of indexed items for any one partition key value can’t exceed 10 GB. Also, a local secondary index shares provisioned throughput settings for read and write activity with the table it is indexing.

Each table in DynamoDB is limited to 20 global secondary indexes (default limit) and 5 local secondary indexes.

For more information about the differences between global secondary indexes and local secondary indexes, see Improving Data Access with Secondary Indexes (p. 497).

In general, you should use global secondary indexes rather than local secondary indexes. The exception is when you need strong consistency in your query results, which a local secondary index can provide but a global secondary index cannot (global secondary index queries only support eventual consistency).

The following are some general principles and design patterns to keep in mind when creating indexes in DynamoDB:

**Topics**

- Use Indexes Efficiently (p. 908)
- Choose Projections Carefully (p. 908)
- Optimize Frequent Queries to Avoid Fetches (p. 909)
- Be Aware of Item-Collection Size Limits When Creating Local Secondary Indexes (p. 909)

**Use Indexes Efficiently**

Keep the number of indexes to a minimum. Don’t create secondary indexes on attributes that you don’t query often. Indexes that are seldom used contribute to increased storage and I/O costs without improving application performance.

**Choose Projections Carefully**

Because secondary indexes consume storage and provisioned throughput, you should keep the size of the index as small as possible. Also, the smaller the index, the greater the performance advantage compared to querying the full table. If your queries usually return only a small subset of attributes, and the total size of those attributes is much smaller than the whole item, project only the attributes that you regularly request.

If you expect a lot of write activity on a table compared to reads, follow these best practices:

- Consider projecting fewer attributes to minimize the size of items written to the index. However, this only applies if the size of projected attributes would otherwise be larger than a single write capacity unit (1 KB). For example, if the size of an index entry is only 200 bytes, DynamoDB rounds this up to...
1 KB. In other words, as long as the index items are small, you can project more attributes at no extra cost.

- Avoid projecting attributes that you know will rarely be needed in queries. Every time you update an attribute that is projected in an index, you incur the extra cost of updating the index as well. You can still retrieve non-projected attributes in a query at a higher provisioned throughput cost, but the query cost may be significantly lower than the cost of updating the index frequently.

- Specify ALL only if you want your queries to return the entire table item sorted by a different sort key. Projecting all attributes eliminates the need for table fetches, but in most cases, it doubles your costs for storage and write activity.

Balance the need to keep your indexes as small as possible against the need to keep fetches to a minimum, as explained in the next section.

**Optimize Frequent Queries to Avoid Fetches**

To get the fastest queries with the lowest possible latency, project all the attributes that you expect those queries to return. In particular, if you query a local secondary index for attributes that are not projected, DynamoDB automatically fetches those attributes from the table, which requires reading the entire item from the table. This introduces latency and additional I/O operations that you can avoid.

Keep in mind that "occasional" queries can often turn into "essential" queries. If there are attributes that you don't intend to project because you anticipate querying them only occasionally, consider whether circumstances might change and you might regret not projecting those attributes after all.

For more information about table fetches, see Provisioned Throughput Considerations for Local Secondary Indexes (p. 543).

**Be Aware of Item-Collection Size Limits When Creating Local Secondary Indexes**

An item collection is all the items in a table and its local secondary indexes that have the same partition key. No item collection can exceed 10 GB, so it's possible to run out of space for a particular partition key value.

When you add or update a table item, DynamoDB updates all local secondary indexes that are affected. If the indexed attributes are defined in the table, the local secondary indexes grow too.

When you create a local secondary index, think about how much data will be written to it, and how many of those data items will have the same partition key value. If you expect that the sum of table and index items for a particular partition key value might exceed 10 GB, consider whether you should avoid creating the index.

If you can't avoid creating the local secondary index, you must anticipate the item collection size limit and take action before you exceed it. For strategies on working within the limit and taking corrective action, see Item Collection Size Limit (p. 547).

**Take Advantage of Sparse Indexes**

For any item in a table, DynamoDB writes a corresponding index entry only if the index sort key value is present in the item. If the sort key doesn't appear in every table item, the index is said to be sparse.

Sparse indexes are useful for queries over a small subsection of a table. For example, suppose that you have a table where you store all your customer orders, with the following key attributes:

- Partition key: CustomerId
- Sort key: OrderId
To track open orders, you can insert a Boolean attribute named `isOpen` in order items that have not already shipped. Then when the order ships, you can delete the attribute. If you then create an index on `CustomerId` (partition key) and `isOpen` (sort key), only those orders with `isOpen` defined appear in it. When you have thousands of orders of which only a small number are open, it's faster and less expensive to query that index for open orders than to scan the entire table.

Instead of using a Boolean type of attribute like `isOpen`, you could use an attribute with a value that results in a useful sort order in the index. For example, you could use an `OrderOpenDate` attribute set to the date on which each order was placed, and then delete it after the order is fulfilled. That way, when you query the sparse index, the items are returned sorted by the date on which each order was placed.

**Examples of Sparse Indexes in DynamoDB**

Global secondary indexes are sparse by default. When you create a global secondary index, you specify a partition key and optionally a sort key. Only items in the base table that contain those attributes appear in the index.

By designing a global secondary index to be sparse, you can provision it with lower write throughput than that of the base table, while still achieving excellent performance.

For example, a gaming application might track all scores of every user, but generally only needs to query a few high scores. The following design handles this scenario efficiently:

<table>
<thead>
<tr>
<th>Primary Key</th>
<th>Data Attributes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Player_ID</td>
<td>Attribute 1</td>
</tr>
<tr>
<td>Game_ID</td>
<td>Score: 36,750</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
<tr>
<td>Game_1</td>
<td>Score: 69,450</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
<tr>
<td>Game_2</td>
<td>Score: 135,000</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
<tr>
<td>Game_3</td>
<td>Score: 25,350</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
<tr>
<td>Game_4</td>
<td>Score: 69,450</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
<tr>
<td>Game_5</td>
<td>Score: 147,300</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
<tr>
<td>Game_6</td>
<td>Score: 169,100</td>
</tr>
<tr>
<td></td>
<td>(game score)</td>
</tr>
</tbody>
</table>

Here, Rick has played three games and achieved Champ status in one of them. Padma has played four games and achieved Champ status in two of them. Notice that the Award attribute is present only in items where the user achieved an award. The associated global secondary index looks like the following:

<table>
<thead>
<tr>
<th>Projected Attributes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Award</td>
</tr>
<tr>
<td>Player_ID</td>
</tr>
<tr>
<td>Rick</td>
</tr>
<tr>
<td>Padma</td>
</tr>
<tr>
<td>Padma</td>
</tr>
</tbody>
</table>
The global secondary index contains only the high scores that are frequently queried, which are a small subset of the items in the base table.

**Using Global Secondary Indexes for Materialized Aggregation Queries**

Maintaining near real-time aggregations and key metrics on top of rapidly changing data is becoming increasingly valuable to businesses for making rapid decisions. For example, a music library might want to showcase its most downloaded songs in near-real time.

Consider the following music library table layout:

<table>
<thead>
<tr>
<th>Primary Key</th>
<th>Data-Item Attributes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>**Partition Key</td>
<td>Sort Key**</td>
</tr>
<tr>
<td><strong>Details</strong></td>
<td>songID</td>
</tr>
<tr>
<td><strong>Month-2018-01</strong></td>
<td>download month</td>
</tr>
<tr>
<td><strong>Song-129</strong></td>
<td>songID</td>
</tr>
<tr>
<td><strong>Dld-9349823681</strong></td>
<td>songID</td>
</tr>
<tr>
<td><strong>Dld-9349823682</strong></td>
<td>songID</td>
</tr>
<tr>
<td><strong>Dld-9349823683</strong></td>
<td>songID</td>
</tr>
</tbody>
</table>

The table in this example stores songs with the songID as the partition key. You can enable Amazon DynamoDB Streams on this table and attach a Lambda function to the streams so that as each song is downloaded, an entry is added to the table with Partition-Key=SongID and Sort-Key=DownloadID. As these updates are made, they trigger a Lambda function in DynamoDB Streams. The Lambda function can aggregate and group the downloads by songID and update the top-level item, Partition-Key=sonID, and Sort-Key=Month. Keep in mind that if a lambda execution fails just after writing the new aggregated value, it may be retried and aggregate the value more than once, leaving you with an approximate value.

To read the updates in near-real time, with single-digit millisecond latency, use the global secondary index with query conditions Month=2018-01, ScanIndexForward=False, Limit=1.

Another key optimization used here is that the global secondary index is a sparse index and is available only on the items that need to be queried to retrieve the data in real time. The global secondary index can serve additional workflows that need information on the top 10 songs that were popular, or any song downloaded in that month.

**Overloading Global Secondary Indexes**

Although Amazon DynamoDB has a default limit of 20 global secondary indexes per table, in practice, you can index across far more than 20 data fields. As opposed to a table in a relational database management system (RDBMS), in which the schema is uniform, a table in DynamoDB can hold many different types of data items at one time. In addition, the same attribute in different items can contain entirely different types of information.
Consider the following example of a DynamoDB table layout that saves a variety of different kinds of data.

<table>
<thead>
<tr>
<th>Primary Key</th>
<th>Data-Item Attributes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition Key</td>
<td>Attribute 1</td>
</tr>
<tr>
<td>Sort Key</td>
<td>Attribute 2</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td>Employee_Name</td>
<td>Data: Murphy, John</td>
</tr>
<tr>
<td></td>
<td>(employee name)</td>
</tr>
<tr>
<td></td>
<td>Start: 2008-11-08</td>
</tr>
<tr>
<td></td>
<td>(start date)</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td>YYYYY-Q1</td>
<td>Data: $5,477</td>
</tr>
<tr>
<td></td>
<td>(order totals in USD)</td>
</tr>
<tr>
<td></td>
<td>Name: Murphy, John</td>
</tr>
<tr>
<td></td>
<td>(employee name)</td>
</tr>
<tr>
<td>HR_confidential</td>
<td>Data: 2008-11-08</td>
</tr>
<tr>
<td></td>
<td>(hire date)</td>
</tr>
<tr>
<td></td>
<td>Name: Murphy, John</td>
</tr>
<tr>
<td></td>
<td>(employee name)</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td>Warehouse_01</td>
<td>Data: Murphy, John</td>
</tr>
<tr>
<td></td>
<td>(employee name)</td>
</tr>
<tr>
<td>v0_Job_title</td>
<td>Data: Operator-1</td>
</tr>
<tr>
<td></td>
<td>(job title)</td>
</tr>
<tr>
<td></td>
<td>Start: 2008-11-08</td>
</tr>
<tr>
<td></td>
<td>(start date)</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td>v1_Job_title</td>
<td>Data: Operator-2</td>
</tr>
<tr>
<td></td>
<td>(job title)</td>
</tr>
<tr>
<td></td>
<td>Start: 2016-11-04</td>
</tr>
<tr>
<td></td>
<td>(start date)</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td>v2_Job_title</td>
<td>Data: Supervisor-1</td>
</tr>
<tr>
<td></td>
<td>(job title)</td>
</tr>
<tr>
<td></td>
<td>Start: 2017-11-01</td>
</tr>
<tr>
<td></td>
<td>(start date)</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>

The `Data` attribute, which is common to all the items, has different content depending on its parent item. If you create a global secondary index for the table that uses the table's sort key as its partition key and the `Data` attribute as its sort key, you can make a variety of different queries using that single global secondary index. These queries might include the following:

- Look up an employee by name in the global secondary index, by searching on the `Employee_Name` attribute value.
- Use the global secondary index to find all employees working in a particular warehouse by searching on a warehouse ID (such as `Warehouse_01`).
- Get a list of recent hires, querying the global secondary index on `HR_confidential` as a partition key value and `Data` as the sort key value.

**Using Global Secondary Index Write Sharding for Selective Table Queries**

Applications frequently need to identify a small subset of items in an Amazon DynamoDB table that meet a certain condition. When these items are distributed randomly across the partition keys of the table, you could resort to a table scan to retrieve them. This option can be expensive, but it works well when a large number of items on the table meet the search condition. However, when the key space is large and the search condition is very selective, this strategy can cause a lot of unnecessary processing.

To enable selective queries across the entire key space, you can use write sharding by adding an attribute containing a `(0-N)` value to every item that you will use for the global secondary index partition key.
The following is an example of a schema that uses this in a Critical-Event workflow:

<table>
<thead>
<tr>
<th>Event_ID</th>
<th>Time</th>
<th>State</th>
<th>Attribute 1</th>
<th>Attribute 2</th>
<th>GSI PK</th>
<th>Attribute 3</th>
<th>GSI SK</th>
</tr>
</thead>
<tbody>
<tr>
<td>EID_12345</td>
<td>2018-02-07T08:42:40</td>
<td>INFO</td>
<td>Event_ID</td>
<td>Time</td>
<td>(random GSI-PK value)</td>
<td>INFO#2018-02-07T08:42:40</td>
<td></td>
</tr>
<tr>
<td>EID_12346</td>
<td>2018-02-07T08:32:40</td>
<td>CRITICAL</td>
<td>Event_ID</td>
<td>Time</td>
<td>(random GSI-PK value)</td>
<td>CRITICAL#2018-02-07T08:32:40</td>
<td></td>
</tr>
<tr>
<td>EID_12348</td>
<td>2018-02-07T08:12:40</td>
<td>INFO</td>
<td>Event_ID</td>
<td>Time</td>
<td>(random GSI-PK value)</td>
<td>INFO#2018-02-07T08:12:40</td>
<td></td>
</tr>
</tbody>
</table>

Using this schema design, the event items are distributed across 0–N partitions on the GSI, allowing a scatter read using a sort condition on the composite key to retrieve all items with a given state during a specified time period.

This schema pattern delivers a highly selective result set at minimal cost, without requiring a table scan.

**Using Global Secondary Indexes to Create an Eventually Consistent Replica**

You can use a global secondary index to create an eventually consistent replica of a table. Creating a replica can allow you to do the following:

- **Set different provisioned read capacity for different readers.** For example, suppose that you have two applications: one application handles high-priority queries and needs the highest levels of read performance, whereas the other handles low-priority queries that can tolerate throttling of read activity.

  If both of these applications read from the same table, a heavy read load from the low-priority application could consume all the available read capacity for the table. This would throttle the high-priority application's read activity.

  Instead, you can create a replica through a global secondary index whose read capacity you can set separate from that of the table itself. You can then have your low-priority app query the replica instead of the table.

- **Eliminate reads from a table entirely.** For example, you might have an application that captures a high volume of clickstream activity from a website, and you don't want to risk having reads interfere with that. You can isolate this table and prevent reads by other applications (see Using IAM Policy API Version 2012-08-10).
Conditions for Fine-Grained Access Control (p. 841), while letting other applications read a replica created using a global secondary index.

To create a replica, set up a global secondary index that has the same key schema as the parent table, with some or all of the non-key attributes projected into it. In applications, you can direct some or all read activity to this global secondary index rather than to the parent table. You can then adjust the provisioned read capacity of the global secondary index to handle those reads without changing the parent table's provisioned read capacity.

There is always a short propagation delay between a write to the parent table and the time when the written data appears in the index. In other words, your applications should take into account that the global secondary index replica is only eventually consistent with the parent table.

You can create multiple global secondary index replicas to support different read patterns. When you create the replicas, project only the attributes that each read pattern actually requires. An application can then consume less provisioned read capacity to obtain only the data it needs rather than having to read the item from the parent table. This optimization can result in significant cost savings over time.

**Best Practices for Storing Large Items and Attributes**

Amazon DynamoDB currently limits the size of each item that you store in a table (see Service, Account, and Table Limits in Amazon DynamoDB (p. 961)). If your application needs to store more data in an item than the DynamoDB size limit permits, you can try compressing one or more large attributes or breaking the item into multiple items (efficiently indexed by sort keys). You can also store the item as an object in Amazon Simple Storage Service (Amazon S3) and store the Amazon S3 object identifier in your DynamoDB item.

**Compressing Large Attribute Values**

Compressing large attribute values can let them fit within item limits in DynamoDB and reduce your storage costs. Compression algorithms such as GZIP or LZO produce binary output that you can then store in a Binary attribute type.

For example, the Reply table in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section stores messages written by forum users. These user replies might consist of long strings of text, which makes them excellent candidates for compression.

For sample code that demonstrates how to compress such messages in DynamoDB, see the following:

- Example: Handling Binary Type Attributes Using the AWS SDK for Java Document API (p. 433)
- Example: Handling Binary Type Attributes Using the AWS SDK for .NET Low-Level API (p. 456)

**Storing Large Attribute Values in Amazon S3**

As mentioned previously, you can also use Amazon S3 to store large attribute values that cannot fit in a DynamoDB item. You can store them as an object in Amazon S3 and then store the object identifier in your DynamoDB item.

You can also use the object metadata support in Amazon S3 to provide a link back to the parent item in DynamoDB. Store the primary key value of the item as Amazon S3 metadata of the object in Amazon S3. Doing this often helps with maintenance of the Amazon S3 objects.
For example, consider the ProductCatalog table in the Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326) section. Items in this table store information about item price, description, book authors, and dimensions for other products. If you wanted to store an image of each product that was too large to fit in an item, you could store the images in Amazon S3 instead of in DynamoDB.

When implementing this strategy, keep the following in mind:

- DynamoDB doesn't support transactions that cross Amazon S3 and DynamoDB. Therefore, your application must deal with any failures, which could include cleaning up orphaned Amazon S3 objects.
- Amazon S3 limits the length of object identifiers. So you must organize your data in a way that doesn't generate excessively long object identifiers or violate other Amazon S3 constraints.

For more information about how to use Amazon S3, see the Amazon Simple Storage Service Developer Guide.

Best Practices for Handling Time Series Data in DynamoDB

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. For most applications, a single table is all you need. However, for time series data, you can often best handle it by using one table per application per period.

Design Pattern for Time Series Data

Consider a typical time series scenario, where you want to track a high volume of events. Your write access pattern is that all the events being recorded have today's date. Your read access pattern might be to read today's events most frequently, yesterday's events much less frequently, and then older events very little at all. One way to handle this is by building the current date and time into the primary key.

The following design pattern often handles this kind of scenario effectively:

- Create one table per period, provisioned with the required read and write capacity and the required indexes.
- Before the end of each period, prebuild the table for the next period. Just as the current period ends, direct event traffic to the new table. You can assign names to these tables that specify the periods they have recorded.
- As soon as a table is no longer being written to, reduce its provisioned write capacity to a lower value (for example, 1 WCU), and provision whatever read capacity is appropriate. Reduce the provisioned read capacity of earlier tables as they age. You might choose to archive or delete the tables whose contents are rarely or never needed.

The idea is to allocate the required resources for the current period that will experience the highest volume of traffic and scale down provisioning for older tables that are not used actively, therefore saving costs. Depending on your business needs, you might consider write sharding to distribute traffic evenly to the logical partition key. For more information, see Using Write Sharding to Distribute Workloads Evenly (p. 904).

Time Series Table Examples

The following is a time series data example in which the current table is provisioned at a higher read/write capacity and the older tables are scaled down because they are accessed infrequently.
Many-to-Many Relationships

Adjacency lists are a design pattern that is useful for modeling many-to-many relationships in Amazon DynamoDB. More generally, they provide a way to represent graph data (nodes and edges) in DynamoDB.

Adjacency List Design Pattern

When different entities of an application have a many-to-many relationship between them, the relationship can be modeled as an adjacency list. In this pattern, all top-level entities (synonymous to nodes in the graph model) are represented using the partition key. Any relationships with other entities (edges in a graph) are represented as an item within the partition by setting the value of the sort key to the target entity ID (target node).

The advantages of this pattern include minimal data duplication and simplified query patterns to find all entities (nodes) related to a target entity (having an edge to a target node).

A real-world example where this pattern has been useful is an invoicing system where invoices contain multiple bills. One bill can belong in multiple invoices. The partition key in this example is either an InvoiceID or a BillID. BillID partitions have all attributes specific to bills. InvoiceID partitions have an item storing invoice-specific attributes, and an item for each BillID that rolls up to the invoice.

The schema looks like the following.

<table>
<thead>
<tr>
<th>Primary Key</th>
<th>Sort Key (and GSI PK)</th>
<th>Data Attributes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invoice-92551</td>
<td>Invoice-92551 (invoice ID)</td>
<td>Dated: 2018-02-07 (date created)</td>
</tr>
<tr>
<td>BillID: Bill-4224693 (bill ID)</td>
<td>Dated: 2017-12-03 (date created)</td>
<td>Attributes of this bill in this invoice...</td>
</tr>
<tr>
<td>BillID: Bill-4224687 (bill ID)</td>
<td>Dated: 2018-01-09 (date created)</td>
<td>Attributes of this bill in this invoice...</td>
</tr>
<tr>
<td>Invoice-92552</td>
<td>Invoice-92552 (invoice ID)</td>
<td>Dated: 2018-03-04 (date created)</td>
</tr>
<tr>
<td>BillID: Bill-4224687 (bill ID)</td>
<td>Dated: 2018-01-09 (date created)</td>
<td>Attributes of this bill in this invoice...</td>
</tr>
<tr>
<td>BillID: Bill-4224663 (bill ID)</td>
<td>Dated: 2017-12-03 (date created)</td>
<td>More attributes of this bill...</td>
</tr>
<tr>
<td>BillID: Bill-4224687 (bill ID)</td>
<td>Dated: 2018-01-09 (date created)</td>
<td>More attributes of this bill...</td>
</tr>
</tbody>
</table>
Using the preceding schema, you can see that all bills for an invoice can be queried using the primary key on the table. To look up all invoices that contain a part of a bill, create a global secondary index on the table’s sort key.

The projections for the global secondary index look like the following.

<table>
<thead>
<tr>
<th>Primary Key</th>
<th>Projected Attributes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bill-4224663</td>
<td>Attributes of this bill...</td>
</tr>
<tr>
<td>Inv_ID: Invoice-92551 (table primary key)</td>
<td>Attributes of this bill in this invoice...</td>
</tr>
<tr>
<td>Bill-4224687</td>
<td>Attributes of this bill...</td>
</tr>
<tr>
<td>Inv_ID: Invoice-92551 (table primary key)</td>
<td>Attributes of this bill in this invoice...</td>
</tr>
<tr>
<td>Inv_ID: Invoice-92552 (table primary key)</td>
<td>Attributes of this bill in this invoice...</td>
</tr>
<tr>
<td>Invoice-92551</td>
<td>Attributes of this Invoice...</td>
</tr>
<tr>
<td>Inv_ID: Invoice-92551 (table primary key)</td>
<td>Attributes of this Invoice...</td>
</tr>
<tr>
<td>Invoice-92552</td>
<td>Attributes of this Invoice...</td>
</tr>
<tr>
<td>Inv_ID: Invoice-92552 (table primary key)</td>
<td>Attributes of this Invoice...</td>
</tr>
</tbody>
</table>

Materialized Graph Pattern

Many applications are built around understanding rankings across peers, common relationships between entities, neighbor entity state, and other types of graph style workflows. For these types of applications, consider the following schema design pattern.
### Materialized Graphs

Materialized Graphs

The preceding schema shows a graph data structure that is defined by a set of data partitions containing the items that define the edges and nodes of the graph. Edge items contain a Target and a Type attribute. These attributes are used as part of a composite key name "TypeTarget" to identify the item in a partition in the primary table or in a second global secondary index.

The first global secondary index is built on the Data attribute. This attribute uses global secondary index-overloading as described earlier to index several different attribute types, namely Dates, Names, Places, and Skills. Here, one global secondary index is effectively indexing four different attributes.

As you insert items into the table, you can use an intelligent sharding strategy to distribute item sets with large aggregations (birthdate, skill) across as many logical partitions on the global secondary indexes as are needed to avoid hot read/write problems.

The result of this combination of design patterns is a solid datastore for highly efficient real-time graph workflows. These workflows can provide high-performance neighbor entity state and edge aggregation queries for recommendation engines, social-networking applications, node rankings, subtree aggregations, and other common graph use cases.

If your use case isn’t sensitive to real-time data consistency, you can use a scheduled Amazon EMR process to populate edges with relevant graph summary aggregations for your workflows. If your application doesn’t need to know immediately when an edge is added to the graph, you can use a scheduled process to aggregate results.

To maintain some level of consistency, the design could include Amazon DynamoDB Streams and AWS Lambda to process edge updates. It could also use an Amazon EMR job to validate results on a regular interval. This approach is illustrated by the following diagram. It is commonly used in social networking applications, where the cost of a real-time query is high and the need to immediately know individual user updates is low.
IT service-management (ITSM) and security applications generally need to respond in real time to entity state changes composed of complex edge aggregations. Such applications need a system that can support real-time multiple node aggregations of second- and third-level relationships, or complex edge traversals. If your use case requires these types of real-time graph query workflows, we recommend that you consider using Amazon Neptune to manage these workflows.

Best Practices for Implementing a Hybrid Database System

In some circumstances, migrating from one or more relational database management systems (RDBMS) to Amazon DynamoDB might not be advantageous. In these cases, it might be preferable to create a hybrid system.

If You Don’t Want to Migrate Everything to DynamoDB

For example, some organizations have large investments in the code that produces a multitude of reports needed for accounting and operations. The time it takes to generate a report is not important to them. The flexibility of a relational system is well suited to this kind of task, and re-creating all those reports in a NoSQL context might be prohibitively difficult.

Some organizations also maintain a variety of legacy relational systems that they have acquired or inherited over decades. Migrating data from these systems might be too risky and expensive to justify the effort.

However, the same organizations may now find that their operations depend on high-traffic customer-facing websites, where millisecond response is essential. Relational systems can’t scale to meet this requirement except at huge (and often unacceptable) expense.
In these situations, the answer might be to create a hybrid system, in which DynamoDB creates a materialized view of data stored in one or more relational systems and handles high-traffic requests against this view. This type of system can potentially reduce costs by eliminating server hardware, maintenance, and RDBMS licenses that were previously needed to handle customer-facing traffic.

**How a Hybrid System Can Be Implemented**

DynamoDB can take advantage of DynamoDB Streams and AWS Lambda to integrate seamlessly with one or more existing relational database systems:

A system that integrates DynamoDB Streams and AWS Lambda can provide several advantages:

- It can operate as a persisted cache of materialized views.
- It can be set up to fill gradually with data as that data is queried for, and as data is modified in the SQL system. This means that the entire view does not need to be pre-populated. This in turn means that provisioned throughput capacity is more likely to be used efficiently.
- It has low administrative costs and is highly available and reliable.

For this kind of integration to be implemented, essentially three kinds of interoperation must be provided.

1. **Fill the DynamoDB cache incrementally.** When an item is queried, look for it first in DynamoDB. If it is not there, look for it in the SQL system, and load it into DynamoDB.
2. **Write through a DynamoDB cache.** When a customer changes a value in DynamoDB, a Lambda function is triggered to write the new data back to the SQL system.
3. **Update DynamoDB from the SQL system.** When internal processes such as inventory management or pricing change a value in the SQL system, a stored procedure is triggered to propagate the change to the DynamoDB materialized view.

These operations are straightforward, and not all of them are needed for every scenario.

A hybrid solution can also be useful when you want to rely primarily on DynamoDB, but you also want to maintain a small relational system for one-time queries, or for operations that need special security or that are not time-critical.

**Best Practices for Modeling Relational Data in DynamoDB**

Traditional relational database management system (RDBMS) platforms store data in a normalized relational structure. This structure reduces hierarchical data structures to a set of common elements that are stored across multiple tables. The following schema is an example of a generic order-entry application with supporting HR schema backing the operational and business support systems of a theoretical manufacturer.
RDBMS platforms use an ad hoc query language (generally a flavor of SQL) to generate or materialize views of the normalized data to support application-layer access patterns.

For example, to generate a list of purchase order items sorted by the quantity in stock at all warehouses that can ship each item, you could issue the following query against the preceding schema.
SELECT * FROM Orders
INNER JOIN Order_Items ON Orders.Order_ID = Order_Items.Order_ID
INNER JOIN Products ON Products.Product_ID = Order_Items.Product_ID
INNER JOIN Inventories ON Products.Product_ID = Inventories.Product_ID
ORDER BY Quantity_on_Hand DESC

One-time queries of this kind provide a flexible API for accessing data, but they require a significant amount of processing. You must often query the data from multiple locations, and the results must be assembled for presentation. The preceding query initiates complex queries across a number of tables and then sorts and integrates the resulting data.

Another factor that can slow down RDBMS systems is the need to support an ACID-compliant transaction framework. The hierarchical data structures used by most online transaction processing (OLTP) applications must be broken down and distributed across multiple logical tables when they are stored in an RDBMS. Therefore, an ACID-compliant transaction framework is necessary to avoid race conditions that could occur if an application tries to read an object that is in the process of being written. Such a transaction framework necessarily adds significant overhead to the write process.

These two factors are the primary barriers to scale for traditional RDBMS platforms. It remains to be seen whether the NewSQL community can be successful in delivering a distributed RDBMS solution. But it is unlikely that even that would resolve the two limitations described earlier. No matter how the solution is delivered, the processing costs of normalization and ACID transactions must remain significant.

For this reason, when your business requires low-latency response to high-traffic queries, taking advantage of a NoSQL system generally makes technical and economic sense. Amazon DynamoDB helps solve the problems that limit relational system scalability by avoiding them.

A relational database system does not scale well for the following reasons:

- It normalizes data and stores it on multiple tables that require multiple queries to write to disk.
- It generally incurs the performance costs of an ACID-compliant transaction system.
- It uses expensive joins to reassemble required views of query results.

DynamoDB scales well for these reasons:

- Schema flexibility lets DynamoDB store complex hierarchical data within a single item.
- Composite key design lets it store related items close together on the same table.

Queries against the data store become much simpler, often in the following form:

```
SELECT * FROM Table_X WHERE Attribute_Y = "somevalue"
```

DynamoDB does far less work to return the requested data compared to the RDBMS in the earlier example.

**First Steps for Modeling Relational Data in DynamoDB**

**Important**

NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. By contrast, in Amazon DynamoDB, you shouldn't start designing your schema until you know the questions that it needs to answer. Understanding the business problems and the application use cases up front is absolutely essential.
To start designing a DynamoDB table that will scale efficiently, you must take several steps first to identify the access patterns that are required by the operations and business support systems (OSS/BSS) that it needs to support:

- For new applications, review user stories about activities and objectives. Document the various use cases you identify, and analyze the access patterns that they require.
- For existing applications, analyze query logs to find out how people are currently using the system and what the key access patterns are.

After completing this process, you should end up with a list that might look something like the following.

<table>
<thead>
<tr>
<th>Access Pattern Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Look up employee details by employee ID</td>
</tr>
<tr>
<td>2. Query employee details by employee name</td>
</tr>
<tr>
<td>3. Find an employee’s phone number(s)</td>
</tr>
<tr>
<td>4. Find a customer’s phone number(s)</td>
</tr>
<tr>
<td>5. Get orders for a given customer within a given date range</td>
</tr>
<tr>
<td>6. Show all open orders within a given date range across all customers</td>
</tr>
<tr>
<td>7. See all employees hired recently</td>
</tr>
<tr>
<td>8. Find all employees working in a given warehouse</td>
</tr>
<tr>
<td>9. Get all items on order for a given product</td>
</tr>
<tr>
<td>10. Get current inventories for a given product at all warehouses</td>
</tr>
<tr>
<td>11. Get customers by account representative</td>
</tr>
<tr>
<td>12. Get orders by account representative and date</td>
</tr>
<tr>
<td>13. Get all items on order for a given product</td>
</tr>
<tr>
<td>14. Get all employees with a given job title</td>
</tr>
<tr>
<td>15. Get inventory by product and warehouse</td>
</tr>
<tr>
<td>16. Get total product inventory</td>
</tr>
<tr>
<td>17. Get account representatives ranked by order total and sales period</td>
</tr>
</tbody>
</table>

In a real application, your list might be much longer. But this collection represents the range of query pattern complexity that you might find in a production environment.

A common approach to DynamoDB schema design is to identify application layer entities and use denormalization and composite key aggregation to reduce query complexity.

In DynamoDB, this means using composite sort keys, overloaded global secondary indexes, partitioned tables/indexes, and other design patterns. You can use these elements to structure the data so that an application can retrieve whatever it needs for a given access pattern using a single query on a table or index. The primary pattern that you can use to model the normalized schema shown in Relational Modeling (p. 921) is the adjacency list pattern. Other patterns used in this design can include global secondary index write sharding, global secondary index overloading, composite keys, and materialized aggregations.

**Important**

In general, you should maintain as few tables as possible in a DynamoDB application. Exceptions include cases where high-volume time series data are involved, or datasets that have very different access patterns. A single table with inverted indexes can usually enable simple queries to create and retrieve the complex hierarchical data structures required by your application.

### Example of Modeling Relational Data in DynamoDB

This example describes how to model relational data in Amazon DynamoDB. A DynamoDB table design corresponds to the relational order entry schema that is shown in Relational Modeling (p. 921). It
follows the Adjacency List Design Pattern (p. 916), which is a common way to represent relational data structures in DynamoDB.

The design pattern requires you to define a set of entity types that usually correlate to the various tables in the relational schema. Entity items are then added to the table using a compound (partition and sort) primary key. The partition key of these entity items is the attribute that uniquely identifies the item and is referred to generically on all items as PK. The sort key attribute contains an attribute value that you can use for an inverted index or global secondary index. It is generically referred to as SK.

You define the following entities, which support the relational order entry schema.

1. HR-Employee - PK: EmployeeID, SK: Employee Name
2. HR-Region - PK: RegionID, SK: Region Name
3. HR-Country - PK: CountryId, SK: Country Name
4. HR-Location - PK: LocationID, SK: Country Name
5. HR-Job - PK: JobID, SK: Job Title
6. HR-Department - PK: DepartmentID, SK: DepartmentID
8. OE-Order - PK OrderID, SK: CustomerID
9. OE-Product - PK: ProductID, SK: Product Name
10. OE-Warehouse - PK: WarehouseID, SK: Region Name

After adding these entity items to the table, you can define the relationships between them by adding edge items to the entity item partitions. The following table demonstrates this step.

In this example, the Employee, Order, and Product Entity partitions on the table have additional edge items that contain pointers to other entity items on the table. Next, define a few global secondary indexes (GSIs) to support all the access patterns defined previously. The entity items don't all use the same type of value for the primary key or the sort key attribute. All that is required is to have the primary key and sort key attributes present to be inserted on the table.

The fact that some of these entities use proper names and others use other entity IDs as sort key values allows the same global secondary index to support multiple types of queries. This technique is called GSI overloading. It effectively eliminates the default limit of 20 global secondary indexes for tables that contain multiple item types. This is shown in the following diagram as GSI 1.

GSI 2 is designed to support a fairly common application access pattern, which is to get all the items on the table that have a certain state. For a large table with an uneven distribution of items across available states, this access pattern can result in a hot key, unless the items are distributed across more than one logical partition that can be queried in parallel. This design pattern is called write sharding.

To accomplish this for GSI 2, the application adds the GSI 2 primary key attribute to every Order item. It populates that with a random number in a range of 0–N, where N can generically be calculated using the following formula, unless there is a specific reason to do otherwise.

\[
\text{ItemsPerRCU} = \frac{4\text{KB}}{\text{AvgItemSize}}
\]

\[
\text{PartitionMaxReadRate} = 3K \times \text{ItemsPerRCU}
\]

\[
N = \frac{\text{MaxRequiredIO}}{\text{PartitionMaxReadRate}}
\]

For example, assume that you expect the following:

- Up to 2 million orders will be in the system, growing to 3 million in 5 years.
• Up to 20 percent of these orders will be in an OPEN state at any given time.
• The average order record is around 100 bytes, with three OrderItem records in the order partition that are around 50 bytes each, giving you an average order entity size of 250 bytes.

For that table, the N factor calculation would look like the following.

| ItemsPerRCU = 4KB / 250B = 16  |
|-----------------|-----------------|
| PartitionMaxReadRate = 3K * 16 = 48K |
| N = (0.2 * 3M) / 48K = 13 |

In this case, you need to distribute all the orders across at least 13 logical partitions on GSI 2 to ensure that a read of all Order items with an OPEN status doesn’t cause a hot partition on the physical storage layer. It is a good practice to pad this number to allow for anomalies in the dataset. So a model using N = 15 is probably fine. As mentioned earlier, you do this by adding the random 0–N value to the GSI 2 PK attribute of each Order and OrderItem record that is inserted on the table.

This breakdown assumes that the access pattern that requires gathering all OPEN invoices occurs relatively infrequently so that you can use burst capacity to fulfill the request. You can query the following global secondary index using a State and Date Range Sort Key condition to produce a subset or all Orders in a given state as needed.

In this example, the items are randomly distributed across the 15 logical partitions. This structure works because the access pattern requires a large number of items to be retrieved. Therefore, it's unlikely that any of the 15 threads will return empty result sets that could potentially represent wasted capacity. A query always uses 1 read capacity unit (RCU) or 1 write capacity unit (WCU), even if nothing is returned or no data is written.

If the access pattern requires a high velocity query on this global secondary index that returns a sparse result set, it's probably better to use a hash algorithm to distribute the items rather than a random pattern. In this case, you might select an attribute that is known when the query is executed at runtime and hash that attribute into a 0–14 key space when the items are inserted. Then they can be efficiently read from the global secondary index.

Finally, you can revisit the access patterns that were defined earlier. Following is the list of access patterns and the query conditions that you will use with the new DynamoDB version of the application to accommodate them.

Best Practices for Querying and Scanning Data

This section covers some best practices for using Query and Scan operations in Amazon DynamoDB.

Performance Considerations for Scans

In general, Scan operations are less efficient than other operations in DynamoDB. A Scan operation always scans the entire table or secondary index. It then filters out values to provide the result you want, essentially adding the extra step of removing data from the result set.

If possible, you should avoid using a Scan operation on a large table or index with a filter that removes many results. Also, as a table or index grows, the Scan operation slows. The Scan operation examines every item for the requested values and can use up the provisioned throughput for a large table or index in a single operation. For faster response times, design your tables and indexes so that your
applications can use `Query` instead of `Scan`. (For tables, you can also consider using the `GetItem` and `BatchGetItem` APIs.)

Alternatively, design your application to use `Scan` operations in a way that minimizes the impact on your request rate.

### Avoiding Sudden Spikes in Read Activity

When you create a table, you set its read and write capacity unit requirements. For reads, the capacity units are expressed as the number of strongly consistent 4 KB data read requests per second. For eventually consistent reads, a read capacity unit is two 4 KB read requests per second. A `Scan` operation performs eventually consistent reads by default, and it can return up to 1 MB (one page) of data. Therefore, a single `Scan` request can consume \( \frac{1 \text{ MB page size}}{4 \text{ KB item size}} \times \frac{1}{2} \) (eventually consistent reads) = 128 read operations. If you request strongly consistent reads instead, the `Scan` operation would consume twice as much provisioned throughput—256 read operations.

This represents a sudden spike in usage, compared to the configured read capacity for the table. This usage of capacity units by a scan prevents other potentially more important requests for the same table from using the available capacity units. As a result, you likely get a `ProvisionedThroughputExceeded` exception for those requests.

The problem is not just the sudden increase in capacity units that the `Scan` uses. The scan is also likely to consume all of its capacity units from the same partition because the scan requests read items that are next to each other on the partition. This means that the request is hitting the same partition, causing all of its capacity units to be consumed, and throttling other requests to that partition. If the request to read data is spread across multiple partitions, the operation would not throttle a specific partition.

The following diagram illustrates the impact of a sudden spike of capacity unit usage by `Query` and `Scan` operations, and its impact on your other requests against the same table.
As illustrated here, the usage spike can impact the table's provisioned throughput in several ways:

1. Good: Even distribution of requests and size
2. Not as good: Frequent requests in bursts
3. Bad: A few random large requests
4. Bad: Large scan operations
Instead of using a large Scan operation, you can use the following techniques to minimize the impact of a scan on a table’s provisioned throughput.

- **Reduce page size**
  
  Because a Scan operation reads an entire page (by default, 1 MB), you can reduce the impact of the scan operation by setting a smaller page size. The Scan operation provides a Limit parameter that you can use to set the page size for your request. Each Query or Scan request that has a smaller page size uses fewer read operations and creates a “pause” between each request. For example, suppose that each item is 4 KB and you set the page size to 40 items. A Query request would then consume only 20 eventually consistent read operations or 40 strongly consistent read operations. A larger number of smaller Query or Scan operations would allow your other critical requests to succeed without throttling.

- **Isolate scan operations**
  
  DynamoDB is designed for easy scalability. As a result, an application can create tables for distinct purposes, possibly even duplicating content across several tables. You want to perform scans on a table that is not taking "mission-critical" traffic. Some applications handle this load by rotating traffic hourly between two tables—one for critical traffic, and one for bookkeeping. Other applications can do this by performing every write on two tables: a "mission-critical" table, and a "shadow" table.

  Configure your application to retry any request that receives a response code that indicates you have exceeded your provisioned throughput. Or, increase the provisioned throughput for your table using the UpdateTable operation. If you have temporary spikes in your workload that cause your throughput to exceed, occasionally, beyond the provisioned level, retry the request with exponential backoff. For more information about implementing exponential backoff, see Error Retries and Exponential Backoff (p. 225).

### Taking Advantage of Parallel Scans

Many applications can benefit from using parallel Scan operations rather than sequential scans. For example, an application that processes a large table of historical data can perform a parallel scan much faster than a sequential one. Multiple worker threads in a background “sweeper” process could scan a table at a low priority without affecting production traffic. In each of these examples, a parallel Scan is used in such a way that it does not starve other applications of provisioned throughput resources.

Although parallel scans can be beneficial, they can place a heavy demand on provisioned throughput. With a parallel scan, your application has multiple workers that are all running Scan operations concurrently. This can quickly consume all of your table’s provisioned read capacity. In that case, other applications that need to access the table might be throttled.

A parallel scan can be the right choice if the following conditions are met:

- The table size is 20 GB or larger.
- The table’s provisioned read throughput is not being fully used.
- Sequential Scan operations are too slow.

### Choosing TotalSegments

The best setting for TotalSegments depends on your specific data, the table’s provisioned throughput settings, and your performance requirements. You might need to experiment to get it right. We recommend that you begin with a simple ratio, such as one segment per 2 GB of data. For example, for a 30 GB table, you could set TotalSegments to 15 (30 GB / 2 GB). Your application would then use 15 workers, with each worker scanning a different segment.

You can also choose a value for TotalSegments that is based on client resources. You can set TotalSegments to any number from 1 to 1000000, and DynamoDB lets you scan that number of
segments. For example, if your client limits the number of threads that can run concurrently, you can gradually increase `TotalSegments` until you get the best `Scan` performance with your application.

Monitor your parallel scans to optimize your provisioned throughput use, while also making sure that your other applications aren't starved of resources. Increase the value for `TotalSegments` if you don't consume all of your provisioned throughput but still experience throttling in your `Scan` requests. Reduce the value for `TotalSegments` if the `Scan` requests consume more provisioned throughput than you want to use.

**Best Practices for Using Global Tables**

There are several requirements and best practices that you must consider when using global tables. For more information, see Best Practices and Requirements for Managing Global Tables (p. 628).
DynamoDB Integration with Other AWS Services

Amazon DynamoDB is integrated with other AWS services, letting you automate repeating tasks or build applications that span multiple services. For example:

- Configuring AWS Credentials in Your Files Using Amazon Cognito (p. 931)
- Loading Data From DynamoDB Into Amazon Redshift (p. 933)
- Processing DynamoDB Data With Apache Hive on Amazon EMR (p. 934)

**Configuring AWS Credentials in Your Files Using Amazon Cognito**

The recommended way to obtain AWS credentials for your web and mobile applications is to use Amazon Cognito. Amazon Cognito helps you avoid hardcoding your AWS credentials on your files. It uses AWS Identity and Access Management (IAM) roles to generate temporary credentials for your application's authenticated and unauthenticated users.

For example, to configure your JavaScript files to use an Amazon Cognito unauthenticated role to access the Amazon DynamoDB web service, do the following.

**To configure credentials to integrate with Amazon Cognito**

1. Create an Amazon Cognito identity pool that allows unauthenticated identities.
   
   ```bash
   aws cognito-identity create-identity-pool \
   --identity-pool-name DynamoPool \
   --allow-unauthenticated-identities \
   --output json
   ```
   
   ```json
   {
   "IdentityPoolId": "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
   "AllowUnauthenticatedIdentities": true,
   "IdentityPoolName": "DynamoPool"
   }
   ```

2. Copy the following policy into a file named myCognitoPolicy.json. Replace the identity pool ID (`us-west-2:12345678-1ab2-123a-1234-a12345ab12`) with your own `IdentityPoolId` obtained in the previous step.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   ```
3. Create an IAM role that assumes the previous policy. In this way, Amazon Cognito becomes a trusted entity that can assume the `Cognito_DynamoPoolUnauth` role.

```bash
aws iam create-role --role-name Cognito_DynamoPoolUnauth --assume-role-policy-document file://PathToFile/myCognitoPolicy.json --output json
```

4. Grant the `Cognito_DynamoPoolUnauth` role full access to DynamoDB by attaching a managed policy (`AmazonDynamoDBFullAccess`).

```bash
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonDynamoDBFullAccess --role-name Cognito_DynamoPoolUnauth
```

**Note**

Alternatively, you can grant fine-grained access to DynamoDB. For more information, see [Using IAM Policy Conditions for Fine-Grained Access Control](#).

5. Obtain and copy the IAM role Amazon Resource Name (ARN).

```bash
aws iam get-role --role-name Cognito_DynamoPoolUnauth --output json
```

6. Add the `Cognito_DynamoPoolUnauth` role to the DynamoPool identity pool. The format to specify is `KeyName=string`, where `KeyName` is `unauthenticated` and the string is the role ARN obtained in the previous step.

```bash
```

7. Specify the Amazon Cognito credentials in your files. Modify the `IdentityPoolId` and `RoleArn` accordingly.

```javascript
AWS.config.credentials = new AWS.CognitoIdentityCredentials({
  IdentityPoolId: "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
  RoleArn: "arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth"
});
```

You can now run your JavaScript programs against the DynamoDB web service using Amazon Cognito credentials. For more information, see [Setting Credentials in a Web Browser](#) in the [AWS SDK for JavaScript Getting Started Guide](#).
Loading Data From DynamoDB Into Amazon Redshift

Amazon Redshift complements Amazon DynamoDB with advanced business intelligence capabilities and a powerful SQL-based interface. When you copy data from a DynamoDB table into Amazon Redshift, you can perform complex data analysis queries on that data, including joins with other tables in your Amazon Redshift cluster.

In terms of provisioned throughput, a copy operation from a DynamoDB table counts against that table's read capacity. After the data is copied, your SQL queries in Amazon Redshift do not affect DynamoDB in any way. This is because your queries act upon a copy of the data from DynamoDB, rather than upon DynamoDB itself.

Before you can load data from a DynamoDB table, you must first create an Amazon Redshift table to serve as the destination for the data. Keep in mind that you are copying data from a NoSQL environment into a SQL environment, and that there are certain rules in one environment that do not apply in the other. Here are some of the differences to consider:

- DynamoDB table names can contain up to 255 characters, including '.' (dot) and '-' (dash) characters, and are case-sensitive. Amazon Redshift table names are limited to 127 characters, cannot contain dots or dashes and are not case-sensitive. In addition, table names cannot conflict with any Amazon Redshift reserved words.
- DynamoDB does not support the SQL concept of NULL. You need to specify how Amazon Redshift interprets empty or blank attribute values in DynamoDB, treating them either as NULLs or as empty fields.
- DynamoDB data types do not correspond directly with those of Amazon Redshift. You need to ensure that each column in the Amazon Redshift table is of the correct data type and size to accommodate the data from DynamoDB.

Here is an example COPY command from Amazon Redshift SQL:

```sql
COPY favoritemovies FROM 'dynamodb://my-favorite-movies-table'
CREDENTIALS 'aws_access_key_id=Your-Access-Key-ID;aws_secret_access_key=Your-Secret-Access-Key'
READRATIO 50;
```

In this example, the source table in DynamoDB is `my-favorite-movies-table`. The target table in Amazon Redshift is `favoritemovies`. The `readratio 50` clause regulates the percentage of provisioned throughput that is consumed; in this case, the COPY command will use no more than 50 percent of the read capacity units provisioned for `my-favorite-movies-table`. We highly recommend setting this ratio to a value less than the average unused provisioned throughput.

For detailed instructions on loading data from DynamoDB into Amazon Redshift, refer to the following sections in the Amazon Redshift Database Developer Guide:

Processing DynamoDB Data With Apache Hive on Amazon EMR

Amazon DynamoDB is integrated with Apache Hive, a data warehousing application that runs on Amazon EMR. Hive can read and write data in DynamoDB tables, allowing you to:

- Query live DynamoDB data using a SQL-like language (HiveQL).
- Copy data from a DynamoDB table to an Amazon S3 bucket, and vice-versa.
- Copy data from a DynamoDB table into Hadoop Distributed File System (HDFS), and vice-versa.
- Perform join operations on DynamoDB tables.

Overview

Amazon EMR is a service that makes it easy to quickly and cost-effectively process vast amounts of data. To use Amazon EMR, you launch a managed cluster of Amazon EC2 instances running the Hadoop open source framework. Hadoop is a distributed application that implements the MapReduce algorithm, where a task is mapped to multiple nodes in the cluster. Each node processes its designated work, in parallel with the other nodes. Finally, the outputs are reduced on a single node, yielding the final result.

You can choose to launch your Amazon EMR cluster so that it is persistent or transient:

- A persistent cluster runs until you shut it down. Persistent clusters are ideal for data analysis, data warehousing, or any other interactive use.
- A transient cluster runs long enough to process a job flow, and then shuts down automatically. Transient clusters are ideal for periodic processing tasks, such as running scripts.

For information about Amazon EMR architecture and administration, see the Amazon EMR Management Guide.

When you launch an Amazon EMR cluster, you specify the initial number and type of Amazon EC2 instances. You also specify other distributed applications (in addition to Hadoop itself) that you want to run on the cluster. These applications include Hue, Mahout, Pig, Spark, and more.

For information about applications for Amazon EMR, see the Amazon EMR Release Guide.

Depending on the cluster configuration, you might have one or more of the following node types:

- Master node — Manages the cluster, coordinating the distribution of the MapReduce executable and subsets of the raw data, to the core and task instance groups. It also tracks the status of each task performed and monitors the health of the instance groups. There is only one master node in a cluster.
- Core nodes — Runs MapReduce tasks and stores data using the Hadoop Distributed File System (HDFS).
• Task nodes (optional) — Runs MapReduce tasks.

**Tutorial: Working with Amazon DynamoDB and Apache Hive**

In this tutorial, you will launch an Amazon EMR cluster, and then use Apache Hive to process data stored in a DynamoDB table.

*Hive* is a data warehouse application for Hadoop that allows you to process and analyze data from multiple sources. Hive provides a SQL-like language, *HiveQL*, that lets you work with data stored locally in the Amazon EMR cluster or in an external data source (such as Amazon DynamoDB).

For more information, see to the *Hive Tutorial*.

**Topics**

- **Before You Begin** (p. 935)
- **Step 1: Create an Amazon EC2 Key Pair** (p. 935)
- **Step 2: Launch an Amazon EMR Cluster** (p. 936)
- **Step 3: Connect to the Master Node** (p. 937)
- **Step 4: Load Data into HDFS** (p. 937)
- **Step 5: Copy Data to DynamoDB** (p. 939)
- **Step 6: Query the Data in the DynamoDB Table** (p. 940)
- **Step 7: (Optional) Clean Up** (p. 941)

**Before You Begin**

For this tutorial, you will need the following:

- An AWS account. If you do not have one, see *Signing Up for AWS* (p. 53).
- An SSH client (Secure Shell). You use the SSH client to connect to the master node of the Amazon EMR cluster and run interactive commands. SSH clients are available by default on most Linux, Unix, and Mac OS X installations. Windows users can download and install the PuTTY client, which has SSH support.

**Next Step**

**Step 1: Create an Amazon EC2 Key Pair** (p. 935)

**Step 1: Create an Amazon EC2 Key Pair**

In this step, you will create the Amazon EC2 key pair you need to connect to an Amazon EMR master node and run Hive commands.

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose a region (for example, US West (Oregon)). This should be the same region in which your DynamoDB table is located.
3. In the navigation pane, choose **Key Pairs**.
4. Choose **Create Key Pair**.
5. In **Key pair name**, type a name for your key pair (for example, mykeypair), and then choose **Create**.
6. Download the private key file. The file name will end with .pem (such as mykeypair.pem). Keep this private key file in a safe place. You will need it to access any Amazon EMR cluster that you launch with this key pair.

   **Important**
   If you lose the key pair, you cannot connect to the master node of your Amazon EMR cluster.

   For more information about key pairs, see Amazon EC2 Key Pairs in the Amazon EC2 User Guide for Linux Instances.

**Next Step**

**Step 2: Launch an Amazon EMR Cluster (p. 936)**

**Step 2: Launch an Amazon EMR Cluster**

In this step, you will configure and launch an Amazon EMR cluster. Hive and a storage handler for DynamoDB will already be installed on the cluster.

1. Open the Amazon EMR console at https://console.aws.amazon.com/elasticmapreduce/.
2. Choose **Create Cluster**.
3. On the **Create Cluster - Quick Options** page, do the following:
   a. In **Cluster name**, type a name for your cluster (for example: *My EMR cluster*).
   b. In **EC2 key pair**, choose the key pair you created earlier.

   Leave the other settings at their defaults.
4. Choose **Create cluster**.

It will take several minutes to launch your cluster. You can use the **Cluster Details** page in the Amazon EMR console to monitor its progress.

When the status changes to **Waiting**, the cluster is ready for use.

**Cluster Log Files and Amazon S3**

An Amazon EMR cluster generates log files that contain information about the cluster status and debugging information. The default settings for **Create Cluster - Quick Options** include setting up Amazon EMR logging.

If one does not already exist, the AWS Management Console creates an Amazon S3 bucket. The bucket name is *aws-logs-account-id-region*, where *account-id* is your AWS account number and *region* is the region in which you launched the cluster (for example, *aws-logs-123456789012-us-west-2*).

   **Note**
   You can use the Amazon S3 console to view the log files. For more information, see **View Log Files** in the *Amazon EMR Management Guide*.

You can use this bucket for purposes in addition to logging. For example, you can use the bucket as a location for storing a Hive script or as a destination when exporting data from Amazon DynamoDB to Amazon S3.

**Next Step**

**Step 3: Connect to the Master Node (p. 937)**
Step 3: Connect to the Master Node

When the status of your Amazon EMR cluster changes to Waiting, you will be able to connect to the master node using SSH and perform command line operations.

1. In the Amazon EMR console, choose your cluster's name to view its status.
2. On the Cluster Details page, find the Master public DNS field. This is the public DNS name for the master node of your Amazon EMR cluster.
3. To the right of the DNS name, choose the SSH link.
4. Follow the instructions in Connect to the Master Node Using SSH.

Depending on your operating system, choose the Windows tab or the Mac/Linux tab, and follow the instructions for connecting to the master node.

After you connect to the master node using either SSH or PuTTY, you should see a command prompt similar to the following:

[hadoop@ip-192-0-2-0 ~]$

Next Step

Step 4: Load Data into HDFS (p. 937)

Step 4: Load Data into HDFS

In this step, you will copy a data file into Hadoop Distributed File System (HDFS), and then create an external Hive table that maps to the data file.

Download the Sample Data

1. Download the sample data archive (features.zip):

   wget https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/features.zip

2. Extract the features.txt file from the archive:

   unzip features.zip

3. View the first few lines of the features.txt file:

   head features.txt

The result should look similar to this:

The data file contains a subset of data provided by the United States Board on Geographic Names (http://geonames.usgs.gov/domestic/download_data.htm).

The features.txt file contains a subset of data from the United States Board on Geographic Names (http://geonames.usgs.gov/domestic/download_data.htm). The fields in each line represent the following:

- Feature ID (unique identifier)
- Name
- Class (lake; forest; stream; and so on)
- State
- Latitude (degrees)
- Longitude (degrees)
- Height (in feet)

4. At the command prompt, enter the following command:

```
hive
```

The command prompt changes to this: hive>

5. Enter the following HiveQL statement to create a native Hive table:

```
CREATE TABLE hive_features
(feature_id             BIGINT,
 feature_name            STRING ,
 feature_class           STRING ,
 state_alpha             STRING ,
 prim_lat_dec            DOUBLE ,
 prim_long_dec           DOUBLE ,
 elev_in_ft              BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY '|'|
LINES TERMINATED BY '\n';
```

6. Enter the following HiveQL statement to load the table with data:

```
LOAD DATA
LOCAL
INPATH './features.txt'
OVERWRITE
INTO TABLE hive_features;
```

7. You now have a native Hive table populated with data from the features.txt file. To verify, enter the following HiveQL statement:
```
SELECT state_alpha, COUNT(*)
FROM hive_features
GROUP BY state_alpha;
```

The output should show a list of states and the number of geographic features in each.

**Next Step**

**Step 5: Copy Data to DynamoDB (p. 939)**

**Step 5: Copy Data to DynamoDB**

In this step, you will copy data from the Hive table (hive_features) to a new table in DynamoDB.

2. Choose **Create Table**.
3. On the **Create DynamoDB table** page, do the following:
   a. In **Table**, type **Features**.
   b. For **Primary key**, in the **Partition key** field, type **Id**. Set the data type to **Number**.

   Clear Use Default Settings. For **Provisioned Capacity**, type the following:

   - **Read Capacity Units**—10
   - **Write Capacity Units**—10

   Choose **Create**.
4. At the Hive prompt, enter the following HiveQL statement:

   ```
   CREATE EXTERNAL TABLE ddb_features
   (feature_id   BIGINT,
    feature_name  STRING,
    feature_class STRING,
    state_alpha   STRING,
    prim_lat_dec  DOUBLE,
    prim_long_dec DOUBLE,
    elev_in_ft    BIGINT)
   STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
   TBLPROPERTIES(
     "dynamodb.table.name" = "Features",
     "dynamodb.column.mapping"="feature_id:Id,feature_name:Name,feature_class:Class,state_alpha:State,prim_lat_dec:Latitude,prim_long_dec:Longitude,elev_in_ft:Elevation";
   )
   ``

   You have now established a mapping between Hive and the Features table in DynamoDB.
5. Enter the following HiveQL statement to import data to DynamoDB:

   ```
   INSERT OVERWRITE TABLE ddb_features
   SELECT
    feature_id,
   ```
Hive will submit a MapReduce job, which will be processed by your Amazon EMR cluster. It will take several minutes to complete the job.

6. Verify that the data has been loaded into DynamoDB:
   a. In the DynamoDB console navigation pane, choose **Tables**.
   b. Choose the Features table, and then choose the **Items** tab to view the data.

Next Step

**Step 6: Query the Data in the DynamoDB Table**

In this step, you will use HiveQL to query the Features table in DynamoDB. Try the following Hive queries:

1. All of the feature types (**feature_class**) in alphabetical order:

   ```sql
   SELECT DISTINCT feature_class
   FROM ddb_features
   ORDER BY feature_class;
   ```

2. All of the lakes that begin with the letter "M":

   ```sql
   SELECT feature_name, state_alpha
   FROM ddb_features
   WHERE feature_class = 'Lake'
   AND feature_name LIKE 'M%'
   ORDER BY feature_name;
   ```

3. States with at least three features higher than a mile (5,280 feet):

   ```sql
   SELECT state_alpha, feature_class, COUNT(*)
   FROM ddb_features
   WHERE elev_in_ft > 5280
   GROUP by state_alpha, feature_class
   HAVING COUNT(*) >= 3
   ORDER BY state_alpha, feature_class;
   ```

**Step 7: (Optional) Clean Up**

Step 7: (Optional) Clean Up

Now that you have completed the tutorial, you can continue reading this section to learn more about working with DynamoDB data in Amazon EMR. You might decide to keep your Amazon EMR cluster up and running while you do this.

If you don't need the cluster anymore, you should terminate it and remove any associated resources. This will help you avoid being charged for resources you don't need.

1. Terminate the Amazon EMR cluster:
   a. Open the Amazon EMR console at https://console.aws.amazon.com/elasticmapreduce/.
   b. Choose the Amazon EMR cluster, choose Terminate, and then confirm.

2. Delete the Features table in DynamoDB:
   b. In the navigation pane, choose Tables.
   c. Choose the Features table. From the Actions menu, choose Delete Table.

3. Delete the Amazon S3 bucket containing the Amazon EMR log files:
   a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
   b. From the list of buckets, choose `aws-logs-accountID-region`, where `accountID` is your AWS account number and `region` is the region in which you launched the cluster.
   c. From the Action menu, choose Delete.

Creating an External Table in Hive

In Tutorial: Working with Amazon DynamoDB and Apache Hive (p. 935), you created an external Hive table that mapped to a DynamoDB table. When you issued HiveQL statements against the external table, the read and write operations were passed through to the DynamoDB table.

You can think of an external table as a pointer to a data source that is managed and stored elsewhere. In this case, the underlying data source is a DynamoDB table. (The table must already exist. You cannot create, update, or delete a DynamoDB table from within Hive.) You use the `CREATE EXTERNAL TABLE` statement to create the external table. After that, you can use HiveQL to work with data in DynamoDB, as if that data were stored locally within Hive.

**Note**
You can use `INSERT` statements to insert data into an external table and `SELECT` statements to select data from it. However, you cannot use `UPDATE` or `DELETE` statements to manipulate data in the table.

If you no longer need the external table, you can remove it using the `DROP TABLE` statement. In this case, `DROP TABLE` only removes the external table in Hive. It does not affect the underlying DynamoDB table or any of its data.

**Topics**
- CREATE EXTERNAL TABLE Syntax (p. 941)
- Data Type Mappings (p. 942)

**CREATE EXTERNAL TABLE Syntax**

The following shows the HiveQL syntax for creating an external Hive table that maps to a DynamoDB table:
CREATE EXTERNAL TABLE hive_table
  (hive_column1_name hive_column1_datatype, hive_column2_name hive_column2_datatype...)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "dynamodb_table",
  "dynamodb.column.mapping" = "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name...");

Line 1 is the start of the CREATE EXTERNAL TABLE statement, where you provide the name of the Hive table (hive_table) you want to create.

Line 2 specifies the columns and data types for hive_table. You need to define columns and data types that correspond to the attributes in the DynamoDB table.

Line 3 is the STORED BY clause, where you specify a class that handles data management between the Hive and the DynamoDB table. For DynamoDB, STORED BY should be set to 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'.

Line 4 is the start of the TBLPROPERTIES clause, where you define the following parameters for DynamoDBStorageHandler:

- dynamodb.table.name—the name of the DynamoDB table.
- dynamodb.column.mapping—pairs of column names in the Hive table and their corresponding attributes in the DynamoDB table. Each pair is of the form hive_column_name:dynamodb_attribute_name, and the pairs are separated by commas.

Note the following:

- The name of the Hive table name does not have to be the same as the DynamoDB table name.
- The Hive table column names do not have to be the same as those in the DynamoDB table.
- The table specified by dynamodb.table.name must exist in DynamoDB.
- For dynamodb.column.mapping:
  - You must map the key schema attributes for the DynamoDB table. This includes the partition key and the sort key (if present).
  - You do not have to map the non-key attributes of the DynamoDB table. However, you will not see any data from those attributes when you query the Hive table.
  - If the data types of a Hive table column and a DynamoDB attribute are incompatible, you will see NULL in these columns when you query the Hive table.

**Note**
The CREATE EXTERNAL TABLE statement does not perform any validation on the TBLPROPERTIES clause. The values you provide for dynamodb.table.name and dynamodb.column.mapping are only evaluated by the DynamoDBStorageHandler class when you attempt to access the table.

**Data Type Mappings**

The following table shows DynamoDB data types and compatible Hive data types:

<table>
<thead>
<tr>
<th>DynamoDB Data Type</th>
<th>Hive Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>STRING</td>
</tr>
</tbody>
</table>
### DynamoDB Data Type
<table>
<thead>
<tr>

<td>BIGINT or DOUBLE</td>
</tr>
<tr>
<td>Binary</td>

<tr>
<td>Number Set</td>
<td>ARRAY&lt;BIGINT&gt; or ARRAY&lt;DOUBLE&gt;</td>
</tr>
<tr>
<td>Binary Set</td>
<td>ARRAY&lt;BINARY&gt;</td>
</tr>
</tbody>
</table>

#### Note
The following DynamoDB data types are not supported by the `DynamoDBStorageHandler` class, so they cannot be used with `dynamodb.column.mapping`:
- Map
- List
- Boolean
- Null

If you want to map a DynamoDB attribute of type Number, you must choose an appropriate Hive type:
- The Hive `BIGINT` type is for 8-byte signed integers. It is the same as the `long` data type in Java.
- The Hive `DOUBLE` type is for 8-bit double precision floating point numbers. It is the same as the `double` type in Java.

If you have numeric data stored in DynamoDB that has a higher precision than the Hive data type you choose, then accessing the DynamoDB data could cause a loss of precision.

If you export data of type Binary from DynamoDB to (Amazon S3) or HDFS, the data is stored as a Base64-encoded string. If you import data from Amazon S3 or HDFS into the DynamoDB Binary type, you must ensure the data is encoded as a Base64 string.

### Processing HiveQL Statements
Hive is an application that runs on Hadoop, which is a batch-oriented framework for running MapReduce jobs. When you issue a HiveQL statement, Hive determines whether it can return the results immediately or whether it must submit a MapReduce job.

For example, consider the `ddb_features` table (from Tutorial: Working with Amazon DynamoDB and Apache Hive (p. 935)). The following Hive query prints state abbreviations and the number of summits in each:

```sql
SELECT state_alpha, count(*)
FROM ddb_features
WHERE feature_class = 'Summit'
GROUP BY state_alpha;
```

Hive does not return the results immediately. Instead, it submits a MapReduce job, which is processed by the Hadoop framework. Hive will wait until the job is complete before it shows the results from the query:
Monitoring and Canceling Jobs

When Hive launches a Hadoop job, it prints output from that job. The job completion status is updated as the job progresses. In some cases, the status might not be updated for a long time. (This can happen when you are querying a large DynamoDB table that has a low provisioned read capacity setting.)

If you need to cancel the job before it is complete, you can type `Ctrl+C` at any time.

Querying Data in DynamoDB

The following examples show some ways that you can use HiveQL to query data stored in DynamoDB.

These examples refer to the `ddb_features` table in the tutorial (Step 5: Copy Data to DynamoDB (p. 939)).

Topics

- Using Aggregate Functions (p. 944)
- Using the GROUP BY and HAVING Clauses (p. 945)
- Joining Two DynamoDB tables (p. 945)
- Joining Tables from Different Sources (p. 946)

Using Aggregate Functions

HiveQL provides built-in functions for summarizing data values. For example, you can use the `MAX` function to find the largest value for a selected column. The following example returns the elevation of the highest feature in the state of Colorado.

```
SELECT MAX(elev_in_ft)
FROM ddb_features
WHERE state_alpha = 'CO';
```
Using the GROUP BY and HAVING Clauses

You can use the `GROUP BY` clause to collect data across multiple records. This is often used with an aggregate function such as `SUM`, `COUNT`, `MIN`, or `MAX`. You can also use the `HAVING` clause to discard any results that do not meet certain criteria.

The following example returns a list of the highest elevations from states that have more than five features in the `ddb_features` table.

```sql
SELECT state_alpha, max(elev_in_ft)
FROM ddb_features
GROUP BY state_alpha
HAVING count(*) >= 5;
```

Joining Two DynamoDB tables

The following example maps another Hive table (`east_coast_states`) to a table in DynamoDB. The `SELECT` statement is a join across these two tables. The join is computed on the cluster and returned. The join does not take place in DynamoDB.

Consider a DynamoDB table named `EastCoastStates` that contains the following data:

<table>
<thead>
<tr>
<th>StateName</th>
<th>StateAbbrev</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maine</td>
<td>ME</td>
</tr>
<tr>
<td>New Hampshire</td>
<td>NH</td>
</tr>
<tr>
<td>Massachusetts</td>
<td>MA</td>
</tr>
<tr>
<td>Rhode Island</td>
<td>RI</td>
</tr>
<tr>
<td>Connecticut</td>
<td>CT</td>
</tr>
<tr>
<td>New York</td>
<td>NY</td>
</tr>
<tr>
<td>New Jersey</td>
<td>NJ</td>
</tr>
<tr>
<td>Delaware</td>
<td>DE</td>
</tr>
<tr>
<td>Maryland</td>
<td>MD</td>
</tr>
<tr>
<td>Virginia</td>
<td>VA</td>
</tr>
<tr>
<td>North Carolina</td>
<td>NC</td>
</tr>
<tr>
<td>South Carolina</td>
<td>SC</td>
</tr>
<tr>
<td>Georgia</td>
<td>GA</td>
</tr>
<tr>
<td>Florida</td>
<td>FL</td>
</tr>
</tbody>
</table>

Let's assume the table is available as a Hive external table named `east_coast_states`:

```sql
CREATE EXTERNAL TABLE ddb_east_coast_states (state_name STRING, state_alpha STRING)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "EastCoastStates",
"dynamodb.column.mapping" = "state_name:StateName,state_alpha:StateAbbrev");
```

The following join returns the states on the East Coast of the United States that have at least three features:

```sql
SELECT ecs.state_name, f.feature_class, COUNT(*)
FROM ddb_east_coast_states ecs
JOIN ddb_features f
ON ecs.state_name = f.state_name
GROUP BY ecs.state_name, f.feature_class
HAVING count(*) >= 3;
```
Joining Tables from Different Sources

In the following example, s3_east_coast_states is a Hive table associated with a CSV file stored in Amazon S3. The ddb_features table is associated with data in DynamoDB. The following example joins these two tables, returning the geographic features from states whose names begin with "New."

```sql
create external table s3_east_coast_states (state_name STRING, state_alpha STRING) ROW FORMAT DELIMITED FIELDS TERMINATED BY ',://' LOCATION 's3://bucketname/path/subpath/';

SELECT ecs.state_name, f.feature_name, f.feature_class
FROM s3_east_coast_states ecs
JOIN ddb_features f
ON ecs.state_alpha = f.state_alpha
WHERE ecs.state_name LIKE 'New%';
```

Copying Data to and from Amazon DynamoDB

In the Tutorial: Working with Amazon DynamoDB and Apache Hive (p. 935), you copied data from a native Hive table into an external DynamoDB table, and then queried the external DynamoDB table. The table is external because it exists outside of Hive. Even if you drop the Hive table that maps to it, the table in DynamoDB is not affected.

Hive is an excellent solution for copying data among DynamoDB tables, Amazon S3 buckets, native Hive tables, and Hadoop Distributed File System (HDFS). This section provides examples of these operations.

Topics
- Copying Data Between DynamoDB and a Native Hive Table (p. 946)
- Copying Data Between DynamoDB and Amazon S3 (p. 947)
- Copying Data Between DynamoDB and HDFS (p. 951)
- Using Data Compression (p. 956)
- Reading Non-Printable UTF-8 Character Data (p. 956)

Copying Data Between DynamoDB and a Native Hive Table

If you have data in a DynamoDB table, you can copy the data to a native Hive table. This will give you a snapshot of the data, as of the time you copied it.

You might decide to do this if you need to perform many HiveQL queries, but do not want to consume provisioned throughput capacity from DynamoDB. Because the data in the native Hive table is a copy of the data from DynamoDB, and not "live" data, your queries should not expect that the data is up-to-date.

The examples in this section are written with the assumption you followed the steps in Tutorial: Working with Amazon DynamoDB and Apache Hive (p. 935) and have an external table that is mastered in DynamoDB (ddb_features).
Example From DynamoDB to Native Hive Table

You can create a native Hive table and populate it with data from `ddb_features`, like this:

```
CREATE TABLE features_snapshot AS
SELECT * FROM ddb_features;
```

You can then refresh the data at any time:

```
INSERT OVERWRITE TABLE features_snapshot
SELECT * FROM ddb_features;
```

In these examples, the subquery `SELECT * FROM ddb_features` will retrieve all of the data from `ddb_features`. If you only want to copy a subset of the data, you can use a `WHERE` clause in the subquery.

The following example creates a native Hive table, containing only some of the attributes for lakes and summits:

```
CREATE TABLE lakes_and_summits AS
SELECT feature_name, feature_class, state_alpha
FROM ddb_features
WHERE feature_class IN ('Lake','Summit');
```

Example From Native Hive Table to DynamoDB

Use the following HiveQL statement to copy the data from the native Hive table to `ddb_features`:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM features_snapshot;
```

Copying Data Between DynamoDB and Amazon S3

If you have data in a DynamoDB table, you can use Hive to copy the data to an Amazon S3 bucket.

You might do this if you want to create an archive of data in your DynamoDB table. For example, suppose you have a test environment where you need to work with a baseline set of test data in DynamoDB. You can copy the baseline data to an Amazon S3 bucket, and then run your tests. Afterward, you can reset the test environment by restoring the baseline data from the Amazon S3 bucket to DynamoDB.

If you worked through Tutorial: Working with Amazon DynamoDB and Apache Hive (p. 935), then you already have an Amazon S3 bucket that contains your Amazon EMR logs. You can use this bucket for the examples in this section, if you know the root path for the bucket:

1. Open the Amazon EMR console at https://console.aws.amazon.com/elasticmapreduce/.
2. For Name, choose your cluster.
3. The URI is listed in Log URI under Configuration Details.
4. Make a note of the root path of the bucket. The naming convention is:

\[ \text{s3://aws-logs-}\text{accountID-region} \]

where `accountID` is your AWS account ID and region is the AWS region for the bucket.

**Note**

For these examples, we will use a subpath within the bucket, as in this example:

\[ \text{s3://aws-logs-123456789012-us-west-2/hive-test} \]

The following procedures are written with the assumption you followed the steps in the tutorial and have an external table that is mastered in DynamoDB (`ddb_features`).

**Topics**

- Copying Data Using the Hive Default Format (p. 948)
- Copying Data with a User-Specified Format (p. 949)
- Copying Data Without a Column Mapping (p. 950)
- Viewing the Data in Amazon S3 (p. 951)

**Copying Data Using the Hive Default Format**

**Example From DynamoDB to Amazon S3**

Use an `INSERT OVERWRITE` statement to write directly to Amazon S3.

```
INSERT OVERWRITE DIRECTORY 's3://aws-logs-123456789012-us-west-2/hive-test'
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135
1178153^AJones Run^AStream^APA^A41.2120086^A-79.25920781260
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133
264054^ANeverSweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900
115905^AChacaloochee Bay^ABay^AAA^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as `^A`.

**Example From Amazon S3 to DynamoDB**

1. Create an external table pointing to the unformatted data in Amazon S3.

```
CREATE EXTERNAL TABLE s3_features_unformatted
(feature_id BIGINT, feature_name STRING, feature_class STRING, state_alpha STRING, prim_lat_dec DOUBLE, prim_long_dec DOUBLE, elev_in_ft BIGINT)
```
Copying Data to and from Amazon DynamoDB

LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';

2. Copy the data to DynamoDB.

```sql
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM s3_features_unformatted;
```

Copying Data with a User-Specified Format

If you want to specify your own field separator character, you can create an external table that maps to the Amazon S3 bucket. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to Amazon S3

1. Create a Hive external table that maps to Amazon S3. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

```sql
CREATE EXTERNAL TABLE s3_features_csv
(feature_id       BIGINT,
feature_name      STRING,
feature_class     STRING,
state_alpha       STRING,
prim_lat_dec      DOUBLE,
prim_long_dec     DOUBLE,
elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data from DynamoDB.

```sql
INSERT OVERWRITE TABLE s3_features_csv
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```sql
CREATE EXTERNAL TABLE s3_features_csv
(feature_id       BIGINT,
feature_name      STRING,
feature_class     STRING,
state_alpha       STRING,
prim_lat_dec      DOUBLE,
prim_long_dec     DOUBLE,
elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data from DynamoDB.

```sql
INSERT OVERWRITE TABLE s3_features_csv
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260

```

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```sql
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM s3_features_unformatted;
```
Copying Data Without a Column Mapping

You can copy data from DynamoDB in a raw format and write it to Amazon S3 without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in Amazon S3.

**Note**

If your DynamoDB table contains attributes of type Map, List, Boolean or Null, then this is the only way you can use Hive to copy data from DynamoDB to Amazon S3.

**Example From DynamoDB to Amazon S3**

1. Create an external table associated with your DynamoDB table. (There is no `dynamodb.column.mapping` in this HiveQL statement.)

   ```sql
   CREATE EXTERNAL TABLE ddb_features_no_mapping
   (item MAP<STRING, STRING>)
   STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
   TBLPROPERTIES ("dynamodb.table.name" = "Features");
   ```

2. Create another external table associated with your Amazon S3 bucket.

   ```sql
   CREATE EXTERNAL TABLE s3_features_no_mapping
   (item MAP<STRING, STRING>)
   ROW FORMAT DELIMITED
   FIELDS TERMINATED BY '\t'
   LINES TERMINATED BY '\n'
   LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
   ```

3. Copy the data from DynamoDB to Amazon S3.

   ```sql
   INSERT OVERWRITE TABLE s3_features_no_mapping
   SELECT * FROM ddb_features_no_mapping;
   ```

The data file in Amazon S3 looks like this:

```

**Example From Amazon S3 to DynamoDB**

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```sql
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM s3_features_no_mapping;
```

**Viewing the Data in Amazon S3**

If you use SSH to connect to the master node, you can use the AWS Command Line Interface (AWS CLI) to access the data that Hive wrote to Amazon S3.

The following steps are written with the assumption you have copied data from DynamoDB to Amazon S3 using one of the procedures in this section.

1. **If you are currently at the Hive command prompt, exit to the Linux command prompt.**

   hive> exit;

2. **List the contents of the hive-test directory in your Amazon S3 bucket.** (This is where Hive copied the data from DynamoDB.)

   ```bash
   aws s3 ls s3://aws-logs-123456789012-us-west-2/hive-test/
   ```

   The response should look similar to this:

   ```
   2016-11-01 23:19:54 81983 000000_0
   ```

   The file name (000000_0) is system-generated.

3. **(Optional) You can copy the data file from Amazon S3 to the local file system on the master node.** After you do this, you can use standard Linux command line utilities to work with the data in the file.

   ```bash
   aws s3 cp s3://aws-logs-123456789012-us-west-2/hive-test/000000_0 .
   ```

   The response should look similar to this:

   ```
   download: s3://aws-logs-123456789012-us-west-2/hive-test/000000_0
to ./000000_0
   ```

   **Note**

   The local file system on the master node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

**Copying Data Between DynamoDB and HDFS**

If you have data in a DynamoDB table, you can use Hive to copy the data to the Hadoop Distributed File System (HDFS).
You might do this if you are running a MapReduce job that requires data from DynamoDB. If you copy
the data from DynamoDB into HDFS, Hadoop can process it, using all of the available nodes in the
Amazon EMR cluster in parallel. When the MapReduce job is complete, you can then write the results
from HDFS to DDB.

In the following examples, Hive will read from and write to the following HDFS directory: /user/
hadoop/hive-test

The examples in this section are written with the assumption you followed the steps in Tutorial: Working
with Amazon DynamoDB and Apache Hive (p. 935) and you have an external table that is mastered in
DynamoDB (ddb_features).

## Copying Data Using the Hive Default Format

### Example From DynamoDB to HDFS

Use an `INSERT OVERWRITE` statement to write directly to HDFS.

```sql
INSERT OVERWRITE DIRECTORY 'hdfs:///user/hadoop/hive-test'
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANN^A32.3564729^A1-108.33004616135

115905^ACHacaloochee Bay^ABay^AAP^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as ^A.

### Example From HDFS to DynamoDB

1. Create an external table that maps to the unformatted data in HDFS.

```sql
CREATE EXTERNAL TABLE hdfs_features_unformatted
  (feature_id       BIGINT,
   feature_name      STRING ,
   feature_class     STRING ,
   state_alpha       STRING,
   prim_lat_dec      DOUBLE ,
   prim_long_dec     DOUBLE ,
   elev_in_ft        BIGINT)
LOCATION 'hdfs:///user/hadoop/hive-test';
```
2. Copy the data to DynamoDB.

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM hdfs_features_unformatted;
```

## Copying Data with a User-Specified Format

If you want to use a different field separator character, you can create an external table that maps to the HDFS directory. You might use this technique for creating data files with comma-separated values (CSV).

### Example From DynamoDB to HDFS

1. Create a Hive external table that maps to HDFS. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

```
CREATE EXTERNAL TABLE hdfs_features_csv
(feature_id       BIGINT,  
feature_name      STRING,  
feature_class     STRING,  
state_alpha       STRING,  
prim_lat_dec      DOUBLE,  
prim_long_dec     DOUBLE,  
elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 'hdfs:///user/hadoop/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE hdfs_features_csv
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900

```

### Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM hdfs_features_csv;
```
Copying Data Without a Column Mapping

You can copy data from DynamoDB in a raw format and write it to HDFS without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in HDFS.

**Note**
If your DynamoDB table contains attributes of type Map, List, Boolean or Null, then this is the only way you can use Hive to copy data from DynamoDB to HDFS.

Example From DynamoDB to HDFS

1. Create an external table associated with your DynamoDB table. (There is no dynamodb.column.mapping in this HiveQL statement.)

   ```sql
   CREATE EXTERNAL TABLE ddb_features_no_mapping
   (item MAP<STRING, STRING>)
   STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
   TBLPROPERTIES ("dynamodb.table.name" = "Features");
   ```

2. Create another external table associated with your HDFS directory.

   ```sql
   CREATE EXTERNAL TABLE hdfs_features_no_mapping
   (item MAP<STRING, STRING>)
   ROW FORMAT DELIMITED
   FIELDS TERMINATED BY '	'
   LINES TERMINATED BY '
'
   LOCATION 'hdfs:///user/hadoop/hive-test';
   ```

3. Copy the data from DynamoDB to HDFS.

   ```sql
   INSERT OVERWRITE TABLE hdfs_features_no_mapping
   SELECT * FROM ddb_features_no_mapping;
   ```

The data file in HDFS looks like this:

```
Name: "Soldiers Farewell Hill"
State: "NM"
Class: "Summit"
Elevation: "6135"
Latitude: "32.3564729"
Id: "920709"

```

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as ^B and ETX appears as ^C.
Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```sql
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM hdfs_features_no_mapping;
```

Accessing the Data in HDFS

HDFS is a distributed file system, accessible to all of the nodes in the Amazon EMR cluster. If you use SSH to connect to the master node, you can use command line tools to access the data that Hive wrote to HDFS.

HDFS is not the same thing as the local file system on the master node. You cannot work with files and directories in HDFS using standard Linux commands (such as `cat`, `cp`, `mv`, or `rm`). Instead, you perform these tasks using the `hadoop fs` command.

The following steps are written with the assumption you have copied data from DynamoDB to HDFS using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

   ```bash
   hive> exit;
   ```

2. List the contents of the `/user/hadoop/hive-test` directory in HDFS. (This is where Hive copied the data from DynamoDB.)

   ```bash
   hadoop fs -ls /user/hadoop/hive-test
   ```

   The response should look similar to this:

   ```
   Found 1 items
   -rw-r--r-- 1 hadoop hadoop 29504 2016-06-08 23:40 /user/hadoop/hive-test/000000_0
   ```

   The file name (`000000_0`) is system-generated.

3. View the contents of the file:

   ```bash
   hadoop fs -cat /user/hadoop/hive-test/000000_0
   ```

   **Note**

   In this example, the file is relatively small (approximately 29 KB). Be careful when you use this command with files that are very large or contain non-printable characters.

4. (Optional) You can copy the data file from HDFS to the local file system on the master node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

   ```bash
   hadoop fs -get /user/hadoop/hive-test/000000_0
   ```
Using Data Compression

When you use Hive to copy data among different data sources, you can request on-the-fly data compression. Hive provides several compression codecs. You can choose one during your Hive session. When you do this, the data is compressed in the specified format.

The following example compresses data using the Lempel-Ziv-Oberhumer (LZO) algorithm.

```
SET hive.exec.compress.output=true;
SET io.seqfile.compression.type=BLOCK;
SET mapred.output.compression.codec = com.hadoop.compression.lzo.LzopCodec;

CREATE EXTERNAL TABLE lzo_compression_table (line STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE lzo_compression_table SELECT * FROM hiveTableName;
```

The resulting file in Amazon S3 will have a system-generated name with .lzo at the end (for example, 8d436957-57ba-4af7-840c-96c2fc7bb6f5-000000.lzo).

The available compression codecs are:

- `org.apache.hadoop.io.compress.GzipCodec`
- `org.apache.hadoop.io.compress.DefaultCodec`
- `com.hadoop.compression.lzo.LzoCodec`
- `com.hadoop.compression.lzo.LzopCodec`
- `org.apache.hadoop.io.compress.BZip2Codec`
- `org.apache.hadoop.io.compress.SnappyCodec`

Reading Non-Printable UTF-8 Character Data

To read and write non-printable UTF-8 character data, you can use the `STORED AS SEQUENCEFILE` clause when you create a Hive table. A SequenceFile is a Hadoop binary file format. You need to use Hadoop to read this file. The following example shows how to export data from DynamoDB into Amazon S3. You can use this functionality to handle non-printable UTF-8 encoded characters.

```
CREATE EXTERNAL TABLE s3_export(a_col string, b_col bigint, c_col array<string>) STORED AS SEQUENCEFILE
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3_export SELECT * FROM hiveTableName;
```
Performance Tuning

When you create a Hive external table that maps to a DynamoDB table, you do not consume any read or write capacity from DynamoDB. However, read and write activity on the Hive table (such as INSERT or SELECT) translates directly into read and write operations on the underlying DynamoDB table.

Apache Hive on Amazon EMR implements its own logic for balancing the I/O load on the DynamoDB table and seeks to minimize the possibility of exceeding the table's provisioned throughput. At the end of each Hive query, Amazon EMR returns runtime metrics, including the number of times your provisioned throughput was exceeded. You can use this information, together with CloudWatch metrics on your DynamoDB table, to improve performance in subsequent requests.

The Amazon EMR console provides basic monitoring tools for your cluster. For more information, see View and Monitor a Cluster in the Amazon EMR Management Guide.

You can also monitor your cluster and Hadoop jobs using web-based tools, such as Hue, Ganglia, and the Hadoop web interface. For more information, see View Web Interfaces Hosted on Amazon EMR Clusters in the Amazon EMR Management Guide.

This section describes steps you can take to performance-tune Hive operations on external DynamoDB tables.

Topics

• DynamoDB Provisioned Throughput (p. 957)
• Adjusting the Mappers (p. 959)
• Additional Topics (p. 960)

DynamoDB Provisioned Throughput

When you issue HiveQL statements against the external DynamoDB table, the DynamoDBStorageHandler class makes the appropriate low-level DynamoDB API requests, which consume provisioned throughput. If there is not enough read or write capacity on the DynamoDB table, the request will be throttled, resulting in slow HiveQL performance. For this reason, you should ensure that the table has enough throughput capacity.

For example, suppose that you have provisioned 100 read capacity units for your DynamoDB table. This will let you read 409,600 bytes per second (100 × 4 KB read capacity unit size). Now suppose that the table contains 20 GB of data (21,474,836,480 bytes) and you want to use the SELECT statement to select all of the data using HiveQL. You can estimate how long the query will take to run like this:

\[
\frac{21,474,836,480}{409,600} = 52,429 \text{ seconds} = 14.56 \text{ hours}
\]

In this scenario, the DynamoDB table is a bottleneck. It won't help to add more Amazon EMR nodes, because the Hive throughput is constrained to only 409,600 bytes per second. The only way to decrease the time required for the SELECT statement is to increase the provisioned read capacity of the DynamoDB table.

You can perform a similar calculation to estimate how long it would take to bulk-load data into a Hive external table mapped to a DynamoDB table. Determine the total number of bytes in the data you want to load, and then divide it by the size of one DynamoDB write capacity unit (1 KB). This will yield the number of seconds it will take to load the table.

You should regularly monitor the CloudWatch metrics for your table. For a quick overview in the DynamoDB console, choose your table and then choose the Metrics tab. From here, you can view read and write capacity units consumed and read and write requests that have been throttled.
Read Capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of ProvisionedThroughputExceeded messages in the job output, you can adjust the default read rate. To do this, you can modify the dynamodb.throughput.read.percent configuration variable. You can use the `SET` command to set this variable at the Hive command prompt:

```sql
SET dynamodb.throughput.read.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, `dynamodb.throughput.read.percent` will return to its default value.

The value of `dynamodb.throughput.read.percent` can be between 0.1 and 1.5, inclusively. 0.5 represents the default read rate, meaning that Hive will attempt to consume half of the read capacity of the table. If you increase the value above 0.5, Hive will increase the request rate; decreasing the value below 0.5 decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned read capacity of the table, or if your read requests are being throttled too much, try reducing `dynamodb.throughput.read.percent` below 0.5. If you have sufficient read capacity in the table and want more responsive HiveQL operations, you can set the value above 0.5.

Write Capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of ProvisionedThroughputExceeded messages in the job output, you can adjust the default write rate. To do this, you can modify the `dynamodb.throughput.write.percent` configuration variable. You can use the `SET` command to set this variable at the Hive command prompt:

```sql
SET dynamodb.throughput.write.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, `dynamodb.throughput.write.percent` will return to its default value.

The value of `dynamodb.throughput.write.percent` can be between 0.1 and 1.5, inclusively. 0.5 represents the default write rate, meaning that Hive will attempt to consume half of the write capacity of the table. If you increase the value above 0.5, Hive will increase the request rate; decreasing the value below 0.5 decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned write capacity of the table, or if your write requests are being throttled too much, try reducing `dynamodb.throughput.write.percent` below 0.5. If you have sufficient capacity in the table and want more responsive HiveQL operations, you can set the value above 0.5.

When you write data to DynamoDB using Hive, ensure that the number of write capacity units is greater than the number of mappers in the cluster. For example, consider an Amazon EMR cluster consisting of 10 `m1.xlarge` nodes. The `m1.xlarge` node type provides 8 mapper tasks, so the cluster would have a total of 80 mappers (10 × 8). If your DynamoDB table has fewer than 80 write capacity units, then a Hive write operation could consume all of the write throughput for that table.
To determine the number of mappers for Amazon EMR node types, see Task Configuration in the Amazon EMR Developer Guide.

For more information on mappers, see Adjusting the Mappers (p. 959).

**Adjusting the Mappers**

When Hive launches a Hadoop job, the job is processed by one or more mapper tasks. Assuming that your DynamoDB table has sufficient throughput capacity, you can modify the number of mappers in the cluster, potentially improving performance.

**Note**

The number of mapper tasks used in a Hadoop job are influenced by input splits, where Hadoop subdivides the data into logical blocks. If Hadoop does not perform enough input splits, then your write operations might not be able to consume all the write throughput available in the DynamoDB table.

**Increasing the Number of Mappers**

Each mapper in an Amazon EMR has a maximum read rate of 1 MiB per second. The number of mappers in a cluster depends on the size of the nodes in your cluster. (For information about node sizes and the number of mappers per node, see Task Configuration in the Amazon EMR Developer Guide.)

If your DynamoDB table has ample throughput capacity for reads, you can try increasing the number of mappers by doing one of the following:

- Increase the size of the nodes in your cluster. For example, if your cluster is using m1.large nodes (three mappers per node), you can try upgrading to m1.xlarge nodes (eight mappers per node).
- Increase the number of nodes in your cluster. For example, if you have three-node cluster of m1.xlarge nodes, you have a total of 24 mappers available. If you were to double the size of the cluster, with the same type of node, you would have 48 mappers.

You can use the AWS Management Console to manage the size or the number of nodes in your cluster. (You might need to restart the cluster for these changes to take effect.)

Another way to increase the number of mappers is to modify the mapred.tasktracker.map.tasks.maximum Hadoop configuration parameter. (This is a Hadoop parameter, not a Hive parameter. You cannot modify it interactively from the command prompt.) If you increase the value of mapred.tasktracker.map.tasks.maximum, you can increase the number of mappers without increasing the size or number of nodes. However, it is possible for the cluster nodes to run out of memory if you set the value too high.

You set the value for mapred.tasktracker.map.tasks.maximum as a bootstrap action when you first launch your Amazon EMR cluster. For more information, see (Optional) Create Bootstrap Actions to Install Additional Software in the Amazon EMR Management Guide.

**Decreasing the Number of Mappers**

If you use the SELECT statement to select data from an external Hive table that maps to DynamoDB, the Hadoop job can use as many tasks as necessary, up to the maximum number of mappers in the cluster. In this scenario, it is possible that a long-running Hive query can consume all of the provisioned read capacity of the DynamoDB table, negatively impacting other users.

You can use the dynamodb.max.map.tasks parameter to set an upper limit for map tasks:

```
SET dynamodb.max.map.tasks=1
```
This value must be equal to or greater than 1. When Hive processes your query, the resulting Hadoop job will use no more than `dynamodb.max.map.tasks` when reading from the DynamoDB table.

**Additional Topics**

The following are some more ways to tune applications that use Hive to access DynamoDB.

**Retry Duration**

By default, Hive will rerun a Hadoop job if it has not returned any results from DynamoDB within two minutes. You can adjust this interval by modifying the `dynamodb.retry.duration` parameter:

```
SET dynamodb.retry.duration=2;
```

The value must be a nonzero integer, representing the number of minutes in the retry interval. The default for `dynamodb.retry.duration` is 2 (minutes).

**Parallel Data Requests**

Multiple data requests, either from more than one user or more than one application to a single table can drain read provisioned throughput and slow performance.

**Process Duration**

Data consistency in DynamoDB depends on the order of read and write operations on each node. While a Hive query is in progress, another application might load new data into the DynamoDB table or modify or delete existing data. In this case, the results of the Hive query might not reflect changes made to the data while the query was running.

**Request Time**

Scheduling Hive queries that access a DynamoDB table when there is lower demand on the DynamoDB table improves performance. For example, if most of your application's users live in San Francisco, you might choose to export daily data at 4:00 A.M. PST when the majority of users are asleep and not updating records in your DynamoDB database.
Service, Account, and Table Limits in Amazon DynamoDB

This section describes current limits within Amazon DynamoDB (or no limit, in some cases). Each limit applies on a per-Region basis unless otherwise specified.

Read/Write Capacity Mode and Throughput

You can switch between read/write capacity modes once every 24 hours.

Capacity Unit Sizes (for Provisioned Tables)

One read capacity unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write capacity unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read capacity units to perform one read per second for items up to 4 KB.

Transactional write requests require two write capacity units to perform one write per second for items up to 1 KB.

Request Unit Sizes (for On-Demand Tables)

One read request unit = one strongly consistent read, or two eventually consistent reads, for items up to 4 KB in size.

One write request unit = one write, for items up to 1 KB in size.

Transactional read requests require two read request units to perform one read for items up to 4 KB.
Transactional write requests require two write request units to perform one write for items up to 1 KB.

**Throughput Default Limits**

AWS places some default limits on the throughput you can provision. These are the limits unless you request a higher amount. To request a service limit increase, see [https://aws.amazon.com/support](https://aws.amazon.com/support).

<table>
<thead>
<tr>
<th></th>
<th>On-Demand</th>
<th>Provisioned</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Per table</strong></td>
<td>40,000 read request units and 40,000 write request units</td>
<td>40,000 read capacity units and 40,000 write capacity units</td>
</tr>
<tr>
<td><strong>Per account</strong></td>
<td>Not applicable</td>
<td>80,000 read capacity units and 80,000 write capacity units</td>
</tr>
<tr>
<td><strong>Minimum throughput</strong></td>
<td>Not applicable</td>
<td>1 read capacity unit and 1 write capacity unit</td>
</tr>
<tr>
<td><strong>any table or global secondary index</strong></td>
<td>Not applicable</td>
<td>1 read capacity unit and 1 write capacity unit</td>
</tr>
</tbody>
</table>

**Note**

All the account's available throughput can be applied to a single table or across multiple tables.

The provisioned throughput limit includes the sum of the capacity of the table together with the capacity of all of its global secondary indexes.

On the AWS Management Console, you can use Amazon CloudWatch to see what your current read and write throughput is in a given AWS Region by looking at the read capacity and write capacity graphs on the Metrics tab. Make sure that you are not too close to the limits.

If you increased your provisioned throughput default limits, you can use the `DescribeLimits` operation to see the current limit values.

**Increasing or Decreasing Throughput (for Provisioned Tables)**

**Increasing Provisioned Throughput**

You can increase `ReadCapacityUnits` or `WriteCapacityUnits` as often as necessary, using the AWS Management Console or the `UpdateTable` operation. In a single call, you can increase the provisioned throughput for a table, for any global secondary indexes on that table, or for any combination of these. The new settings do not take effect until the `UpdateTable` operation is complete.

You can't exceed your per-account limits when you add provisioned capacity, and DynamoDB doesn't allow you to increase provisioned capacity very rapidly. Aside from these restrictions, you can increase the provisioned capacity for your tables as high as you need. For more information about per-account limits, see the preceding section, Throughput Default Limits (p. 962).

**Decreasing Provisioned Throughput**

For every table and global secondary index in an `UpdateTable` operation, you can decrease `ReadCapacityUnits` or `WriteCapacityUnits` (or both). The new settings don't take effect until the `UpdateTable` operation is complete. A decrease is allowed up to four times, anytime per day. A day is
defined according to Universal Coordinated Time (UTC). Additionally, if there was no decrease in the past hour, an additional decrease is allowed. This effectively brings the maximum number of decreases in a day to 27 times (4 decreases in the first hour, and 1 decrease for each of the subsequent 1-hour windows in a day).

Important
Table and global secondary index decrease limits are decoupled, so any global secondary indexes for a particular table have their own decrease limits. However, if a single request decreases the throughput for a table and a global secondary index, it is rejected if either exceeds the current limits. Requests are not partially processed.

Example
In the first 4 hours of a day, a table with a global secondary index can be modified as follows:

- Decrease the table's WriteCapacityUnits or ReadCapacityUnits (or both) four times.
- Decrease the WriteCapacityUnits or ReadCapacityUnits (or both) of the global secondary index four times.

At the end of that same day, the table and the global secondary index throughput can potentially be decreased a total of 27 times each.

Tables

Table Size

There is no practical limit on a table's size. Tables are unconstrained in terms of the number of items or the number of bytes.

Tables Per Account

For any AWS account, there is an initial limit of 256 tables per AWS Region.

To request a service limit increase, see https://aws.amazon.com/support.

Global Tables

AWS places some default limits on the throughput you can provision or utilize when using global tables.

<table>
<thead>
<tr>
<th></th>
<th>On-Demand</th>
<th>Provisioned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Per table</td>
<td>40,000 read request units and 40,000 write request units</td>
<td>40,000 read capacity units and 40,000 write capacity units</td>
</tr>
<tr>
<td>Per table, per day</td>
<td>10 TB for all source tables to which a replica was added</td>
<td>10 TB for all source tables to which a replica was added</td>
</tr>
</tbody>
</table>

If you are adding a replica for a table that is configured to use more than 40,000 write capacity units (WCU), you must request a service limit increase for your add replica WCU limit. To request a service limit increase see https://aws.amazon.com/support.
Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the AWS Region where the write is made originally. Transactions are not supported across Regions in global tables. For example, suppose that you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and you perform a TransactWriteItems operation in the US East (N. Virginia) Region. In this case, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

**Secondary Indexes**

**Secondary Indexes Per Table**

You can define a maximum of 5 local secondary indexes.

There is an initial limit of 20 global secondary indexes per table. To request a service limit increase, see https://aws.amazon.com/support.

You can create or delete only one global secondary index per UpdateTable operation.

**Projected Secondary Index Attributes Per Table**

You can project a total of up to 100 attributes into all of a table's local and global secondary indexes. This only applies to user-specified projected attributes.

In a CreateTable operation, if you specify a ProjectionType of INCLUDE, the total count of attributes specified in NonKeyAttributes, summed across all of the secondary indexes, must not exceed 100. If you project the same attribute name into two different indexes, this counts as two distinct attributes when determining the total.

This limit does not apply for secondary indexes with a ProjectionType of KEYS_ONLY or ALL.

**Partition Keys and Sort Keys**

**Partition Key Length**

The minimum length of a partition key value is 1 byte. The maximum length is 2048 bytes.

**Partition Key Values**

There is no practical limit on the number of distinct partition key values, for tables or for secondary indexes.

**Sort Key Length**

The minimum length of a sort key value is 1 byte. The maximum length is 1024 bytes.

**Sort Key Values**

In general, there is no practical limit on the number of distinct sort key values per partition key value.
The exception is for tables with secondary indexes. With a local secondary index, there is a limit on item collection sizes: For every distinct partition key value, the total sizes of all table and index items cannot exceed 10 GB. This might constrain the number of sort keys per partition key value. For more information, see Item Collection Size Limit (p. 547).

Naming Rules

Table Names and Secondary Index Names

Names for tables and secondary indexes must be at least 3 characters long, but no greater than 255 characters long. The following are the allowed characters:

- A–Z
- a–z
- 0–9
- _ (underscore)
- – (hyphen)
- . (dot)

Attribute Names

In general, an attribute name must be at least one character long, but no greater than 64 KB long. The following are the exceptions. These attribute names must be no greater than 255 characters long:

- Secondary index partition key names.
- Secondary index sort key names.
- The names of any user-specified projected attributes (applicable only to local secondary indexes). In a CreateTable operation, if you specify a ProjectionType of INCLUDE, the names of the attributes in the NonKeyAttributes parameter are length-restricted. The KEYS_ONLY and ALL projection types are not affected.

These attribute names must be encoded using UTF-8, and the total size of each name (after encoding) cannot exceed 255 bytes.

Data Types

String

The length of a String is constrained by the maximum item size of 400 KB.

Strings are Unicode with UTF-8 binary encoding. Because UTF-8 is a variable width encoding, DynamoDB determines the length of a String using its UTF-8 bytes.

Number

A Number can have up to 38 digits of precision, and can be positive, negative, or zero.

- Positive range: $1E-130$ to $9.9999999999999999999999999999999999999E+125$
• Negative range: $-9.9999999999999999999999999999999999999E+125$ to $-1E-130$

DynamoDB uses JSON strings to represent Number data in requests and replies. For more information, see DynamoDB Low-Level API (p. 217).

If number precision is important, you should pass numbers to DynamoDB using strings that you convert from a number type.

**Binary**

The length of a Binary is constrained by the maximum item size of 400 KB.

Applications that work with Binary attributes must encode the data in base64 format before sending it to DynamoDB. Upon receipt of the data, DynamoDB decodes it into an unsigned byte array and uses that as the length of the attribute.

**Items**

**Item Size**

The maximum item size in DynamoDB is 400 KB, which includes both attribute name binary length (UTF-8 length) and attribute value lengths (again binary length). The attribute name counts towards the size limit.

For example, consider an item with two attributes: one attribute named "shirt-color" with value "R" and another attribute named "shirt-size" with value "M". The total size of that item is 23 bytes.

**Item Size for Tables with Local Secondary Indexes**

For each local secondary index on a table, there is a 400 KB limit on the total of the following:

• The size of an item's data in the table.
• The size of the local secondary index entry corresponding to that item, including its key values and projected attributes.

**Attributes**

**Attribute Name-Value Pairs Per Item**

The cumulative size of attributes per item must fit within the maximum DynamoDB item size (400 KB).

**Number of Values in List, Map, or Set**

There is no limit on the number of values in a List, a Map, or a Set, as long as the item containing the values fits within the 400 KB item size limit.

**Attribute Values**

Empty String and Binary attribute values are allowed, if the attribute is not used as a key attribute for a table or index. Empty String and Binary values are allowed inside Set, List, and Map types. An attribute
value cannot be an empty Set (String Set, Number Set, or Binary Set). However, empty Lists and Maps are allowed.

**Nested Attribute Depth**

DynamoDB supports nested attributes up to 32 levels deep.

**Expression Parameters**

Expression parameters include `ProjectionExpression`, `ConditionExpression`, `UpdateExpression`, and `FilterExpression`.

**Lengths**

The maximum length of any expression string is 4 KB. For example, the size of the `ConditionExpression a=b` is 3 bytes.

The maximum length of any single expression attribute name or expression attribute value is 255 bytes. For example, `#name` is 5 bytes; `:val` is 4 bytes.

The maximum length of all substitution variables in an expression is 2 MB. This is the sum of the lengths of all `ExpressionAttributeNames` and `ExpressionAttributeValues`.

**Operators and Operands**

The maximum number of operators or functions allowed in an `UpdateExpression` is 300. For example, the `UpdateExpression` `SET a = :val1 + :val2 + :val3` contains two `+` operators.

The maximum number of operands for the `IN` comparator is 100.

**Reserved Words**

DynamoDB does not prevent you from using names that conflict with reserved words. (For a complete list, see Reserved Words in DynamoDB (p. 1027).)

However, if you use a reserved word in an expression parameter, you must also specify `ExpressionAttributeNames`. For more information, see Expression Attribute Names in DynamoDB (p. 390).

**DynamoDB Transactions**

DynamoDB transactional API operations have the following constraints:

- A transaction cannot contain more than 25 unique items.
- A transaction cannot contain more than 4 MB of data.
- No two actions in a transaction can work against the same item in the same table. For example, you cannot both `ConditionCheck` and `Update` the same item in one transaction.
- A transaction cannot operate on tables in more than one AWS account or Region.
- Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the AWS Region where the write is made originally. Transactions are not supported across Regions in global tables. For example, suppose that you have a global table with replicas in the US East
(Ohio) and US West (Oregon) Regions and you perform a `TransactWriteItems` operation in the US East (N. Virginia) Region. In this case, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

**DynamoDB Streams**

**Simultaneous Readers of a Shard in DynamoDB Streams**

Do not allow more than two processes to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling.

**Maximum Write Capacity for a Table with a Stream Enabled**

AWS places some default limits on the write capacity for DynamoDB tables with DynamoDB Streams enabled. These are the limits unless you request a higher amount. To request a service limit increase, see [https://aws.amazon.com/support](https://aws.amazon.com/support).

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), South America (São Paulo), Europe (Frankfurt), Europe (Ireland), Asia Pacific (Tokyo), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), China (Beijing) Regions:
  - Per table – 40,000 write capacity units
- All other Regions:
  - Per table – 10,000 write capacity units

**Note**

The provisioned throughput limits also apply for DynamoDB tables with DynamoDB Streams enabled. For more information, see [Throughput Default Limits](#) (p. 962).

**DynamoDB Accelerator (DAX)**

**AWS Region Availability**

For a list of AWS Regions in which DAX is available, see [DynamoDB Accelerator (DAX)](#) in the [AWS General Reference](#).

**Nodes**

A DAX cluster consists of exactly one primary node, and between zero and nine read replica nodes.

The total number of nodes (per AWS account) cannot exceed 50 in a single AWS Region.

**Parameter Groups**

You can create up to 20 DAX parameter groups per Region.
Subnet Groups

You can create up to 50 DAX subnet groups per Region.

Within a subnet group, you can define up to 20 subnets.

API-Specific Limits

CreateTable/UpdateTable/DeleteTable

In general, you can have up to 50 CreateTable, UpdateTable, and DeleteTable requests running simultaneously (in any combination). In other words, the total number of tables in the CREATING, UPDATING, or DELETING state cannot exceed 50.

The only exception is when you are creating a table with one or more secondary indexes. You can have up to 25 such requests running at a time. However, if the table or index specifications are complex, DynamoDB might temporarily reduce the number of concurrent operations.

BatchGetItem

A single BatchGetItem operation can retrieve a maximum of 100 items. The total size of all the items retrieved cannot exceed 16 MB.

BatchWriteItem

A single BatchWriteItem operation can contain up to 25 PutItem or DeleteItem requests. The total size of all the items written cannot exceed 16 MB.

DescribeTableReplicaAutoScaling

DescribeTableReplicaAutoScaling method supports only 10 requests per second.

DescribeLimits

DescribeLimits should be called only periodically. You can expect throttling errors if you call it more than once in a minute.

DescribeContributorInsights/ListContributorInsights/UpdateContributorInsights

DescribeContributorInsights, ListContributorInsights and UpdateContributorInsights should be called only periodically. DynamoDB supports up to five requests per second for each of these APIs.

Query

The result set from a Query is limited to 1 MB per call. You can use the LastEvaluatedKey from the query response to retrieve more results.

Scan

The result set from a Scan is limited to 1 MB per call. You can use the LastEvaluatedKey from the scan response to retrieve more results.
UpdateTableReplicaAutoScaling

UpdateTableReplicaAutoScaling method supports only 10 requests per second.

DynamoDB Encryption at Rest

You can switch from an AWS owned customer master key (CMK) to an AWS managed CMK up to four times, anytime per 24-hour window, starting from when the table was created. And if there was no change in the past 6 hours, an additional change is allowed. This effectively brings the maximum number of changes in a day to eight times (four changes in the first 6 hours, and one change for each of the subsequent 6-hour windows in a day).

You can switch encryption keys to use an AWS owned CMK as often as necessary.

These are the limits unless you request a higher amount. To request a service limit increase, see https://aws.amazon.com/support.
Low-Level API Reference

The Amazon DynamoDB API Reference contains a complete list of operations supported by:

- DynamoDB.
- DynamoDB Streams.
- DynamoDB Accelerator (DAX).
Troubleshooting SSL/TLS connection establishment issues

Amazon DynamoDB is in the process of moving our endpoints to secure certificates signed by the Amazon Trust Services (ATS) Certificate Authority instead of third-party Certificate Authority. In December 2017, we launched the EU-WEST-3 (Paris) Region with the secure certificates issued by the Amazon Trust Services. All new regions launched after December 2017 have endpoints with the certificates issued by the Amazon Trust Services. This guide shows you how to validate and troubleshoot SSL/TLS connection issues.

Testing your application or service

Most AWS SDKs and Command Line Interfaces (CLI's) support the Amazon Trust Services Certificate Authority. If you are using a version of the Python AWS SDK or CLI released before October 29, 2013, you must upgrade. The .NET, Java, PHP, Go, JavaScript, and C++ SDKs and CLI's do not bundle any certificates, their certificates come from the underlying operating system. The Ruby SDK has included at least one of the required CAs since June 10, 2015. Before that date, the Ruby V2 SDK did not bundle certificates. If you use an unsupported, custom, or modified version of the AWS SDK, or if you use custom trust store, you might not have the support needed for Amazon Trust Services Certificate Authority.

To validate access to DynamoDB endpoints, you will need to develop a test that accesses DynamoDB API or DynamoDB Streams API in the EU-WEST-3 region and validate that the TLS handshake succeeds. The specific endpoints you will need to access in such test are:

- DynamoDB: https://dynamodb.eu-west-3.amazonaws.com
- DynamoDB Streams: https://streams.dynamodb.eu-west-3.amazonaws.com

If your application does not support Amazon Trust Services Certificate Authority you will see one of the following failures:

- SSL/TLS Negotiation errors
- A long delay before your software receives an error indicating SSL/TLS negotiation failure. The delay time depends on the retry strategy and timeout configuration of your client.
Testing your client browser

To verify that your browser can connect to Amazon DynamoDB, open the following URL: https://dynamodb.eu-west-3.amazonaws.com. If the test is successful, you will see a message like this:

healthy: dynamodb.eu-west-3.amazonaws.com

If the test is unsuccessful, it will display an error similar to this: https://untrusted-root.badssl.com/.

Updating your software application client

Applications accessing DynamoDB or DynamoDB Streams API endpoints (whether through browsers or programmatically) will need to update the trusted CA list on the client machines if they do not already support any of the following CAs:

- Amazon Root CA 1
- Starfield Services Root Certificate Authority - G2
- Starfield Class 2 Certification Authority

If the clients already trust ANY of the above three CAs then these will trust certificates used by DynamoDB and no action is required. However, if your clients do not already trust any of the above CAs, the HTTPS connections to the DynamoDB or DynamoDB Streams APIs will fail. For more information, please visit this blog post: https://aws.amazon.com/blogs/security/how-to-prepare-for-aws-move-to-its-own-certificate-authority/.

Updating your client browser

You can update the certificate bundle in your browser simply by updating your browser. Instructions for the most common browsers can be found on the browsers' websites:

- Chrome: https://support.google.com/chrome/answer/95414?hl=en
- Safari: https://support.apple.com/en-us/HT204416
- Internet Explorer: https://support.microsoft.com/en-us/help/17295/windows-internet-explorer-which-version#ie=other

Manually updating your certificate bundle

If you cannot access the DynamoDB API or DynamoDB Streams API then you need to update your certificate bundle. To do this, you need to import at least one of the required CAs. You can find these at https://www.amazontrust.com/repository/.

The following operating systems and programming languages support Amazon Trust Services certificates:

- Microsoft Windows versions that have January 2005 or later updates installed, Windows Vista, Windows 7, Windows Server 2008, and newer versions.
- Mac OS X 10.4 with Java for Mac OS X 10.4 Release 5, Mac OS X 10.5 and newer versions.
- Red Hat Enterprise Linux 5 (March 2007), Linux 6, and Linux 7 and CentOS 5, CentOS 6, and CentOS 7
- Ubuntu 8.10
- Debian 5.0
Example Tables and Data

The Amazon DynamoDB Developer Guide uses sample tables to illustrate various aspects of DynamoDB.

<table>

<td>• ReplyDateTime (String)</td>
</tr>
</tbody>
</table>

The Reply table has a global secondary index named PostedBy-Message-Index. This index will facilitate queries on two non-key attributes of the Reply table.

<table>

For more information about these tables, see Use Case 1: Product Catalog (p. 326) and Use Case 2: Forum Application (p. 326).

Sample Data Files

Topics

- ProductCatalog Sample Data (p. 975)
- Forum Sample Data (p. 979)
- Thread Sample Data (p. 980)
- Reply Sample Data (p. 982)
The following sections show the sample data files that are used for loading the ProductCatalog, Forum, Thread and Reply tables.

Each data file contains multiple PutRequest elements, each of which contain a single item. These PutRequest elements are used as input to the BatchWriteItem operation, using the AWS Command Line Interface (AWS CLI).

For more information, see Step 2: Load Data into Tables (p. 328) in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326).

Creating Example Tables and Uploading Data

Topics

- Creating Example Tables and Uploading Data Using the AWS SDK for Java (p. 983)
- Creating Example Tables and Uploading Data Using the AWS SDK for .NET (p. 990)

In Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326), you first create tables using the DynamoDB console and then use the AWS CLI to add data to the tables. This appendix provides code to both create the tables and add data programmatically.

Creating Example Tables and Uploading Data Using the AWS SDK for Java

The following Java code example creates tables and uploads data to the tables. The resulting table structure and data is shown in Creating Tables and Loading Data for Code Examples in DynamoDB (p. 326). For step-by-step instructions to run this code using Eclipse, see Java Code Examples (p. 331).

Creating Example Tables and Uploading Data Using
the AWS SDK for .NET

The following C# code example creates tables and uploads data to the tables. The resulting
table structure and data is shown in Creating Tables and Loading Data for Code Examples in
DynamoDB (p. 326). For step-by-step instructions to run this code in Visual Studio, see .NET Code
Examples (p. 333).

```java
System.out.println("Adding data to " + tableName);

// Add threads.

Item item = new Item().withPrimaryKey("Id", "Amazon DynamoDB#DynamoDB Thread 1")
    .withString("ReplyDateTime", dateFormatter.format(date3))
    .withString("Message", "DynamoDB Thread 1 Reply 1 text")
    .withString("PostedBy", "User A");
table.putItem(item);

item = new Item().withPrimaryKey("Id", "Amazon DynamoDB#DynamoDB Thread 1")
    .withString("ReplyDateTime", dateFormatter.format(date2))
    .withString("Message", "DynamoDB Thread 1 Reply 2 text")
    .withString("PostedBy", "User B");
table.putItem(item);

item = new Item().withPrimaryKey("Id", "Amazon DynamoDB#DynamoDB Thread 2")
    .withString("ReplyDateTime", dateFormatter.format(date1))
    .withString("Message", "DynamoDB Thread 2 Reply 1 text")

table.putItem(item);

} catch (Exception e) {

DynamoDB Example Application Using the AWS SDK for Python (Boto): Tic-Tac-Toe

Topics
- Step 1: Deploy and Test Locally (p. 999)
- Step 2: Examine the Data Model and Implementation Details (p. 1003)
- Step 3: Deploy in Production Using the DynamoDB Service (p. 1011)
- Step 4: Clean Up Resources (p. 1017)

The Tic-Tac-Toe game is an example web application built on Amazon DynamoDB. The application uses the AWS SDK for Python (Boto) to make the necessary DynamoDB calls to store game data in a DynamoDB table, and the Python web framework Flask to illustrate end-to-end application development in DynamoDB, including how to model data. It also demonstrates best practices when it comes to modeling data in DynamoDB, including the table you create for the game application, the primary key you define, additional indexes you need based on your query requirements, and the use of concatenated value attributes.

You play the Tic-Tac-Toe application on the web as follows:
1. You log in to the application home page.
2. You then invite another user to play the game as your opponent.
   
   Until another user accepts your invitation, the game status remains as PENDING. After an opponent accepts the invite, the game status changes to IN_PROGRESS.
3. The game begins after the opponent logs in and accepts the invite.
4. The application stores all game moves and status information in a DynamoDB table.
5. The game ends with a win or a draw, which sets the game status to FINISHED.

The end-to-end application building exercise is described in steps:

- Step 1: Deploy and Test Locally (p. 999) – In this section, you download, deploy, and test the application on your local computer. You will create the required tables in the downloadable version of DynamoDB.
- Step 2: Examine the Data Model and Implementation Details (p. 1003) – This section first describes in detail the data model, including the indexes and the use of the concatenated value attribute. Then the section explains how the application works.
- Step 3: Deploy in Production Using the DynamoDB Service (p. 1011) – This section focuses on deployment considerations in production. In this step, you create a table using the Amazon DynamoDB service and deploy the application using AWS Elastic Beanstalk. When you have the application in production, you also grant appropriate permissions so the application can access the DynamoDB table. The instructions in this section walk you through the end-to-end production deployment.
- Step 4: Clean Up Resources (p. 1017) – This section highlights areas that are not covered by this example. The section also provides steps for you to remove the AWS resources you created in the preceding steps so that you avoid incurring any charges.

Step 1: Deploy and Test Locally

Topics
- 1.1: Download and Install the Required Packages (p. 1000)
1.2: Test the Game Application (p. 1000)

In this step you download, deploy, and test the Tic-Tac-Toe game application on your local computer. Instead of using the Amazon DynamoDB web service, you will download DynamoDB to your computer, and create the required table there.

1.1: Download and Install the Required Packages

You will need the following to test this application locally:

- Python
- Flask (a microframework for Python)
- AWS SDK for Python (Boto)
- DynamoDB running on your computer
- Git

To get these tools, do the following:

1. Install Python. For step-by-step instructions, see Download Python.

   The Tic-Tac-Toe application has been tested using Python version 2.7.

2. Install Flask and AWS SDK for Python (Boto) using the Python Package Installer (PIP):
   - Install PIP. For instructions, see Install PIP. On the installation page, choose the get-pip.py link, and then save the file. Then open a command terminal as an administrator, and enter the following at the command prompt.

     ```
     python.exe get-pip.py
     ```

   On Linux, you don't specify the .exe extension. You only specify python get-pip.py.

   - Using PIP, install the Flask and Boto packages using the following code.

   ```
   pip install Flask
   pip install boto
   pip install configparser
   ```

3. Download DynamoDB to your computer. For instructions on how to run it, see Setting Up DynamoDB Local (Downloadable Version) (p. 46).

4. Download the Tic-Tac-Toe application:
   a. Install Git. For instructions, see git Downloads.
   b. Execute the following code to download the application.

   ```
   git clone https://github.com/awslabs/dynamodb-tictactoe-example-app.git
   ```

1.2: Test the Game Application

To test the Tic-Tac-Toe application, you need to run DynamoDB locally on your computer.

To run the Tic-Tac-Toe application

1. Start DynamoDB.
2. Start the web server for the Tic-Tac-Toe application.

   To do so, open a command terminal, navigate to the folder where you downloaded the Tic-Tac-Toe application, and run the application locally using the following code.

   ```
   python.exe application.py --mode local --serverPort 5000 --port 8000
   ```

   On Linux, you don't specify the `.exe` extension.

3. Open your web browser, and enter the following.

   ```
   http://localhost:5000/
   ```

   The browser shows the home page.

4. Enter `user1` in the Log in box to log in as user1.

   **Note**
   This example application does not perform any user authentication. The user ID is only used to identify players. If two players log in with the same alias, the application works as if you are playing in two different browsers.

5. If this is your first time playing the game, a page appears requesting you to create the required table (Games) in DynamoDB. Choose **CREATE TABLE**.

6. Choose **CREATE** to create the first tic-tac-toe game.

7. Enter `user2` in the Choose an Opponent box, and choose Create Game!
Doing this creates the game by adding an item in the Games table. It sets the game status to PENDING.

8. Open another browser window, and enter the following.

```
http://localhost:5000/
```

The browser passes information through cookies, so you should use incognito mode or private browsing so that your cookies don't carry over.

9. Log in as user2.

A page appears that shows a pending invitation from user1.

10. Choose accept to accept the invitation.
The game page appears with an empty tic-tac-toe grid. The page also shows relevant game information such as the game ID, whose turn it is, and game status.

11. Play the game.

For each user move, the web service sends a request to DynamoDB to conditionally update the game item in the `Games` table. For example, the conditions ensure that the move is valid, the square that the user chose is available, and that it was the turn of the user who made the move. For a valid move, the update operation adds a new attribute corresponding to the selection on the board. The update operation also sets the value of the existing attribute to the user who can make the next move.

On the game page, the application makes asynchronous JavaScript calls every second, for up to 5 minutes, to check if the game state in DynamoDB has changed. If it has, the application updates the page with new information. After 5 minutes, the application stops making the requests, and you need to refresh the page to get updated information.

**Step 2: Examine the Data Model and Implementation Details**

**Topics**

- 2.1: Basic Data Model (p. 1003)
- 2.2: Application in Action (Code Walkthrough) (p. 1006)

**2.1: Basic Data Model**

This example application highlights the following DynamoDB data model concepts:

- **Table** – In DynamoDB, a table is a collection of items (that is, records), and each item is a collection of name-value pairs called attributes.
In this Tic-Tac-Toe example, the application stores all game data in a table, Games. The application creates one item in the table per game and stores all game data as attributes. A tic-tac-toe game can have up to nine moves. Because DynamoDB tables do not have a schema in cases where only the primary key is the required attribute, the application can store varying number of attributes per game item.

The Games table has a simple primary key made of one attribute, GameId, of string type. The application assigns a unique ID to each game. For more information on DynamoDB primary keys, see Primary Key (p. 6).

When a user initiates a tic-tac-toe game by inviting another user to play, the application creates a new item in the Games table with attributes storing game metadata, such as the following:

- HostId, the user who initiated the game.
- Opponent, the user who was invited to play.
- The user whose turn it is to play. The user who initiated the game plays first.
- The user who uses the O symbol on the board. The user who initiates the games uses the O symbol.

In addition, the application creates a StatusDate concatenated attribute, marking the initial game state as PENDING. The following screenshot shows an example item as it appears in the DynamoDB console:

As the game progresses, the application adds one attribute to the table for each game move. The attribute name is the board position, for example TopLeft or BottomRight. For example, a move might have a TopLeft attribute with the value O, a TopRight attribute with the value O, and a BottomRight attribute with the value X. The attribute value is either O or X, depending on which user made the move. For example, consider the following board.
• **Concatenated value attributes** – The `StatusDate` attribute illustrates a concatenated value attribute. In this approach, instead of creating separate attributes to store game status (PENDING, IN_PROGRESS, and FINISHED) and date (when the last move was made), you combine them as a single attribute, for example `IN_PROGRESS_2014-04-30 10:20:32`.

The application then uses the `StatusDate` attribute in creating secondary indexes by specifying `StatusDate` as a sort key for the index. The benefit of using the `StatusDate` concatenated value attribute is further illustrated in the indexes discussed next.

• **Global secondary indexes** – You can use the table's primary key, `GameId`, to efficiently query the table to find a game item. To query the table on attributes other than the primary key attributes, DynamoDB supports the creation of secondary indexes. In this example application, you build the following two secondary indexes:

- **HostId-StatusDate-index**. This index has `HostId` as a partition key and `StatusDate` as a sort key. You can use this index to query on `HostId`, for example to find games hosted by a particular user.

- **OpponentId-StatusDate-index**. This index has `OpponentId` as a partition key and `StatusDate` as a sort key. You can use this index to query on `Opponent`, for example to find games where a particular user is the opponent.

These indexes are called global secondary indexes because the partition key in these indexes is not the same as the partition key (`GameId`), used in the primary key of the table.

Note that both the indexes specify `StatusDate` as a sort key. Doing this enables the following:
• You can query using the \texttt{BEGINS\_WITH} comparison operator. For example, you can find all games with the \texttt{IN\_PROGRESS} attribute hosted by a particular user. In this case, the \texttt{BEGINS\_WITH} operator checks for the \texttt{StatusDate} value that begins with \texttt{IN\_PROGRESS}.

• DynamoDB stores the items in the index in sorted order, by sort key value. So if all status prefixes are the same (for example, \texttt{IN\_PROGRESS}), the ISO format used for the date part will have items sorted from oldest to the newest. This approach enables certain queries to be performed efficiently, for example the following:
  
  • Retrieve up to 10 of the most recent \texttt{IN\_PROGRESS} games hosted by the user who is logged in. For this query, you specify the \texttt{HostId-StatusDate-index} index.
  
  • Retrieve up to 10 of the most recent \texttt{IN\_PROGRESS} games where the user logged in is the opponent. For this query, you specify the \texttt{OpponentId-StatusDate-index} index.

For more information about secondary indexes, see Improving Data Access with Secondary Indexes (p. 497).

2.2: Application in Action (Code Walkthrough)

This application has two main pages:

• **Home page** – This page provides the user a simple login, a \texttt{CREATE} button to create a new tic-tac-toe game, a list of games in progress, game history, and any active pending game invitations.

  The home page is not refreshed automatically; you must refresh the page to refresh the lists.

• **Game page** – This page shows the tic-tac-toe grid where users play.

  The application updates the game page automatically every second. The JavaScript in your browser calls the Python web server every second to query the Games table whether the game items in the table have changed. If they have, JavaScript triggers a page refresh so that the user sees the updated board.

Let us see in detail how the application works.

Home Page

After the user logs in, the application displays the following three lists of information.
• **Invitations** – This list shows up to the 10 most recent invitations from others that are pending acceptance by the user who is logged in. In the preceding screenshot, user1 has invitations from user5 and user2 pending.

• **Games In-Progress** – This list shows up to the 10 most recent games that are in progress. These are games that the user is actively playing, which have the status `IN_PROGRESS`. In the screenshot, user1 is actively playing a tic-tac-toe game with user3 and user4.

• **Recent History** – This list shows up to the 10 most recent games that the user finished, which have the status `FINISHED`. In game shown in the screenshot, user1 has previously played with user2. For each completed game, the list shows the game result.

In the code, the `index` function (in `application.py`) makes the following three calls to retrieve game status information:

```python
def index():
    inviteGames = controller.getGameInvites(session["username"])
    inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
    finishedGames = controller.getGamesWithStatus(session["username"], "FINISHED")

    return render_template("index.html",
        user=session["username"],
        invites=inviteGames,
        inprogress=inProgressGames,
        finished=finishedGames)
```

Each of these calls returns a list of items from DynamoDB that are wrapped by the `Game` objects. It is easy to extract data from these objects in the view. The index function passes these object lists to the view to render the HTML.

The Tic-Tac-Toe application defines the `Game` class primarily to store game data retrieved from DynamoDB. These functions return lists of `Game` objects that enable you to isolate the rest of the application from code related to Amazon DynamoDB items. Thus, these functions help you decouple your application code from the details of the data store layer.

The architectural pattern described here is also referred to as the model-view-controller (MVC) UI pattern. In this case, the `Game` object instances (representing data) are the model, and the HTML page is the view. The controller is divided into two files. The `application.py` file has the controller logic for the Flask framework, and the business logic is isolated in the `gameController.py` file. That is, the application stores everything that has to do with DynamoDB SDK in its own separate file in the `dynamodb` folder.

Let us review the three functions and how they query the Games table using global secondary indexes to retrieve relevant data.

**Using `getGameInvites` to Get the List of Pending Game Invitations**

The `getGameInvites` function retrieves the list of the 10 most recent pending invitations. These games have been created by users, but the opponents have not accepted the game invitations. For these games, the status remains `PENDING` until the opponent accepts the invite. If the opponent declines the invite, the application removes the corresponding item from the table.

The function specifies the query as follows:

- It specifies the `OpponentId-StatusDate-index` index to use with the following index key values and comparison operators:
  - The partition key is `OpponentId` and takes the index key `user ID`.
  - The sort key is `StatusDate` and takes the comparison operator and index key value `beginswith=“PENDING_”`. 

API Version 2012-08-10

1007
You use the OpponentId-StatusDate-index index to retrieve games to which the logged-in user is invited—that is, where the logged-in user is the opponent.

- The query limits the result to 10 items.

```python
gameInvitesIndex = self.cm.getGamesTable().query(
    Opponent__eq=user,
    StatusDate__beginswith="PENDING_",
    index="OpponentId-StatusDate-index",
    limit=10)
```

In the index, for each OpponentId (the partition key) DynamoDB keeps items sorted by StatusDate (the sort key). Therefore, the games that the query returns will be the 10 most recent games.

**Using getGamesWithStatus to Get the List of Games with a Specific Status**

After an opponent accepts a game invitation, the game status changes to IN_PROGRESS. After the game completes, the status changes to FINISHED.

Queries to find games that are either in progress or finished are the same except for the different status value. Therefore, the application defines the getGamesWithStatus function, which takes the status value as a parameter.

```python
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
finishedGames   = controller.getGamesWithStatus(session["username"], "FINISHED")
```

The following section discusses in-progress games, but the same description also applies to finished games.

A list of in-progress games for a given user includes both the following:

- In-progress games hosted by the user
- In-progress games where the user is the opponent

The getGamesWithStatus function runs the following two queries, each time using the appropriate secondary index.

- The function queries the Games table using the HostId-StatusDate-index index. For the index, the query specifies primary key values—both the partition key (HostId) and sort key (StatusDate) values, along with comparison operators.

```python
hostGamesInProgress = self.cm.getGamesTable ().query(HostId__eq=user,
                                                        StatusDate__beginswith=status,
                                                        index="HostId-StatusDate-index",
                                                        limit=10)
```

Note the Python syntax for comparison operators:

- HostId__eq=user specifies the equality comparison operator.
- StatusDate__beginswith=status specifies the BEGINS_WITH comparison operator.
- The function queries the Games table using the OpponentId-StatusDate-index index.

```python
oppGamesInProgress = self.cm.getGamesTable().query(Opponent__eq=user,
                                                        StatusDate__beginswith=status,
                                                        index="OpponentId-StatusDate-index",
```
The function then combines the two lists, sorts, and for the first 0 to 10 items creates a list of the Game objects and returns the list to the calling function (that is, the index).

```python
games = self.mergeQueries(hostGamesInProgress, oppGamesInProgress)
return games
```

**Game Page**

The game page is where the user plays tic-tac-toe games. It shows the game grid along with game-relevant information. The following screenshot shows an example game in progress:

![Game screenshot](image)

The application displays the game page in the following situations:

- The user creates a game inviting another user to play.

  In this case, the page shows the user as host and the game status as PENDING, waiting for the opponent to accept.

- The user accepts one of the pending invitations on the home page.

  In this case, the page shows the user as the opponent and game status as IN_PROGRESS.

A user selection on the board generates a form `POST` request to the application. That is, Flask calls the `selectSquare` function (in `application.py`) with the HTML form data. This function, in turn, calls the `updateBoardAndTurn` function (in `gameController.py`) to update the game item as follows:

- It adds a new attribute specific to the move.
- It updates the `Turn` attribute value to the user whose turn is next.
The function returns true if the item update was successful; otherwise, it returns false. Note the following about the updateBoardAndTurn function:

- The function calls the update_item function of the SDK for Python to make a finite set of updates to an existing item. The function maps to the UpdateItem operation in DynamoDB. For more information, see UpdateItem.

  **Note**
  The difference between the UpdateItem and PutItem operations is that PutItem replaces the entire item. For more information, see PutItem.

For the update_item call, the code identifies the following:

- The primary key of the Games table (that is, ItemId).

  ```
  key = { "GameId" : { "S" : gameId } }
  ```

- The new attribute to add, specific to the current user move, and its value (for example, TopLeft="X").

  ```
  attributeUpdates = {
    position : {
      "Action" : "PUT",
      "Value" : { "S" : representation }
    }
  }
  ```

- Conditions that must be true for the update to take place:
  - The game must be in progress. That is, the StatusDate attribute value must begin with IN_PROGRESS.
  - The current turn must be a valid user turn as specified by the Turn attribute.
  - The square that the user chose must be available. That is, the attribute corresponding to the square must not exist.

  ```
  expectations = {
    "StatusDate" : {
      "AttributeValueList" : [ { "S" : "IN_PROGRESS_" } ],
      "ComparisonOperator" : "BEGINS_WITH"},
    "Turn" : { "Value" : { "S" : current_player }},
    "position" : { "Exists" : False}
  }
  ```

Now the function calls update_item to update the item.

```python
self.cm.db.update_item("Games", key=key,
    attribute_updates=attributeUpdates,
    expected=expectations)
```

After the function returns, the selectSquare function calls redirect, as shown in the following example.

```python
redirect("/game="+gameId)
```

This call causes the browser to refresh. As part of this refresh, the application checks to see if the game has ended in a win or draw. If it has, the application updates the game item accordingly.
Step 3: Deploy in Production Using the DynamoDB Service

Topics
- 3.1: Create an IAM Role for Amazon EC2 (p. 1012)
- 3.2: Create the Games Table in Amazon DynamoDB (p. 1012)
- 3.3: Bundle and Deploy the Tic-Tac-Toe Application Code (p. 1012)
- 3.4: Set Up the AWS Elastic Beanstalk Environment (p. 1013)

In the preceding sections, you deployed and tested the Tic-Tac-Toe application locally on your computer using DynamoDB Local. Now, you deploy the application in production as follows:

- Deploy the application using AWS Elastic Beanstalk, an easy-to-use service for deploying and scaling web applications and services. For more information, see Deploying a Flask Application to AWS Elastic Beanstalk.

  Elastic Beanstalk launches one or more Amazon Elastic Compute Cloud (Amazon EC2) instances, which you configure through Elastic Beanstalk, on which your Tic-Tac-Toe application will run.

- Using the Amazon DynamoDB service, create a Games table that exists on AWS rather than locally on your computer.

In addition, you also have to configure permissions. Any AWS resources you create, such as the Games table in DynamoDB, are private by default. Only the resource owner, that is the AWS account that created the Games table, can access this table. Thus, by default your Tic-Tac-Toe application cannot update the Games table.

To grant necessary permissions, you create an AWS Identity and Access Management (IAM) role and grant this role permissions to access the Games table. Your Amazon EC2 instance first assumes this role. In response, AWS returns temporary security credentials that the Amazon EC2 instance can use to update the Games table on behalf of the Tic-Tac-Toe application. When you configure your Elastic Beanstalk application, you specify the IAM role that the Amazon EC2 instance or instances can assume. For more information about IAM roles, see IAM Roles for Amazon EC2 in the Amazon EC2 User Guide for Linux Instances.

Note
Before you create Amazon EC2 instances for the Tic-Tac-Toe application, you must first decide the AWS Region where you want Elastic Beanstalk to create the instances. After you create the Elastic Beanstalk application, you provide the same Region name and endpoint in a configuration file. The Tic-Tac-Toe application uses information in this file to create the Games table and send subsequent requests in a specific AWS Region. Both the DynamoDB Games table and the Amazon EC2 instances that Elastic Beanstalk launches must be in the same Region. For a list of available Regions, see Amazon DynamoDB in the Amazon Web Services General Reference.

In summary, you do the following to deploy the Tic-Tac-Toe application in production:

1. Create an IAM role using the IAM service. You attach a policy to this role granting permissions for DynamoDB actions to access the Games table.

2. Bundle the Tic-Tac-Toe application code and a configuration file, and create a .zip file. You use this .zip file to give the Tic-Tac-Toe application code to Elastic Beanstalk to put on your servers. For more information about creating a bundle, see Creating an Application Source Bundle in the AWS Elastic Beanstalk Developer Guide.

In the configuration file (beanstalk.config), you provide AWS Region and endpoint information. The Tic-Tac-Toe application uses this information to determine which DynamoDB Region to talk to.
3. Set up the Elastic Beanstalk environment. Elastic Beanstalk launches an Amazon EC2 instance or instances and deploys your Tic-Tac-Toe application bundle on them. After the Elastic Beanstalk environment is ready, you provide the configuration file name by adding the CONFIG_FILE environment variable.

4. Create the DynamoDB table. Using the Amazon DynamoDB service, you create the Games table on AWS, rather than locally on your computer. Remember, this table has a simple primary key made of the GameId partition key of string type.

5. Test the game in production.

### 3.1: Create an IAM Role for Amazon EC2

Creating an IAM role of the Amazon EC2 type allows the Amazon EC2 instance that is running your Tic-Tac-Toe application to assume the correct role and make application requests to access the Games table. When creating the role, choose the Custom Policy option and copy and paste the following policy.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": ["dynamodb:ListTables"],
            "Effect":"Allow",
            "Resource":"*
        },
        {
            "Action": ["dynamodb:*"],
            "Effect":"Allow",
        }
    ]
}
```

For further instructions, see Creating a Role for an AWS Service (AWS Management Console) in the IAM User Guide.

### 3.2: Create the Games Table in Amazon DynamoDB

The Games table in DynamoDB stores game data. If the table does not exist, the application creates the table for you. In this case, let the application create the Games table.

### 3.3: Bundle and Deploy the Tic-Tac-Toe Application Code

If you followed this example's steps, then you already have the downloaded the Tic-Tac-Toe application. If not, download the application and extract all the files to a folder on your local computer. For instructions, see Step 1: Deploy and Test Locally (p. 999).

After you extract all files, you will have a code folder. To hand off this folder to Elastic Beanstalk, you bundle the contents of this folder as a .zip file. First, you add a configuration file to that folder. Your application uses the Region and endpoint information to create a DynamoDB table in the specified Region and make subsequent table operation requests using the specified endpoint.

1. Switch to the folder where you downloaded the Tic-Tac-Toe application.
2. In the root folder of the application, create a text file named `beanstalk.config` with the following content.

```
[dynamodb]
region=<AWS region>
endpoint=<DynamoDB endpoint>
```

For example, you might use the following content.

```
[dynamodb]
region=us-west-2
endpoint=dynamodb.us-west-2.amazonaws.com
```

For a list of available Regions, see Amazon DynamoDB in the Amazon Web Services General Reference.

**Important**

The Region specified in the configuration file is the location where the Tic-Tac-Toe application creates the `Games` table in DynamoDB. You must create the Elastic Beanstalk application discussed in the next section in the same Region.

**Note**

When you create your Elastic Beanstalk application, you request to launch an environment where you can choose the environment type. To test the Tic-Tac-Toe example application, you can choose the Single Instance environment type, skip the following, and go to the next step.

However, the Load balancing, autoscaling environment type provides a highly available and scalable environment, something you should consider when you create and deploy other applications. If you choose this environment type, you also need to generate a UUID and add it to the configuration file, as shown following.

```
[dynamodb]
region=us-west-2
endpoint=dynamodb.us-west-2.amazonaws.com
[flask]
secret_key=284e784d-1a25-4a19-92bf-8eeb7a9example
```

In client-server communication, when the server sends a response, for security's sake the server sends a signed cookie that the client sends back to the server in the next request. When there is only one server, the server can locally generate an encryption key when it starts. When there are many servers, they all need to know the same encryption key; otherwise, they won't be able to read cookies set by the peer servers. By adding `secret_key` to the configuration file, you tell all servers to use this encryption key.

3. Zip the content of the root folder of the application (which includes the `beanstalk.config` file)—for example, TicTacToe.zip.

4. Upload the `.zip` file to an Amazon Simple Storage Service (Amazon S3) bucket. In the next section, you provide this `.zip` file to Elastic Beanstalk to upload on the server or servers.

For instructions on how to upload to an Amazon S3 bucket, see Create a Bucket and Add an Object to a Bucket in the Amazon Simple Storage Service Getting Started Guide.

### 3.4: Set Up the AWS Elastic Beanstalk Environment

In this step, you create an Elastic Beanstalk application, which is a collection of components including environments. For this example, you launch one Amazon EC2 instance to deploy and run your Tic-Tac-Toe application.
1. Enter the following custom URL to set up an Elastic Beanstalk console to set up the environment.

   https://console.aws.amazon.com/elasticbeanstalk/?region=<AWS-Region>#/newApplication
   ?applicationName=TicTacToeyour-name
   &solutionStackName=Python
   &sourceBundleUrl=https://s3.amazonaws.com/<bucket-name>/TicTacToe.zip
   &environmentType=SingleInstance
   &instanceType=t1.micro

   For more information about custom URLs, see Constructing a Launch Now URL in the AWS Elastic Beanstalk Developer Guide. For the URL, note the following:

   • You must provide an AWS Region name (the same as the one you provided in the configuration file), an Amazon S3 bucket name, and the object name.
   • For testing, the URL requests the SingleInstance environment type, and t1.micro as the instance type.
   • The application name must be unique. Thus, in the preceding URL, we suggest you prepend your name to the applicationName.

   Doing this opens the Elastic Beanstalk console. In some cases, you might need to sign in.

2. In the Elastic Beanstalk console, choose Review and Launch, and then choose Launch.

3. Note the URL for future reference. This URL opens your Tic-Tac-Toe application home page.

4. Configure the Tic-Tac-Toe application so it knows the location of the configuration file.

   After Elastic Beanstalk creates the application, choose Configuration.

   a. Choose the gear icon next to Software Configuration, as shown in the following screenshot.
b. At the end of the Environment Properties section, enter `CONFIG_FILE` and its value `beanstalk.config`, and then choose Save.

It might take a few minutes for this environment update to complete.

After the update completes, you can play the game.

5. In the browser, enter the URL you copied in the previous step, as shown in the following example.

```
http://<pen-name>.elasticbeanstalk.com
```
Doing this opens the application home page.

6. Log in as testuser1, and choose **CREATE** to start a new tic-tac-toe game.

7. Enter **testuser2** in the Choose an Opponent box.

8. Open another browser window.

   Make sure that you clear all cookies in your browser window so you won't be logged in as same user.

9. Enter the same URL to open the application home page, as shown in the following example.

```
http://<env-name>.elasticbeanstalk.com
```

10. Log in as testuser2.

11. For the invitation from testuser1 in the list of pending invitations, choose **accept**.
12. Now the game page appears.

Both testuser1 and testuser2 can play the game. For each move, the application saves the move in the corresponding item in the Games table.

**Step 4: Clean Up Resources**

Now you have completed the Tic-Tac-Toe application deployment and testing. The application covers end-to-end web application development on Amazon DynamoDB, except for user authentication. The application uses the login information on the home page only to add a player name when creating a game. In a production application, you would add the necessary code to perform user login and authentication.
If you are done testing, you can remove the resources you created to test the Tic-Tac-Toe application to avoid incurring any charges.

To remove the resources you created

1. Remove the Games table that you created in DynamoDB.
2. Terminate the Elastic Beanstalk environment to free up the Amazon EC2 instances.
3. Delete the IAM role that you created.
4. Remove the object that you created in Amazon S3.

Exporting and Importing DynamoDB Data Using AWS Data Pipeline

You can use AWS Data Pipeline to export data from a DynamoDB table to a file in an Amazon S3 bucket. You can also use the console to import data from Amazon S3 into a DynamoDB table, in the same AWS region or in a different region.

The ability to export and import data is useful in many scenarios. For example, suppose you want to maintain a baseline set of data, for testing purposes. You could put the baseline data into a DynamoDB table and export it to Amazon S3. Then, after you run an application that modifies the test data, you could "reset" the data set by importing the baseline from Amazon S3 back into the DynamoDB table. Another example involves accidental deletion of data, or even an accidental DeleteTable operation. In these cases, you could restore the data from a previous export file in Amazon S3. You can even copy data from a DynamoDB table in one AWS region, store the data in Amazon S3, and then import the data from Amazon S3 to an identical DynamoDB table in a second region. Applications in the second region could then access their nearest DynamoDB endpoint and work with their own copy of the data, with reduced network latency.

The following diagram shows an overview of exporting and importing DynamoDB data using AWS Data Pipeline.
Exporting Data from DynamoDB to Amazon S3

DynamoDB Table Amazon S3 Bucket

Importing Data from Amazon S3 to DynamoDB

AWS Data Pipeline --- launches an --- Amazon EMR Cluster

reads from  writes to

Amazon S3 Bucket DynamoDB Table
To export a DynamoDB table, you use the AWS Data Pipeline console to create a new pipeline. The pipeline launches an Amazon EMR cluster to perform the actual export. Amazon EMR reads the data from DynamoDB, and writes the data to an export file in an Amazon S3 bucket.

The process is similar for an import, except that the data is read from the Amazon S3 bucket and written to the DynamoDB table.

**Important**
When you export or import DynamoDB data, you will incur additional costs for the underlying AWS services that are used:

- **AWS Data Pipeline**— manages the import/export workflow for you.
- **Amazon S3**— contains the data that you export from DynamoDB, or import into DynamoDB.
- **Amazon EMR**— runs a managed Hadoop cluster to perform reads and writes between DynamoDB to Amazon S3. The cluster configuration is one `m3.xlarge` instance master node and one `m3.xlarge` instance core node.

For more information see [AWS Data Pipeline Pricing](https://aws.amazon.com/das팔/), [Amazon EMR Pricing](https://aws.amazon.com/EMR/), and [Amazon S3 Pricing](https://aws.amazon.com/s3/).

**Prerequisites to Export and Import Data**

When you use AWS Data Pipeline for exporting and importing data, you must specify the actions that the pipeline is allowed to perform, and which resources the pipeline can consume. The permitted actions and resources are defined using AWS Identity and Access Management (IAM) roles.

You can also control access by creating IAM policies and attaching them to IAM users or groups. These policies let you specify which users are allowed to import and export your DynamoDB data.

**Important**
The IAM user that performs the exports and imports must have an active AWS Access Key Id and Secret Key. For more information, see [Administering Access Keys for IAM Users](https://aws.amazon.com/iam/) in the *IAM User Guide*.

**Creating IAM Roles for AWS Data Pipeline**

In order to use AWS Data Pipeline, the following IAM roles must be present in your AWS account:

- **DataPipelineDefaultRole** — the actions that your pipeline can take on your behalf.
- **DataPipelineDefaultResourceRole** — the AWS resources that the pipeline will provision on your behalf. For exporting and importing DynamoDB data, these resources include an Amazon EMR cluster and the Amazon EC2 instances associated with that cluster.

If you have never used AWS Data Pipeline before, you will need to create `DataPipelineDefaultRole` and `DataPipelineDefaultResourceRole` yourself. Once you have created these roles, you can use them any time you want to export or import DynamoDB data.

**Note**
If you have previously used the AWS Data Pipeline console to create a pipeline, then `DataPipelineDefaultRole` and `DataPipelineDefaultResourceRole` were created for you at that time. No further action is required; you can skip this section and begin creating pipelines using the DynamoDB console. For more information, see [Exporting Data From DynamoDB to Amazon S3](https://aws.amazon.com/das_pal/) (p. 1023) and [Importing Data From Amazon S3 to DynamoDB](https://aws.amazon.com/dasm_pal/) (p. 1024).

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. From the IAM Console Dashboard, click **Roles**.
3. Click **Create Role** and do the following:
   a. In the **AWS Service** trusted entity, choose **Data Pipeline**.
   b. In the **Select your use case** panel, choose **Data Pipeline** and then choose **Next:Permissions**.
   c. Notice that the **AWSDataPipelineRole** policy is automatically attached. Choose **Next:Review**.
   d. In the **Role name** field, type **DataPipelineDefaultRole** as the role name and choose **Create role**.

4. Click **Create Role** and do the following:
   a. In the **AWS Service** trusted entity, choose **Data Pipeline**.
   b. In the **Select your use case** panel, choose **EC2 Role for Data Pipeline** and then choose **Next:Permissions**.
   c. Notice that the **AmazonEC2RoleForDataPipelineRole** policy is automatically attached. Choose **Next:Review**.
   d. In the **Role name** field, type **DataPipelineDefaultResourceRole** as the role name and choose **Create role**.

Now that you have created these roles, you can begin creating pipelines using the DynamoDB console. For more information, see Exporting Data From DynamoDB to Amazon S3 (p. 1023) and Importing Data From Amazon S3 to DynamoDB (p. 1024).

**Granting IAM Users and Groups Permission to Perform Export and Import Tasks**

If you want to allow other IAM users or groups to export and import your DynamoDB table data, you can create an IAM policy and attach it to the users or groups that you designate. The policy contains only the necessary permissions for performing these tasks.

**Granting Full Access Using an AWS Managed Policy**

The following procedure describes how to attach the AWS managed policy **AmazonDynamoDBFullAccesswithDataPipeline** to an IAM user. This managed policy provides full access to AWS Data Pipeline and to DynamoDB resources.

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. From the IAM Console Dashboard, click **Users** and select the user you want to modify.
3. In the **Permissions** tab, click **Attach Policy**.
4. In the **Attach Policy** panel, select **AmazonDynamoDBFullAccesswithDataPipeline** and click **Attach Policy**.

   **Note**
   You can use a similar procedure to attach this managed policy to a group, rather than to a user.

**Restricting Access to Particular DynamoDB Tables**

If you want to restrict access so that a user can only export or import a subset of your tables, you will need to create a customized IAM policy document. You can use the AWS managed policy **AmazonDynamoDBFullAccesswithDataPipeline** as a starting point for your custom policy, and then modify the policy so that a user can only work with the tables that you specify.

For example, suppose that you want to allow an IAM user to export and import only the **Forum**, **Thread**, and **Reply** tables. This procedure describes how to create a custom policy so that a user can work with those tables, but no others.
1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. From the IAM Console Dashboard, click Policies and then click Create Policy.

3. In the Create Policy panel, go to Copy an AWS Managed Policy and click Select.

4. In the Copy an AWS Managed Policy panel, go to AmazonDynamoDBFullAccesswithDataPipeline and click Select.

5. In the Review Policy panel, do the following:
   a. Review the autogenerated Policy Name and Description. If you want, you can modify these values.
   b. In the Policy Document text box, edit the policy to restrict access to specific tables. By default, the policy permits all DynamoDB actions on all of your tables:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [

   "Action": [
   "cloudwatch:DeleteAlarms",
   "cloudwatch:DescribeAlarmHistory",
   "cloudwatch:DescribeAlarms",
   "cloudwatch:DescribeAlarmsForMetric",
   "cloudwatch:GetMetricStatistics",
   "cloudwatch:ListMetrics",
   "cloudwatch:PutMetricAlarm",
   "dynamodb:*",
   "sns:CreateTopic",
   "sns:DeleteTopic",
   "sns:ListSubscriptions",
   "sns:ListSubscriptionsByTopic",
   "sns:ListTopics",
   "sns:Subscribe",
   "sns:Unsubscribe"
   ],
   "Effect": "Allow",
   "Resource": "*",
   "Sid": "DDBConsole"
   ],
   "...remainder of document omitted..."
   }
   
   To restrict the policy, first remove the following line:

   "dynamodb:*",

   Next, construct a new Action that allows access to only the Forum, Thread and Reply tables:

   ```json
   {
   "Action": [
   "dynamodb:*"
   ],
   "Effect": "Allow",
   "Resource": [
   ]
   },
   ```
Note
Replace `us-west-2` with the region in which your DynamoDB tables reside. Replace 123456789012 with your AWS account number.

Finally, add the new Action to the policy document:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": ["dynamodb:*"],
         "Effect": "Allow",
         "Resource": [
         ]
      },
      {
         "Action": ["cloudwatch:DeleteAlarms",
                     "cloudwatch:DescribeAlarmHistory",
                     "cloudwatch:DescribeAlarms",
                     "cloudwatch:DescribeAlarmsForMetric",
                     "cloudwatch:GetMetricStatistics",
                     "cloudwatch:ListMetrics",
                     "cloudwatch:PutMetricAlarm",
                     "sns:CreateTopic",
                     "sns:DeleteTopic",
                     "sns:ListSubscriptions",
                     "sns:ListSubscriptionsByTopic",
                     "sns:ListTopics",
                     "sns:Subscribe",
                     "sns:Unsubscribe"],
         "Effect": "Allow",
         "Resource": "*",
         "Sid": "DDBConsole"
      }
   ]
}
```

6. When the policy settings are as you want them, click Create Policy.

After you have created the policy, you can attach it to an IAM user.

1. From the IAM Console Dashboard, click Users and select the user you want to modify.
2. In the Permissions tab, click Attach Policy.
3. In the Attach Policy panel, select the name of your policy and click Attach Policy.

Note
You can use a similar procedure to attach your policy to a group, rather than to a user.

Exporting Data From DynamoDB to Amazon S3

This section describes how to export data from one or more DynamoDB tables to an Amazon S3 bucket. You need to create the Amazon S3 bucket before you can perform the export.
Important

If you have never used AWS Data Pipeline before, you will need to set up two IAM roles before following this procedure. For more information, see Creating IAM Roles for AWS Data Pipeline (p. 1020).

1. Sign in to the AWS Management Console and open the AWS Data Pipeline console at https://console.aws.amazon.com/datapipeline/.

2. If you do not already have any pipelines in the current AWS region, choose Get started now.

Otherwise, if you already have at least one pipeline, choose Create new pipeline.

3. On the Create Pipeline page, do the following:
   a. In the Name field, type a name for your pipeline. For example: MyDynamoDBExportPipeline.
   b. For the Source parameter, select Build using a template. From the drop-down template list, choose Export DynamoDB table to S3.
   c. In the Source DynamoDB table name field, type the name of the DynamoDB table that you want to export.
   d. In the Output S3 Folder text box, enter an Amazon S3 URI where the export file will be written. For example: s3://mybucket/exports

      The format of this URI is s3://bucketname/folder where:
      • bucketname is the name of your Amazon S3 bucket.
      • folder is the name of a folder within that bucket. If the folder does not exist, it will be created automatically. If you do not specify a name for the folder, a name will be assigned for it in the form s3://bucketname/region/tablename.
   e. In the S3 location for logs text box, enter an Amazon S3 URI where the log file for the export will be written. For example: s3://mybucket/logs/

      The URI format for S3 Log Folder is the same as for Output S3 Folder. The URI must resolve to a folder; log files cannot be written to the top level of the S3 bucket.

4. When the settings are as you want them, click Activate.

Your pipeline will now be created; this process can take several minutes to complete. You can monitor the progress in the AWS Data Pipeline console.

When the export has finished, you can go to the Amazon S3 console to view your export file. The output file name is an identifier value with no extension, such as this example: ae10f955-fb2f-4790-9b11-fbfea01a871e_000000. The internal format of this file is described at Verify Data Export File in the AWS Data Pipeline Developer Guide.

Importing Data From Amazon S3 to DynamoDB

This section assumes that you have already exported data from a DynamoDB table, and that the export file has been written to your Amazon S3 bucket. The internal format of this file is described at Verify Data Export File in the AWS Data Pipeline Developer Guide. Note that this is the only file format that DynamoDB can import using AWS Data Pipeline.

We will use the term source table for the original table from which the data was exported, and destination table for the table that will receive the imported data. You can import data from an export file in Amazon S3, provided that all of the following are true:

- The destination table already exists. (The import process will not create the table for you.)
- The destination table has the same key schema as the source table.
The destination table does not have to be empty. However, the import process will replace any data items in the table that have the same keys as the items in the export file. For example, suppose you have a Customer table with a key of CustomerId, and that there are only three items in the table (CustomerId 1, 2, and 3). If your export file also contains data items for CustomerID 1, 2, and 3, the items in the destination table will be replaced with those from the export file. If the export file also contains a data item for CustomerID 4, then that item will be added to the table.

The destination table can be in a different AWS region. For example, suppose you have a Customer table in the US West (Oregon) region and export its data to Amazon S3. You could then import that data into an identical Customer table in the Europe (Ireland) region. This is referred to as a cross-region export and import. For a list of AWS regions, go to Regions and Endpoints in the AWS General Reference.

Note that the AWS Management Console lets you export multiple source tables at once. However, you can only import one table at a time.

1. Sign in to the AWS Management Console and open the AWS Data Pipeline console at https://console.aws.amazon.com/datapipeline/.
2. (Optional) If you want to perform a cross region import, go to the upper right corner of the window and choose the destination region.
3. Choose Create new pipeline.
4. On the Create Pipeline page, do the following:
   a. In the Name field, type a name for your pipeline. For example: MyDynamoDBImportPipeline.
   b. For the Source parameter, select Build using a template. From the drop-down template list, choose Import DynamoDB backup data from S3.
   c. In the Input S3 Folder text box, enter an Amazon S3 URI where the export file can be found. For example: s3://mybucket/exports
      The format of this URI is s3://bucketname/folder where:
      • bucketname is the name of your Amazon S3 bucket.
      • folder is the name of the folder that contains the export file.
      The import job will expect to find a file at the specified Amazon S3 location. The internal format of the file is described at Verify Data Export File in the AWS Data Pipeline Developer Guide.
   d. In the Target DynamoDB table name field, type the name of the DynamoDB table into which you want to import the data.
   e. In the S3 location for logs text box, enter an Amazon S3 URI where the log file for the import will be written. For example: s3://mybucket/logs/
      The URI format for S3 Log Folder is the same as for Output S3 Folder. The URI must resolve to a folder; log files cannot be written to the top level of the S3 bucket.
5. When the settings are as you want them, click Activate.

Your pipeline will now be created; this process can take several minutes to complete. The import job will begin immediately after the pipeline has been created.

Troubleshooting

This section covers some basic failure modes and troubleshooting for DynamoDB exports.

If an error occurs during an export or import, the pipeline status in the AWS Data Pipeline console will display as ERROR. If this happens, click the name of the failed pipeline to go to its detail page. This will show details about all of the steps in the pipeline, and the status of each one. In particular, examine any execution stack traces that you see.
Finally, go to your Amazon S3 bucket and look for any export or import log files that were written there.

The following are some common issues that may cause a pipeline to fail, along with corrective actions. To diagnose your pipeline, compare the errors you have seen with the issues noted below.

- For an import, ensure that the destination table already exists, and the destination table has the same key schema as the source table. These conditions must be met, or the import will fail.
- Ensure that the Amazon S3 bucket you specified has been created, and that you have read and write permissions on it.
- The pipeline might have exceeded its execution timeout. (You set this parameter when you created the pipeline.) For example, you might have set the execution timeout for 1 hour, but the export job might have required more time than this. Try deleting and then re-creating the pipeline, but with a longer execution timeout interval this time.
- Update the manifest file if you restore from a Amazon S3 bucket that is not the original bucket that the export was performed with (contains a copy of the export).
- You might not have the correct permissions for performing an export or import. For more information, see Prerequisites to Export and Import Data (p. 1020).
- You might have reached a resource limit in your AWS account, such as the maximum number of Amazon EC2 instances or the maximum number of AWS Data Pipeline pipelines. For more information, including how to request increases in these limits, see AWS Service Limits in the AWS General Reference.

**Note**
For more details on troubleshooting a pipeline, go to Troubleshooting in the AWS Data Pipeline Developer Guide.

Predefined Templates for AWS Data Pipeline and DynamoDB

If you would like a deeper understanding of how AWS Data Pipeline works, we recommend that you consult the AWS Data Pipeline Developer Guide. This guide contains step-by-step tutorials for creating and working with pipelines; you can use these tutorials as starting points for creating your own pipelines. We recommend that you read the DynamoDB tutorial, which walks you through the steps required to create an import and export pipeline that you can customize for your requirements. See Tutorial: Amazon DynamoDB Import and Export Using AWS Data Pipeline in the AWS Data Pipeline Developer Guide.

AWS Data Pipeline offers several templates for creating pipelines; the following templates are relevant to DynamoDB.

Exporting Data Between DynamoDB and Amazon S3

The AWS Data Pipeline console provides two predefined templates for exporting data between DynamoDB and Amazon S3. For more information about these templates, see the following sections of the AWS Data Pipeline Developer Guide:

- Export DynamoDB to Amazon S3
- Export Amazon S3 to DynamoDB

Amazon DynamoDB Storage Backend for Titan

The DynamoDB Storage Backend for Titan project has been superseded by the Amazon DynamoDB Storage Backend for JanusGraph, which is available on GitHub.
Reserved Words in DynamoDB

The following keywords are reserved for use by DynamoDB. Do not use any of these words as attribute names in expressions.

If you need to write an expression containing an attribute name that conflicts with a DynamoDB reserved word, you can define an expression attribute name to use in the place of the reserved word. For more information, see Expression Attribute Names in DynamoDB (p. 390).

Legacy Conditional Parameters

This section compares the legacy conditional parameters with expression parameters in DynamoDB.

With the introduction of expression parameters (see Using Expressions in DynamoDB (p. 386)), several older parameters have been deprecated. New applications should not use these legacy parameters, but should use expression parameters instead. (For more information, see Using Expressions in DynamoDB (p. 386).)

Note
DynamoDB does not allow mixing legacy conditional parameters and expression parameters in a single call. For example, calling the Query operation with AttributesToGet and ConditionExpression will result in an error.

The following table shows the DynamoDB APIs that still support these legacy parameters, and which expression parameter to use instead. This table can be helpful if you are considering updating your applications so that they use expression parameters instead.

AttributesToGet

AttributesToGet is an array of one or more attributes to retrieve from DynamoDB. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

AttributesToGet allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.

Note that AttributesToGet has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

Use ProjectionExpression Instead

Suppose you wanted to retrieve an item from the Music table, but that you only wanted to return some of the attributes. You could use a GetItem request with an AttributesToGet parameter, as in this AWS CLI example:

```bash
aws dynamodb get-item \
--table-name Music \
--attributes-to-get '"Artist", "Genre"' \
--key '{
  "Artist": "{S":"No One You Know"},
  "SongTitle": "{S":"Call Me Today"}
}'
```

But you could use a ProjectionExpression instead:

```bash
aws dynamodb get-item \
--table-name Music \
--projection-expression "Artist, Genre" \
--key '{
  "Artist": "{S":"No One You Know"},
  "SongTitle": "{S":"Call Me Today"}
}'
```

AttributeUpdates

In an UpdateItem operation, AttributeUpdates are the names of attributes to be modified, the action to perform on each, and the new value for each. If you are updating an attribute that is an index key attribute for any indexes on that table, the attribute type must match the index key type defined in the AttributesDefinition of the table description. You can use UpdateItem to update any non-key attributes.

Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes must not be empty. Requests with empty values will be rejected with a ValidationException exception.

Each AttributeUpdates element consists of an attribute name to modify, along with the following:

- **Value** - The new value, if applicable, for this attribute.
- **Action** - A value that specifies how to perform the update. This action is only valid for an existing attribute whose data type is Number or is a set; do not use ADD for other data types.

If an item with the specified primary key is found in the table, the following values perform the following actions:
• **PUT** - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.

• **DELETE** - Removes the attribute and its value, if no value is specified for **DELETE**. The data type of the specified value must match the existing value's data type.

If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set \([a, b, c]\) and the **DELETE** action specifies \([a, c]\), then the final attribute value is \([b]\). Specifying an empty set is an error.

• **ADD** - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of **ADD** depends on the data type of the attribute:

  - If the existing attribute is a number, and if **Value** is also a number, then **Value** is mathematically added to the existing attribute. If **Value** is a negative number, then it is subtracted from the existing attribute.

    **Note**
    If you use **ADD** to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses 0 as the initial value.
    Similarly, if you use **ADD** for an existing item to increment or decrement an attribute value that doesn't exist before the update, DynamoDB uses 0 as the initial value. For example, suppose that the item you want to update doesn't have an attribute named *itemcount*, but you decide to **ADD** the number 3 to this attribute anyway. DynamoDB will create the *itemcount* attribute, set its initial value to 0, and finally add 3 to it. The result will be a new *itemcount* attribute, with a value of 3.

  - If the existing data type is a set, and if **Value** is also a set, then **Value** is appended to the existing set. For example, if the attribute value is the set \([1, 2]\) and the **ADD** action specified \([3]\), then the final attribute value is \([1, 2, 3]\). An error occurs if an **ADD** action is specified for a set attribute and the attribute type specified does not match the existing set type.

    Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, **Value** must also be a set of strings.

If no item with the specified key is found in the table, the following values perform the following actions:

• **PUT** - Causes DynamoDB to create a new item with the specified primary key, and then adds the attribute.

• **DELETE** - Nothing happens, because attributes cannot be deleted from a nonexistent item. The operation succeeds, but DynamoDB does not create a new item.

• **ADD** - Causes DynamoDB to create an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are Number and Number Set.

If you provide any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table's attribute definition.

**Use **UpdateExpression** Instead**

Suppose you wanted to modify an item in the **Music** table. You could use an **UpdateItem** request with an **AttributeUpdates** parameter, as in this AWS CLI example:

```bash
aws dynamodb update-item \
  --table-name Music \
  --key '{
    "SongTitle": {"S":"Call Me Today"},
    "Artist": {"S":"No One You Know"}
  }' \
  --attribute-updates '{
    "Genre": {
```
"Action": "PUT",
"Value": {"S":"Rock"}
}
'

But you could use a UpdateExpression instead:

```bash
aws dynamodb update-item \
  --table-name Music \
  --key '{
    "SongTitle": {"S":"Call Me Today"},
    "Artist": {"S":"No One You Know"}
  }', \
  --update-expression 'SET Genre = :g' \
  --expression-attribute-values '{
    "g": {"S":"Rock"}
  }',
```

**ConditionalOperator**

A logical operator to apply to the conditions in a Expected, QueryFilter or ScanFilter map:

- **AND** - If all of the conditions evaluate to true, then the entire map evaluates to true.
- **OR** - If at least one of the conditions evaluate to true, then the entire map evaluates to true.

If you omit ConditionalOperator, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

**Note**

This parameter does not support attributes of type List or Map.

**Expected**

Expected is a conditional block for an UpdateItem operation. Expected is a map of attribute/condition pairs. Each element of the map consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each Expected element, the result of the evaluation is either true or false.

If you specify more than one element in the Expected map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the Expected map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

Expected contains the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

  For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.
• **ComparisonOperator** - A comparator for evaluating attributes in the AttributeValueList. When performing the comparison, DynamoDB uses strongly consistent reads.

The following comparison operators are available:

```
EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS |
BEGINsWith | IN | BETWEEN
```

The following are descriptions of each comparison operator.

• **EQ**: Equal. EQ is supported for all datatypes, including lists and maps.

  AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

• **NE**: Not equal. NE is supported for all datatypes, including lists and maps.

  AttributeValueList can contain only one AttributeValue of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS": ["6", "2", "1"]}`.

• **LE**: Less than or equal.

  AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **LT**: Less than.

  AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **GE**: Greater than or equal.

  AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **GT**: Greater than.

  AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS": ["6", "2", "1"]}`.

• **NOT_NULL**: The attribute exists. NOT_NULL is supported for all datatypes, including lists and maps.

  **Note**
  This operator tests for the existence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using NOT_NULL, the result is a Boolean true. This result is because the attribute "a" exists; its data type is not relevant to the NOT_NULL comparison operator.

• **NULL**: The attribute does not exist. NULL is supported for all datatypes, including lists and maps.
**Note**
This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using `NULL`, the result is a Boolean `false`. This is because the attribute "a" exists; its data type is not relevant to the `NULL` comparison operator.

- **CONTAINS**: Checks for a subsequence, or value in a set.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set.

  `CONTAINS` is supported for lists: When evaluating "a CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- **NOT_CONTAINS**: Checks for absence of a subsequence, or absence of a value in a set.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set.

  `NOT_CONTAINS` is supported for lists: When evaluating "a NOT CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- **begins_with**: Checks for a prefix.

  `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- **IN**: Checks for matching elements within two sets.

  `AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value.

  `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`

The following parameters can be used instead of `AttributeValueList` and `ComparisonOperator`:

- **Value** - A value for DynamoDB to compare with an attribute.
- **Exists** - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation:
  - If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluate to false.
KeyConditions

- If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for `Exists` is `true`.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

**Note**
This parameter does not support attributes of type List or Map.

**Use `ConditionExpression` Instead**

Suppose you wanted to modify an item in the `Music` table, but only if a certain condition was true. You could use an `UpdateItem` request with an `Expected` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \
  --table-name Music \
  --key '{
    "Artist": {"S":"No One You Know"},
    "SongTitle": {"S":"Call Me Today"}
  }' \
  --attribute-updates '{
    "Price": {
      "Action": "PUT",
      "Value": {"N":"1.98"}
    }
  }' \
  --expected '{
    "Price": {
      "ComparisonOperator": "LE",
      "AttributeValueList": [ {"N":"2.00"} ]
    }
  }'
```

But you could use a `ConditionExpression` instead:

```
aws dynamodb update-item \
  --table-name Music \
  --key '{
    "Artist": {"S":"No One You Know"},
    "SongTitle": {"S":"Call Me Today"}
  }' \
  --update-expression 'SET Price = :p1' \n  --condition-expression 'Price <= :p2' \n  --expression-attribute-values '{
    "p1": {"N":"1.98"},
    "p2": {"N":"2.00"}
  }'
```

**KeyConditions**

`KeyConditions` are the selection criteria for a `Query` operation. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the partition key name and value as an `EQ` condition. You can optionally provide a second condition, referring to the sort key.
Note
If you don't provide a sort key condition, all of the items that match the partition key will be retrieved. If a FilterExpression or QueryFilter is present, it will be applied after the items are retrieved.

For a query on an index, you can have conditions only on the index key attributes. You must provide the index partition key name and value as an EQ condition. You can optionally provide a second condition, referring to the index sort key.

Each KeyConditions element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes, for example, equals, greater than, less than, and so on.

  For KeyConditions, only the following comparison operators are supported:

  **EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN**

The following are descriptions of these comparison operators.

- **EQ**: Equal.

  AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one specified in the request, the value does not match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not equal \{"NS":\["6", "2", "1"]\}.

- **LE**: Less than or equal.

  AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS":\["6", "2", "1"]\}.

- **LT**: Less than.

  AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS":\["6", "2", "1"]\}.

- **GE**: Greater than or equal.

  AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS":\["6", "2", "1"]\}.

- **GT**: Greater than.

  AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, \{"S":"6"\} does not equal \{"N":"6"\}. Also, \{"N":"6"\} does not compare to \{"NS":\["6", "2", "1"]\}.
• **BEGINS_WITH**: Checks for a prefix.

  `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

• **BETWEEN**: Greater than or equal to the first value, and less than or equal to the second value.

  `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S": "6"}` does not compare to `{"N": "6"}`. Also, `{"N": "6"}` does not compare to `{"NS": ["6", "2", "1"]}`

### Use `KeyConditionExpression` Instead

Suppose you wanted to retrieve several items with the same partition key from the `Music` table. You could use a `Query` request with a `KeyConditions` parameter, as in this AWS CLI example:

```bash
aws dynamodb query
  --table-name Music
  --key-conditions '{
    "Artist":{
      "ComparisonOperator": "EQ",
      "AttributeValueList": [ { "S": "No One You Know" } ]
    },
    "SongTitle":{
      "ComparisonOperator": "BETWEEN",
      "AttributeValueList": [ { "S": "A" }, { "S": "M" } ]
    }
  }
'
```

But you could use a `KeyConditionExpression` instead:

```bash
aws dynamodb query
  --table-name Music
  --key-condition-expression 'Artist = :a AND SongTitle BETWEEN :t1 AND :t2'
  --expression-attribute-values '{
    "a": { "S": "No One You Know" },
    "t1": { "S": "A" },
    "t2": { "S": "M" }
  }'
```

### QueryFilter

In a `Query` operation, `QueryFilter` is a condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

**Note**

A `QueryFilter` is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

If you provide more than one condition in the `QueryFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDeD together. (You can use the
ConditionalOperator (p. 1039) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that QueryFilter does not allow key attributes. You cannot define a filter condition on a partition key or a sort key.

Each QueryFilter element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in ComparisonOperator.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than b.

  For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

  For information on specifying data types in JSON, see DynamoDB Low-Level API (p. 217).

- **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

  The following comparison operators are available:

  EQ | NE | LE | LT | GE | LT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN

**Use FilterExpression Instead**

Suppose you wanted to query the **Music** table and apply a condition to the matching items. You could use a Query request with a QueryFilter parameter, as in this AWS CLI example:

```bash
aws dynamodb query \
  --table-name Music \
  --key-conditions ' {
      "Artist": { 
        "ComparisonOperator": "EQ", 
        "AttributeValueList": [ { "S": "No One You Know" } ]
      }
  }' \
  --query-filter ' {
      "Price": { 
        "ComparisonOperator": "GT",  
        "AttributeValueList": [ { "N": "1.00" } ]
      }
  }'
```

But you could use a FilterExpression instead:

```bash
aws dynamodb query \
  --table-name Music \
  --key-condition-expression 'Artist = :a' \
  --filter-expression 'Price > :p' \
  --expression-attribute-values ' {
    "p": { "N": "1.00" }, 
    "a": { "S": "No One You Know" } 
  }'
```
ScanFilter

In a Scan operation, ScanFilter is a condition that evaluates the scan results and returns only the desired values.

**Note**

This parameter does not support attributes of type List or Map.

If you specify more than one condition in the ScanFilter map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator (p. 1039) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Each ScanFilter element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in ComparisonOperator.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than b.

  For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

  For information on specifying data types in JSON, see DynamoDB Low-Level API (p. 217).

- **ComparisonOperator** - A comparator for evaluating attributes. For example, equals, greater than, less than, etc.

  The following comparison operators are available:

  EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN

**Use FilterExpression Instead**

Suppose you wanted to scan the Music table and apply a condition to the matching items. You could use a Scan request with a ScanFilter parameter, as in this AWS CLI example:

```bash
code
aws dynamodb scan \
  --table-name Music \
  --scan-filter '{
    "Genre":{
      "AttributeValueList": [ {"S":"Rock"} ],
      "ComparisonOperator": "EQ"
    }
  }'
```

But you could use a FilterExpression instead:

```bash
code
aws dynamodb scan \
  --table-name Music \
  --filter-expression 'Genre = :g' \n  --expression-attribute-values '(
    "g": {"S":"Rock"}
  )'
```
Writing Conditions With Legacy Parameters

The following section describes how to write conditions for use with legacy parameters, such as Expected, QueryFilter, and ScanFilter.

**Note**
New applications should use expression parameters instead. For more information, see Using Expressions in DynamoDB (p. 386).

Simple Conditions

With attribute values, you can write conditions for comparisons against table attributes. A condition always evaluates to true or false, and consists of:

- **ComparisonOperator** — greater than, less than, equal to, and so on.
- **AttributeValueList** (optional) — attribute value(s) to compare against. Depending on the ComparisonOperator being used, the AttributeValueList might contain one, two, or more values; or it might not be present at all.

The following sections describe the various comparison operators, along with examples of how to use them in conditions.

Comparison Operators with No Attribute Values

- **NOT_NULL** - true if an attribute exists.
- **NULL** - true if an attribute does not exist.

Use these operators to check whether an attribute exists, or doesn't exist. Because there is no value to compare against, do not specify AttributeValueList.

**Example**

The following expression evaluates to true if the Dimensions attribute exists.

```json
...
  "Dimensions": {
    ComparisonOperator: "NOT_NULL"
  }
...
```

Comparison Operators with One Attribute Value

- **EQ** - true if an attribute is equal to a value.

  AttributeValueList can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match. For example, the string "3" is not equal to the number 3. Also, the number 3 is not equal to the number set [3, 2, 1].

- **NE** - true if an attribute is not equal to a value.

  AttributeValueList can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match.

- **LE** - true if an attribute is less than or equal to a value.
AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains an AttributeValue of a different type than the one specified in the request, the value does not match.

- **LT** - true if an attribute is less than a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- **GE** - true if an attribute is greater than or equal to a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- **GT** - true if an attribute is greater than a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- **CONTAINS** - true if a value is present within a set, or if one value contains another.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for a substring match. If the target attribute of the comparison is Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it finds an exact match with any member of the set.

- **NOT_CONTAINS** - true if a value is not present within a set, or if one value does not contain another value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it does not find an exact match with any member of the set.

- **BEGINS_WITH** - true if the first few characters of an attribute match the provided value. Do not use this operator for comparing numbers.

AttributeValueList can contain only one value of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).

Use these operators to compare an attribute with a value. You must specify an AttributeValueList consisting of a single value. For most of the operators, this value must be a scalar; however, the **EQ** and **NE** operators also support sets.

**Examples**

The following expressions evaluate to true if:

- A product's price is greater than 100.

```json
...  
    "Price": { 
      ComparisonOperator: "GT", 
      AttributeValueList: [ ("N":100") ] 
    } 
... 
```
• A product category begins with "Bo".

```json
...  "ProductCategory": {    ComparisonOperator: "BEGINS_WITH",    AttributeValueList: [ {"S":"Bo"} ]  }
...
```

• A product is available in either red, green, or black:

```json
...  "Color": {    ComparisonOperator: "EQ",    AttributeValueList: [      [ {"S":"Black"}, {"S":"Red"}, {"S":"Green"} ]      ]    }  }
...
```

**Note**
When comparing set data types, the order of the elements does not matter. DynamoDB will return only the items with the same set of values, regardless of the order in which you specify them in your request.

**Comparison Operators with Two Attribute Values**

• **BETWEEN** - true if a value is between a lower bound and an upper bound, endpoints inclusive.

  AttributeValueList must contain two elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains a value of a different type than the one specified in the request, the value does not match.

  Use this operator to determine if an attribute value is within a range. The AttributeValueList must contain two scalar elements of the same type - String, Number, or Binary.

**Example**

The following expression evaluates to true if a product's price is between 100 and 200.

```json
...  "Price": {    ComparisonOperator: "BETWEEN",    AttributeValueList: [ {"N":"100"}, {"N":"200"} ]  }
...
```

**Comparison Operators with N Attribute Values**

• **IN** - true if a value is equal to any of the values in an enumerated list. Only scalar values are supported in the list, not sets. The target attribute must be of the same type and exact value in order to match.

  AttributeValueList can contain one or more elements of type String, Number, or Binary (not a set). These attributes are compared against an existing non-set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.
AttributeValueList can contain one or more values of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.

Use this operator to determine whether the supplied value is within an enumerated list. You can specify any number of scalar values in AttributeValueList, but they all must be of the same data type.

Example

The following expression evaluates to true if the value for Id is 201, 203, or 205.

```
...,
   "Id": {
     ComparisonOperator: "IN",
     AttributeValueList: [ {"N":"201"}, {"N":"203"}, {"N":"205"} ]
   }
...,
```

Using Multiple Conditions

DynamoDB lets you combine multiple conditions to form complex expressions. You do this by providing at least two expressions, with an optional ConditionalOperator (p. 1039).

By default, when you specify more than one condition, all of the conditions must evaluate to true in order for the entire expression to evaluate to true. In other words, an implicit AND operation takes place.

Example

The following expression evaluates to true if a product is a book which has at least 600 pages. Both of the conditions must evaluate to true, since they are implicitly ANDed together.

```
...,
   "ProductCategory": {
     ComparisonOperator: "EQ",
     AttributeValueList: [ {"S":"Book"} ]
   },
   "PageCount": {
     ComparisonOperator: "GE",
     AttributeValueList: [ {"N":600} ]
   }
...,
```

You can use ConditionalOperator (p. 1039) to clarify that an AND operation will take place. The following example behaves in the same manner as the previous one.

```
...,
   "ConditionalOperator": "AND",
   "ProductCategory": {
     ComparisonOperator: "EQ",
     AttributeValueList: [ {"N":"Book"} ]
   },
   "PageCount": {
     ComparisonOperator: "GE",
     AttributeValueList: [ {"N":600} ]
   }
...,
You can also set **ConditionalOperator** to *OR*, which means that *at least one* of the conditions must evaluate to true.

**Example**

The following expression evaluates to true if a product is a mountain bike, if it is a particular brand name, or if its price is greater than 100.

```
...  
  ConditionalOperator : "OR",  
  "BicycleType": {  
    "ComparisonOperator": "EQ",  
    "AttributeValueList": [ {"S":"Mountain"} ]  
  },  
  "Brand": {  
    "ComparisonOperator": "EQ",  
    "AttributeValueList": [ {"S":"Brand-Company A"} ]  
  },  
  "Price": {  
    "ComparisonOperator": "GT",  
    "AttributeValueList": [ {"N":"100"} ]  
  }  
...  
```

**Note**

In a complex expression, the conditions are processed in order, from the first condition to the last.

You cannot use both AND and OR in a single expression.

**Other Conditional Operators**

In previous releases of DynamoDB, the **Expected** parameter behaved differently for conditional writes. Each item in the **Expected** map represented an attribute name for DynamoDB to check, along with the following:

- **Value** — a value to compare against the attribute.
- **Exists** — determine whether the value exists prior to attempting the operation.

The **Value** and **Exists** options continue to be supported in DynamoDB; however, they only let you test for an equality condition, or whether an attribute exists. We recommend that you use **ComparisonOperator** and **AttributeValueList** instead, because these options let you construct a much wider range of conditions.

**Example**

A **DeleteItem** can check to see whether a book is no longer in publication, and only delete it if this condition is true. Here is an AWS CLI example using a legacy condition:

```
aws dynamodb delete-item  
  --table-name ProductCatalog  
  --key '{  
    "Id": {"N":"600"}  
  }'  
  --expected '{  
    "InPublication": {  
      "Exists": true,  
      "Value": {"BOOL":false}  
    }  
  }'  
```

API Version 2012-08-10
1051
The following example does the same thing, but does not use a legacy condition:

```bash
aws dynamodb delete-item \
  --table-name ProductCatalog \
  --key '{ 
    "Id": {"N":"600"} 
 }' \
  --expected '{ 
    "InPublication": { 
      "ComparisonOperator": "EQ", 
      "AttributeValueList": [ {"BOOL":false} ] 
    } 
  }
```

Example

A `PutItem` operation can protect against overwriting an existing item with the same primary key attributes. Here is an example using a legacy condition:

```bash
aws dynamodb put-item \
  --table-name ProductCatalog \
  --item '{ 
    "Id": {"N":"500"}, 
    "Title": {"S":"Book 500 Title"} 
  }' \
  --expected '{ 
    "Id": { "Exists": false } 
  }
```

The following example does the same thing, but does not use a legacy condition:

```bash
aws dynamodb put-item \
  --table-name ProductCatalog \
  --item '{ 
    "Id": {"N":"500"}, 
    "Title": {"S":"Book 500 Title"} 
  }' \
  --expected '{ 
    "Id": { "ComparisonOperator": "NULL" } 
  }
```

Note

For conditions in the `Expected` map, do not use the legacy `Value` and `Exists` options together with `ComparisonOperator` and `AttributeValueList`. If you do this, your conditional write will fail.

Previous Low-Level API Version (2011-12-05)

This section documents the operations available in the previous DynamoDB low-level API version (2011-12-05). This version of the low-level API is maintained for backward compatibility with existing applications.
New applications should use the current API version (2012-08-10). For more information, see Low-Level API Reference (p. 971).

Note
We recommend that you migrate your applications to the latest API version (2012-08-10), since new DynamoDB features will not be backported to the previous API version.

BatchGetItem

Important
This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.
For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description
The BatchGetItem operation returns the attributes for multiple items from multiple tables using their primary keys. The maximum number of items that can be retrieved for a single operation is 100. Also, the number of items retrieved is constrained by a 1 MB size limit. If the response size limit is exceeded or a partial result is returned because the table's provisioned throughput is exceeded, or because of an internal processing failure, DynamoDB returns an UnprocessedKeys value so you can retry the operation starting with the next item to get. DynamoDB automatically adjusts the number of items returned per page to enforce this limit. For example, even if you ask to retrieve 100 items, but each individual item is 50 KB in size, the system returns 20 items and an appropriate UnprocessedKeys value so you can get the next page of results. If desired, your application can include its own logic to assemble the pages of results into one set.

If no items could be processed because of insufficient provisioned throughput on each of the tables involved in the request, DynamoDB returns a ProvisionedThroughputExceededException error.

Note
By default, BatchGetItem performs eventually consistent reads on every table in the request. You can set the ConsistentRead parameter to true, on a per-table basis, if you want consistent reads instead.
BatchGetItem fetches items in parallel to minimize response latencies. When designing your application, keep in mind that DynamoDB does not guarantee how attributes are ordered in the returned response. Include the primary key values in the AttributesToGet for the items in your request to help parse the response by item.
If the requested items do not exist, nothing is returned in the response for those items. Requests for non-existent items consume the minimum read capacity units according to the type of read. For more information, see DynamoDB Item Sizes and Formats (p. 346).

BatchWriteItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

This operation enables you to put or delete several items across multiple tables in a single call.

To upload one item, you can use PutItem, and to delete one item, you can use DeleteItem. However, when you want to upload or delete large amounts of data, such as uploading large amounts of data from Amazon EMR (Amazon EMR) or migrating data from another database into DynamoDB, BatchWriteItem offers an efficient alternative.

If you use languages such as Java, you can use threads to upload items in parallel. This adds complexity in your application to handle the threads. Other languages don’t support threading. For example, if you are using PHP, you must upload or delete items one at a time. In both situations, BatchWriteItem provides an alternative where the specified put and delete operations are processed in parallel, giving you the power of the thread pool approach without having to introduce complexity in your application.

Note that each individual put and delete specified in a BatchWriteItem operation costs the same in terms of consumed capacity units. However, because BatchWriteItem performs the specified operations in parallel, you get lower latency. Delete operations on non-existent items consume 1 write capacity unit. For more information about consumed capacity units, see Working with Tables and Data in DynamoDB (p. 336).

When using BatchWriteItem, note the following limitations:

- **Maximum operations in a single request**—You can specify a total of up to 25 put or delete operations; however, the total request size cannot exceed 1 MB (the HTTP payload).
- **You can use the BatchWriteItem operation only to put and delete items. You cannot use it to update existing items.**
- **Not an atomic operation**—Individual operations specified in a BatchWriteItem are atomic; however BatchWriteItem as a whole is a "best-effort" operation and not an atomic operation. That is, in a BatchWriteItem request, some operations might succeed and others might fail. The failed operations are returned in an UnprocessedItems field in the response. Some of these failures might be because you exceeded the provisioned throughput configured for the table or a transient failure such as a network error. You can investigate and optionally resend the requests. Typically, you call BatchWriteItem in a loop and in each iteration check for unprocessed items, and submit a new BatchWriteItem request with those unprocessed items.
- **Does not return any items**—The BatchWriteItem is designed for uploading large amounts of data efficiently. It does not provide some of the sophistication offered by PutItem and DeleteItem. For example, DeleteItem supports the ReturnValues field in your request body to request the deleted item in the response. The BatchWriteItem operation does not return any items in the response.
- **Unlike PutItem and DeleteItem, BatchWriteItem does not allow you to specify conditions on individual write requests in the operation.**
- **Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that have empty values will be rejected with a ValidationException.**

DynamoDB rejects the entire batch write operation if any one of the following is true:
• If one or more tables specified in the BatchWriteItem request does not exist.
• If primary key attributes specified on an item in the request does not match the corresponding table's primary key schema.
• If you try to perform multiple operations on the same item in the same BatchWriteItem request. For example, you cannot put and delete the same item in the same BatchWriteItem request.
• If the total request size exceeds the 1 MB request size (the HTTP payload) limit.
• If any individual item in a batch exceeds the 64 KB item size limit.

Requests

Syntax

// This header is abbreviated. For a sample of a complete header, see DynamoDB Low-Level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{
  "RequestItems" : RequestItems
}

RequestItems
{
  "TableName1" : [ Request, Request, ... ],
  "TableName2" : [ Request, Request, ... ],
  ...
}

Request ::= PutRequest | DeleteRequest

PutRequest ::= {
  "PutRequest" : {
    "Item" : {
      "Attribute-Name1" : Attribute-Value,
      "Attribute-Name2" : Attribute-Value,
      ...
    }
  }
}

DeleteRequest ::= {
  "DeleteRequest" : {
    "Key" : PrimaryKey-Value
  }
}

PrimaryKey-Value ::= HashTypePK | HashAndRangeTypePK

HashTypePK ::= {
  "HashKeyElement" : Attribute-Value
}

HashAndRangeTypePK
{
  "HashKeyElement" : Attribute-Value,
"RangeKeyElement" : Attribute-Value,
}

Attribute-Value ::= String | Numeric | Binary | StringSet | NumericSet | BinarySet

Numeric ::= 
{    "N": "Number"
}

String ::= 
{    "S": "String"
}

Binary ::= 
{    "B": "Base64 encoded binary data"
}

StringSet ::= 
{    "SS": [ "String1", "String2", ... ]
}

NumberSet ::= 
{    "NS": [ "Number1", "Number2", ... ]
}

BinarySet ::= 
{    "BS": [ "Binary1", "Binary2", ... ]
}

In the request body, the RequestItems JSON object describes the operations that you want to perform. The operations are grouped by tables. You can use BatchWriteItem to update or delete several items across multiple tables. For each specific write request, you must identify the type of request (PutItem, DeleteItem) followed by detail information about the operation.

• For a PutRequest, you provide the item, that is, a list of attributes and their values.
• For a DeleteRequest, you provide the primary key name and value.

Responses

Syntax

The following is the syntax of the JSON body returned in the response.

Special Errors
No errors specific to this operation.

Examples
The following example shows an HTTP POST request and the response of a BatchWriteItem operation. The request specifies the following operations on the Reply and the Thread tables:

- Put an item and delete an item from the Reply table
- Put an item into the Thread table

For examples using the AWS SDK, see Working with Items and Attributes (p. 375).

Sample Response

The following example response shows a put operation on both the Thread and Reply tables succeeded and a delete operation on the Reply table failed (for reasons such as throttling that is caused when you exceed the provisioned throughput on the table). Note the following in the JSON response:

- The Responses object shows one capacity unit was consumed on both the Thread and Reply tables as a result of the successful put operation on each of these tables.
- The UnprocessedItems object shows the unsuccessful delete operation on the Reply table. You can then issue a new BatchWriteItem call to address these unprocessed requests.

CreateTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.
Description

The CreateTable operation adds a new table to your account.

The table name must be unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-2.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called “MyTable,” one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data.

The CreateTable operation triggers an asynchronous workflow to begin creating the table. DynamoDB immediately returns the state of the table (CREATING) until the table is in the ACTIVE state. Once the table is in the ACTIVE state, you can perform data plane operations.

Use the DescribeTables (p. 1074) operation to check the status of the table.

DeleteItem

Important
This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications. For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description
Deletes a single item in a table by primary key. You can perform a conditional delete operation that deletes the item if it exists, or if it has an expected attribute value.

Note
If you specify DeleteItem without attributes or values, all the attributes for the item are deleted.

Unless you specify conditions, the DeleteItem is an idempotent operation; running it multiple times on the same item or attribute does not result in an error response.

Conditional deletes are useful for only deleting items and attributes if specific conditions are met. If the conditions are met, DynamoDB performs the delete. Otherwise, the item is not deleted.

You can perform the expected conditional check on one attribute per operation.

### Sample Response

HTTP/1.1 200 OK
DeleteTable

Important
This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.
For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description
The `DeleteTable` operation deletes a table and all of its items. After a `DeleteTable` request, the specified table is in the `DELETING` state until DynamoDB completes the deletion. If the table is in the `ACTIVE` state, you can delete it. If a table is in the `CREATING` or `UPDATING` states, then DynamoDB returns a `ResourceInUseException` error. If the specified table does not exist, DynamoDB returns a `ResourceNotFoundException`. If table is already in the `DELETING` state, no error is returned.

Note
DynamoDB might continue to accept data plane operation requests, such as `GetItem` and `PutItem`, on a table in the `DELETING` state until the table deletion is complete.

Tables are unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-1.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data; deleting one does not delete the other.

Use the `DescribeTables` operation to check the status of the table.

DescribeTables

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

Returns information about the table, including the current status of the table, the primary key schema and when the table was created. DescribeTable results are eventually consistent. If you use DescribeTable too early in the process of creating a table, DynamoDB returns a ResourceNotFoundException. If you use DescribeTable too early in the process of updating a table, the new values might not be immediately available.

GetItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

The GetItem operation returns a set of Attributes for an item that matches the primary key. If there is no matching item, GetItem does not return any data.

The GetItem operation provides an eventually consistent read by default. If eventually consistent reads are not acceptable for your application, use ConsistentRead. Although this operation might take longer than a standard read, it always returns the last updated value. For more information, see Read Consistency (p. 16).

### Examples

For examples using the AWS SDK, see Working with Items and Attributes (p. 375).
Sample Request

```plaintext
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB Low-Level API.
POST / HTTP/1.1

Sample Response

Notice the ConsumedCapacityUnits value is 1, because the optional parameter ConsistentRead is set to true. If ConsistentRead is set to false (or not specified) for the same request, the response is eventually consistent and the ConsumedCapacityUnits value would be 0.5.

ListTables

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

Returns an array of all the tables associated with the current account and endpoint.

Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-east-1.amazonaws.com, they are completely independent and do not share any data. The ListTables operation returns all of the table names associated with the account making the request, for the endpoint that receives the request.

PutItem

**Important**

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

Creates a new item, or replaces an old item with a new item (including all the attributes). If an item already exists in the specified table with the same primary key, the new item completely replaces the existing item. You can perform a conditional put (insert a new item if one with the specified primary key doesn't exist), or replace an existing item if it has certain attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a ValidationException.

**Note**

To ensure that a new item does not replace an existing item, use a conditional put operation with Exists set to false for the primary key attribute, or attributes.
For more information about using `PutItem`, see Working with Items and Attributes (p. 375).

**Requests**

**Syntax**

**Note**

If you specify "Exists":true without an attribute value to check, DynamoDB returns an error.
ReturnValues

Use this parameter if you want to get the attribute name-value pairs before they were updated with the PutItem request. Possible parameter values are NONE (default) or ALL_OLD. If ALL_OLD is specified, and PutItem overwrote an attribute name-value pair, the content of the old item is returned. If this parameter is not provided or is NONE, nothing is returned.

Type: String

Responses

Syntax

The following syntax example assumes the request specified a ReturnValues parameter of ALL_OLD; otherwise, the response has only the ConsumedCapacityUnits element.

Query

Important
This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.
For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

A query operation gets the values of one or more items and their attributes by primary key (Query is only available for hash-and-range primary key tables). You must provide a specific HashKeyValue, and can narrow the scope of the query using comparison operators on the RangeKeyValue of the primary key. Use the ScanIndexForward parameter to get results in forward or reverse order by range key.

Queries that do not return results consume the minimum read capacity units according to the type of read.

Note
If the total number of items meeting the query parameters exceeds the 1MB limit, the query stops and results are returned to the user with a LastEvaluatedKey to continue the query in a subsequent operation. Unlike a Scan operation, a Query operation never returns an empty result set and a LastEvaluatedKey. The LastEvaluatedKey is only provided if the results exceed 1MB, or if you have used the Limit parameter.
The result can be set for a consistent read using the ConsistentRead parameter.

Important
This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.
For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description
The `Scan` operation returns one or more items and its attributes by performing a full scan of a table. Provide a `ScanFilter` to get more specific results.

Note
If the total number of scanned items exceeds the 1MB limit, the scan stops and results are returned to the user with a `LastEvaluatedKey` to continue the scan in a subsequent operation. The results also include the number of items exceeding the limit. A scan can result in no table data meeting the filter criteria. The result set is eventually consistent.

UpdateItem

Important
This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.
For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

Edits an existing item's attributes. You can perform a conditional update (insert a new attribute name-value pair if it doesn't exist, or replace an existing name-value pair if it has certain expected attribute values).
You cannot update the primary key attributes using UpdateItem. Instead, delete the item and use PutItem to create a new item with new attributes.

The UpdateItem operation includes an *Action* parameter, which defines how to perform the update. You can put, delete, or add attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a *ValidationException*.

If an existing item has the specified primary key:

- **PUT**— Adds the specified attribute. If the attribute exists, it is replaced by the new value.
- **DELETE**— If no value is specified, this removes the attribute and its value. If a set of values is specified, then the values in the specified set are removed from the old set. So if the attribute value contains \([a,b,c]\) and the delete action contains \([a,c]\), then the final attribute value is \([b]\). The type of the specified value must match the existing value type. Specifying an empty set is not valid.
- **ADD**— Only use the add action for numbers or if the target attribute is a set (including string sets). ADD does not work if the target attribute is a single string value or a scalar binary value. The specified value is added to a numeric value (incrementing or decrementing the existing numeric value) or added as an additional value in a string set. If a set of values is specified, the values are added to the existing set. For example if the original set is \([1,2]\) and supplied value is \([3]\), then after the add operation the set is \([1,2,3]\), not \([4,5]\). An error occurs if an Add action is specified for a set attribute and the attribute type specified does not match the existing set type.

  If you use ADD for an attribute that does not exist, the attribute and its values are added to the item.

If no item matches the specified primary key:

- **PUT**— Creates a new item with specified primary key. Then adds the specified attribute.
- **DELETE**— Nothing happens.
- **ADD**— Creates an item with supplied primary key and number (or set of numbers) for the attribute value. Not valid for a string or a binary type.

**Note**

If you use ADD to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses 0 as the initial value. Also, if you update an item using ADD to increment or decrement a number value for an attribute that doesn't exist before the update (but the item does) DynamoDB uses 0 as the initial value. For example, you use ADD to add +3 to an attribute that did not exist before the update. DynamoDB uses 0 for the initial value, and the value after the update is 3.

For more information about using this operation, see Working with Items and Attributes (p. 375).

UpdateTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.
For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

Updates the provisioned throughput for the given table. Setting the throughput for a table helps you manage performance and is part of the provisioned throughput feature of DynamoDB. For more information, see Managing Settings on DynamoDB Provisioned Capacity Tables (p. 342).

The provisioned throughput values can be upgraded or downgraded based on the maximums and minimums listed in Service, Account, and Table Limits in Amazon DynamoDB (p. 961).

The table must be in the ACTIVE state for this operation to succeed. UpdateTable is an asynchronous operation; while executing the operation, the table is in the UPDATING state. While the table is in the UPDATING state, the table still has the provisioned throughput from before the call. The new provisioned throughput setting is in effect only when the table returns to the ACTIVE state after the UpdateTable operation.

| ProvisionedThroughput:ReadCapacityUnits | Sets the minimum number of consistent ReadCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations.  
Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second. | Yes      |

</tr>
<tr>
<td>Auto Scaling for DynamoDB</td>
<td>DynamoDB auto scaling eliminates the need for manually defining or adjust provisioned throughput settings. Instead, DynamoDB auto scaling dynamically adjusts read and write capacity in response to actual traffic patterns. This allows a table or a global secondary index to increase its provisioned read and write capacity to handle sudden increases in traffic, without throttling. When the workload decreases, DynamoDB auto scaling decreases the provisioned capacity. For more information, see Managing Throughput Capacity Automatically with DynamoDB Auto Scaling (p. 346).</td>

<td>New DynamoDB DescribeLimits API</td>
<td>The DescribeLimits API returns the current provisioned capacity limits for your AWS account in a region, both for the region as a whole and for any one DynamoDB table that you create there. It lets you determine what your current account-level limits are so that you can compare them to the provisioned capacity that you are currently using, and have plenty of time to apply for an increase before you hit a limit. | DynamoDB Console Update and New Terminology for Primary Key Attributes | The DynamoDB management console has been redesigned to be more intuitive and easy to use. As part of this update, we are introducing new terminology for primary key attributes:  
  - **Partition Key**—also known as a *hash attribute*.  
  - **Sort Key**—also known as a *range attribute*.  
  Only the names have changed; the functionality remains the same.  
  When you create a table or a secondary index, you can choose either a simple primary key (partition key only), or a composite primary key (partition key and sort key). The DynamoDB documentation has been updated to reflect these changes. | November 12, 2015 |

<td>DynamoDB Streams, Cross-Region Replication, and Scan with Strongly Consistent Reads</td>
<td>DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table, and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near real time. For more information, see Capturing Table Activity with DynamoDB Streams (p. 574) and the DynamoDB Streams API Reference. DynamoDB cross-region replication is a client-side solution for maintaining identical copies of DynamoDB tables across different AWS regions, in near real time. You can use cross region replication to back up DynamoDB tables, or to provide low-latency access to data where users are geographically distributed. For more information, see Cross-Region Replication (p. 595). The DynamoDB Scan operation uses eventually consistent reads, by default. You can use strongly consistent reads instead by setting the ConsistentRead parameter to true. For more information, see Read Consistency for Scan (p. 480) and Scan in the Amazon DynamoDB API Reference.</td>

<td>Improved support for Query expressions</td>
<td>This release adds a new KeyConditionExpression parameter to the Query API. A Query reads items from a table or an index using primary key values. The KeyConditionExpression parameter is a string that identifies primary key names, and conditions to be applied to the key values; the Query retrieves only those items that satisfy the expression. The syntax of KeyConditionExpression is similar to that of other expression parameters in DynamoDB, and allows you to define substitution variables for names and values within the expression. For more information, see Working with Queries in DynamoDB (p. 459).</td>

<tr>
<td>New comparison functions for conditional writes</td>
<td>In DynamoDB, the ConditionExpression parameter determines whether a PutItem, UpdateItem, or DeleteItem succeeds: The item is written only if the condition evaluates to true. This release adds two new functions, attribute_type and size, for use withConditionExpression. These functions allow you to perform a conditional writes based on the data type or size of an attribute in a table. For more information, see Condition Expressions (p. 393).</td>

<td>Scan API for secondary indexes</td>
<td>In DynamoDB, a Scan operation reads all of the items in a table, applies user-defined filtering criteria, and returns the selected data items to the application. This same capability is now available for secondary indexes too. To scan a local secondary index or a global secondary index, you specify the index name and the name of its parent table. By default, an index Scan returns all of the data in the index; you can use a filter expression to narrow the results that are returned to the application. For more information, see Working with Scans in DynamoDB (p. 476).</td>

<tr>
<td>Online operations for global secondary indexes</td>
<td>Online indexing lets you add or remove global secondary indexes on existing tables. With online indexing, you do not need to define all of a table's indexes when you create a table; instead, you can add a new index at any time. Similarly, if you decide you no longer need an index, you can remove it at any time. Online indexing operations are non-blocking, so that the table remains available for read and write activity while indexes are being added or removed. For more information, see Managing Global Secondary Indexes (p. 508).</td>

New data types are fully compatible with the JSON standard and allow you to nest document elements within one another. You can use document path dereference operators to read and write individual elements, without having to retrieve the entire document. This release also introduces new expression parameters for specifying projections, conditions and update actions when reading or writing data items. <td>Improved conditional expressions</td>
<td>DynamoDB expands the operators that are available for conditional expressions, giving you additional flexibility for conditional puts, updates, and deletes. The newly available operators let you check whether an attribute does or does not exist, is greater than or less than a particular value, is between two values, begins with certain characters, and much more. DynamoDB also provides an optional OR operator for evaluating multiple conditions. By default, multiple conditions in an expression are ANDed together, so the expression is true only if all of its conditions are true. If you specify OR instead, the expression is true if one or more one conditions are true. For more information, see Working with Items and Attributes (p. 375).</td>

<td>Global secondary indexes</td>
<td>DynamoDB adds support for global secondary indexes. As with a local secondary index, you define a global secondary index by using an alternate key from a table and then issuing Query requests on the index. Unlike a local secondary index, the partition key for the global secondary index does not have to be the same as that of the table; it can be any scalar attribute from the table. The sort key is optional and can also be any scalar table attribute. A global secondary index also has its own provisioned throughput settings, which are separate from those of the parent table. For more information, see Improving Data Access with Secondary Indexes (p. 497) and Using Global Secondary Indexes in DynamoDB (p. 500).</td>

<tr>
<td>Fine-grained access control</td>
<td>DynamoDB adds support for fine-grained access control. This feature allows customers to specify which principals (users, groups, or roles) can access individual items and attributes in a DynamoDB table or secondary index. Applications can also leverage web identity federation to offload the task of user authentication to a third-party identity provider, such as Facebook, Google, or Login with Amazon. In this way, applications (including mobile apps) can handle very large numbers of users, while ensuring that no one can access DynamoDB data items unless they are authorized to do so. For example, prior to this release, reading a 10 KB item would consume 10 read capacity units; now that same 10 KB read would consume only 3 units (10 KB / 4 KB, rounded up to the next 4 KB boundary). For more information, see Read/Write Capacity Mode (p. 17).</td>

| DynamoDB implements support for CRC32 checksums, supports strongly consistent batch gets, and removes restrictions on concurrent table updates. | • DynamoDB calculates a CRC32 checksum of the HTTP payload and returns this checksum in a new header, x-amz-crc32. For more information, see DynamoDB Low-Level API (p. 217).  
• By default, read operations performed by the BatchGetItem API are eventually consistent. A new ConsistentRead parameter in BatchGetItem lets you choose strong read consistency instead, for any table(s) in the request. For more information, see Description (p. 1053).  
• This release removes some restrictions when updating many tables simultaneously. The total number of tables that can be updated at once is still 10; however, these tables can now be any combination of CREATING, UPDATING or DELETING status. Additionally, there is no longer any minimum amount for increasing or reducing the ReadCapacityUnits or WriteCapacityUnits for a table. For more information, see Service, Account, and Table Limits in Amazon DynamoDB (p. 961). | November 2, 2012   |

| Support for binary data type | In addition to the Number and String types, DynamoDB now supports Binary data type. Prior to this release, to store binary data, you converted your binary data into string format and stored it in DynamoDB. In addition to the required conversion work on the client-side, the conversion often increased the size of the data item requiring more storage and potentially additional provisioned throughput capacity. With the binary type attributes you can now store any binary data, for example compressed data, encrypted data, and images. For more information see Data Types (p. 13). For working examples of handling binary type data using the AWS SDKs, see the following sections:  
  - Example: Handling Binary Type Attributes Using the AWS SDK for Java Document API (p. 433)  
  - Example: Handling Binary Type Attributes Using the AWS SDK for .NET Low-Level API (p. 456)  
  For the added binary data type support in the AWS SDKs, you will need to download the latest SDKs and you might also need to update any existing applications. For information about downloading the AWS SDKs, see .NET Code Examples (p. 333). | August 21, 2012 |
